3 RXQ_FRM_ARBIT	Receive Queue Packet Arbitration When this bit is set, the DWC_ether_qos drives the packet data to the ARI interface such that the entire packet data of currently-selected queue is transmitted before switching to other queue. Receive Queue Packet Arbitration When this bit is set, the DWC_ether_qos drives the packet data to the ARI interface such that the entire packet data of currently-selected queue is transmitted before switching to other queue. When this bit is reset, the DWC_ether_qos drives the packet data to the ARI interface such that the following amount of data of currently-selected queue is transmitted before switching to other queue: - PBL amount of data (indicated by ari_qN_pbl_i[]) or - Complete data of a packet The status and the timestamp are not a part of the PBL data. Therefore, the DWC_ether_qos drives the complete status (including timestamp status) during first PBL request for the packet (in store-and-forward mode) or the last PBL request for the packet (in Threshold mode). 0b - Receive Queue Packet Arbitration is disabled 1b - Receive Queue Packet Arbitration is enabled
2-0 RXQ_WEGT	Receive Queue Weight This field indicates the weight assigned to the Rx Queue 2. Receive Queue Weight This field indicates the weight assigned to the Rx Queue 2. The weight is used as the number of continuous PBL or packets requests (depending on the RXQ_FRM_ARBIT) allocated to the queue in one arbitration cycle.

61.7.1.435 Queue 3 Transmit Operation Mode (MTL_TXQ3_OPERATION_MODE)

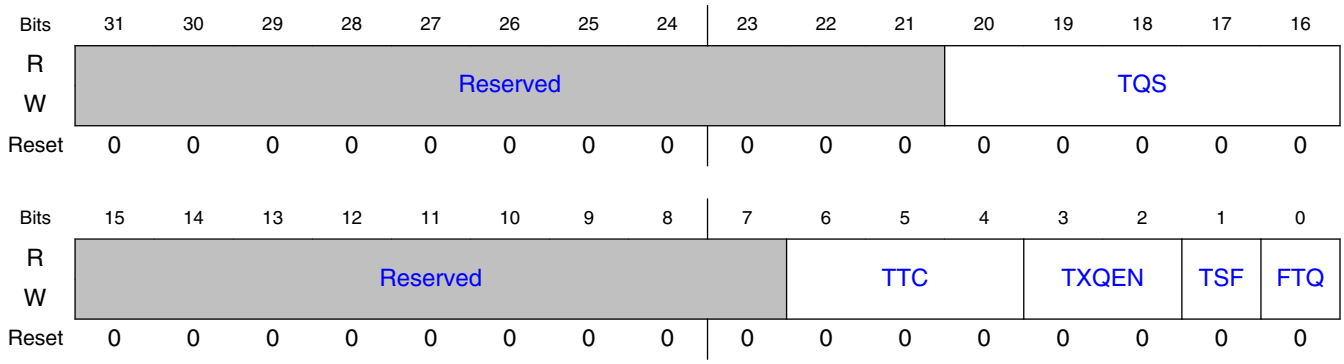
61.7.1.435.1 Offset

Register	Offset
MTL_TXQ3_OPERATION_MODE	DC0h

61.7.1.435.2 Function

The Queue 3 Transmit Operation Mode register establishes the Transmit queue operating modes and commands.

61.7.1.435.3 Diagram



61.7.1.435.4 Fields

Field	Function
31-21 —	Reserved
20-16 TQS	Transmit Queue Size This field indicates the size of the allocated Transmit queues in blocks of 256 bytes. Transmit Queue Size This field indicates the size of the allocated Transmit queues in blocks of 256 bytes. The TQS field is read-write only if the number of Tx Queues more than one, the reset value is 0x0 and indicates size of 256 bytes. When the number of Tx Queues is one, the field is read-only and the configured TX FIFO size in blocks of 256 bytes is reflected in the reset value. The width of this field depends on the Tx memory size selected in your configuration. For example, if the memory size is 2048, the width of this field is 3 bits: LOG2(2048/256) = LOG2(8) = 3 bits
15-7 —	Reserved
6-4 TTC	Transmit Threshold Control These bits control the threshold level of the MTL Tx Queue. Transmit Threshold Control These bits control the threshold level of the MTL Tx Queue. The transmission starts when the packet size within the MTL Tx Queue is larger than the threshold. In addition, full packets with length less than the threshold are also transmitted. These bits are used only when the TSF bit is reset. 000b - 32 001b - 64 010b - 96 011b - 128 100b - 192 101b - 256 110b - 384 111b - 512
3-2 TXQEN	Transmit Queue Enable This field is used to enable/disable the transmit queue 0. Transmit Queue Enable

Table continues on the next page...

Field	Function
	This field is used to enable/disable the transmit queue 0. - 2'b00: Not enabled - 2'b01: Enable in AV mode - 2'b10: Enabled - 2'b11: Reserved Note: In multiple Tx queues configuration, all the queues are disabled by default. Enable the Tx queue by programming this field. 00b - Not enabled 01b - Enable in AV mode (Reserved in non-AV) 10b - Enabled 11b - Reserved
1 TSF	Transmit Store and Forward When this bit is set, the transmission starts when a full packet resides in the MTL Tx queue. Transmit Store and Forward When this bit is set, the transmission starts when a full packet resides in the MTL Tx queue. When this bit is set, the TTC values specified in Bits[6:4] of this register are ignored. This bit should be changed only when the transmission is stopped. 0b - Transmit Store and Forward is disabled 1b - Transmit Store and Forward is enabled
0 FTQ	Flush Transmit Queue When this bit is set, the Tx queue controller logic is reset to its default values. Flush Transmit Queue When this bit is set, the Tx queue controller logic is reset to its default values. Therefore, all the data in the Tx queue is lost or flushed. This bit is internally reset when the flushing operation is complete. Until this bit is reset, you should not write to the MTL_TXQ3_OPERATION_MODE register. The data which is already accepted by the MAC transmitter is not flushed. It is scheduled for transmission and results in underflow and runt packet transmission. Note: The flush operation is complete only when the Tx queue is empty and the application has accepted the pending Tx Status of all transmitted packets. To complete this flush operation, the PHY Tx clock (clk_tx_i) should be active. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0b - Flush Transmit Queue is disabled 1b - Flush Transmit Queue is enabled

61.7.1.436 Queue 3 Underflow Counter (MTL_TXQ3_UNDERFLOW)

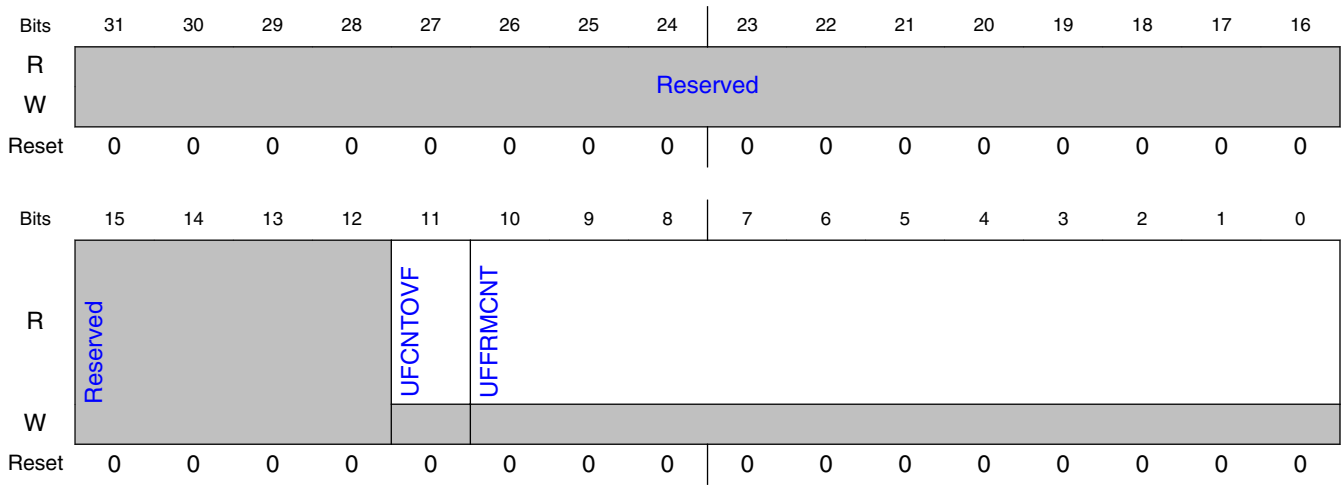
61.7.1.436.1 Offset

Register	Offset
MTL_TXQ3_UNDERFLOW	DC4h

61.7.1.436.2 Function

The Queue 3 Underflow Counter register contains the counter for packets aborted because of Transmit queue underflow and packets missed because of Receive queue packet flush

61.7.1.436.3 Diagram



61.7.1.436.4 Fields

Field	Function
31-12 —	Reserved
11 UFCNTOVF	Overflow Bit for Underflow Packet Counter This bit is set every time the Tx queue Underflow Packet Counter field overflows, that is, it has crossed the maximum count. Overflow Bit for Underflow Packet Counter This bit is set every time the Tx queue Underflow Packet Counter field overflows, that is, it has crossed the maximum count. In such a scenario, the overflow packet counter is reset to all-zeros and this bit indicates that the rollover happened. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0b - Overflow not detected for Underflow Packet Counter 1b - Overflow detected for Underflow Packet Counter
10-0 UFFRMCNT	Underflow Packet Counter This field indicates the number of packets aborted by the controller because of Tx Queue Underflow. Underflow Packet Counter This field indicates the number of packets aborted by the controller because of Tx Queue Underflow. This counter is incremented each time the MAC aborts outgoing packet because of underflow. The counter is cleared when this register is read with mci_be_i[0] at 1'b1. Access restriction applies. Clears on read. Self-set to 1 on internal event.

61.7.1.437 Queue 3 Transmit Debug (MTL_TXQ3_DEBUG)

61.7.1.437.1 Offset

Register	Offset
MTL_TXQ3_DEBUG	DC8h

61.7.1.437.2 Function

The Queue 3 Transmit Debug register gives the debug status of various blocks related to the Transmit queue.

61.7.1.440.4 Fields

Field	Function
31-21 —	Reserved
20-0 ISCQW	idleSlopeCredit, Quantum or Weights - idleSlopeCredit When AV feature is enabled, this field contains the idleSlopeCredit value required for the credit-based shaper algorithm for Queue 3. idleSlopeCredit, Quantum or Weights - idleSlopeCredit When AV feature is enabled, this field contains the idleSlopeCredit value required for the credit-based shaper algorithm for Queue 3. This is the rate of change of credit in bits per cycle (40 ns for 100 Mbps; 8 ns for 1000 Mbps; 3.2 ns for 2500 Mbps) when the credit is increasing. The software should program this field with computed credit in bits per cycle scaled by 1,024. The maximum value is portTransmitRate, that is, 0x2000 in 1000/2500 Mbps mode and 0x1000 in 100 Mbps mode. Bits[20:14] must be written to zero. - Quantum When the DCB operation is enabled with DWRR algorithm for Queue 3 traffic, this field contains the quantum value in bytes to be added to credit during every queue scanning cycle. The maximum value is 0x1312D0 bytes. - Weights When DCB operation is enabled with WFQ algorithm for Queue 3 traffic, this field contains the weight for this queue. The maximum value is 0x3FFF where weight of 0 indicates 100% bandwidth. Bits[20:14] must be written to zero. When DCB operation or generic queuing operation is enabled with WRR algorithm for Queue 3 traffic, this field contains the weight for this queue. The maximum value is 0x64. Bits [20:7] must be written to zero. - Note 1: In multiple Queue configuration this field in respective per queue register must be programmed to some non-zero value when multiple queues are enabled or single queue other than Q0 is enabled. This field need not be programmed when only Q0 is enabled. In general, when WRR algorithm is selected a non-zero value must be programmed on both Receive and Transmit. In Receive, the register is OPERATION_MODE register.

Field	Function
	- Note 2: For WFQ algorithm, higher the programmed weights lesser the bandwidth allocated for that Transmit Queue. The finish time is not a function of particular packet alone but it is as per the formula: (previous_finish_time of particular Transmit Queue + (weights*packet_size)) - Note 3: The weights programmed do not correspond to the number of packets but the fraction of bandwidth or time allocated for particular queue w.r.t. total BW or time.

61.7.1.441 Queue 3 sendSlopeCredit (MTL_TXQ3_SENDSLOPECREDIT)

61.7.1.441.1 Offset

Register	Offset
MTL_TXQ3_SENDSLOPECREDIT	DDCh

61.7.1.441.2 Function

Field	Function
17-14 RFD	Threshold for Deactivating Flow Control (in half-duplex and full-duplex modes) These bits control the threshold (fill-level of Rx queue) at which the flow control is de-asserted after activation: - 0: Full minus 1 KB, that is, FULL 1 KB - 1: Full minus 1. Threshold for Deactivating Flow Control (in half-duplex and full-duplex modes) These bits control the threshold (fill-level of Rx queue) at which the flow control is de-asserted after activation: - 0: Full minus 1 KB, that is, FULL 1 KB - 1: Full minus 1.5 KB, that is, FULL 1.5 KB - 2: Full minus 2 KB, that is, FULL 2 KB - 3: Full minus 2.5 KB, that is, FULL 2.5 KB - ... - 14: Full minus 8 KB, that is, FULL 8 KB - 15: Full minus 8.5 KB, that is, FULL 8.5 KB The de-assertion is effective only after flow control is asserted. Note: The value must be programmed in such a way to make sure that the threshold is a positive number. When the EHFC is set high, these values are applicable only when the Rx queue size determined by the RQS field of this register, is equal to or greater than 4 KB. For a given queue size, the values ranges between 0 and the encoding for FULL minus (QSIZE - 0.5 KB) and all other values are illegal. Here the term FULL and QSIZE refers to the queue size determined by the RQS field of this register. The width of this field depends on RX FIFO size selected during the configuration. Remaining bits are reserved and read only.
13-12 —	Reserved
11-8 RFA	Threshold for Activating Flow Control (in half-duplex and full-duplex These bits control the threshold (fill-level of Rx queue) at which the flow control is activated: For more information on encoding for this field, see RFD.
7 EHFC	Enable Hardware Flow Control When this bit is set, the flow control signal operation, based on the fill-level of Rx queue, is enabled. Enable Hardware Flow Control When this bit is set, the flow control signal operation, based on the fill-level of Rx queue, is enabled. When reset, the flow control operation is disabled. 0b - Hardware Flow Control is disabled 1b - Hardware Flow Control is enabled
6 DIS_TCP_EF	Disable Dropping of TCP/IP Checksum Error Packets When this bit is set, the MAC does not drop the packets which only have the errors detected by the Receive Checksum Offload engine. Disable Dropping of TCP/IP Checksum Error Packets When this bit is set, the MAC does not drop the packets which only have the errors detected by the Receive Checksum Offload engine. Such packets have errors only in the encapsulated payload. There are no errors (including FCS error) in the Ethernet packet received by the MAC. When this bit is reset, all error packets are dropped if the FEP bit is reset. 0b - Dropping of TCP/IP Checksum Error Packets is enabled 1b - Dropping of TCP/IP Checksum Error Packets is disabled

Table continues on the next page...

Field	Function
5 RSF	Receive Queue Store and Forward When this bit is set, the DWC_ether_qos reads a packet from the Rx queue only after the complete packet has been written to it, ignoring the RTC field of this register. Receive Queue Store and Forward When this bit is set, the DWC_ether_qos reads a packet from the Rx queue only after the complete packet has been written to it, ignoring the RTC field of this register. When this bit is reset, the Rx queue operates in the Threshold (cut-through) mode, subject to the threshold specified by the RTC field of this register. 0b - Receive Queue Store and Forward is disabled 1b - Receive Queue Store and Forward is enabled
4 FEP	Forward Error Packets When this bit is reset, the Rx queue drops packets with error status (CRC error, GMII_ER, watchdog timeout, or overflow). Forward Error Packets When this bit is reset, the Rx queue drops packets with error status (CRC error, GMII_ER, watchdog timeout, or overflow). However, if the start byte (write) pointer of a packet is already transferred to the read controller side (in Threshold mode), the packet is not dropped. When this bit is set, all packets except the runt error packets are forwarded to the application or DMA. If the RSF bit is set and the Rx queue overflows when a partial packet is written, the packet is dropped irrespective of the setting of this bit. However, if the RSF bit is reset and the Rx queue overflows when a partial packet is written, a partial packet may be forwarded to the application or DMA. 0b - Forward Error Packets is disabled 1b - Forward Error Packets is enabled
3 FUP	Forward Undersized Good Packets When this bit is set, the Rx queue forwards the undersized good packets (packets with no error and length less than 64 bytes), including pad-bytes and CRC. Forward Undersized Good Packets When this bit is set, the Rx queue forwards the undersized good packets (packets with no error and length less than 64 bytes), including pad-bytes and CRC. When this bit is reset, the Rx queue drops all packets of less than 64 bytes, unless a packet is already transferred because of the lower value of Rx Threshold, for example, RTC = 01. 0b - Forward Undersized Good Packets is disabled 1b - Forward Undersized Good Packets is enabled
2 —	Reserved
1-0 RTC	Receive Queue Threshold Control These bits control the threshold level of the MTL Rx queue (in bytes): The received packet is transferred to the application or DMA when the packet size within the MTL Rx queue is larger than the threshold. Receive Queue Threshold Control These bits control the threshold level of the MTL Rx queue (in bytes): The received packet is transferred to the application or DMA when the packet size within the MTL Rx queue is larger than the threshold. In addition, full packets with length less than the threshold are automatically transferred. This field is valid only when the RSF bit is zero. This field is ignored when the RSF bit is set to 1. 00b - 64 01b - 32 10b - 96 11b - 128

61.7.1.446 Queue 3 Missed Packet and Overflow Counter (MTL_RXQ3_MISSED_PACKET_OVERFLOW_CNT)

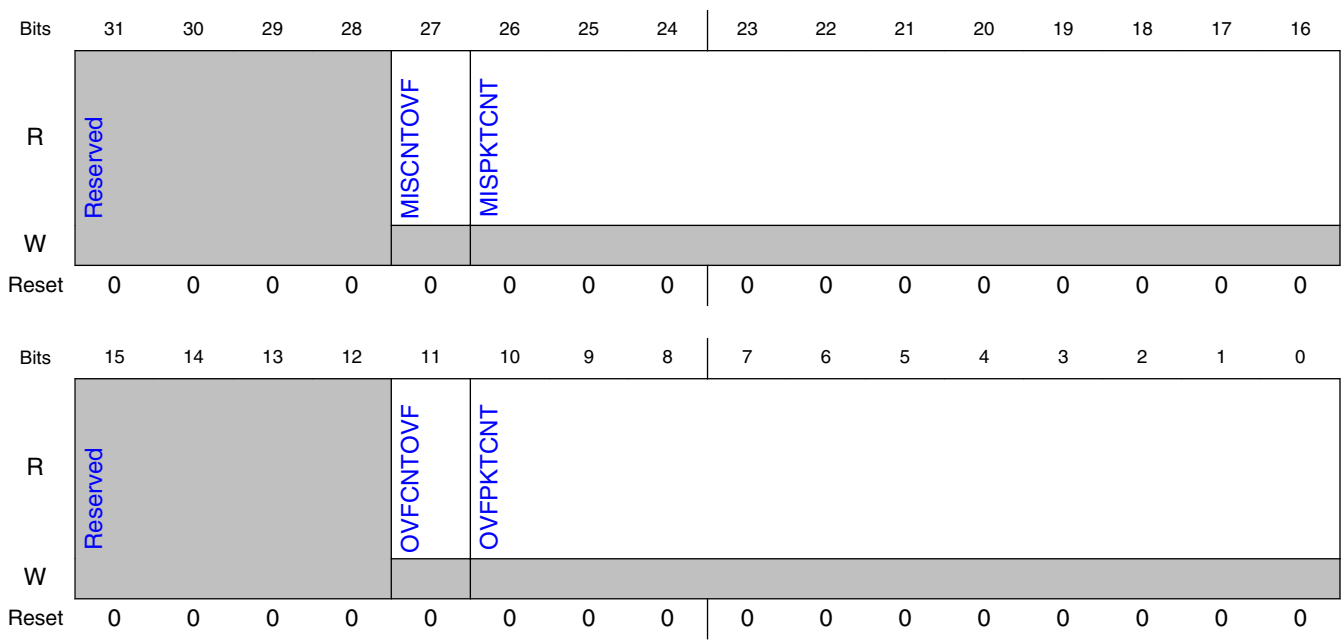
61.7.1.446.1 Offset

Register	Offset
MTL_RXQ3_MISSED_PACKET_OVERFLOW_CNT	DF4h

61.7.1.446.2 Function

The Queue 3 Missed Packet and Overflow Counter register contains the counter for packets missed because of Receive queue packet flush and packets discarded because of Receive queue overflow.

61.7.1.446.3 Diagram



61.7.1.446.4 Fields

Field	Function
31-28	Reserved

3 RXQ_FRM_ARBIT	Receive Queue Packet Arbitration When this bit is set, the DWC_ether_qos drives the packet data to the ARI interface such that the entire packet data of currently-selected queue is transmitted before switching to other queue. Receive Queue Packet Arbitration When this bit is set, the DWC_ether_qos drives the packet data to the ARI interface such that the entire packet data of currently-selected queue is transmitted before switching to other queue. When this bit is reset, the DWC_ether_qos drives the packet data to the ARI interface such that the following amount of data of currently-selected queue is transmitted before switching to other queue: - PBL amount of data (indicated by ari_qN_pbl_i[]) or - Complete data of a packet The status and the timestamp are not a part of the PBL data. Therefore, the DWC_ether_qos drives the complete status (including timestamp status) during first PBL request for the packet (in store-and-forward mode) or the last PBL request for the packet (in Threshold mode). 0b - Receive Queue Packet Arbitration is disabled 1b - Receive Queue Packet Arbitration is enabled
2-0 RXQ_WEGT	Receive Queue Weight This field indicates the weight assigned to the Rx Queue 3. Receive Queue Weight This field indicates the weight assigned to the Rx Queue 3. The weight is used as the number of continuous PBL or packets requests (depending on the RXQ_FRM_ARBIT) allocated to the queue in one arbitration cycle.

61.7.1.449 Queue 4 Transmit Operation Mode (MTL_TXQ4_OPERATION_MODE)

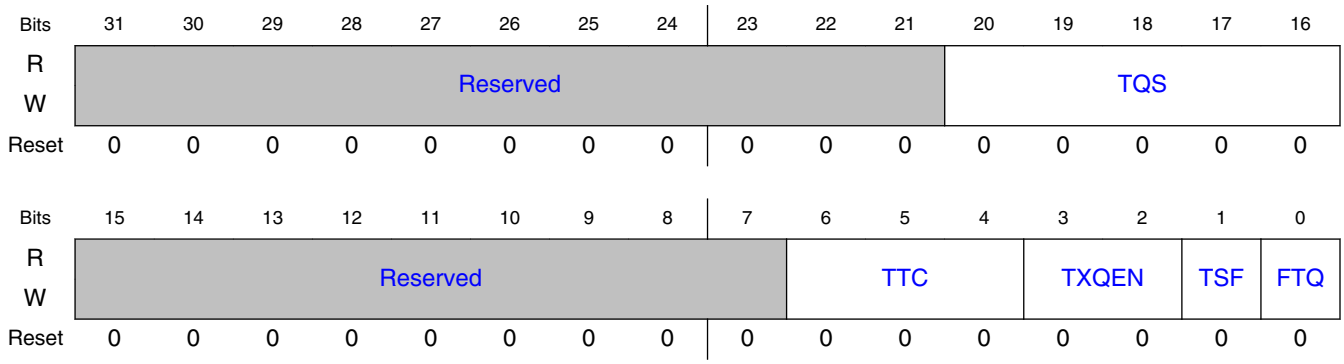
61.7.1.449.1 Offset

Register	Offset
MTL_TXQ4_OPERATION_MODE	E00h

61.7.1.449.2 Function

The Queue 4 Transmit Operation Mode register establishes the Transmit queue operating modes and commands.

61.7.1.449.3 Diagram



61.7.1.449.4 Fields

Field	Function
31-21 —	Reserved
20-16 TQS	Transmit Queue Size This field indicates the size of the allocated Transmit queues in blocks of 256 bytes. Transmit Queue Size This field indicates the size of the allocated Transmit queues in blocks of 256 bytes. The TQS field is read-write only if the number of Tx Queues more than one, the reset value is 0x0 and indicates size of 256 bytes. When the number of Tx Queues is one, the field is read-only and the configured TX FIFO size in blocks of 256 bytes is reflected in the reset value. The width of this field depends on the Tx memory size selected in your configuration. For example, if the memory size is 2048, the width of this field is 3 bits: LOG2(2048/256) = LOG2(8) = 3 bits
15-7 —	Reserved
6-4 TTC	Transmit Threshold Control These bits control the threshold level of the MTL Tx Queue. Transmit Threshold Control These bits control the threshold level of the MTL Tx Queue. The transmission starts when the packet size within the MTL Tx Queue is larger than the threshold. In addition, full packets with length less than the threshold are also transmitted. These bits are used only when the TSF bit is reset. 000b - 32 001b - 64 010b - 96 011b - 128 100b - 192 101b - 256 110b - 384 111b - 512
3-2 TXQEN	Transmit Queue Enable This field is used to enable/disable the transmit queue 0. Transmit Queue Enable

Table continues on the next page...

Field	Function
	This field is used to enable/disable the transmit queue 0. - 2'b00: Not enabled - 2'b01: Enable in AV mode - 2'b10: Enabled - 2'b11: Reserved Note: In multiple Tx queues configuration, all the queues are disabled by default. Enable the Tx queue by programming this field. 00b - Not enabled 01b - Enable in AV mode (Reserved in non-AV) 10b - Enabled 11b - Reserved
1 TSF	Transmit Store and Forward When this bit is set, the transmission starts when a full packet resides in the MTL Tx queue. Transmit Store and Forward When this bit is set, the transmission starts when a full packet resides in the MTL Tx queue. When this bit is set, the TTC values specified in Bits[6:4] of this register are ignored. This bit should be changed only when the transmission is stopped. 0b - Transmit Store and Forward is disabled 1b - Transmit Store and Forward is enabled
0 FTQ	Flush Transmit Queue When this bit is set, the Tx queue controller logic is reset to its default values. Flush Transmit Queue When this bit is set, the Tx queue controller logic is reset to its default values. Therefore, all the data in the Tx queue is lost or flushed. This bit is internally reset when the flushing operation is complete. Until this bit is reset, you should not write to the MTL_TXQ4_OPERATION_MODE register. The data which is already accepted by the MAC transmitter is not flushed. It is scheduled for transmission and results in underflow and runt packet transmission. Note: The flush operation is complete only when the Tx queue is empty and the application has accepted the pending Tx Status of all transmitted packets. To complete this flush operation, the PHY Tx clock (clk_tx_i) should be active. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0b - Flush Transmit Queue is disabled 1b - Flush Transmit Queue is enabled

61.7.1.450 Queue 4 Underflow Counter (MTL_TXQ4_UNDERFLOW)

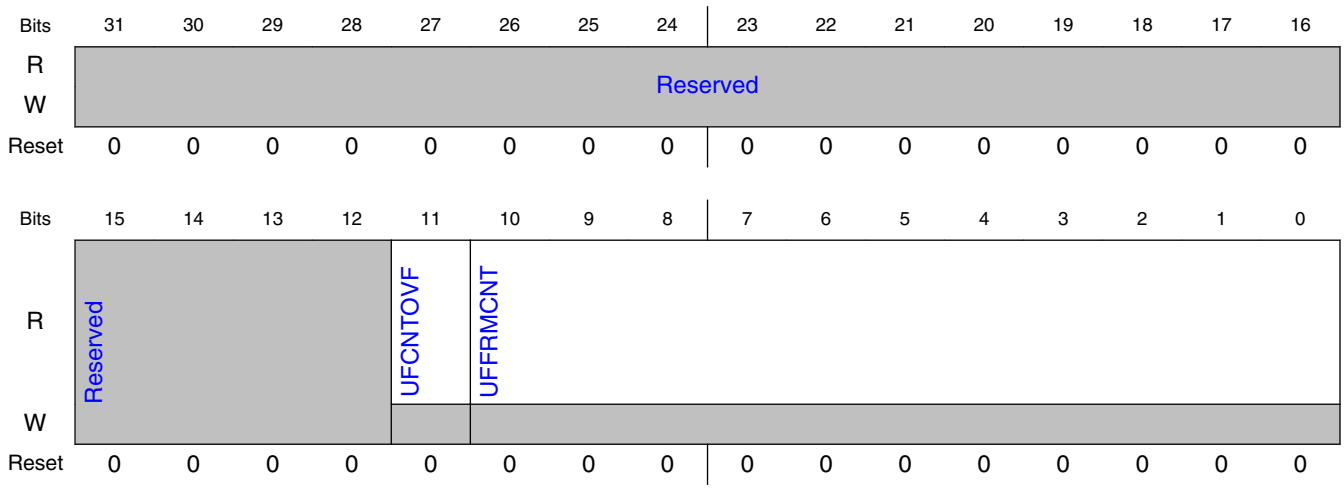
61.7.1.450.1 Offset

Register	Offset
MTL_TXQ4_UNDERFLOW	E04h

61.7.1.450.2 Function

The Queue 4 Underflow Counter register contains the counter for packets aborted because of Transmit queue underflow and packets missed because of Receive queue packet flush

61.7.1.450.3 Diagram



61.7.1.450.4 Fields

Field	Function
31-12 —	Reserved
11 UFCNTOVF	Overflow Bit for Underflow Packet Counter This bit is set every time the Tx queue Underflow Packet Counter field overflows, that is, it has crossed the maximum count. Overflow Bit for Underflow Packet Counter This bit is set every time the Tx queue Underflow Packet Counter field overflows, that is, it has crossed the maximum count. In such a scenario, the overflow packet counter is reset to all-zeros and this bit indicates that the rollover happened. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0b - Overflow not detected for Underflow Packet Counter 1b - Overflow detected for Underflow Packet Counter
10-0 UFFRMCNT	Underflow Packet Counter This field indicates the number of packets aborted by the controller because of Tx Queue Underflow. Underflow Packet Counter This field indicates the number of packets aborted by the controller because of Tx Queue Underflow. This counter is incremented each time the MAC aborts outgoing packet because of underflow. The counter is cleared when this register is read with mci_be_i[0] at 1'b1. Access restriction applies. Clears on read. Self-set to 1 on internal event.

61.7.1.451 Queue 4 Transmit Debug (MTL_TXQ4_DEBUG)

61.7.1.451.1 Offset

Register	Offset
MTL_TXQ4_DEBUG	E08h

61.7.1.451.2 Function

The Queue 4 Transmit Debug register gives the debug status of various blocks related to the Transmit queue.

61.7.1.454.4 Fields

Field	Function
31-21 —	Reserved
20-0 ISCQW	idleSlopeCredit, Quantum or Weights - idleSlopeCredit When AV feature is enabled, this field contains the idleSlopeCredit value required for the credit-based shaper algorithm for Queue 4. idleSlopeCredit, Quantum or Weights - idleSlopeCredit When AV feature is enabled, this field contains the idleSlopeCredit value required for the credit-based shaper algorithm for Queue 4. This is the rate of change of credit in bits per cycle (40 ns for 100 Mbps; 8 ns for 1000 Mbps; 3.2 ns for 2500 Mbps) when the credit is increasing. The software should program this field with computed credit in bits per cycle scaled by 1,024. The maximum value is portTransmitRate, that is, 0x2000 in 1000/2500 Mbps mode and 0x1000 in 100 Mbps mode. Bits[20:14] must be written to zero. - Quantum When the DCB operation is enabled with DWRR algorithm for Queue 4 traffic, this field contains the quantum value in bytes to be added to credit during every queue scanning cycle. The maximum value is 0x1312D0 bytes. - Weights When DCB operation is enabled with WFQ algorithm for Queue 4 traffic, this field contains the weight for this queue. The maximum value is 0x3FFF where weight of 0 indicates 100% bandwidth. Bits[20:14] must be written to zero. When DCB operation or generic queuing operation is enabled with WRR algorithm for Queue 4 traffic, this field contains the weight for this queue. The maximum value is 0x64. Bits [20:7] must be written to zero. - Note 1: In multiple Queue configuration this field in respective per queue register must be programmed to some non-zero value when multiple queues are enabled or single queue other than Q0 is enabled. This field need not be programmed when only Q0 is enabled. In general, when WRR algorithm is selected a non-zero value must be programmed on both Receive and Transmit. In Receive, the register is OPERATION_MODE register.

Field	Function
	- Note 2: For WFQ algorithm, higher the programmed weights lesser the bandwidth allocated for that Transmit Queue. The finish time is not a function of particular packet alone but it is as per the formula: (previous_finish_time of particular Transmit Queue + (weights*packet_size)) - Note 3: The weights programmed do not correspond to the number of packets but the fraction of bandwidth or time allocated for particular queue w.r.t. total BW or time.

61.7.1.455 Queue 4 sendSlopeCredit (MTL_TXQ4_SENDSLOPECREDIT)

61.7.1.455.1 Offset

Register	Offset
MTL_TXQ4_SENDSLOPECREDIT	E1Ch

61.7.1.455.2 Function

The sendSlopeCredit register contains the sendSlope credit value required for the credit-based shaper algorithm for the Queue.

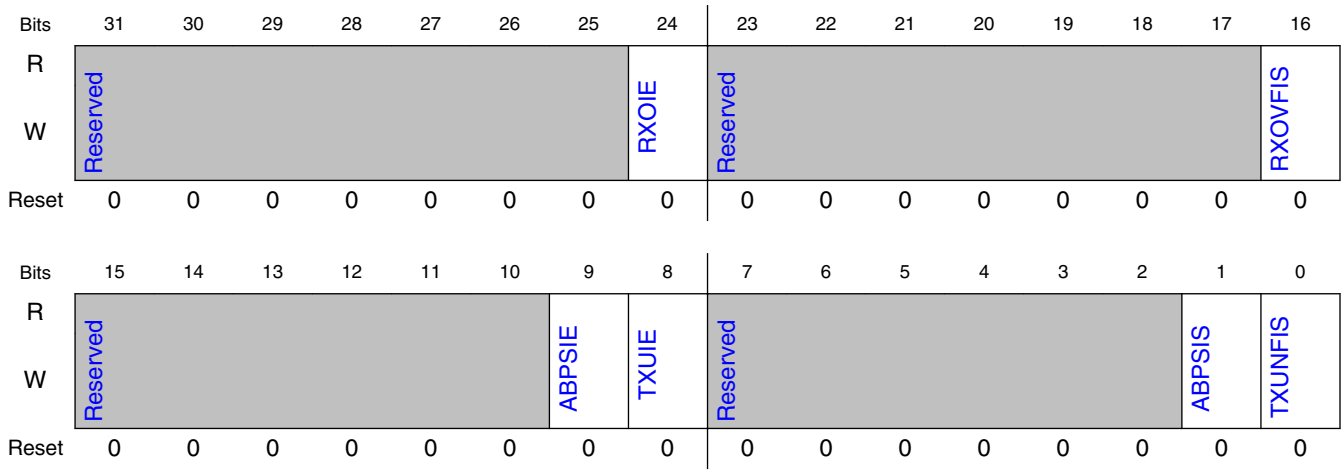
61.7.1.458.1 Offset

Register	Offset
MTL_Q4_INTERRUPT_CONTROL_STATUS	E2Ch

61.7.1.458.2 Function

This register contains the interrupt enable and status bits for the queue 4 interrupts.

61.7.1.458.3 Diagram



61.7.1.458.4 Fields

Field	Function
31-25 —	Reserved
24 RXOIE	Receive Queue Overflow Interrupt Enable When this bit is set, the Receive Queue Overflow interrupt is enabled. Receive Queue Overflow Interrupt Enable When this bit is set, the Receive Queue Overflow interrupt is enabled. When this bit is reset, the Receive Queue Overflow interrupt is disabled. 0b - Receive Queue Overflow Interrupt is disabled 1b - Receive Queue Overflow Interrupt is enabled
23-17 —	Reserved
16 RXOVFIS	Receive Queue Overflow Interrupt Status This bit indicates that the Receive Queue had an overflow while receiving the packet. Receive Queue Overflow Interrupt Status This bit indicates that the Receive Queue had an overflow while receiving the packet. If a partial packet is transferred to the application, the overflow status is set in RDES3[21]. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Receive Queue Overflow Interrupt Status not detected 1b - Receive Queue Overflow Interrupt Status detected
15-10 —	Reserved
9 ABPSIE	Average Bits Per Slot Interrupt Enable When this bit is set, the MAC asserts the sbd_intr_o or mci_intr_o interrupt when the average bits per slot status is updated. Average Bits Per Slot Interrupt Enable

Table continues on the next page...

Field	Function
	When this bit is set, the MAC asserts the sbd_intr_o or mci_intr_o interrupt when the average bits per slot status is updated. When this bit is cleared, the interrupt is not asserted for such an event. 0b - Average Bits Per Slot Interrupt is disabled 1b - Average Bits Per Slot Interrupt is enabled
8 TXUIE	Transmit Queue Underflow Interrupt Enable When this bit is set, the Transmit Queue Underflow interrupt is enabled. Transmit Queue Underflow Interrupt Enable When this bit is set, the Transmit Queue Underflow interrupt is enabled. When this bit is reset, the Transmit Queue Underflow interrupt is disabled. 0b - Transmit Queue Underflow Interrupt Status is disabled 1b - Transmit Queue Underflow Interrupt Status is enabled
7-2 —	Reserved
1 ABPSIS	Average Bits Per Slot Interrupt Status When set, this bit indicates that the MAC has updated the ABS value. Average Bits Per Slot Interrupt Status When set, this bit indicates that the MAC has updated the ABS value. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Average Bits Per Slot Interrupt Status not detected 1b - Average Bits Per Slot Interrupt Status detected
0 TXUNFIS	Transmit Queue Underflow Interrupt Status This bit indicates that the Transmit Queue had an underflow while transmitting the packet. Transmit Queue Underflow Interrupt Status This bit indicates that the Transmit Queue had an underflow while transmitting the packet. Transmission is suspended and an Underflow Error TDES3[2] is set. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Transmit Queue Underflow Interrupt Status not detected 1b - Transmit Queue Underflow Interrupt Status detected

61.7.1.459 Queue 4 Receive Operation Mode (MTL_RXQ4_OPERATION_MODE)

61.7.1.459.1 Offset

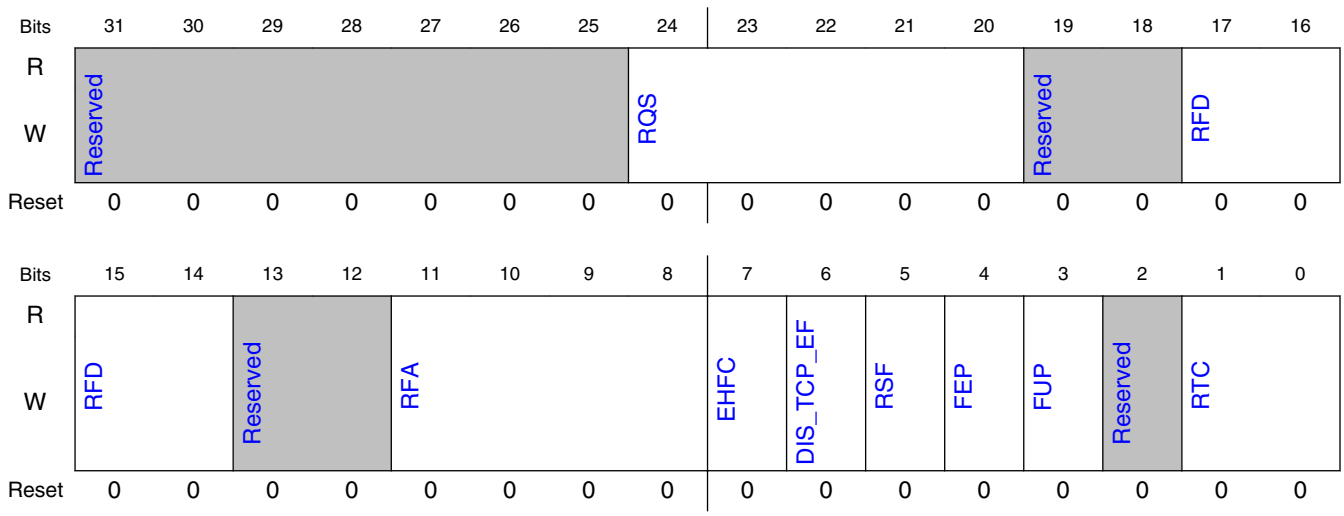
Register	Offset
MTL_RXQ4_OPERATION_MODE	E30h

61.7.1.459.2 Function

The Queue 4 Receive Operation Mode register establishes the Receive queue operating modes and command.

The RFA and RFD fields are not backward compatible with the RFA and RFD fields of 4.00a release

61.7.1.459.3 Diagram



61.7.1.459.4 Fields

Field	Function
31-25 —	Reserved
24-20 RQS	Receive Queue Size This field indicates the size of the allocated Receive queues in blocks of 256 bytes. Receive Queue Size This field indicates the size of the allocated Receive queues in blocks of 256 bytes. The RQS field is read-write only if the number of Rx Queues more than one, the reset value is 0x0 and indicates size of 256 bytes. When the number of Rx Queues is one, the field is read-only and the configured RX FIFO size in blocks of 256 bytes is reflected in the reset value. The width of this field depends on the Rx memory size selected in your configuration. For example, if the memory size is 2048, the width of this field is 3 bits: LOG2(2048/256) = LOG2(8) = 3 bits
19-18 —	Reserved

Table continues on the next page...

Field	Function
17-14 RFD	Threshold for Deactivating Flow Control (in half-duplex and full-duplex modes) These bits control the threshold (fill-level of Rx queue) at which the flow control is de-asserted after activation: - 0: Full minus 1 KB, that is, FULL 1 KB - 1: Full minus 1. Threshold for Deactivating Flow Control (in half-duplex and full-duplex modes) These bits control the threshold (fill-level of Rx queue) at which the flow control is de-asserted after activation: - 0: Full minus 1 KB, that is, FULL 1 KB - 1: Full minus 1.5 KB, that is, FULL 1.5 KB - 2: Full minus 2 KB, that is, FULL 2 KB - 3: Full minus 2.5 KB, that is, FULL 2.5 KB - ... - 14: Full minus 8 KB, that is, FULL 8 KB - 15: Full minus 8.5 KB, that is, FULL 8.5 KB The de-assertion is effective only after flow control is asserted. Note: The value must be programmed in such a way to make sure that the threshold is a positive number. When the EHFC is set high, these values are applicable only when the Rx queue size determined by the RQS field of this register, is equal to or greater than 4 KB. For a given queue size, the values ranges between 0 and the encoding for FULL minus (QSIZE - 0.5 KB) and all other values are illegal. Here the term FULL and QSIZE refers to the queue size determined by the RQS field of this register. The width of this field depends on RX FIFO size selected during the configuration. Remaining bits are reserved and read only.
13-12 —	Reserved
11-8 RFA	Threshold for Activating Flow Control (in half-duplex and full-duplex These bits control the threshold (fill-level of Rx queue) at which the flow control is activated: For more information on encoding for this field, see RFD.
7 EHFC	Enable Hardware Flow Control When this bit is set, the flow control signal operation, based on the fill-level of Rx queue, is enabled. Enable Hardware Flow Control When this bit is set, the flow control signal operation, based on the fill-level of Rx queue, is enabled. When reset, the flow control operation is disabled. 0b - Hardware Flow Control is disabled 1b - Hardware Flow Control is enabled
6 DIS_TCP_EF	Disable Dropping of TCP/IP Checksum Error Packets When this bit is set, the MAC does not drop the packets which only have the errors detected by the Receive Checksum Offload engine. Disable Dropping of TCP/IP Checksum Error Packets When this bit is set, the MAC does not drop the packets which only have the errors detected by the Receive Checksum Offload engine. Such packets have errors only in the encapsulated payload. There are no errors (including FCS error) in the Ethernet packet received by the MAC. When this bit is reset, all error packets are dropped if the FEP bit is reset. 0b - Dropping of TCP/IP Checksum Error Packets is enabled 1b - Dropping of TCP/IP Checksum Error Packets is disabled

Table continues on the next page...

Field	Function
5 RSF	Receive Queue Store and Forward When this bit is set, the DWC_ether_qos reads a packet from the Rx queue only after the complete packet has been written to it, ignoring the RTC field of this register. Receive Queue Store and Forward When this bit is set, the DWC_ether_qos reads a packet from the Rx queue only after the complete packet has been written to it, ignoring the RTC field of this register. When this bit is reset, the Rx queue operates in the Threshold (cut-through) mode, subject to the threshold specified by the RTC field of this register. 0b - Receive Queue Store and Forward is disabled 1b - Receive Queue Store and Forward is enabled
4 FEP	Forward Error Packets When this bit is reset, the Rx queue drops packets with error status (CRC error, GMII_ER, watchdog timeout, or overflow). Forward Error Packets When this bit is reset, the Rx queue drops packets with error status (CRC error, GMII_ER, watchdog timeout, or overflow). However, if the start byte (write) pointer of a packet is already transferred to the read controller side (in Threshold mode), the packet is not dropped. When this bit is set, all packets except the runt error packets are forwarded to the application or DMA. If the RSF bit is set and the Rx queue overflows when a partial packet is written, the packet is dropped irrespective of the setting of this bit. However, if the RSF bit is reset and the Rx queue overflows when a partial packet is written, a partial packet may be forwarded to the application or DMA. 0b - Forward Error Packets is disabled 1b - Forward Error Packets is enabled
3 FUP	Forward Undersized Good Packets When this bit is set, the Rx queue forwards the undersized good packets (packets with no error and length less than 64 bytes), including pad-bytes and CRC. Forward Undersized Good Packets When this bit is set, the Rx queue forwards the undersized good packets (packets with no error and length less than 64 bytes), including pad-bytes and CRC. When this bit is reset, the Rx queue drops all packets of less than 64 bytes, unless a packet is already transferred because of the lower value of Rx Threshold, for example, RTC = 01. 0b - Forward Undersized Good Packets is disabled 1b - Forward Undersized Good Packets is enabled
2 —	Reserved
1-0 RTC	Receive Queue Threshold Control These bits control the threshold level of the MTL Rx queue (in bytes): The received packet is transferred to the application or DMA when the packet size within the MTL Rx queue is larger than the threshold. Receive Queue Threshold Control These bits control the threshold level of the MTL Rx queue (in bytes): The received packet is transferred to the application or DMA when the packet size within the MTL Rx queue is larger than the threshold. In addition, full packets with length less than the threshold are automatically transferred. This field is valid only when the RSF bit is zero. This field is ignored when the RSF bit is set to 1. 00b - 64 01b - 32 10b - 96 11b - 128

61.7.1.460 Queue 4 Missed Packet and Overflow Counter (MTL_RXQ4_MISSED_PACKET_OVERFLOW_CNT)

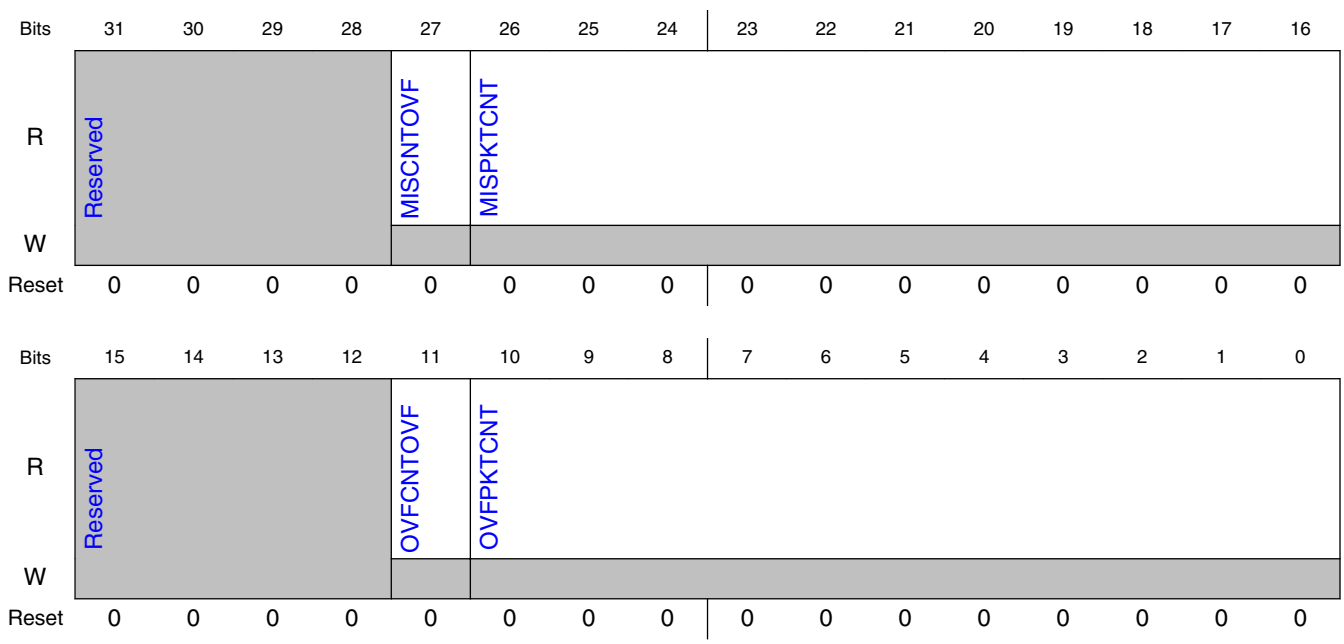
61.7.1.460.1 Offset

Register	Offset
MTL_RXQ4_MISSED_PACKET_OVERFLOW_CNT	E34h

61.7.1.460.2 Function

The Queue 4 Missed Packet and Overflow Counter register contains the counter for packets missed because of Receive queue packet flush and packets discarded because of Receive queue overflow.

61.7.1.460.3 Diagram



61.7.1.460.4 Fields

Field	Function
31-28	Reserved

Table continues on the next page...

Field	Function
—	
27 MISCNTOVF	Missed Packet Counter Overflow Bit When set, this bit indicates that the Rx Queue Missed Packet Counter crossed the maximum limit. Missed Packet Counter Overflow Bit When set, this bit indicates that the Rx Queue Missed Packet Counter crossed the maximum limit. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0b - Missed Packet Counter overflow not detected 1b - Missed Packet Counter overflow detected
26-16 MISPKTCNT	Missed Packet Counter This field indicates the number of packets missed by the DWC_ether_qos because the application asserted ari_pkt_flush_i[] for this queue. Missed Packet Counter This field indicates the number of packets missed by the DWC_ether_qos because the application asserted ari_pkt_flush_i[] for this queue. This counter is reset when this register is read with mci_be_i[0] at 1b1. This counter is incremented by 1 when the DMA discards the packet because of buffer unavailability. Access restriction applies. Clears on read. Self-set to 1 on internal event.
15-12 —	Reserved
11 OVFCNTOVF	Overflow Counter Overflow Bit When set, this bit indicates that the Rx Queue Overflow Packet Counter field crossed the maximum limit. Overflow Counter Overflow Bit When set, this bit indicates that the Rx Queue Overflow Packet Counter field crossed the maximum limit. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0b - Overflow Counter overflow not detected 1b - Overflow Counter overflow detected
10-0 OVFPKTCNT	Overflow Packet Counter This field indicates the number of packets discarded by the DWC_ether_qos because of Receive queue overflow. Overflow Packet Counter This field indicates the number of packets discarded by the DWC_ether_qos because of Receive queue overflow. This counter is incremented each time the DWC_ether_qos discards an incoming packet because of overflow. This counter is reset when this register is read with mci_be_i[0] at 1'b1. Access restriction applies. Clears on read. Self-set to 1 on internal event.

61.7.1.461 Queue 4 Receive Debug (MTL_RXQ4_DEBUG)

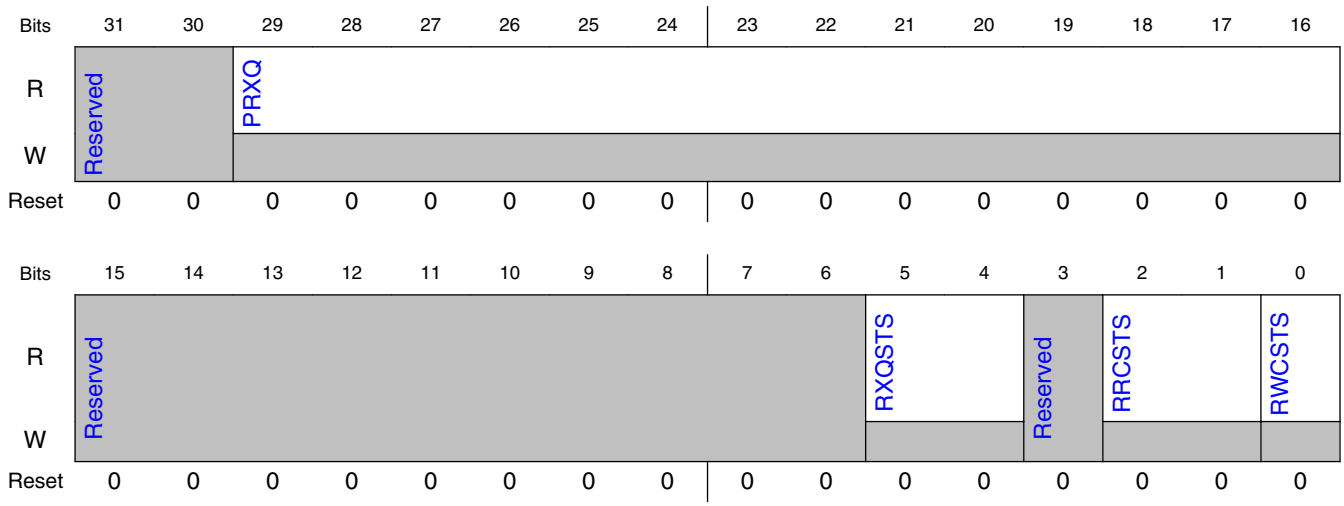
61.7.1.461.1 Offset

Register	Offset
MTL_RXQ4_DEBUG	E38h

61.7.1.461.2 Function

The Queue 4 Receive Debug register gives the debug status of various blocks related to the Receive queue.

61.7.1.461.3 Diagram



61.7.1.461.4 Fields

Field	Function
31-30 —	Reserved
29-16 PRXQ	Number of Packets in Receive Queue This field indicates the current number of packets in the Rx Queue. Number of Packets in Receive Queue This field indicates the current number of packets in the Rx Queue. The theoretical maximum value for this field is 256KB/16B = 16K Packets, that is, Max_Queue_Size/Min_Packet_Size.
15-6 —	Reserved
5-4 RXQSTS	MTL Rx Queue Fill-Level Status This field gives the status of the fill-level of the Rx Queue: 00b - Rx Queue empty 01b - Rx Queue fill-level below flow-control deactivate threshold 10b - Rx Queue fill-level above flow-control activate threshold 11b - Rx Queue full
3 —	Reserved
2-1 RRCSTS	MTL Rx Queue Read Controller State This field gives the state of the Rx queue Read controller: 00b - Idle state 01b - Reading packet data 10b - Reading packet status (or timestamp)

Table continues on the next page...

Field	Function
	11b - Flushing the packet data and status
0 RWCSTS	MTL Rx Queue Write Controller Active Status When high, this bit indicates that the MTL Rx queue Write controller is active, and it is transferring a received packet to the Rx Queue. 0b - MTL Rx Queue Write Controller Active Status not detected 1b - MTL Rx Queue Write Controller Active Status detected

61.7.1.462 Queue 4 Receive Control (MTL_RXQ4_CONTROL)

61.7.1.462.1 Offset

Register	Offset
MTL_RXQ4_CONTROL	E3Ch

61.7.1.462.2 Function

The Queue 4 Receive Control register controls the receive arbitration and passing of received packets to the application.

3 RXQ_FRM_ARBIT	Receive Queue Packet Arbitration When this bit is set, the DWC_ether_qos drives the packet data to the ARI interface such that the entire packet data of currently-selected queue is transmitted before switching to other queue. Receive Queue Packet Arbitration When this bit is set, the DWC_ether_qos drives the packet data to the ARI interface such that the entire packet data of currently-selected queue is transmitted before switching to other queue. When this bit is reset, the DWC_ether_qos drives the packet data to the ARI interface such that the following amount of data of currently-selected queue is transmitted before switching to other queue: - PBL amount of data (indicated by ari_qN_pbl_i[]) or - Complete data of a packet The status and the timestamp are not a part of the PBL data. Therefore, the DWC_ether_qos drives the complete status (including timestamp status) during first PBL request for the packet (in store-and-forward mode) or the last PBL request for the packet (in Threshold mode). 0b - Receive Queue Packet Arbitration is disabled 1b - Receive Queue Packet Arbitration is enabled
2-0 RXQ_WEGT	Receive Queue Weight This field indicates the weight assigned to the Rx Queue 4. Receive Queue Weight This field indicates the weight assigned to the Rx Queue 4. The weight is used as the number of continuous PBL or packets requests (depending on the RXQ_FRM_ARBIT) allocated to the queue in one arbitration cycle.

61.7.1.463 DMA Bus Mode (DMA_MODE)

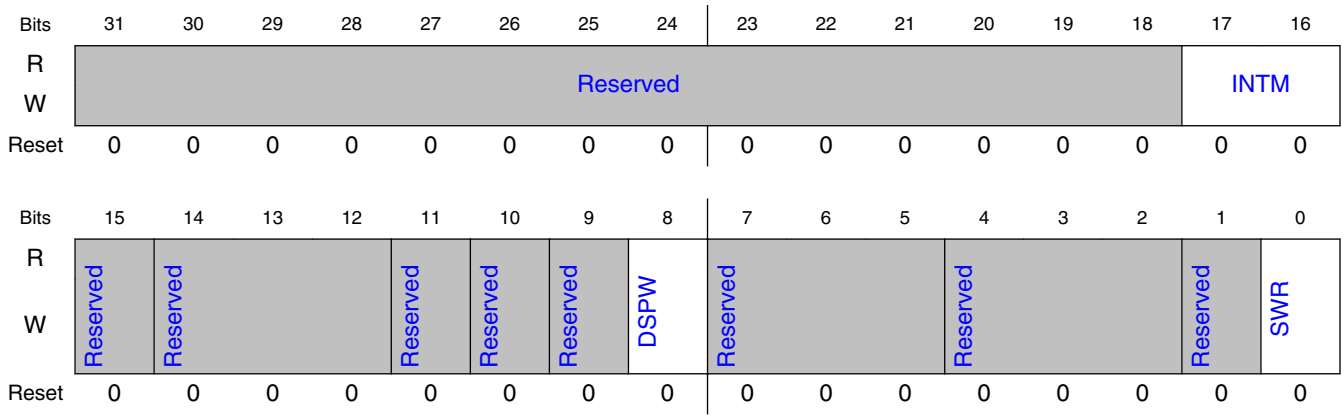
61.7.1.463.1 Offset

Register	Offset
DMA_MODE	1000h

61.7.1.463.2 Function

The Bus Mode register establishes the bus operating modes for the DMA.

61.7.1.463.3 Diagram



61.7.1.463.4 Fields

Field	Function
31-18 —	Reserved
17-16 INTM	Interrupt Mode This field defines the interrupt mode of DWC_ether_qos. Interrupt Mode This field defines the interrupt mode of DWC_ether_qos. The behavior of the following outputs changes depending on the following settings: - sbd_perch_tx_intr_o[] (Transmit Per Channel Interrupt) - sbd_perch_rx_intr_o[] (Receive Per Channel Interrupt) - sbd_intr_o (Common Interrupt) It also changes the behavior of the RI/TI bits in the STATUS. - 00: sbd_perch_* are pulse signals for each TX/RX packet transfer completion events (irrespective of whether corresponding interrupts are enabled) for which IOC bits are enabled in descriptor. sbd_intr_o is also asserted when corresponding interrupts are enabled and cleared only when software clears the corresponding RI/TI status bits. - 01: sbd_perch_* are level signals asserted on TX/RX packet transfer completion event when corresponding interrupts are enabled and de-asserted when the software clears the corresponding RI/TI status bits. The sbd_intr_o is not asserted for these TX/RX packet transfer completion events. - 10: sbd_perch_* are level signals asserted on TX/RX packet transfer completion event when corresponding interrupts are enabled and de-asserted when the software clears the corresponding RI/TI status bits. However, the signal is asserted again if the same event occurred again before it was cleared. The sbd_intr_o is not asserted for these TX/RX packet transfer completion events. - 11: Reserved For more details please refer Table "DWC_ether_qos Transfer Complete Interrupt Behavior". 00b - See above description 01b - See above description 10b - See above description 11b - Reserved

8 DSPW	Descriptor Posted Write When this bit is set to 0, the descriptor writes are always non-posted. Descriptor Posted Write When this bit is set to 0, the descriptor writes are always non-posted. When this bit is set to 1, the descriptor writes are non-posted only when IOC (Interrupt on completion) is set in last descriptor, otherwise the descriptor writes are always posted. 0b - Descriptor Posted Write is disabled 1b - Descriptor Posted Write is enabled
7-5 —	Reserved
4-2 —	Reserved
1 —	Reserved
0 SWR	Software Reset When this bit is set, the MAC and the DMA controller reset the logic and all internal registers of the DMA, MTL, and MAC. Software Reset When this bit is set, the MAC and the DMA controller reset the logic and all internal registers of the DMA, MTL, and MAC. This bit is automatically cleared after the reset operation is complete in all DWC_ether_qos clock domains. Before reprogramming any DWC_ether_qos register, a value of zero should be read in this bit. This bit must be read at least 4 CSR clock cycles after it is written to 1. Note: The reset operation is complete only when all resets in all active clock domains are de-asserted. Therefore, it is essential that all PHY inputs clocks (applicable for the selected PHY interface) are present for software reset completion. The time to complete the software reset operation depends on the frequency of the slowest active clock. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0b - Software Reset is disabled 1b - Software Reset is enabled

61.7.1.464 DMA System Bus Mode (DMA_SYSBUS_MODE)

61.7.1.464.1 Offset

Register	Offset
DMA_SYSBUS_MODE	1004h

61.7.1.464.2 Function

The System Bus mode register controls the behavior of the AHB or AXI master. It mainly controls burst splitting and number of outstanding requests.

61.7.1.466.4 Fields

Field	Function
31-28 TPS2	DMA Channel 2 Transmit Process State This field indicates the Tx DMA FSM state for Channel 2. DMA Channel 2 Transmit Process State This field indicates the Tx DMA FSM state for Channel 2. The MSB of this field always returns 0. This field does not generate an interrupt. 0000b - Stopped (Reset or Stop Transmit Command issued) 0001b - Running (Fetching Tx Transfer Descriptor) 0010b - Running (Waiting for status) 0011b - Running (Reading Data from system memory buffer and queuing it to the Tx buffer (Tx FIFO)) 0100b - Timestamp write state 0101b - Reserved for future use 0110b - Suspended (Tx Descriptor Unavailable or Tx Buffer Underflow) 0111b - Running (Closing Tx Descriptor)
27-24 RPS2	DMA Channel 2 Receive Process State This field indicates the Rx DMA FSM state for Channel 2. DMA Channel 2 Receive Process State This field indicates the Rx DMA FSM state for Channel 2. The MSB of this field always returns 0. This field does not generate an interrupt. 0000b - Stopped (Reset or Stop Receive Command issued) 0001b - Running (Fetching Rx Transfer Descriptor) 0010b - Reserved for future use 0011b - Running (Waiting for Rx packet) 0100b - Suspended (Rx Descriptor Unavailable) 0101b - Running (Closing the Rx Descriptor) 0110b - Timestamp write state 0111b - Running (Transferring the received packet data from the Rx buffer to the system memory)
23-20 TPS1	DMA Channel 1 Transmit Process State This field indicates the Tx DMA FSM state for Channel 1. DMA Channel 1 Transmit Process State This field indicates the Tx DMA FSM state for Channel 1. The MSB of this field always returns 0. This field does not generate an interrupt. 0000b - Stopped (Reset or Stop Transmit Command issued) 0001b - Running (Fetching Tx Transfer Descriptor) 0010b - Running (Waiting for status) 0011b - Running (Reading Data from system memory buffer and queuing it to the Tx buffer (Tx FIFO)) 0100b - Timestamp write state 0101b - Reserved for future use 0110b - Suspended (Tx Descriptor Unavailable or Tx Buffer Underflow) 0111b - Running (Closing Tx Descriptor)
19-16 RPS1	DMA Channel 1 Receive Process State This field indicates the Rx DMA FSM state for Channel 1. DMA Channel 1 Receive Process State This field indicates the Rx DMA FSM state for Channel 1. The MSB of this field always returns 0. This field does not generate an interrupt. 0000b - Stopped (Reset or Stop Receive Command issued)

Table continues on the next page...

Field	Function
	0001b - Running (Fetching Rx Transfer Descriptor) 0010b - Reserved for future use 0011b - Running (Waiting for Rx packet) 0100b - Suspended (Rx Descriptor Unavailable) 0101b - Running (Closing the Rx Descriptor) 0110b - Timestamp write state 0111b - Running (Transferring the received packet data from the Rx buffer to the system memory)
15-12 TPS0	DMA Channel 0 Transmit Process State This field indicates the Tx DMA FSM state for Channel 0. DMA Channel 0 Transmit Process State This field indicates the Tx DMA FSM state for Channel 0. The MSB of this field always returns 0. This field does not generate an interrupt. 0000b - Stopped (Reset or Stop Transmit Command issued) 0001b - Running (Fetching Tx Transfer Descriptor) 0010b - Running (Waiting for status) 0011b - Running (Reading Data from system memory buffer and queuing it to the Tx buffer (Tx FIFO)) 0100b - Timestamp write state 0101b - Reserved for future use 0110b - Suspended (Tx Descriptor Unavailable or Tx Buffer Underflow) 0111b - Running (Closing Tx Descriptor)
11-8 RPS0	DMA Channel 0 Receive Process State This field indicates the Rx DMA FSM state for Channel 0. DMA Channel 0 Receive Process State This field indicates the Rx DMA FSM state for Channel 0. The MSB of this field always returns 0. This field does not generate an interrupt. 0000b - Stopped (Reset or Stop Receive Command issued) 0001b - Running (Fetching Rx Transfer Descriptor) 0010b - Reserved for future use 0011b - Running (Waiting for Rx packet) 0100b - Suspended (Rx Descriptor Unavailable) 0101b - Running (Closing the Rx Descriptor) 0110b - Timestamp write state 0111b - Running (Transferring the received packet data from the Rx buffer to the system memory)
7-2 —	Reserved
1 AXRHSTS	AXI Master Read Channel Status When high, this bit indicates that the read channel of the AXI master is active, and it is transferring the data. 0b - AXI Master Read Channel Status not detected 1b - AXI Master Read Channel Status detected
0 AXWHSTS	AXI Master Write Channel When high, this bit indicates that the write channel of the AXI master is active, and it is transferring data. 0b - AXI Master Write Channel or AHB Master Status not detected 1b - AXI Master Write Channel or AHB Master Status detected

61.7.1.467 DMA Debug Status 1 (DMA_DEBUG_STATUS1)

61.7.1.467.1 Offset

Register	Offset
DMA_DEBUG_STATUS1	1010h

61.7.1.467.2 Function

The Debug Status1 register gives the Receive and Transmit process status for DMA Channel 3-Channel 6.

0 FTOV	Fetch Time Offset Valid When set indicates the FTOS field is valid. When not set, indicates the Fetch Offset is not valid and the DMA engine can fetch the frames from host memory without any time restrictions. 0b - Fetch Time Offset is invalid 1b - Fetch Time Offset is valid

61.7.1.473 DMA Channel 0 Control (DMA_CH0_CONTROL)

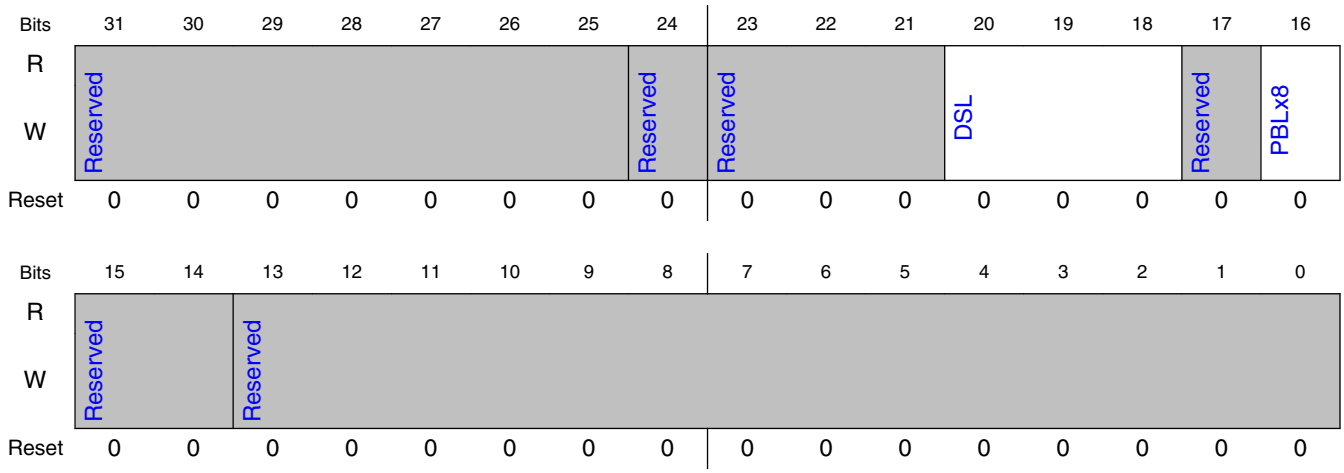
61.7.1.473.1 Offset

Register	Offset
DMA_CH0_CONTROL	1100h

61.7.1.473.2 Function

The DMA Channel 0 Control register specifies the MSS value for segmentation, length to skip between two descriptors, and also the features such as header splitting and 8xPBL mode.

61.7.1.473.3 Diagram



61.7.1.473.4 Fields

Field	Function
31-25 —	Reserved
24 —	Reserved
23-21 —	Reserved
20-18 DSL	Descriptor Skip Length This bit specifies the Word, Dword, or Lword number (depending on the 32-bit, 64-bit, or 128-bit bus) to skip between two unchained descriptors. Descriptor Skip Length This bit specifies the Word, Dword, or Lword number (depending on the 32-bit, 64-bit, or 128-bit bus) to skip between two unchained descriptors. The address skipping starts from the end of the current descriptor to the start of the next descriptor. When the DSL value is equal to zero, the DMA takes the descriptor table as contiguous.
17 —	Reserved
16 PBLx8	8xPBL mode When this bit is set, the PBL value programmed in Bits[21:16] in DMA_CH0_TX_CONTROL and Bits[21:16] in DMA_CH0_RX_CONTROL is multiplied by eight times. 8xPBL mode When this bit is set, the PBL value programmed in Bits[21:16] in DMA_CH0_TX_CONTROL and Bits[21:16] in DMA_CH0_RX_CONTROL is multiplied by eight times. Therefore, the DMA transfers the data in 8, 16, 32, 64, 128, and 256 beats depending on the PBL value. 0b - 8xPBL mode is disabled 1b - 8xPBL mode is enabled
15-14 —	Reserved

Table continues on the next page...

Field	Function

61.7.1.474 DMA Channel 0 Transmit Control (DMA_CH0_TX_CONTROL)

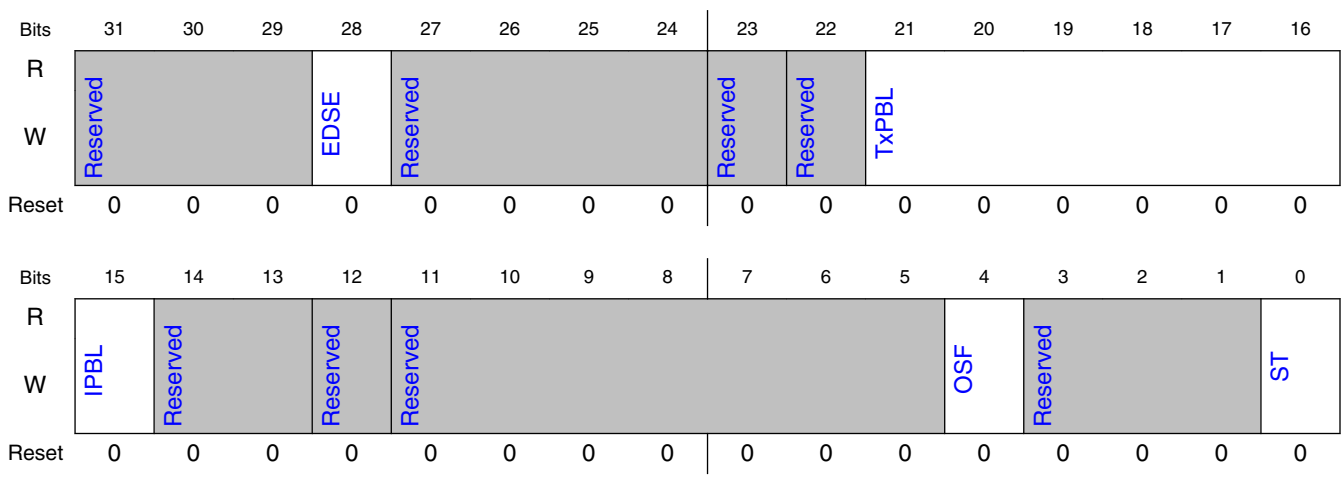
61.7.1.474.1 Offset

Register	Offset
DMA_CH0_TX_CONTROL	1104h

61.7.1.474.2 Function

The DMA Channel 0 Transmit Control register controls the Tx features such as PBL, TCP segmentation, and Tx Channel weights.

61.7.1.474.3 Diagram



61.7.1.474.4 Fields

Field	Function
31-29	Reserved

Table continues on the next page...

Field	Function
—	
28 EDSE	Enhanced Descriptor Enable When this bit is set, the corresponding channel uses Enhanced Descriptors that are 32 Bytes for both Normal and Context Descriptors. Enhanced Descriptor Enable When this bit is set, the corresponding channel uses Enhanced Descriptors that are 32 Bytes for both Normal and Context Descriptors. When reset, the corresponding channel uses the descriptors that are 16 Bytes. 0b - Enhanced Descriptor is disabled 1b - Enhanced Descriptor is enabled
27-24 —	Reserved
23 —	Reserved
22 —	Reserved
21-16 TxPBL	Transmit Programmable Burst Length These bits indicate the maximum number of beats to be transferred in one DMA block data transfer. Transmit Programmable Burst Length These bits indicate the maximum number of beats to be transferred in one DMA block data transfer. The DMA always attempts max burst as specified in PBL each time it starts a burst transfer on the application bus. You can program PBL with any of the following values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior. To transfer more than 32 beats, perform the following steps: 1. Set the 8xPBL mode in CONTROL register. 2. Set the TxPBL. Note: The maximum value of TxPBL must be less than or equal to half the Tx Queue size (TQS field of TXQ0_OPERATION_MODE register) in terms of beats. This is required so that the Tx Queue has space to store at least another Tx PBL worth of data while the MTL Tx Queue Controller is transferring data to MAC. For example, in 64-bit data width configurations the total locations in Tx Queue of size 512 bytes is 64, TxPBL and 8xPBL needs to be programmed to less than or equal to 32.
15 IPBL	Ignore PBL Requirement When this bit is set, the DMA does not check for PBL number of locations in the MTL before initiating a transfer. Ignore PBL Requirement When this bit is set, the DMA does not check for PBL number of locations in the MTL before initiating a transfer. If space is not available, the MTL may use handshaking to slow the DMA. Note: This bit/mode must not be used when multiple Transmit DMA Channels are enabled as it may block other Transmit and Receive DMA Channels from accessing the Read Data Channel of AXI bus until space is available in Transmit Queue for current transfer. 0b - Ignore PBL Requirement is disabled 1b - Ignore PBL Requirement is enabled
14-13 —	Reserved
12 —	Reserved

Table continues on the next page...

Field	Function
11-5 —	Reserved
4 OSF	Operate on Second Packet When this bit is set, it instructs the DMA to process the second packet of the Transmit data even before the status for the first packet is obtained. 0b - Operate on Second Packet disabled 1b - Operate on Second Packet enabled
3-1 —	Reserved
0 ST	Start or Stop Transmission Command When this bit is set, transmission is placed in the Running state. Start or Stop Transmission Command When this bit is set, transmission is placed in the Running state. The DMA checks the Transmit list at the current position for a packet to be transmitted. The DMA tries to acquire descriptor from either of the following positions: - The current position in the list This is the base address of the Transmit list set by the DMA_CH0_TXDESC_LIST_ADDRESS register. - The position at which the transmission was previously stopped If the DMA does not own the current descriptor, the transmission enters the Suspended state and the TBU bit of the STATUS register is set. The Start Transmission command is effective only when the transmission is stopped. If the command is issued before setting the DMA_CH0_TXDESC_LIST_ADDRESS register, the DMA behavior is unpredictable. When this bit is reset, the transmission process is placed in the Stopped state after completing the transmission of the current packet. The Next Descriptor position in the Transmit list is saved, and it becomes the current position when the transmission is restarted. To change the list address, you need to program TXDESC_LIST_ADDRESS register with a new value when this bit is reset. The new value is considered when this bit is set again. The stop transmission command is effective only when the transmission of the current packet is complete or the transmission is in the Suspended state. 0b - Stop Transmission Command 1b - Start Transmission Command

61.7.1.475 DMA Channel 0 Receive Control (DMA_CH0_RX_CONTROL)

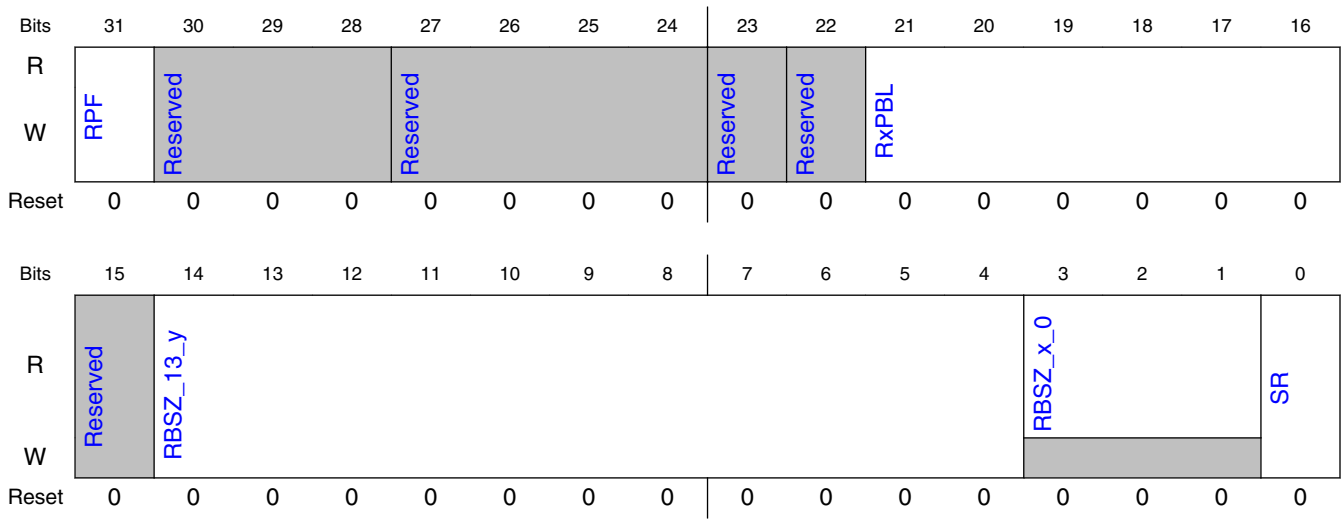
61.7.1.475.1 Offset

Register	Offset
DMA_CH0_RX_CONTROL	1108h

61.7.1.475.2 Function

The DMA Channel 0 Receive Control register controls the Rx features such as PBL, buffer size, and extended status.

61.7.1.475.3 Diagram



61.7.1.475.4 Fields

Field	Function
31 RPF	Rx Packet Flush. Rx Packet Flush. When this bit is set to 1, then DWC_ether_qos automatically flushes the packet from the Rx Queues destined to this DMA Rx Channel, when it is stopped. When this bit remains set and the DMA is re-started by the software driver, the packets residing in the Rx Queues that were received when this RxDMA was stopped, get flushed out. The packets that are received by the MAC after the RxDMA is re-started are routed to the RxDMA. The flushing happens on the Read side of the Rx Queue. When this bit is set to 0, the DWC_ether_qos not flush the packet in the Rx Queue destined to this RxDMA Channel when it is STOP state. This may in turn cause head-of-line blocking in the corresponding RxQueue. 0b - Rx Packet Flush is disabled 1b - Rx Packet Flush is enabled
30-28 —	Reserved
27-24 —	Reserved
23 —	Reserved
22	Reserved

Table continues on the next page...

Field	Function
—	
21-16 RxPBL	Receive Programmable Burst Length These bits indicate the maximum number of beats to be transferred in one DMA block data transfer. Receive Programmable Burst Length These bits indicate the maximum number of beats to be transferred in one DMA block data transfer. The DMA always attempts max burst as specified in PBL each time it starts a burst transfer on the application bus. You can program PBL with any of the following values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior. To transfer more than 32 beats, perform the following steps: 1. Set the 8xPBL mode in the DMA_CH0_CONTROL register. 2. Set the RxPBL. Note: The maximum value of RxPBL must be less than or equal to half the Rx Queue size (RQS field of RXQ0_OPERATION_MODE register) in terms of beats. This is required so that the Rx Queue has space to store at least another Rx PBL worth of data while the Rx DMA is transferring a block of data. For example, in 64-bit data width configurations the total locations in Rx Queue of size 512 bytes is 64, so RxPBL and 8xPBL needs to be programmed to less than or equal to 32.
15 —	Reserved
14-4 RBSZ_13_y	Receive Buffer size High RBSZ[13:0] is split into two fields higher RBSZ_13_y and lower RBSZ_x_0. Receive Buffer size High RBSZ[13:0] is split into two fields higher RBSZ_13_y and lower RBSZ_x_0. The RBSZ[13:0] field indicates the size of the Rx buffers specified in bytes. The maximum buffer size is limited to 16K bytes. The buffer size is applicable to payload buffers when split headers are enabled. Note: The buffer size must be a multiple of 4, 8, or 16 depending on the data bus widths (32-bit, 64-bit, or 128-bit respectively). This is required even if the value of buffer address pointer is not aligned to data bus width. Hence the lower RBSZ_x_0 bits are read-only and the value is considered as all-zero. Thus the RBSZ_13_y indicates the buffer size in terms of locations (with the width same as bus-width).
3-1 RBSZ_x_0	Receive Buffer size Low RBSZ[13:0] is split into two fields RBSZ_13_y and RBSZ_x_0. Receive Buffer size Low RBSZ[13:0] is split into two fields RBSZ_13_y and RBSZ_x_0. The RBSZ_x_0 is the lower field whose width is based on data bus width of the configuration. This field is of width 2, 3, or 4 bits for 32-bit, 64-bit, or 128-bit data bus width respectively. This field is read-only (RO).
0 SR	Start or Stop Receive When this bit is set, the DMA tries to acquire the descriptor from the Receive list and processes the incoming packets. Start or Stop Receive When this bit is set, the DMA tries to acquire the descriptor from the Receive list and processes the incoming packets. The DMA tries to acquire descriptor from either of the following positions: - The current position in the list This is the address set by the DMA_CH0_RXDESC_LIST_ADDRESS register. - The position at which the Rx process was previously stopped

Field	Function
	If the DMA does not own the current descriptor, the reception is suspended and the RBU bit of the DMA_CH0_STATUS register is set. The Start Receive command is effective only when the reception is stopped. If the command is issued before setting the DMA_CH0_RXDESC_LIST_ADDRESS register, the DMA behavior is unpredictable. When this bit is reset, the Rx DMA operation is stopped after the transfer of the current packet. The next descriptor position in the Receive list is saved, and it becomes the current position after the Rx process is restarted. The Stop Receive command is effective only when the Rx process is in the Running (waiting for Rx packet) or Suspended state. 0b - Stop Receive 1b - Start Receive

61.7.1.476 Channel 0 Tx Descriptor List Address register (DMA_CH0_TXDESC_LIST_ADDRESS)

61.7.1.476.1 Offset

Register	Offset
DMA_CH0_TXDESC_LIST_ADDRESS	1114h

61.7.1.476.2 Function

The Channel 0 Tx Descriptor List Address register points the DMA to the start of Transmit descriptor list. The descriptor lists reside in the physical memory space of the application and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LSB to low.

You can write to this register only when the Tx DMA has stopped, that is, the ST bit is set to zero in TX_CONTROL register. When stopped, this register can be written with a new descriptor list address. When you set the ST bit to 1, the DMA takes the newly-programmed descriptor base address. If this register is not changed when the ST bit is set to 0, the DMA takes the descriptor address where it was stopped earlier.

61.7.1.476.3 Diagram

Register	Offset
DMA_CH0_RXDESC_LIST_ADDRESS	111Ch

61.7.1.477.2 Function

The Channel 0 Rx Descriptor List Address register points the DMA to the start of Receive descriptor list.

This register points to the start of the Receive Descriptor List. The descriptor lists reside in the physical memory space of the application and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LS bits low. Writing to this register is permitted only when reception is stopped. When stopped, this register must be written to before the receive Start command is given. You can write to this register only when Rx DMA has stopped, that is, SR bit is set to zero in RX_CONTROL register. When stopped, this register can be written with a new descriptor list address.

When you set the SR bit to 1, the DMA takes the newly programmed descriptor base address.

61.7.1.477.4 Fields

Field	Function
31-3 RDESLA	Start of Receive List This field contains the base address of the first descriptor in the Rx Descriptor list. Start of Receive List This field contains the base address of the first descriptor in the Rx Descriptor list. The DMA ignores the LSB bits (1:0, 2:0, or 3:0) for 32-bit, 64-bit, or 128-bit bus width and internally takes these bits as all-zero. Therefore, these LSB bits are read-only (RO). The width of this field depends on the configuration: - 31:2 for 32-bit configuration - 31:3 for 64-bit configuration - 31:4 for 128-bit configuration
2-0	Reserved

Table continues on the next page...

Field	Function
	For example, when RWT=2 and RWTU=1, the watchdog timer is set for 2*512=1024 system clock cycles.
15-8 —	Reserved
7-0 RWT	Receive Interrupt Watchdog Timer Count This field indicates the number of system clock cycles, multiplied by factor indicated in RWTU field, for which the watchdog timer is set. Receive Interrupt Watchdog Timer Count This field indicates the number of system clock cycles, multiplied by factor indicated in RWTU field, for which the watchdog timer is set. The watchdog timer is triggered with the programmed value after the Rx DMA completes the transfer of a packet for which the RI bit is not set in the STATUS register, because of the setting of Interrupt Enable bit in the corresponding descriptor RDES3[30]. When the watchdog timer runs out, the RI bit is set and the timer is stopped. The watchdog timer is reset when the RI bit is set high because of automatic setting of RI as per the Interrupt Enable bit RDES3[30] of any received packet.

61.7.1.484 Channel 0 Slot Function Control and Status (DMA_CH0_SLOT_FUNCTION_CONTROL_STATUS)

61.7.1.484.1 Offset

Register	Offset
DMA_CH0_SLOT_FUNCTION_CONTROL_STATUS	113Ch

61.7.1.484.2 Function

The Slot Function Control and Status register contains the control bits for slot function and the status for Transmit path.

61.7.1.484.3 Diagram

Field	Function
	-- 1'b0: Error during data buffer access - Bit 19 -- 1'b1: Error during read transfer -- 1'b0: Error during write transfer This field is valid only when the FBE bit is set. This field does not generate an interrupt.
18-16 TEB	Tx DMA Error Bits This field indicates the type of error that caused a Bus Error. Tx DMA Error Bits This field indicates the type of error that caused a Bus Error. For example, error response on the AHB or AXI interface. - Bit 18 -- 1'b1: Error during data transfer by Tx DMA -- 1'b0: No Error during data transfer by Tx DMA - Bit 17 -- 1'b1: Error during descriptor access -- 1'b0: Error during data buffer access - Bit 16 -- 1'b1: Error during read transfer -- 1'b0: Error during write transfer This field is valid only when the FBE bit is set. This field does not generate an interrupt.
15 NIS	Normal Interrupt Summary Normal Interrupt Summary bit value is the logical OR of the following bits when the corresponding interrupt bits are enabled in the DMA_CH0_INTERRUPT_ENABLE register: - Bit 0: Transmit Interrupt - Bit 2: Transmit Buffer Unavailable - Bit 6: Receive Interrupt - Bit 11: Early Receive Interrupt Only unmasked bits (interrupts for which interrupt enable is set in INTERRUPT_ENABLE register) affect the Normal Interrupt Summary bit. Normal Interrupt Summary Normal Interrupt Summary bit value is the logical OR of the following bits when the corresponding interrupt bits are enabled in the DMA_CH0_INTERRUPT_ENABLE register: - Bit 0: Transmit Interrupt - Bit 2: Transmit Buffer Unavailable - Bit 6: Receive Interrupt - Bit 11: Early Receive Interrupt Only unmasked bits (interrupts for which interrupt enable is set in INTERRUPT_ENABLE register) affect the Normal Interrupt Summary bit. This is a sticky bit. You must clear this bit (by writing 1 to this bit) each time a corresponding bit which causes NIS to be set is cleared. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Normal Interrupt Summary status not detected 1b - Normal Interrupt Summary status detected
14 AIS	Abnormal Interrupt Summary Abnormal Interrupt Summary bit value is the logical OR of the following when the corresponding interrupt bits are enabled in the INTERRUPT_ENABLE register: - Bit 1: Transmit Process Stopped - Bit 7: Receive Buffer Unavailable - Bit 8: Receive Process Stopped - Bit 10: Early Transmit Interrupt - Bit 12: Fatal Bus Error - Bit 13: Context Descriptor Error Only unmasked bits affect the Abnormal Interrupt Summary bit.

Table continues on the next page...

Field	Function
	Abnormal Interrupt Summary Abnormal Interrupt Summary bit value is the logical OR of the following when the corresponding interrupt bits are enabled in the DMA_CH0_INTERRUPT_ENABLE register: - Bit 1: Transmit Process Stopped - Bit 7: Receive Buffer Unavailable - Bit 8: Receive Process Stopped - Bit 10: Early Transmit Interrupt - Bit 12: Fatal Bus Error - Bit 13: Context Descriptor Error Only unmasked bits affect the Abnormal Interrupt Summary bit. This is a sticky bit. You must clear this bit (by writing 1 to this bit) each time a corresponding bit, which causes AIS to be set, is cleared. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Abnormal Interrupt Summary status not detected 1b - Abnormal Interrupt Summary status detected
13 CDE	Context Descriptor Error This bit indicates that the DMA Tx/Rx engine received a descriptor error, which indicates invalid context in the middle of packet flow (intermediate descriptor) or all ones descriptor in Tx case and on Rx side it indicates DMA has read a descriptor with either of the buffer address as ones which is considered to be invalid. Context Descriptor Error This bit indicates that the DMA Tx/Rx engine received a descriptor error, which indicates invalid context in the middle of packet flow (intermediate descriptor) or all ones descriptor in Tx case and on Rx side it indicates DMA has read a descriptor with either of the buffer address as ones which is considered to be invalid. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Context Descriptor Error status not detected 1b - Context Descriptor Error status detected
12 FBE	Fatal Bus Error This bit indicates that a bus error occurred (as described in the EB field). Fatal Bus Error This bit indicates that a bus error occurred (as described in the EB field). When this bit is set, the corresponding DMA channel engine disables all bus accesses. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Fatal Bus Error status not detected 1b - Fatal Bus Error status detected
11 ERI	Early Receive Interrupt This bit when set indicates that the RxDMA has completed the transfer of packet data to the memory. Early Receive Interrupt This bit when set indicates that the RxDMA has completed the transfer of packet data to the memory. In configs supporting ERIC, When ERIC=0, this bit is set only after the Rx DMA has filled up a complete receive buffer with packet data. When ERIC=1, this bit is set after every burst transfer of data from the Rx DMA to the buffer. The setting of RI bit automatically clears this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Early Receive Interrupt status not detected

Table continues on the next page...

Field	Function
	1b - Early Receive Interrupt status detected
10 ETI	Early Transmit Interrupt This bit when set indicates that the TxDMA has completed the transfer of packet data to the MTL TXFIFO memory. Early Transmit Interrupt This bit when set indicates that the TxDMA has completed the transfer of packet data to the MTL TXFIFO memory. In configs supporting ETIC: When ETIC=0, this bit is set only after the Tx DMA has transferred a complete packet to MTL. When ETIC=1, this bit is set after completion of (partial) packet data transfer from buffers in the Transmit descriptor in which IOC=1. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Early Transmit Interrupt status not detected 1b - Early Transmit Interrupt status detected
9 RWT	Receive Watchdog Timeout This bit is asserted when a packet with length greater than 2,048 bytes (10,240 bytes when Jumbo Packet mode is enabled) is received. 0b - Receive Watchdog Timeout status not detected 1b - Receive Watchdog Timeout status detected
8 RPS	Receive Process Stopped This bit is asserted when the Rx process enters the Stopped state. Receive Process Stopped This bit is asserted when the Rx process enters the Stopped state. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Receive Process Stopped status not detected 1b - Receive Process Stopped status detected
7 RBU	Receive Buffer Unavailable This bit indicates that the application owns the next descriptor in the Receive list, and the DMA cannot acquire it. Receive Buffer Unavailable This bit indicates that the application owns the next descriptor in the Receive list, and the DMA cannot acquire it. The Rx process is suspended. To resume processing Rx descriptors, the application should change the ownership of the descriptor and issue a Receive Poll Demand command. If this command is not issued, the Rx process resumes when the next recognized incoming packet is received. In ring mode, the application should advance the Receive Descriptor Tail Pointer register of a channel. This bit is set only when the DMA owns the previous Rx descriptor. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Receive Buffer Unavailable status not detected 1b - Receive Buffer Unavailable status detected
6 RI	Receive Interrupt This bit indicates that the packet reception is complete. Receive Interrupt This bit indicates that the packet reception is complete. When packet reception is complete, Bit 31 of RDES3 is reset in the last descriptor, and the specific packet status information is updated in the descriptor. The reception remains in the Running state. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Receive Interrupt status not detected 1b - Receive Interrupt status detected
5-3 —	Reserved

Table continues on the next page...

Field	Function
2 TBU	Transmit Buffer Unavailable This bit indicates that the application owns the next descriptor in the Transmit list, and the DMA cannot acquire it. Transmit Buffer Unavailable This bit indicates that the application owns the next descriptor in the Transmit list, and the DMA cannot acquire it. Transmission is suspended. The TPS0 field of the DEBUG_STATUS0 register explains the Transmit Process state transitions. To resume processing the Transmit descriptors, the application should do the following: 1. Change the ownership of the descriptor by setting Bit 31 of TDES3. 2. Issue a Transmit Poll Demand command. For ring mode, the application should advance the Transmit Descriptor Tail Pointer register of a channel. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Transmit Buffer Unavailable status not detected 1b - Transmit Buffer Unavailable status detected
1 TPS	Transmit Process Stopped This bit is set when the transmission is stopped. Transmit Process Stopped This bit is set when the transmission is stopped. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Transmit Process Stopped status not detected 1b - Transmit Process Stopped status detected
0 TI	Transmit Interrupt This bit indicates that the packet transmission is complete. Transmit Interrupt This bit indicates that the packet transmission is complete. When transmission is complete, Bit 31 of TDES3 is reset in the last descriptor, and the specific packet status information is updated in the descriptor. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Transmit Interrupt status not detected 1b - Transmit Interrupt status detected

61.7.1.490 Channel 0 Missed Frame Counter (DMA_CH0_MISS_FRAME_CNT)

61.7.1.490.1 Offset

Register	Offset
DMA_CH0_MISS_FRAME_CNT	1164h

61.7.1.490.2 Function

This register has the number of packet counter that got dropped by the DMA either due to Bus Error or due to programming RPF field in RX_CONTROL register.

21-16 TxPBL	Transmit Programmable Burst Length These bits indicate the maximum number of beats to be transferred in one DMA block data transfer. Transmit Programmable Burst Length

Table continues on the next page...

Field	Function
	These bits indicate the maximum number of beats to be transferred in one DMA block data transfer. The DMA always attempts max burst as specified in PBL each time it starts a burst transfer on the application bus. You can program PBL with any of the following values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior. To transfer more than 32 beats, perform the following steps: 1. Set the 8xPBL mode in CONTROL register. 2. Set the TxPBL. Note: The maximum value of TxPBL must be less than or equal to half the Tx Queue size (TQS field of TXQ1_OPERATION_MODE register) in terms of beats. This is required so that the Tx Queue has space to store at least another Tx PBL worth of data while the MTL Tx Queue Controller is transferring data to MAC. For example, in 64-bit data width configurations the total locations in Tx Queue of size 512 bytes is 64, TxPBL and 8xPBL needs to be programmed to less than or equal to 32.
15 IPBL	Ignore PBL Requirement When this bit is set, the DMA does not check for PBL number of locations in the MTL before initiating a transfer. Ignore PBL Requirement When this bit is set, the DMA does not check for PBL number of locations in the MTL before initiating a transfer. If space is not available, the MTL may use handshaking to slow the DMA. Note: This bit/mode must not be used when multiple Transmit DMA Channels are enabled as it may block other Transmit and Receive DMA Channels from accessing the Read Data Channel of AXI bus until space is available in Transmit Queue for current transfer. 0b - Ignore PBL Requirement is disabled 1b - Ignore PBL Requirement is enabled
14-13 —	Reserved
12 —	Reserved

4 OSF	Operate on Second Packet When this bit is set, it instructs the DMA to process the second packet of the Transmit data even before the status for the first packet is obtained. 0b - Operate on Second Packet disabled 1b - Operate on Second Packet enabled
3-1 —	Reserved
0 ST	Start or Stop Transmission Command When this bit is set, transmission is placed in the Running state. Start or Stop Transmission Command When this bit is set, transmission is placed in the Running state. The DMA checks the Transmit list at the current position for a packet to be transmitted. The DMA tries to acquire descriptor from either of the following positions: - The current position in the list This is the base address of the Transmit list set by the DMA_CH1_TXDESC_LIST_ADDRESS register. - The position at which the transmission was previously stopped

Field	Function
	If the DMA does not own the current descriptor, the transmission enters the Suspended state and the TBU bit of the DMA_CH1_STATUS register is set. The Start Transmission command is effective only when the transmission is stopped. If the command is issued before setting the DMA_CH1_TXDESC_LIST_ADDRESS register, the DMA behavior is unpredictable. When this bit is reset, the transmission process is placed in the Stopped state after completing the transmission of the current packet. The Next Descriptor position in the Transmit list is saved, and it becomes the current position when the transmission is restarted. To change the list address, you need to program TXDESC_LIST_ADDRESS register with a new value when this bit is reset. The new value is considered when this bit is set again. The stop transmission command is effective only when the transmission of the current packet is complete or the transmission is in the Suspended state. 0b - Stop Transmission Command 1b - Start Transmission Command

21-16 RxPBL	Receive Programmable Burst Length These bits indicate the maximum number of beats to be transferred in one DMA block data transfer. Receive Programmable Burst Length

Table continues on the next page...

Field	Function
	These bits indicate the maximum number of beats to be transferred in one DMA block data transfer. The DMA always attempts max burst as specified in PBL each time it starts a burst transfer on the application bus. You can program PBL with any of the following values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior. To transfer more than 32 beats, perform the following steps: 1. Set the 8xPBL mode in the CONTROL register. 2. Set the RxPBL. Note: The maximum value of RxPBL must be less than or equal to half the Rx Queue size (RQS field of RXQ1_OPERATION_MODE register) in terms of beats. This is required so that the Rx Queue has space to store at least another Rx PBL worth of data while the Rx DMA is transferring a block of data. For example, in 64-bit data width configurations the total locations in Rx Queue of size 512 bytes is 64, so RxPBL and 8xPBL needs to be programmed to less than or equal to 32.
15 —	Reserved
14-4 RBSZ_13_y	Receive Buffer size High RBSZ[13:0] is split into two fields higher RBSZ_13_y and lower RBSZ_x_0. Receive Buffer size High RBSZ[13:0] is split into two fields higher RBSZ_13_y and lower RBSZ_x_0. The RBSZ[13:0] field indicates the size of the Rx buffers specified in bytes. The maximum buffer size is limited to 16K bytes. The buffer size is applicable to payload buffers when split headers are enabled. Note: The buffer size must be a multiple of 4, 8, or 16 depending on the data bus widths (32-bit, 64-bit, or 128-bit respectively). This is required even if the value of buffer address pointer is not aligned to data bus width. Hence the lower RBSZ_x_0 bits are read-only and the value is considered as all-zero. Thus the RBSZ_13_y indicates the buffer size in terms of locations (with the width same as bus-width).
3-1 RBSZ_x_0	Receive Buffer size Low RBSZ[13:0] is split into two fields RBSZ_13_y and RBSZ_x_0. Receive Buffer size Low RBSZ[13:0] is split into two fields RBSZ_13_y and RBSZ_x_0. The RBSZ_x_0 is the lower field whose width is based on data bus width of the configuration. This field is of width 2, 3, or 4 bits for 32-bit, 64-bit, or 128-bit data bus width respectively. This field is read-only (RO).
0 SR	Start or Stop Receive When this bit is set, the DMA tries to acquire the descriptor from the Receive list and processes the incoming packets. Start or Stop Receive When this bit is set, the DMA tries to acquire the descriptor from the Receive list and processes the incoming packets. The DMA tries to acquire descriptor from either of the following positions: - The current position in the list This is the address set by the DMA_CH1_RXDESC_LIST_ADDRESS register. - The position at which the Rx process was previously stopped If the DMA does not own the current descriptor, the reception is suspended and the RBU bit of the DMA_CH1_STATUS register is set. The Start Receive command is effective only when the reception is stopped. If the command is issued before setting the DMA_CH1_RXDESC_LIST_ADDRESS register, the DMA behavior is unpredictable. When this bit is reset, the Rx DMA operation is stopped after the transfer of the current packet. The next descriptor position in the Receive list is saved, and it becomes the current position after the Rx process is restarted. The Stop Receive command is effective only when the Rx process is in the Running (waiting for Rx packet) or Suspended state.

	0b - Stop Receive 1b - Start Receive

61.7.1.495 Channel 1 Tx Descriptor List Address (DMA_CH1_TXDESC_LIST_ADDRESS)

61.7.1.495.1 Offset

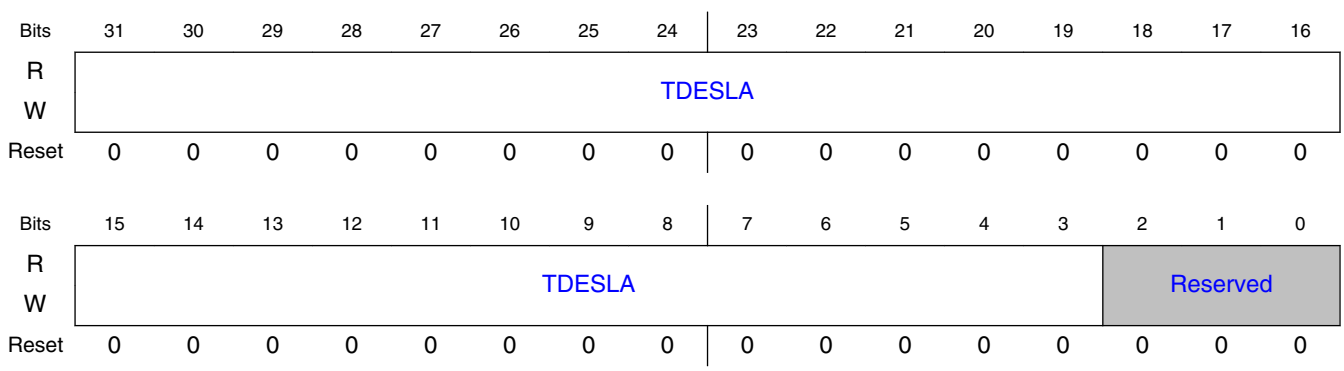
Register	Offset
DMA_CH1_TXDESC_LIST_ADDRESS	1194h

61.7.1.495.2 Function

The Channel 1 Tx Descriptor List Address register points the DMA to the start of Transmit descriptor list. The descriptor lists reside in the physical memory space of the application and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LSB to low.

You can write to this register only when the Tx DMA has stopped, that is, the ST bit is set to zero in DMA_CH1_TX_CONTROL register. When stopped, this register can be written with a new descriptor list address. When you set the ST bit to 1, the DMA takes the newly-programmed descriptor base address. If this register is not changed when the ST bit is set to 0, the DMA takes the descriptor address where it was stopped earlier.

61.7.1.495.3 Diagram



61.7.1.495.4 Fields

Field	Function
31-3 TDESLA	Start of Transmit List This field contains the base address of the first descriptor in the Transmit descriptor list. Start of Transmit List This field contains the base address of the first descriptor in the Transmit descriptor list. The DMA ignores the LSB bits (1:0, 2:0, or 3:0) for 32-bit, 64-bit, or 128-bit bus width and internally takes these bits as all-zero. Therefore, these LSB bits are read-only (RO). The width of this field depends on the configuration: - 31:2 for 32-bit configuration - 31:3 for 64-bit configuration - 31:4 for 128-bit configuration
2-0 —	Reserved

61.7.1.496 Channel 1 Rx Descriptor List Address (DMA_CH1_RXDESC_LIST_ADDRESS)

61.7.1.496.1 Offset

Register	Offset
DMA_CH1_RXDESC_LIST_ADDRESS	119Ch

61.7.1.496.2 Function

The Channel 1 Rx Descriptor List Address register points the DMA to the start of Receive descriptor list.

This register points to the start of the Receive Descriptor List. The descriptor lists reside in the physical memory space of the application and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LS bits low. Writing to this register is permitted only when reception is stopped. When stopped, this register must be written to before the receive Start command is given. You can write to this register only when Rx DMA has stopped, that is, SR bit is set to zero in DMA_CH1_RX_CONTROL register. When stopped, this register can be written with a new descriptor list address.

When you set the SR bit to 1, the DMA takes the newly programmed descriptor base address.

When this bit is reset, the Transmit Interrupt is disabled. 0b - Transmit Interrupt is disabled 1b - Transmit Interrupt is enabled

61.7.1.502 Channel 1 Receive Interrupt Watchdog Timer (DMA_CH1_RX_INTERRUPT_WATCHDOG_TIMER)

61.7.1.502.1 Offset

Register	Offset
DMA_CH1_RX_INTERRUPT_WATCHDOG_TIMER	11B8h

61.7.1.502.2 Function

The Receive Interrupt Watchdog Timer register indicates the watchdog timeout for Receive Interrupt (RI) from the DMA. When this register is written with a non-zero value, it enables the watchdog timer for the RI bit of the DMA_CH1_Status register.

61.7.1.502.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	Reserved														RWTU

Field	Function
31-18 —	Reserved
17-16 RWTU	Receive Interrupt Watchdog Timer Count Units This fields indicates the number of system clock cycles corresponding to one unit in RWT field. Receive Interrupt Watchdog Timer Count Units This fields indicates the number of system clock cycles corresponding to one unit in RWT field. - 2'b00: 256 - 2'b01: 512 - 2'b10: 1024 - 2'b11: 2048 For example, when RWT=2 and RWTU=1, the watchdog timer is set for 2*512=1024 system clock cycles.
15-8 —	Reserved
7-0 RWT	Receive Interrupt Watchdog Timer Count This field indicates the number of system clock cycles, multiplied by factor indicated in RWTU field, for which the watchdog timer is set. Receive Interrupt Watchdog Timer Count This field indicates the number of system clock cycles, multiplied by factor indicated in RWTU field, for which the watchdog timer is set. The watchdog timer is triggered with the programmed value after the Rx DMA completes the transfer of a packet for which the RI bit is not set in the STATUS register, because of the setting of Interrupt Enable bit in the corresponding descriptor RDES3[30]. When the watchdog timer runs out, the RI bit is set and the timer is stopped. The watchdog timer is reset when the RI bit is set high because of automatic setting of RI as per the Interrupt Enable bit RDES3[30] of any received packet.

61.7.1.503 Channel 1 Slot Function Control and Status (DMA_CH1_SLOT_FUNCTION_CONTROL_STATUS)

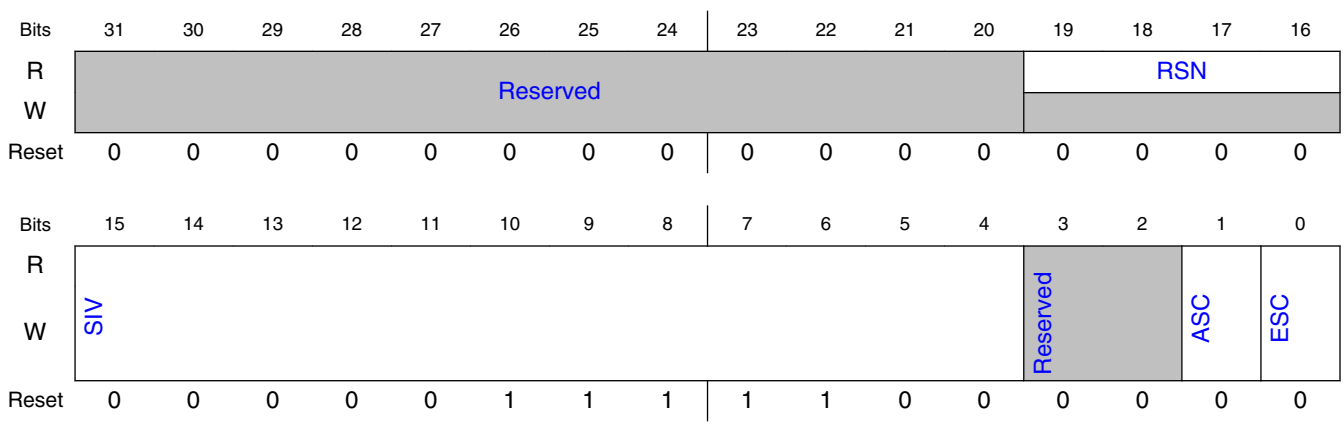
61.7.1.503.1 Offset

Register	Offset
DMA_CH1_SLOT_FUNCTION_CONTROL_STATUS	11BCh

61.7.1.503.2 Function

The Slot Function Control and Status register contains the control bits for slot function and the status for Transmit path.

61.7.1.503.3 Diagram



61.7.1.503.4 Fields

Field	Function
31-20 —	Reserved
19-16 RSN	Reference Slot Number This field gives the current value of the reference slot number in the DMA. Reference Slot Number This field gives the current value of the reference slot number in the DMA. It is used for slot comparison.
15-4 SIV	Slot Interval Value This field controls the period of the slot interval in which the TxDMA fetches the scheduled packets. Slot Interval Value

Table continues on the next page...

Field	Function
	This field controls the period of the slot interval in which the TxDMA fetches the scheduled packets. A value of 0 specifies the slot interval of 1 us while the maximum value 4095 specifies the slot interval of 4096us. The default/reset value is 0x07C which corresponds to slot interval of 125us
3-2 —	Reserved
1 ASC	Advance Slot Check When set, this bit enables the DMA to fetch the data from the buffer when the slot number (SLOTNUM) programmed in the Tx descriptor is - equal to the reference slot number given in the RSN field or - ahead of the reference slot number by up to two slots This bit is applicable only when the ESC bit is set. 0b - Advance Slot Check is disabled 1b - Advance Slot Check is enabled
0 ESC	Enable Slot Comparison When set, this bit enables the checking of the slot numbers programmed in the Tx descriptor with the current reference given in the RSN field. Enable Slot Comparison When set, this bit enables the checking of the slot numbers programmed in the Tx descriptor with the current reference given in the RSN field. The DMA fetches the data from the corresponding buffer only when the slot number is - equal to the reference slot number or - ahead of the reference slot number by one slot When reset, this bit disables the checking of the slot numbers. The DMA fetches the data immediately after the descriptor is processed. Note: The UFO (UDP Fragmentation over IPv4)/TSO/USO should not be enabled along with TBS/AVB Slot number check. The UFO/TSO/USO involves multiple packets/segments/fragments transmission for single packet received from application and the slot number check are applicable for fetching of only first segment/fragment. As a result it might be difficult for software to specify slot number for subsequent packets. 0b - Slot Comparison is disabled 1b - Slot Comparison is enabled

61.7.1.504 Channel 1 Current Application Transmit Descriptor (DMA_CH1_CURRENT_APP_TXDESC)

61.7.1.504.1 Offset

Register	Offset
DMA_CH1_CURRENT_APP_TXDESC	11C4h

61.7.1.504.2 Function

The Channel 1 Current Application Transmit Descriptor register points to the current Transmit descriptor read by the DMA.

Field	Function
	-- 1'b0: Error during data buffer access - Bit 16 -- 1'b1: Error during read transfer -- 1'b0: Error during write transfer This field is valid only when the FBE bit is set. This field does not generate an interrupt.
15 NIS	Normal Interrupt Summary Normal Interrupt Summary bit value is the logical OR of the following bits when the corresponding interrupt bits are enabled in the INTERRUPT_ENABLE register: - Bit 0: Transmit Interrupt - Bit 2: Transmit Buffer Unavailable - Bit 6: Receive Interrupt - Bit 11: Early Receive Interrupt Only unmasked bits (interrupts for which interrupt enable is set in INTERRUPT_ENABLE register) affect the Normal Interrupt Summary bit. Normal Interrupt Summary Normal Interrupt Summary bit value is the logical OR of the following bits when the corresponding interrupt bits are enabled in the DMA_CH1_INTERRUPT_ENABLE register: - Bit 0: Transmit Interrupt - Bit 2: Transmit Buffer Unavailable - Bit 6: Receive Interrupt - Bit 11: Early Receive Interrupt Only unmasked bits (interrupts for which interrupt enable is set in DMA_CH1_INTERRUPT_ENABLE register) affect the Normal Interrupt Summary bit. This is a sticky bit. You must clear this bit (by writing 1 to this bit) each time a corresponding bit which causes NIS to be set is cleared. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Normal Interrupt Summary status not detected 1b - Normal Interrupt Summary status detected
14 AIS	Abnormal Interrupt Summary Abnormal Interrupt Summary bit value is the logical OR of the following when the corresponding interrupt bits are enabled in the INTERRUPT_ENABLE register: - Bit 1: Transmit Process Stopped - Bit 7: Receive Buffer Unavailable - Bit 8: Receive Process Stopped - Bit 10: Early Transmit Interrupt - Bit 12: Fatal Bus Error - Bit 13: Context Descriptor Error Only unmasked bits affect the Abnormal Interrupt Summary bit. Abnormal Interrupt Summary Abnormal Interrupt Summary bit value is the logical OR of the following when the corresponding interrupt bits are enabled in the INTERRUPT_ENABLE register: - Bit 1: Transmit Process Stopped - Bit 7: Receive Buffer Unavailable - Bit 8: Receive Process Stopped - Bit 10: Early Transmit Interrupt - Bit 12: Fatal Bus Error - Bit 13: Context Descriptor Error Only unmasked bits affect the Abnormal Interrupt Summary bit. This is a sticky bit. You must clear this bit (by writing 1 to this bit) each time a corresponding bit, which causes AIS to be set, is cleared. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Abnormal Interrupt Summary status not detected 1b - Abnormal Interrupt Summary status detected

Table continues on the next page...

Field	Function
13 CDE	Context Descriptor Error This bit indicates that the DMA Tx/Rx engine received a descriptor error, which indicates invalid context in the middle of packet flow (intermediate descriptor) or all one's descriptor in Tx case and on Rx side it indicates DMA has read a descriptor with either of the buffer address as ones which is considered to be invalid. Context Descriptor Error This bit indicates that the DMA Tx/Rx engine received a descriptor error, which indicates invalid context in the middle of packet flow (intermediate descriptor) or all one's descriptor in Tx case and on Rx side it indicates DMA has read a descriptor with either of the buffer address as ones which is considered to be invalid. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Context Descriptor Error status not detected 1b - Context Descriptor Error status detected
12 FBE	Fatal Bus Error This bit indicates that a bus error occurred (as described in the EB field). Fatal Bus Error This bit indicates that a bus error occurred (as described in the EB field). When this bit is set, the corresponding DMA channel engine disables all bus accesses. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Fatal Bus Error status not detected 1b - Fatal Bus Error status detected
11 ERI	Early Receive Interrupt This bit when set indicates that the RxDMA has completed the transfer of packet data to the memory. Early Receive Interrupt This bit when set indicates that the RxDMA has completed the transfer of packet data to the memory. In configs supporting ERIC, When ERIC=0, this bit is set only after the Rx DMA has filled up a complete receive buffer with packet data. When ERIC=1, this bit is set after every burst transfer of data from the Rx DMA to the buffer. The setting of RI bit automatically clears this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Early Receive Interrupt status not detected 1b - Early Receive Interrupt status detected
10 ETI	Early Transmit Interrupt This bit when set indicates that the TxDMA has completed the transfer of packet data to the MTL TXFIFO memory. Early Transmit Interrupt This bit when set indicates that the TxDMA has completed the transfer of packet data to the MTL TXFIFO memory. In configs supporting ETIC: When ETIC=0, this bit is set only after the Tx DMA has transferred a complete packet to MTL. When ETIC=1, this bit is set after completion of (partial) packet data transfer from buffers in the Transmit descriptor in which IOC=1. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Early Transmit Interrupt status not detected 1b - Early Transmit Interrupt status detected
9 RWT	Receive Watchdog Timeout This bit is asserted when a packet with length greater than 2,048 bytes (10,240 bytes when Jumbo Packet mode is enabled) is received. 0b - Receive Watchdog Timeout status not detected 1b - Receive Watchdog Timeout status detected
8	Receive Process Stopped This bit is asserted when the Rx process enters the Stopped state.

Table continues on the next page...

Field	Function
RPS	Receive Process Stopped This bit is asserted when the Rx process enters the Stopped state. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Receive Process Stopped status not detected 1b - Receive Process Stopped status detected
7 RBU	Receive Buffer Unavailable This bit indicates that the application owns the next descriptor in the Receive list, and the DMA cannot acquire it. Receive Buffer Unavailable This bit indicates that the application owns the next descriptor in the Receive list, and the DMA cannot acquire it. The Rx process is suspended. To resume processing Rx descriptors, the application should change the ownership of the descriptor and issue a Receive Poll Demand command. If this command is not issued, the Rx process resumes when the next recognized incoming packet is received. In ring mode, the application should advance the Receive Descriptor Tail Pointer register of a channel. This bit is set only when the DMA owns the previous Rx descriptor. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Receive Buffer Unavailable status not detected 1b - Receive Buffer Unavailable status detected
6 RI	Receive Interrupt This bit indicates that the packet reception is complete. Receive Interrupt This bit indicates that the packet reception is complete. When packet reception is complete, Bit 31 of RDES3 is reset in the last descriptor, and the specific packet status information is updated in the descriptor. The reception remains in the Running state. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Receive Interrupt status not detected 1b - Receive Interrupt status detected
5-3 —	Reserved
2 TBU	Transmit Buffer Unavailable This bit indicates that the application owns the next descriptor in the Transmit list, and the DMA cannot acquire it. Transmit Buffer Unavailable This bit indicates that the application owns the next descriptor in the Transmit list, and the DMA cannot acquire it. Transmission is suspended. The TPS0 field of the DEBUG_STATUS0 register explains the Transmit Process state transitions. To resume processing the Transmit descriptors, the application should do the following: 1. Change the ownership of the descriptor by setting Bit 31 of TDES3. 2. Issue a Transmit Poll Demand command. For ring mode, the application should advance the Transmit Descriptor Tail Pointer register of a channel. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Transmit Buffer Unavailable status not detected 1b - Transmit Buffer Unavailable status detected
1 TPS	Transmit Process Stopped This bit is set when the transmission is stopped. Transmit Process Stopped This bit is set when the transmission is stopped.

Table continues on the next page...

Field	Function
	Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Transmit Process Stopped status not detected 1b - Transmit Process Stopped status detected
0 TI	Transmit Interrupt This bit indicates that the packet transmission is complete. Transmit Interrupt This bit indicates that the packet transmission is complete. When transmission is complete, Bit 31 of TDES3 is reset in the last descriptor, and the specific packet status information is updated in the descriptor. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Transmit Interrupt status not detected 1b - Transmit Interrupt status detected

61.7.1.509 Channel 1 Missed Frame Counter (DMA_CH1_MISS_FRAME_CNT)

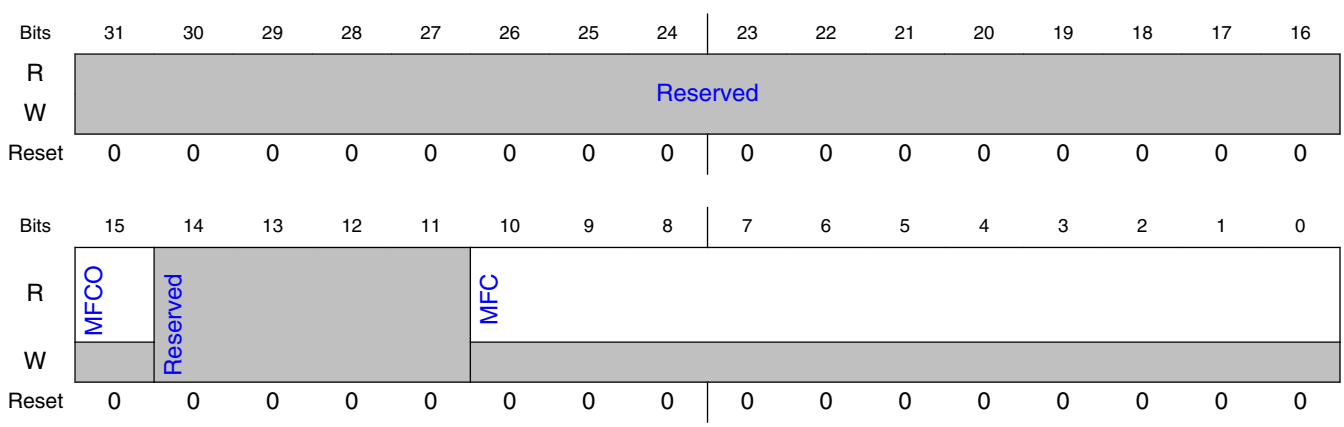
61.7.1.509.1 Offset

Register	Offset
DMA_CH1_MISS_FRAME_CNT	11E4h

61.7.1.509.2 Function

This register has the number of packet counter that got dropped by the DMA either due to Bus Error or due to programming RPF field in RX_CONTROL register.

61.7.1.509.3 Diagram



61.7.1.509.4 Fields

Field	Function

Overflow status of the MFC Counter When this bit is set then the MFC counter does not get incremented further. The bit gets cleared when this register is read. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0b - Miss Frame Counter overflow not occurred 1b - Miss Frame Counter overflow occurred
14-11 —	Reserved
10-0 MFC	Dropped Packet Counters This counter indicates the number of packet counters that are dropped by the DMA either because of bus error or because of programming RPF field in RX_CONTROL register. Dropped Packet Counters This counter indicates the number of packet counters that are dropped by the DMA either because of bus error or because of programming RPF field in DMA_CH1_RX_CONTROL register. The counter gets cleared when this register is read. Access restriction applies. Clears on read. Self-set to 1 on internal event.

61.7.1.510 Channel 1 RXP Frames Accepted Counter (DMA_CH1_RXP_ACCEPT_CNT)

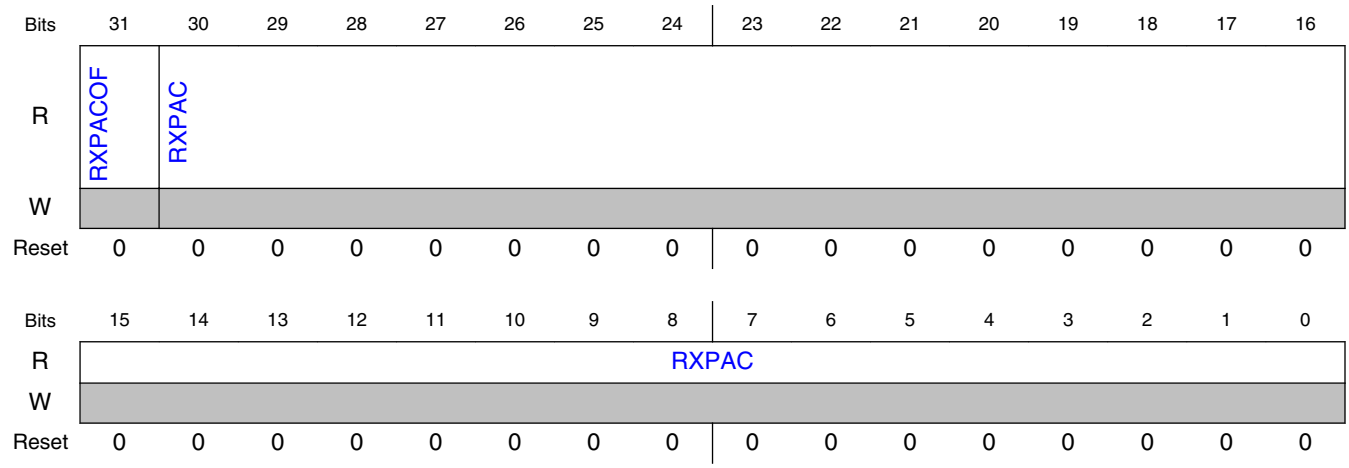
61.7.1.510.1 Offset

Register	Offset
DMA_CH1_RXP_ACCEPT_CNT	11E8h

61.7.1.510.2 Function

The DMA_CH1_RXP_Accept_Cnt register provides the count of the number of frames accepted by Rx Parser.

61.7.1.510.3 Diagram



61.7.1.510.4 Fields

Field	Function
31 RXPACOF	Rx Parser Accept Counter Overflow Bit When set, this bit indicates that the RXPAC Counter field crossed the maximum limit. Rx Parser Accept Counter Overflow Bit When set, this bit indicates that the RXPAC Counter field crossed the maximum limit. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0b - Rx Parser Accept Counter overflow not occurred 1b - Rx Parser Accept Counter overflow occurred
30-0 RXPAC	Rx Parser Accept Counter This 31-bit counter is implemented whenever a Rx Parser Accept a packet due to AF =1. Rx Parser Accept Counter This 31-bit counter is implemented whenever a Rx Parser Accept a packet due to AF =1. The counter is cleared when the register is read.

61.7.1.511 DMA Channel 2 Control (DMA_CH2_CONTROL)

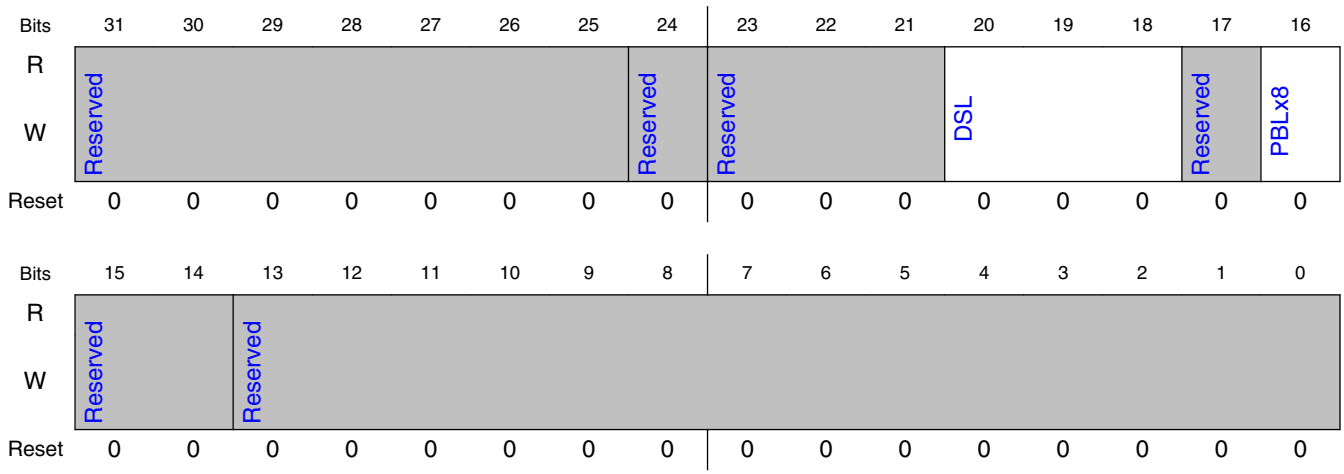
61.7.1.511.1 Offset

Register	Offset
DMA_CH2_CONTROL	1200h

61.7.1.511.2 Function

The DMA Channel 2 Control register specifies the MSS value for segmentation, length to skip between two descriptors, and also the features such as header splitting and 8xPBL mode.

61.7.1.511.3 Diagram



61.7.1.511.4 Fields

Field	Function
31-25 —	Reserved
24 —	Reserved
23-21 —	Reserved
20-18 DSL	Descriptor Skip Length This bit specifies the Word, Dword, or Lword number (depending on the 32-bit, 64-bit, or 128-bit bus) to skip between two unchained descriptors. Descriptor Skip Length This bit specifies the Word, Dword, or Lword number (depending on the 32-bit, 64-bit, or 128-bit bus) to skip between two unchained descriptors. The address skipping starts from the end of the current descriptor to the start of the next descriptor. When the DSL value is equal to zero, the DMA takes the descriptor table as contiguous.
17 —	Reserved
16 PBLx8	8xPBL mode When this bit is set, the PBL value programmed in Bits[21:16] in DMA_CH2_TX_CONTROL and Bits[21:16] in DMA_CH2_RX_CONTROL is multiplied by eight times. 8xPBL mode

Table continues on the next page...

Field	Function
	When this bit is set, the PBL value programmed in Bits[21:16] in DMA_CH2_TX_CONTROL and Bits[21:16] in DMA_CH2_RX_CONTROL is multiplied by eight times. Therefore, the DMA transfers the data in 8, 16, 32, 64, 128, and 256 beats depending on the PBL value. 0b - 8xPBL mode is disabled 1b - 8xPBL mode is enabled

21-16 TxPBL	Transmit Programmable Burst Length These bits indicate the maximum number of beats to be transferred in one DMA block data transfer. Transmit Programmable Burst Length These bits indicate the maximum number of beats to be transferred in one DMA block data transfer. The DMA always attempts max burst as specified in PBL each time it starts a burst transfer on the application bus. You can program PBL with any of the following values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior. To transfer more than 32 beats, perform the following steps: 1. Set the 8xPBL mode in DMA_CH2_CONTROL register. 2. Set the TxPBL. Note: The maximum value of TxPBL must be less than or equal to half the Tx Queue size (TQS field of TXQ2_OPERATION_MODE register) in terms of beats. This is required so that the Tx Queue has space to store at least another Tx PBL worth of data while the MTL Tx Queue Controller is transferring data to MAC. For example, in 64-bit data width configurations the total locations in Tx Queue of size 512 bytes is 64, TxPBL and 8xPBL needs to be programmed to less than or equal to 32.
15 IPBL	Ignore PBL Requirement When this bit is set, the DMA does not check for PBL number of locations in the MTL before initiating a transfer. Ignore PBL Requirement When this bit is set, the DMA does not check for PBL number of locations in the MTL before initiating a transfer. If space is not available, the MTL may use handshaking to slow the DMA. Note: This bit/mode must not be used when multiple Transmit DMA Channels are enabled as it may block other Transmit and Receive DMA Channels from accessing the Read Data Channel of AXI bus until space is available in Transmit Queue for current transfer. 0b - Ignore PBL Requirement is disabled 1b - Ignore PBL Requirement is enabled

21-16 RxPBL	Receive Programmable Burst Length These bits indicate the maximum number of beats to be transferred in one DMA block data transfer. Receive Programmable Burst Length These bits indicate the maximum number of beats to be transferred in one DMA block data transfer. The DMA always attempts max burst as specified in PBL each time it starts a burst transfer on the application bus. You can program PBL with any of the following values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior. To transfer more than 32 beats, perform the following steps: 1. Set the 8xPBL mode in the DMA_CH2_CONTROL register. 2. Set the RxPBL. Note: The maximum value of RxPBL must be less than or equal to half the Rx Queue size (RQS field of RXQ2_OPERATION_MODE register) in terms of beats. This is required so that the Rx Queue has space to store at least another Rx PBL worth of data while the Rx DMA is transferring a block of data. For example, in 64-bit data width configurations the total locations in Rx Queue of size 512 bytes is 64, so RxPBL and 8xPBL needs to be programmed to less than or equal to 32.
15 —	Reserved
14-4 RBSZ_13_y	Receive Buffer size High RBSZ[13:0] is split into two fields higher RBSZ_13_y and lower RBSZ_x_0. Receive Buffer size High RBSZ[13:0] is split into two fields higher RBSZ_13_y and lower RBSZ_x_0. The RBSZ[13:0] field indicates the size of the Rx buffers specified in bytes. The maximum buffer size is limited to 16K bytes. The buffer size is applicable to payload buffers when split headers are enabled. Note: The buffer size must be a multiple of 4, 8, or 16 depending on the data bus widths (32-bit, 64-bit, or 128-bit respectively). This is required even if the value of buffer address pointer is not aligned to data bus width. Hence the lower RBSZ_x_0 bits are read-only and the value is considered as all-zero. Thus the RBSZ_13_y indicates the buffer size in terms of locations (with the width same as bus-width).
3-1 RBSZ_x_0	Receive Buffer size Low RBSZ[13:0] is split into two fields RBSZ_13_y and RBSZ_x_0. Receive Buffer size Low RBSZ[13:0] is split into two fields RBSZ_13_y and RBSZ_x_0. The RBSZ_x_0 is the lower field whose width is based on data bus width of the configuration. This field is of width 2, 3, or 4 bits for 32-bit, 64-bit, or 128-bit data bus width respectively. This field is read-only (RO).
0 SR	Start or Stop Receive When this bit is set, the DMA tries to acquire the descriptor from the Receive list and processes the incoming packets. Start or Stop Receive When this bit is set, the DMA tries to acquire the descriptor from the Receive list and processes the incoming packets. The DMA tries to acquire descriptor from either of the following positions: - The current position in the list This is the address set by the DMA_CH2_RXDESC_LIST_ADDRESS register. - The position at which the Rx process was previously stopped

Field	Function
	If the DMA does not own the current descriptor, the reception is suspended and the RBU bit of the DMA_CH2_STATUS register is set. The Start Receive command is effective only when the reception is stopped. If the command is issued before setting the DMA_CH2_RXDESC_LIST_ADDRESS register, the DMA behavior is unpredictable. When this bit is reset, the Rx DMA operation is stopped after the transfer of the current packet. The next descriptor position in the Receive list is saved, and it becomes the current position after the Rx process is restarted. The Stop Receive command is effective only when the Rx process is in the Running (waiting for Rx packet) or Suspended state. 0b - Stop Receive 1b - Start Receive

61.7.1.514 Channel 2 Tx Descriptor List Address (DMA_CH2_TXDESC_LIST_ADDRESS)

61.7.1.514.1 Offset

Register	Offset
DMA_CH2_TXDESC_LIST_ADDRESS	1214h

61.7.1.514.2 Function

The Channel 2 Tx Descriptor List Address register points the DMA to the start of Transmit descriptor list. The descriptor lists reside in the physical memory space of the application and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LSB to low.

You can write to this register only when the Tx DMA has stopped, that is, the ST bit is set to zero in TX_CONTROL register. When stopped, this register can be written with a new descriptor list address. When you set the ST bit to 1, the DMA takes the newly-programmed descriptor base address. If this register is not changed when the ST bit is set to 0, the DMA takes the descriptor address where it was stopped earlier.

61.7.1.514.3 Diagram

61.7.1.515.1 Offset

Register	Offset
DMA_CH2_RXDESC_LIST_ADDRESS	121Ch

61.7.1.515.2 Function

The Channel 2 Rx Descriptor List Address register points the DMA to the start of Receive descriptor list.

This register points to the start of the Receive Descriptor List. The descriptor lists reside in the physical memory space of the application and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LS bits low. Writing to this register is permitted only when reception is stopped. When stopped, this register must be written to before the receive Start command is given. You can write to this register only when Rx DMA has stopped, that is, SR bit is set to zero in RX_CONTROL register. When stopped, this register can be written with a new descriptor list address.

When you set the SR bit to 1, the DMA takes the newly programmed descriptor base address.

15-4 SIV	Slot Interval Value This field controls the period of the slot interval in which the TxDMA fetches the scheduled packets. Slot Interval Value This field controls the period of the slot interval in which the TxDMA fetches the scheduled packets. A value of 0 specifies the slot interval of 1 us while the maximum value 4095 specifies the slot interval of 4096us. The default/reset value is 0x07C which corresponds to slot interval of 125us
3-2 —	Reserved
1 ASC	Advance Slot Check When set, this bit enables the DMA to fetch the data from the buffer when the slot number (SLOTNUM) programmed in the Tx descriptor is - equal to the reference slot number given in the RSN field or - ahead of the reference slot number by up to two slots This bit is applicable only when the ESC bit is set. 0b - Advance Slot Check is disabled 1b - Advance Slot Check is enabled
0 ESC	Enable Slot Comparison When set, this bit enables the checking of the slot numbers programmed in the Tx descriptor with the current reference given in the RSN field. Enable Slot Comparison When set, this bit enables the checking of the slot numbers programmed in the Tx descriptor with the current reference given in the RSN field. The DMA fetches the data from the corresponding buffer only when the slot number is - equal to the reference slot number or - ahead of the reference slot number by one slot When reset, this bit disables the checking of the slot numbers. The DMA fetches the data immediately after the descriptor is processed. Note: The UFO (UDP Fragmentation over IPv4)/TSO/USO should not be enabled along with TBS/AVB Slot number check. The UFO/TSO/USO involves multiple packets/segments/fragments transmission for single packet received from application and the slot number check are applicable for fetching of only first segment/fragment. As a result it might be difficult for software to specify slot number for subsequent packets. 0b - Slot Comparison is disabled 1b - Slot Comparison is enabled

	-- 1'b0: Error during data buffer access - Bit 16 -- 1'b1: Error during read transfer -- 1'b0: Error during write transfer This field is valid only when the FBE bit is set. This field does not generate an interrupt.
15 NIS	Normal Interrupt Summary Normal Interrupt Summary bit value is the logical OR of the following bits when the corresponding interrupt bits are enabled in the INTERRUPT_ENABLE register: - Bit 0: Transmit Interrupt - Bit 2: Transmit Buffer Unavailable - Bit 6: Receive Interrupt - Bit 11: Early Receive Interrupt Only unmasked bits (interrupts for which interrupt enable is set in DMA_CH2_INTERRUPT_ENABLE register) affect the Normal Interrupt Summary bit. Normal Interrupt Summary Normal Interrupt Summary bit value is the logical OR of the following bits when the corresponding interrupt bits are enabled in the INTERRUPT_ENABLE register: - Bit 0: Transmit Interrupt - Bit 2: Transmit Buffer Unavailable - Bit 6: Receive Interrupt - Bit 11: Early Receive Interrupt Only unmasked bits (interrupts for which interrupt enable is set in DMA_CH2_INTERRUPT_ENABLE register) affect the Normal Interrupt Summary bit. This is a sticky bit. You must clear this bit (by writing 1 to this bit) each time a corresponding bit which causes NIS to be set is cleared. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Normal Interrupt Summary status not detected 1b - Normal Interrupt Summary status detected
14 AIS	Abnormal Interrupt Summary Abnormal Interrupt Summary bit value is the logical OR of the following when the corresponding interrupt bits are enabled in the DMA_CH2_INTERRUPT_ENABLE register: - Bit 1: Transmit Process Stopped - Bit 7: Receive Buffer Unavailable - Bit 8: Receive Process Stopped - Bit 10: Early Transmit Interrupt - Bit 12: Fatal Bus Error - Bit 13: Context Descriptor Error Only unmasked bits affect the Abnormal Interrupt Summary bit. Abnormal Interrupt Summary Abnormal Interrupt Summary bit value is the logical OR of the following when the corresponding interrupt bits are enabled in the DMA_CH2_INTERRUPT_ENABLE register: - Bit 1: Transmit Process Stopped - Bit 7: Receive Buffer Unavailable - Bit 8: Receive Process Stopped - Bit 10: Early Transmit Interrupt - Bit 12: Fatal Bus Error - Bit 13: Context Descriptor Error Only unmasked bits affect the Abnormal Interrupt Summary bit. This is a sticky bit. You must clear this bit (by writing 1 to this bit) each time a corresponding bit, which causes AIS to be set, is cleared. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Abnormal Interrupt Summary status not detected 1b - Abnormal Interrupt Summary status detected

Table continues on the next page...

Field	Function
13 CDE	Context Descriptor Error This bit indicates that the DMA Tx/Rx engine received a descriptor error, which indicates invalid context in the middle of packet flow (intermediate descriptor) or all one's descriptor in Tx case and on Rx side it indicates DMA has read a descriptor with either of the buffer address as ones which is considered to be invalid. Context Descriptor Error This bit indicates that the DMA Tx/Rx engine received a descriptor error, which indicates invalid context in the middle of packet flow (intermediate descriptor) or all one's descriptor in Tx case and on Rx side it indicates DMA has read a descriptor with either of the buffer address as ones which is considered to be invalid. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Context Descriptor Error status not detected 1b - Context Descriptor Error status detected
12 FBE	Fatal Bus Error This bit indicates that a bus error occurred (as described in the EB field). Fatal Bus Error This bit indicates that a bus error occurred (as described in the EB field). When this bit is set, the corresponding DMA channel engine disables all bus accesses. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Fatal Bus Error status not detected 1b - Fatal Bus Error status detected
11 ERI	Early Receive Interrupt This bit when set indicates that the RxDMA has completed the transfer of packet data to the memory. Early Receive Interrupt This bit when set indicates that the RxDMA has completed the transfer of packet data to the memory. In configs supporting ERIC, When ERIC=0, this bit is set only after the Rx DMA has filled up a complete receive buffer with packet data. When ERIC=1, this bit is set after every burst transfer of data from the Rx DMA to the buffer. The setting of RI bit automatically clears this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Early Receive Interrupt status not detected 1b - Early Receive Interrupt status detected
10 ETI	Early Transmit Interrupt This bit when set indicates that the TxDMA has completed the transfer of packet data to the MTL TXFIFO memory. Early Transmit Interrupt This bit when set indicates that the TxDMA has completed the transfer of packet data to the MTL TXFIFO memory. In configs supporting ETIC: When ETIC=0, this bit is set only after the Tx DMA has transferred a complete packet to MTL. When ETIC=1, this bit is set after completion of (partial) packet data transfer from buffers in the Transmit descriptor in which IOC=1. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Early Transmit Interrupt status not detected 1b - Early Transmit Interrupt status detected
9 RWT	Receive Watchdog Timeout This bit is asserted when a packet with length greater than 2,048 bytes (10,240 bytes when Jumbo Packet mode is enabled) is received. 0b - Receive Watchdog Timeout status not detected 1b - Receive Watchdog Timeout status detected
8	Receive Process Stopped This bit is asserted when the Rx process enters the Stopped state.

Table continues on the next page...

Field	Function
RPS	Receive Process Stopped This bit is asserted when the Rx process enters the Stopped state. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Receive Process Stopped status not detected 1b - Receive Process Stopped status detected
7 RBU	Receive Buffer Unavailable This bit indicates that the application owns the next descriptor in the Receive list, and the DMA cannot acquire it. Receive Buffer Unavailable This bit indicates that the application owns the next descriptor in the Receive list, and the DMA cannot acquire it. The Rx process is suspended. To resume processing Rx descriptors, the application should change the ownership of the descriptor and issue a Receive Poll Demand command. If this command is not issued, the Rx process resumes when the next recognized incoming packet is received. In ring mode, the application should advance the Receive Descriptor Tail Pointer register of a channel. This bit is set only when the DMA owns the previous Rx descriptor. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Receive Buffer Unavailable status not detected 1b - Receive Buffer Unavailable status detected
6 RI	Receive Interrupt This bit indicates that the packet reception is complete. Receive Interrupt This bit indicates that the packet reception is complete. When packet reception is complete, Bit 31 of RDES3 is reset in the last descriptor, and the specific packet status information is updated in the descriptor. The reception remains in the Running state. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Receive Interrupt status not detected 1b - Receive Interrupt status detected
5-3 —	Reserved
2 TBU	Transmit Buffer Unavailable This bit indicates that the application owns the next descriptor in the Transmit list, and the DMA cannot acquire it. Transmit Buffer Unavailable This bit indicates that the application owns the next descriptor in the Transmit list, and the DMA cannot acquire it. Transmission is suspended. The TPS0 field of the DEBUG_STATUS0 register explains the Transmit Process state transitions. To resume processing the Transmit descriptors, the application should do the following: 1. Change the ownership of the descriptor by setting Bit 31 of TDES3. 2. Issue a Transmit Poll Demand command. For ring mode, the application should advance the Transmit Descriptor Tail Pointer register of a channel. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Transmit Buffer Unavailable status not detected 1b - Transmit Buffer Unavailable status detected
1 TPS	Transmit Process Stopped This bit is set when the transmission is stopped. Transmit Process Stopped This bit is set when the transmission is stopped.

Table continues on the next page...

Field	Function
	Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Transmit Process Stopped status not detected 1b - Transmit Process Stopped status detected
0 TI	Transmit Interrupt This bit indicates that the packet transmission is complete. Transmit Interrupt This bit indicates that the packet transmission is complete. When transmission is complete, Bit 31 of TDES3 is reset in the last descriptor, and the specific packet status information is updated in the descriptor. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Transmit Interrupt status not detected 1b - Transmit Interrupt status detected

61.7.1.528 Channel 2 Missed Frame Counter (DMA_CH2_MISS_FRAME_CNT)

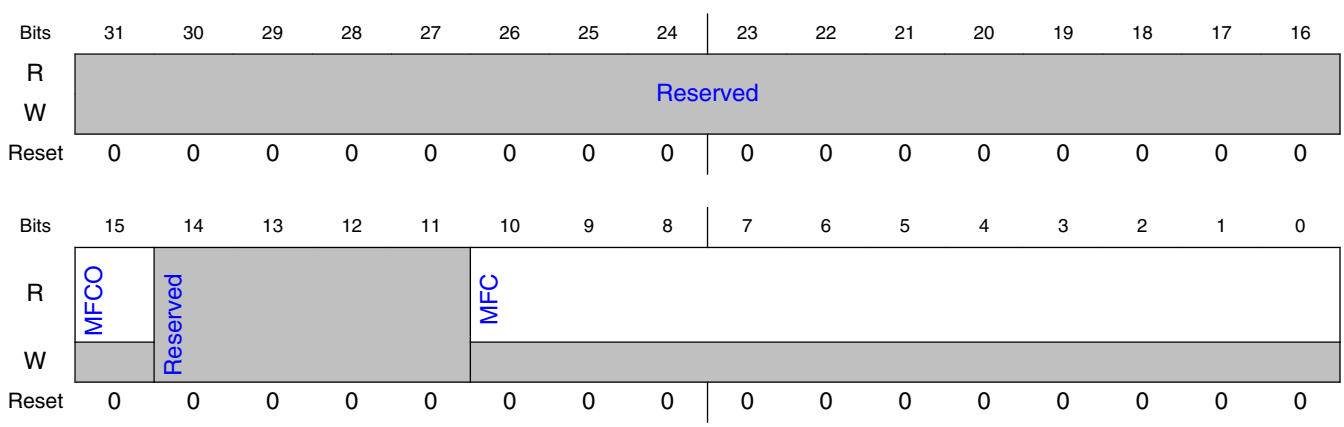
61.7.1.528.1 Offset

Register	Offset
DMA_CH2_MISS_FRAME_CNT	1264h

61.7.1.528.2 Function

This register has the number of packet counter that got dropped by the DMA either due to Bus Error or due to programming RPF field in DMA_CH2_RX_CONTROL register.

61.7.1.528.3 Diagram



61.7.1.528.4 Fields

28 EDSE	Enhanced Descriptor Enable When this bit is set, the corresponding channel uses Enhanced Descriptors that are 32 Bytes for both Normal and Context Descriptors. Enhanced Descriptor Enable When this bit is set, the corresponding channel uses Enhanced Descriptors that are 32 Bytes for both Normal and Context Descriptors. When reset, the corresponding channel uses the descriptors that are 16 Bytes. 0b - Enhanced Descriptor is disabled 1b - Enhanced Descriptor is enabled
27-24 —	Reserved
23 —	Reserved
22 —	Reserved
21-16 TxPBL	Transmit Programmable Burst Length These bits indicate the maximum number of beats to be transferred in one DMA block data transfer. Transmit Programmable Burst Length These bits indicate the maximum number of beats to be transferred in one DMA block data transfer. The DMA always attempts max burst as specified in PBL each time it starts a burst transfer on the application bus. You can program PBL with any of the following values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior. To transfer more than 32 beats, perform the following steps: 1. Set the 8xPBL mode in DMA_CH3_CONTROL register. 2. Set the TxPBL. Note: The maximum value of TxPBL must be less than or equal to half the Tx Queue size (TQS field of TXQ3_OPERATION_MODE register) in terms of beats. This is required so that the Tx Queue has space to store at least another Tx PBL worth of data while the MTL Tx Queue Controller is transferring data to MAC. For example, in 64-bit data width configurations the total locations in Tx Queue of size 512 bytes is 64, TxPBL and 8xPBL needs to be programmed to less than or equal to 32.
15 IPBL	Ignore PBL Requirement When this bit is set, the DMA does not check for PBL number of locations in the MTL before initiating a transfer. Ignore PBL Requirement When this bit is set, the DMA does not check for PBL number of locations in the MTL before initiating a transfer. If space is not available, the MTL may use handshaking to slow the DMA. Note: This bit/mode must not be used when multiple Transmit DMA Channels are enabled as it may block other Transmit and Receive DMA Channels from accessing the Read Data Channel of AXI bus until space is available in Transmit Queue for current transfer. 0b - Ignore PBL Requirement is disabled 1b - Ignore PBL Requirement is enabled

Table continues on the next page...

Field	Function
14-13 —	Reserved
12 —	Reserved
11-5 —	Reserved
4 OSF	Operate on Second Packet When this bit is set, it instructs the DMA to process the second packet of the Transmit data even before the status for the first packet is obtained. 0b - Operate on Second Packet disabled 1b - Operate on Second Packet enabled
3-1 —	Reserved
0 ST	Start or Stop Transmission Command When this bit is set, transmission is placed in the Running state. Start or Stop Transmission Command When this bit is set, transmission is placed in the Running state. The DMA checks the Transmit list at the current position for a packet to be transmitted. The DMA tries to acquire descriptor from either of the following positions: - The current position in the list This is the base address of the Transmit list set by the DMA_CH3_TXDESC_LIST_ADDRESS register. - The position at which the transmission was previously stopped If the DMA does not own the current descriptor, the transmission enters the Suspended state and the TBU bit of the DMA_CH3_STATUS register is set. The Start Transmission command is effective only when the transmission is stopped. If the command is issued before setting the DMA_CH3_TXDESC_LIST_ADDRESS register, the DMA behavior is unpredictable. When this bit is reset, the transmission process is placed in the Stopped state after completing the transmission of the current packet. The Next Descriptor position in the Transmit list is saved, and it becomes the current position when the transmission is restarted. To change the list address, you need to program DMA_CH3_TXDESC_LIST_ADDRESS register with a new value when this bit is reset. The new value is considered when this bit is set again. The stop transmission command is effective only when the transmission of the current packet is complete or the transmission is in the Suspended state. 0b - Stop Transmission Command 1b - Start Transmission Command

61.7.1.532 DMA Channel 3 Receive Control (DMA_CH3_RX_CONTROL)

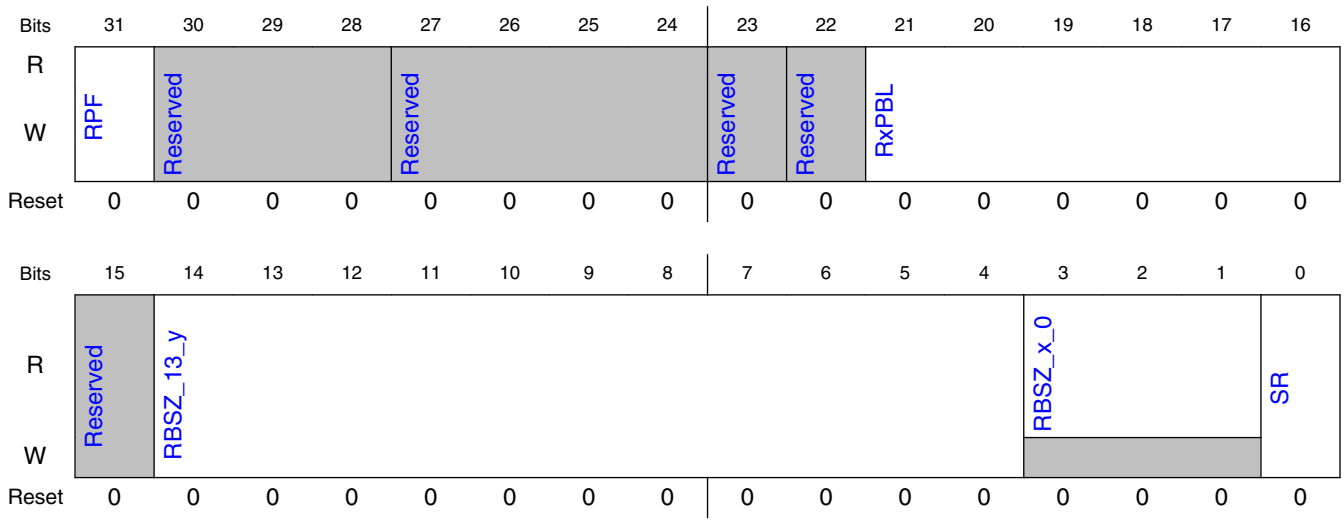
61.7.1.532.1 Offset

Register	Offset
DMA_CH3_RX_CONTROL	1288h

61.7.1.532.2 Function

The DMA Channel 3 Receive Control register controls the Rx features such as PBL, buffer size, and extended status.

61.7.1.532.3 Diagram



61.7.1.532.4 Fields

Field	Function
31 RPF	Rx Packet Flush. Rx Packet Flush. When this bit is set to 1, then DWC_ether_qos automatically flushes the packet from the Rx Queues destined to this DMA Rx Channel, when it is stopped. When this bit remains set and the DMA is re-started by the software driver, the packets residing in the Rx Queues that were received when this RxDMA was stopped, get flushed out. The packets that are received by the MAC after the RxDMA is re-started are routed to the RxDMA. The flushing happens on the Read side of the Rx Queue. When this bit is set to 0, the DWC_ether_qos not flush the packet in the Rx Queue destined to this RxDMA Channel when it is STOP state. This may in turn cause head-of-line blocking in the corresponding RxQueue. 0b - Rx Packet Flush is disabled 1b - Rx Packet Flush is enabled
30-28 —	Reserved
27-24 —	Reserved
23 —	Reserved

21-16 RxPBL	Receive Programmable Burst Length These bits indicate the maximum number of beats to be transferred in one DMA block data transfer. Receive Programmable Burst Length These bits indicate the maximum number of beats to be transferred in one DMA block data transfer. The DMA always attempts max burst as specified in PBL each time it starts a burst transfer on the application bus. You can program PBL with any of the following values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior. To transfer more than 32 beats, perform the following steps: 1. Set the 8xPBL mode in the CONTROL register. 2. Set the RxPBL. Note: The maximum value of RxPBL must be less than or equal to half the Rx Queue size (RQS field of RXQ3_OPERATION_MODE register) in terms of beats. This is required so that the Rx Queue has space to store at least another Rx PBL worth of data while the Rx DMA is transferring a block of data. For example, in 64-bit data width configurations the total locations in Rx Queue of size 512 bytes is 64, so RxPBL and 8xPBL needs to be programmed to less than or equal to 32.
15 —	Reserved
14-4 RBSZ_13_y	Receive Buffer size High RBSZ[13:0] is split into two fields higher RBSZ_13_y and lower RBSZ_x_0. Receive Buffer size High RBSZ[13:0] is split into two fields higher RBSZ_13_y and lower RBSZ_x_0. The RBSZ[13:0] field indicates the size of the Rx buffers specified in bytes. The maximum buffer size is limited to 16K bytes. The buffer size is applicable to payload buffers when split headers are enabled. Note: The buffer size must be a multiple of 4, 8, or 16 depending on the data bus widths (32-bit, 64-bit, or 128-bit respectively). This is required even if the value of buffer address pointer is not aligned to data bus width. Hence the lower RBSZ_x_0 bits are read-only and the value is considered as all-zero. Thus the RBSZ_13_y indicates the buffer size in terms of locations (with the width same as bus-width).
3-1 RBSZ_x_0	Receive Buffer size Low RBSZ[13:0] is split into two fields RBSZ_13_y and RBSZ_x_0. Receive Buffer size Low RBSZ[13:0] is split into two fields RBSZ_13_y and RBSZ_x_0. The RBSZ_x_0 is the lower field whose width is based on data bus width of the configuration. This field is of width 2, 3, or 4 bits for 32-bit, 64-bit, or 128-bit data bus width respectively. This field is read-only (RO).
0 SR	Start or Stop Receive When this bit is set, the DMA tries to acquire the descriptor from the Receive list and processes the incoming packets. Start or Stop Receive When this bit is set, the DMA tries to acquire the descriptor from the Receive list and processes the incoming packets. The DMA tries to acquire descriptor from either of the following positions: - The current position in the list This is the address set by the DMA_CH3_RXDESC_LIST_ADDRESS register. - The position at which the Rx process was previously stopped

Field	Function
	If the DMA does not own the current descriptor, the reception is suspended and the RBU bit of the DMA_CH3_STATUS register is set. The Start Receive command is effective only when the reception is stopped. If the command is issued before setting the DMA_CH3_RXDESC_LIST_ADDRESS register, the DMA behavior is unpredictable. When this bit is reset, the Rx DMA operation is stopped after the transfer of the current packet. The next descriptor position in the Receive list is saved, and it becomes the current position after the Rx process is restarted. The Stop Receive command is effective only when the Rx process is in the Running (waiting for Rx packet) or Suspended state. 0b - Stop Receive 1b - Start Receive

61.7.1.533 Channel 3 Tx Descriptor List Address (DMA_CH3_TXDESC_LIST_ADDRESS)

61.7.1.533.1 Offset

Register	Offset
DMA_CH3_TXDESC_LIST_ADDRESS	1294h

61.7.1.533.2 Function

The Channel 3 Tx Descriptor List Address register points the DMA to the start of Transmit descriptor list. The descriptor lists reside in the physical memory space of the application and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LSB to low.

You can write to this register only when the Tx DMA has stopped, that is, the ST bit is set to zero in TX_CONTROL register. When stopped, this register can be written with a new descriptor list address. When you set the ST bit to 1, the DMA takes the newly-programmed descriptor base address. If this register is not changed when the ST bit is set to 0, the DMA takes the descriptor address where it was stopped earlier.

61.7.1.534 Channel 3 Rx Descriptor List Address (DMA_CH3_RXDESC_LIST_ADDRESS)

61.7.1.534.1 Offset

Register	Offset
DMA_CH3_RXDESC_LIST_ADDRESS	129Ch

61.7.1.534.2 Function

The Channel 3 Rx Descriptor List Address register points the DMA to the start of Receive descriptor list.

This register points to the start of the Receive Descriptor List. The descriptor lists reside in the physical memory space of the application and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LS bits low. Writing to this register is permitted only when reception is stopped. When stopped, this register must be written to before the receive Start command is given. You can write to this register only when Rx DMA has stopped, that is, SR bit is set to zero in RX_CONTROL register. When stopped, this register can be written with a new descriptor list address.

When you set the SR bit to 1, the DMA takes the newly programmed descriptor base address.

	-- 1'b1: Error during descriptor access -- 1'b0: Error during data buffer access - Bit 19 -- 1'b1: Error during read transfer -- 1'b0: Error during write transfer This field is valid only when the FBE bit is set. This field does not generate an interrupt.
18-16 TEB	Tx DMA Error Bits This field indicates the type of error that caused a Bus Error. Tx DMA Error Bits This field indicates the type of error that caused a Bus Error. For example, error response on the AHB or AXI interface. - Bit 18 -- 1'b1: Error during data transfer by Tx DMA -- 1'b0: No Error during data transfer by Tx DMA - Bit 17 -- 1'b1: Error during descriptor access -- 1'b0: Error during data buffer access - Bit 16 -- 1'b1: Error during read transfer -- 1'b0: Error during write transfer This field is valid only when the FBE bit is set. This field does not generate an interrupt.
15 NIS	Normal Interrupt Summary Normal Interrupt Summary bit value is the logical OR of the following bits when the corresponding interrupt bits are enabled in the DMA_CH3_INTERRUPT_ENABLE register: - Bit 0: Transmit Interrupt - Bit 2: Transmit Buffer Unavailable - Bit 6: Receive Interrupt - Bit 11: Early Receive Interrupt Only unmasked bits (interrupts for which interrupt enable is set in DMA_CH3_INTERRUPT_ENABLE register) affect the Normal Interrupt Summary bit. Normal Interrupt Summary Normal Interrupt Summary bit value is the logical OR of the following bits when the corresponding interrupt bits are enabled in the DMA_CH3_INTERRUPT_ENABLE register: - Bit 0: Transmit Interrupt - Bit 2: Transmit Buffer Unavailable - Bit 6: Receive Interrupt - Bit 11: Early Receive Interrupt Only unmasked bits (interrupts for which interrupt enable is set in DMA_CH3_INTERRUPT_ENABLE register) affect the Normal Interrupt Summary bit. This is a sticky bit. You must clear this bit (by writing 1 to this bit) each time a corresponding bit which causes NIS to be set is cleared. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Normal Interrupt Summary status not detected 1b - Normal Interrupt Summary status detected

Table continues on the next page...

Field	Function
14 AIS	Abnormal Interrupt Summary Abnormal Interrupt Summary bit value is the logical OR of the following when the corresponding interrupt bits are enabled in the DMA_CH3_INTERRUPT_ENABLE register: - Bit 1: Transmit Process Stopped - Bit 7: Receive Buffer Unavailable - Bit 8: Receive Process Stopped - Bit 10: Early Transmit Interrupt - Bit 12: Fatal Bus Error - Bit 13: Context Descriptor Error Only unmasked bits affect the Abnormal Interrupt Summary bit. Abnormal Interrupt Summary Abnormal Interrupt Summary bit value is the logical OR of the following when the corresponding interrupt bits are enabled in the DMA_CH3_INTERRUPT_ENABLE register: - Bit 1: Transmit Process Stopped - Bit 7: Receive Buffer Unavailable - Bit 8: Receive Process Stopped - Bit 10: Early Transmit Interrupt - Bit 12: Fatal Bus Error - Bit 13: Context Descriptor Error Only unmasked bits affect the Abnormal Interrupt Summary bit. This is a sticky bit. You must clear this bit (by writing 1 to this bit) each time a corresponding bit, which causes AIS to be set, is cleared. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Abnormal Interrupt Summary status not detected 1b - Abnormal Interrupt Summary status detected
13 CDE	Context Descriptor Error This bit indicates that the DMA Tx/Rx engine received a descriptor error, which indicates invalid context in the middle of packet flow (intermediate descriptor) or all one's descriptor in Tx case and on Rx side it indicates DMA has read a descriptor with either of the buffer address as ones which is considered to be invalid. Context Descriptor Error This bit indicates that the DMA Tx/Rx engine received a descriptor error, which indicates invalid context in the middle of packet flow (intermediate descriptor) or all one's descriptor in Tx case and on Rx side it indicates DMA has read a descriptor with either of the buffer address as ones which is considered to be invalid. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Context Descriptor Error status not detected 1b - Context Descriptor Error status detected
12 FBE	Fatal Bus Error This bit indicates that a bus error occurred (as described in the EB field). Fatal Bus Error This bit indicates that a bus error occurred (as described in the EB field). When this bit is set, the corresponding DMA channel engine disables all bus accesses. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Fatal Bus Error status not detected 1b - Fatal Bus Error status detected
11 ERI	Early Receive Interrupt This bit when set indicates that the RxDMA has completed the transfer of packet data to the memory. Early Receive Interrupt This bit when set indicates that the RxDMA has completed the transfer of packet data to the memory.

Table continues on the next page...

Field	Function
	In configs supporting ERIC, When ERIC=0, this bit is set only after the Rx DMA has filled up a complete receive buffer with packet data. When ERIC=1, this bit is set after every burst transfer of data from the Rx DMA to the buffer. The setting of RI bit automatically clears this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Early Receive Interrupt status not detected 1b - Early Receive Interrupt status detected
10 ETI	Early Transmit Interrupt This bit when set indicates that the TxDMA has completed the transfer of packet data to the MTL TXFIFO memory. Early Transmit Interrupt This bit when set indicates that the TxDMA has completed the transfer of packet data to the MTL TXFIFO memory. In configs supporting ETIC: When ETIC=0, this bit is set only after the Tx DMA has transferred a complete packet to MTL. When ETIC=1, this bit is set after completion of (partial) packet data transfer from buffers in the Transmit descriptor in which IOC=1. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Early Transmit Interrupt status not detected 1b - Early Transmit Interrupt status detected
9 RWT	Receive Watchdog Timeout This bit is asserted when a packet with length greater than 2,048 bytes (10,240 bytes when Jumbo Packet mode is enabled) is received. 0b - Receive Watchdog Timeout status not detected 1b - Receive Watchdog Timeout status detected
8 RPS	Receive Process Stopped This bit is asserted when the Rx process enters the Stopped state. Receive Process Stopped This bit is asserted when the Rx process enters the Stopped state. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Receive Process Stopped status not detected 1b - Receive Process Stopped status detected
7 RBU	Receive Buffer Unavailable This bit indicates that the application owns the next descriptor in the Receive list, and the DMA cannot acquire it. Receive Buffer Unavailable This bit indicates that the application owns the next descriptor in the Receive list, and the DMA cannot acquire it. The Rx process is suspended. To resume processing Rx descriptors, the application should change the ownership of the descriptor and issue a Receive Poll Demand command. If this command is not issued, the Rx process resumes when the next recognized incoming packet is received. In ring mode, the application should advance the Receive Descriptor Tail Pointer register of a channel. This bit is set only when the DMA owns the previous Rx descriptor. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Receive Buffer Unavailable status not detected 1b - Receive Buffer Unavailable status detected
6 RI	Receive Interrupt This bit indicates that the packet reception is complete. Receive Interrupt This bit indicates that the packet reception is complete. When packet reception is complete, Bit 31 of RDES3 is reset in the last descriptor, and the specific packet status information is updated in the descriptor. The reception remains in the Running state.

21-16 TxPBL	Transmit Programmable Burst Length These bits indicate the maximum number of beats to be transferred in one DMA block data transfer. Transmit Programmable Burst Length These bits indicate the maximum number of beats to be transferred in one DMA block data transfer. The DMA always attempts max burst as specified in PBL each time it starts a burst transfer on the application bus. You can program PBL with any of the following values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior. To transfer more than 32 beats, perform the following steps: 1. Set the 8xPBL mode in CONTROL register. 2. Set the TxPBL. Note: The maximum value of TxPBL must be less than or equal to half the Tx Queue size (TQS field of TXQ4_OPERATION_MODE register) in terms of beats. This is required so that the Tx Queue has space to store at least another Tx PBL worth of data while the MTL Tx Queue Controller is transferring data to MAC. For example, in 64-bit data width configurations the total locations in Tx Queue of size 512 bytes is 64, TxPBL and 8xPBL needs to be programmed to less than or equal to 32.
15 IPBL	Ignore PBL Requirement When this bit is set, the DMA does not check for PBL number of locations in the MTL before initiating a transfer. Ignore PBL Requirement When this bit is set, the DMA does not check for PBL number of locations in the MTL before initiating a transfer. If space is not available, the MTL may use handshaking to slow the DMA. Note: This bit/mode must not be used when multiple Transmit DMA Channels are enabled as it may block other Transmit and Receive DMA Channels from accessing the Read Data Channel of AXI bus until space is available in Transmit Queue for current transfer. 0b - Ignore PBL Requirement is disabled 1b - Ignore PBL Requirement is enabled

21-16 RxPBL	Receive Programmable Burst Length These bits indicate the maximum number of beats to be transferred in one DMA block data transfer. Receive Programmable Burst Length These bits indicate the maximum number of beats to be transferred in one DMA block data transfer. The DMA always attempts max burst as specified in PBL each time it starts a burst transfer on the application bus. You can program PBL with any of the following values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior. To transfer more than 32 beats, perform the following steps: 1. Set the 8xPBL mode in the DMA_CH4_CONTROL register. 2. Set the RxPBL. Note: The maximum value of RxPBL must be less than or equal to half the Rx Queue size (RQS field of RXQ4_OPERATION_MODE register) in terms of beats. This is required so that the Rx Queue has space to store at least another Rx PBL worth of data while the Rx DMA is transferring a block of data. For example, in 64-bit data width configurations the total locations in Rx Queue of size 512 bytes is 64, so RxPBL and 8xPBL needs to be programmed to less than or equal to 32.
15 —	Reserved
14-4 RBSZ_13_y	Receive Buffer size High RBSZ[13:0] is split into two fields higher RBSZ_13_y and lower RBSZ_x_0. Receive Buffer size High RBSZ[13:0] is split into two fields higher RBSZ_13_y and lower RBSZ_x_0. The RBSZ[13:0] field indicates the size of the Rx buffers specified in bytes. The maximum buffer size is limited to 16K bytes. The buffer size is applicable to payload buffers when split headers are enabled. Note: The buffer size must be a multiple of 4, 8, or 16 depending on the data bus widths (32-bit, 64-bit, or 128-bit respectively). This is required even if the value of buffer address pointer is not aligned to data bus width. Hence the lower RBSZ_x_0 bits are read-only and the value is considered as all-zero. Thus the RBSZ_13_y indicates the buffer size in terms of locations (with the width same as bus-width).
3-1 RBSZ_x_0	Receive Buffer size Low RBSZ[13:0] is split into two fields RBSZ_13_y and RBSZ_x_0. Receive Buffer size Low RBSZ[13:0] is split into two fields RBSZ_13_y and RBSZ_x_0. The RBSZ_x_0 is the lower field whose width is based on data bus width of the configuration. This field is of width 2, 3, or 4 bits for 32-bit, 64-bit, or 128-bit data bus width respectively. This field is read-only (RO).
0 SR	Start or Stop Receive When this bit is set, the DMA tries to acquire the descriptor from the Receive list and processes the incoming packets. Start or Stop Receive When this bit is set, the DMA tries to acquire the descriptor from the Receive list and processes the incoming packets. The DMA tries to acquire descriptor from either of the following positions: - The current position in the list This is the address set by the DMA_CH4_RXDESC_LIST_ADDRESS register. - The position at which the Rx process was previously stopped

Field	Function
	If the DMA does not own the current descriptor, the reception is suspended and the RBU bit of the DMA_CH4_STATUS register is set. The Start Receive command is effective only when the reception is stopped. If the command is issued before setting the DMA_CH4_RXDESC_LIST_ADDRESS register, the DMA behavior is unpredictable. When this bit is reset, the Rx DMA operation is stopped after the transfer of the current packet. The next descriptor position in the Receive list is saved, and it becomes the current position after the Rx process is restarted. The Stop Receive command is effective only when the Rx process is in the Running (waiting for Rx packet) or Suspended state. 0b - Stop Receive 1b - Start Receive

61.7.1.552 Channel 4 Tx Descriptor List Address (DMA_CH4_TXDESC_LIST_ADDRESS)

61.7.1.552.1 Offset

Register	Offset
DMA_CH4_TXDESC_LIST_ADDRESS	1314h

61.7.1.552.2 Function

The Channel 4 Tx Descriptor List Address register points the DMA to the start of Transmit descriptor list. The descriptor lists reside in the physical memory space of the application and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LSB to low.

You can write to this register only when the Tx DMA has stopped, that is, the ST bit is set to zero in TX_CONTROL register. When stopped, this register can be written with a new descriptor list address. When you set the ST bit to 1, the DMA takes the newly-programmed descriptor base address. If this register is not changed when the ST bit is set to 0, the DMA takes the descriptor address where it was stopped earlier.

61.7.1.552.3 Diagram

Field	Function
31-3 TDESLA	Start of Transmit List This field contains the base address of the first descriptor in the Transmit descriptor list. Start of Transmit List This field contains the base address of the first descriptor in the Transmit descriptor list. The DMA ignores the LSB bits (1:0, 2:0, or 3:0) for 32-bit, 64-bit, or 128-bit bus width and internally takes these bits as all-zero. Therefore, these LSB bits are read-only (RO). The width of this field depends on the configuration: - 31:2 for 32-bit configuration - 31:3 for 64-bit configuration - 31:4 for 128-bit configuration
2-0 —	Reserved

61.7.1.553 Channel 4 Rx Descriptor List Address (DMA_CH4_RXDESC_LIST_ADDRESS)

61.7.1.553.1 Offset

Register	Offset
DMA_CH4_RXDESC_LIST_ADDRESS	131Ch

61.7.1.553.2 Function

The Channel 4 Rx Descriptor List Address register points the DMA to the start of Receive descriptor list.

This register points to the start of the Receive Descriptor List. The descriptor lists reside in the physical memory space of the application and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LS bits low. Writing to this register is permitted only when reception is stopped. When stopped, this register must be written to before the receive Start command is given. You can write to this register only when Rx DMA has stopped, that is, SR bit is set to zero in RX_CONTROL register. When stopped, this register can be written with a new descriptor list address.

When you set the SR bit to 1, the DMA takes the newly programmed descriptor base address.

61.7.1.555 Channel 4 Rx Descriptor Tail Pointer (DMA_CH4_RXDESC_TAIL_POINTER)

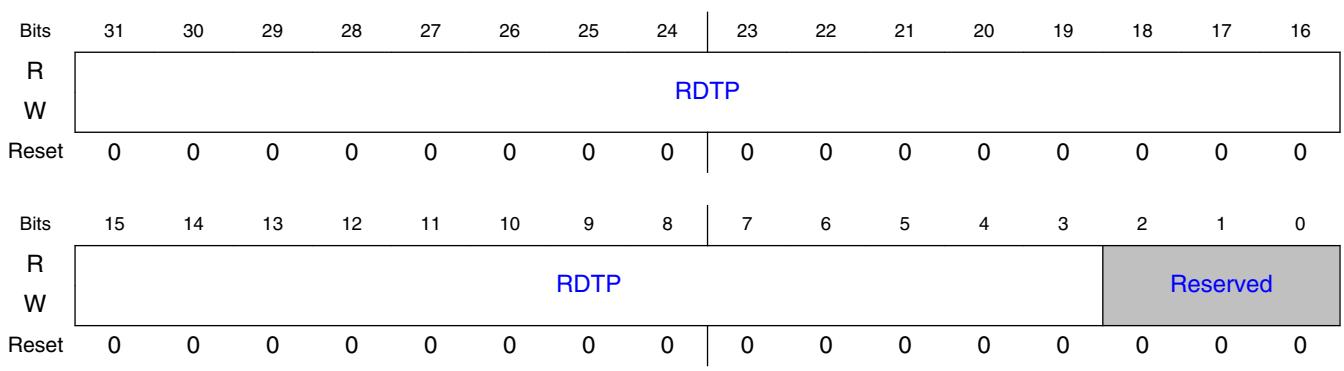
61.7.1.555.1 Offset

Register	Offset
DMA_CH4_RXDESC_TAIL_POINTER	1328h

61.7.1.555.2 Function

The Channel 4 Rx Descriptor Tail Pointer points to an offset from the base and indicates the location of the last valid descriptor.

61.7.1.555.3 Diagram



61.7.1.555.4 Fields

Field	Function
31-3 RDTP	Receive Descriptor Tail Pointer This field contains the tail pointer for the Rx descriptor ring. Receive Descriptor Tail Pointer

Table continues on the next page...

Field	Function
	This field contains the tail pointer for the Rx descriptor ring. The software writes the tail pointer to add more descriptors to the Rx channel. The hardware tries to write all received packets to the descriptors referenced between the head and the tail pointer registers. The width of this field depends on the configuration: - 31:2 for 32-bit configuration - 31:3 for 64-bit configuration - 31:4 for 128-bit configuration
2-0 —	Reserved

61.7.1.556 Channel 4 Tx Descriptor Ring Length (DMA_CH4_TXDESC_RING_LENGTH)

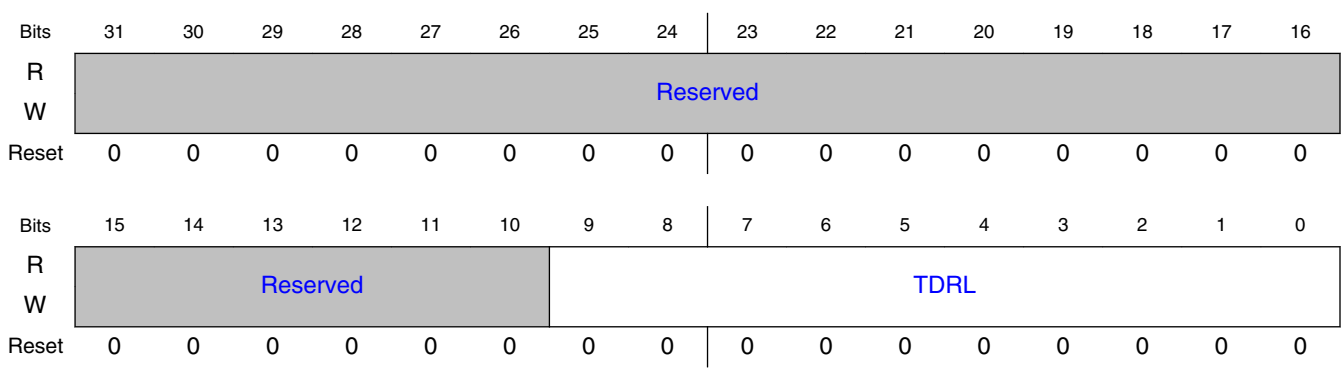
61.7.1.556.1 Offset

Register	Offset
DMA_CH4_TXDESC_RING_LENGTH	132Ch

61.7.1.556.2 Function

The Channel 4 Tx Descriptor Ring Length register contains the length of the Transmit descriptor ring.

61.7.1.556.3 Diagram



61.7.1.556.4 Fields

Field	Function
31-10 —	Reserved
9-0 TDRL	Transmit Descriptor Ring Length This field sets the maximum number of Tx descriptors in the circular descriptor ring. Transmit Descriptor Ring Length This field sets the maximum number of Tx descriptors in the circular descriptor ring. The maximum number of descriptors is limited to 1K descriptors. We recommend a minimum ring descriptor length of 4. For example, You can program any value up to 0x3FF in this field. This field is 10 bits wide, if you program 0x3FF, you can have 1024 descriptors. If you want to have 10 descriptors, program it to a value of 0x9.

61.7.1.557 DMA Channel 4 Receive Control 2 register (DMA_CH4_RX_CONTROL2)

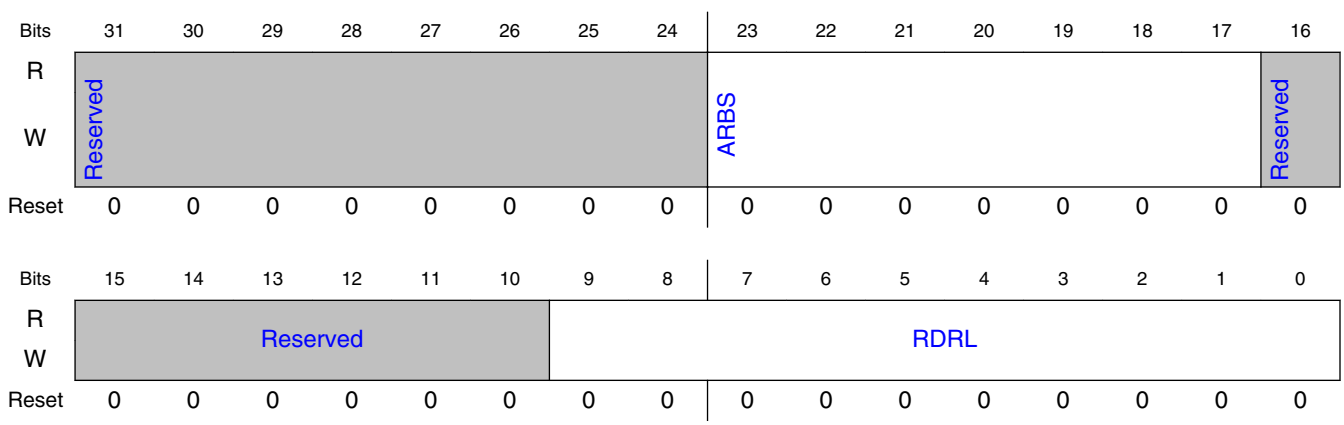
61.7.1.557.1 Offset

Register	Offset
DMA_CH4_RX_CONTROL2	1330h

61.7.1.557.2 Function

The Channel 4 Receive Control register controls Rx Descriptor Ring Length and Alternate Rx Buffer Size.

61.7.1.557.3 Diagram



61.7.1.557.4 Fields

Field	Function
31-24 —	Reserved
23-17 ARBS	Alternate Receive Buffer Size Indicates size in bytes for Buffer 1 when ARBS is programmed to a non-zero value (when split header feature is not enabled). When split header feature is enabled, ARBS indicates the buffer size for header data. The maximum alternate buffer is limited to 1020, 1016 or 1008-bytes depending on the data bus widths (32-bit, 64-bit, or 128-bit respectively). When ARBS=0, Rx Buffer1 and Rx Buffer2 sizes are based on DMA_CH2_RX_CONTROL[RBSZ]. Width of ARBS field is 8, 7 or 6-bits depending on the data bus widths (32-bit, 64-bit, or 128-bit respectively).
16-10 —	Reserved
9-0 RDRL	Receive Descriptor Ring Length This register sets the maximum number of Rx descriptors in the circular descriptor ring. Receive Descriptor Ring Length This register sets the maximum number of Rx descriptors in the circular descriptor ring. The maximum number of descriptors is limited to 1K descriptors. For example, You can program any value up to 0x3FF in this field. This field is 10 bits wide, if you program 0x3FF, you can have 1024 descriptors. If you want to have 10 descriptors, program it to a value of 0x9.

61.7.1.558 Channel 4 Interrupt Enable (DMA_CH4_INTERRUPT_ENABLE)

61.7.1.558.1 Offset

Register	Offset
DMA_CH4_INTERRUPT_ENABLE	1334h

61.7.1.558.2 Function

The Channel 4 Interrupt Enable register enables the interrupts reported by the Status register.

	0b - Abnormal Interrupt Summary is disabled 1b - Abnormal Interrupt Summary is enabled
13 CDEE	Context Descriptor Error Enable When this bit is set along with the AIE bit, the Descriptor error interrupt is enabled. Context Descriptor Error Enable When this bit is set along with the AIE bit, the Descriptor error interrupt is enabled. When this bit is reset, the Descriptor error interrupt is disabled. 0b - Context Descriptor Error is disabled 1b - Context Descriptor Error is enabled
12 FBEE	Fatal Bus Error Enable When this bit is set along with the AIE bit, the Fatal Bus error interrupt is enabled. Fatal Bus Error Enable When this bit is set along with the AIE bit, the Fatal Bus error interrupt is enabled. When this bit is reset, the Fatal Bus Error error interrupt is disabled. 0b - Fatal Bus Error is disabled 1b - Fatal Bus Error is enabled
11 ERIE	Early Receive Interrupt Enable When this bit is set along with the NIE bit, the Early Receive interrupt is enabled. Early Receive Interrupt Enable When this bit is set along with the NIE bit, the Early Receive interrupt is enabled. When this bit is reset, the Early Receive interrupt is disabled. 0b - Early Receive Interrupt is disabled 1b - Early Receive Interrupt is enabled
10 ETIE	Early Transmit Interrupt Enable When this bit is set along with the AIE bit, the Early Transmit interrupt is enabled. Early Transmit Interrupt Enable When this bit is set along with the AIE bit, the Early Transmit interrupt is enabled. When this bit is reset, the Early Transmit interrupt is disabled. 0b - Early Transmit Interrupt is disabled 1b - Early Transmit Interrupt is enabled
9 RWTE	Receive Watchdog Timeout Enable When this bit is set along with the AIE bit, the Receive Watchdog Timeout interrupt is enabled. Receive Watchdog Timeout Enable When this bit is set along with the AIE bit, the Receive Watchdog Timeout interrupt is enabled. When this bit is reset, the Receive Watchdog Timeout interrupt is disabled. 0b - Receive Watchdog Timeout is disabled 1b - Receive Watchdog Timeout is enabled
8 RSE	Receive Stopped Enable When this bit is set along with the AIE bit, the Receive Stopped Interrupt is enabled. Receive Stopped Enable When this bit is set along with the AIE bit, the Receive Stopped Interrupt is enabled. When this bit is reset, the Receive Stopped interrupt is disabled. 0b - Receive Stopped is disabled 1b - Receive Stopped is enabled
7 RBUE	Receive Buffer Unavailable Enable When this bit is set along with the AIE bit, the Receive Buffer Unavailable interrupt is enabled.

Table continues on the next page...

Field	Function
	Receive Buffer Unavailable Enable When this bit is set along with the AIE bit, the Receive Buffer Unavailable interrupt is enabled. When this bit is reset, the Receive Buffer Unavailable interrupt is disabled. 0b - Receive Buffer Unavailable is disabled 1b - Receive Buffer Unavailable is enabled
6 RIE	Receive Interrupt Enable When this bit is set along with the NIE bit, the Receive Interrupt is enabled. Receive Interrupt Enable When this bit is set along with the NIE bit, the Receive Interrupt is enabled. When this bit is reset, the Receive Interrupt is disabled. 0b - Receive Interrupt is disabled 1b - Receive Interrupt is enabled
5-3 —	Reserved
2 TBUE	Transmit Buffer Unavailable Enable When this bit is set along with the NIE bit, the Transmit Buffer Unavailable interrupt is enabled. Transmit Buffer Unavailable Enable When this bit is set along with the NIE bit, the Transmit Buffer Unavailable interrupt is enabled. When this bit is reset, the Transmit Buffer Unavailable interrupt is disabled. 0b - Transmit Buffer Unavailable is disabled 1b - Transmit Buffer Unavailable is enabled
1 TXSE	Transmit Stopped Enable When this bit is set along with the AIE bit, the Transmission Stopped interrupt is enabled. Transmit Stopped Enable When this bit is set along with the AIE bit, the Transmission Stopped interrupt is enabled. When this bit is reset, the Transmission Stopped interrupt is disabled. 0b - Transmit Stopped is disabled 1b - Transmit Stopped is enabled
0 TIE	Transmit Interrupt Enable When this bit is set along with the NIE bit, the Transmit Interrupt is enabled. Transmit Interrupt Enable When this bit is set along with the NIE bit, the Transmit Interrupt is enabled. When this bit is reset, the Transmit Interrupt is disabled. 0b - Transmit Interrupt is disabled 1b - Transmit Interrupt is enabled

61.7.1.559 Channel 4 Receive Interrupt Watchdog Timer (DMA_CH4_RX_INTERRUPT_WATCHDOG_TIMER)

61.7.1.559.1 Offset

Register	Offset
DMA_CH4_RX_INTERRUPT_WATCHDOG_TIMER	1338h

61.7.1.559.2 Function

The Channel 4 Receive Interrupt Watchdog Timer register indicates the watchdog timeout for Receive Interrupt (RI) from the DMA. When this register is written with a non-zero value, it enables the watchdog timer for the RI bit of the DMA_CH4_Status register.

61.7.1.559.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Function
31-18 —	Reserved
17-16 RWTU	Receive Interrupt Watchdog Timer Count Units This fields indicates the number of system clock cycles corresponding to one unit in RWT field. Receive Interrupt Watchdog Timer Count Units This fields indicates the number of system clock cycles corresponding to one unit in RWT field. - 2'b00: 256 - 2'b01: 512 - 2'b10: 1024 - 2'b11: 2048 For example, when RWT=2 and RWTU=1, the watchdog timer is set for 2*512=1024 system clock cycles.

Table continues on the next page...

Field	Function
15-8 —	Reserved
7-0 RWT	Receive Interrupt Watchdog Timer Count This field indicates the number of system clock cycles, multiplied by factor indicated in RWTU field, for which the watchdog timer is set. Receive Interrupt Watchdog Timer Count This field indicates the number of system clock cycles, multiplied by factor indicated in RWTU field, for which the watchdog timer is set. The watchdog timer is triggered with the programmed value after the Rx DMA completes the transfer of a packet for which the RI bit is not set in the DMA_CH4_STATUS register, because of the setting of Interrupt Enable bit in the corresponding descriptor RDES3[30]. When the watchdog timer runs out, the RI bit is set and the timer is stopped. The watchdog timer is reset when the RI bit is set high because of automatic setting of RI as per the Interrupt Enable bit RDES3[30] of any received packet.

61.7.1.560 Channel 4 Slot Function Control and Status (DMA_CH4_SLOT_FUNCTION_CONTROL_STATUS)

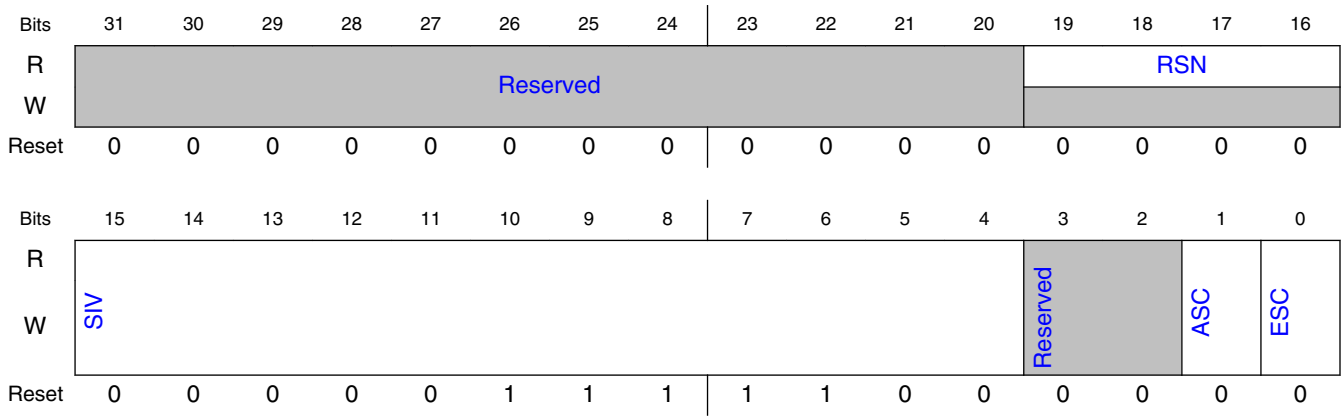
61.7.1.560.1 Offset

Register	Offset
DMA_CH4_SLOT_FUNCTION_CONTROL_STATUS	133Ch

61.7.1.560.2 Function

The Channel 4 Slot Function Control and Status register contains the control bits for slot function and the status for Transmit path.

61.7.1.560.3 Diagram



61.7.1.560.4 Fields

Field	Function
31-20 —	Reserved
19-16 RSN	Reference Slot Number This field gives the current value of the reference slot number in the DMA. Reference Slot Number This field gives the current value of the reference slot number in the DMA. It is used for slot comparison.
15-4 SIV	Slot Interval Value This field controls the period of the slot interval in which the TxDMA fetches the scheduled packets. Slot Interval Value This field controls the period of the slot interval in which the TxDMA fetches the scheduled packets. A value of 0 specifies the slot interval of 1 us while the maximum value 4095 specifies the slot interval of 4096us. The default/reset value is 0x07C which corresponds to slot interval of 125us
3-2 —	Reserved
1 ASC	Advance Slot Check When set, this bit enables the DMA to fetch the data from the buffer when the slot number (SLOTNUM) programmed in the Tx descriptor is - equal to the reference slot number given in the RSN field or - ahead of the reference slot number by up to two slots This bit is applicable only when the ESC bit is set. 0b - Advance Slot Check is disabled 1b - Advance Slot Check is enabled
0 ESC	Enable Slot Comparison When set, this bit enables the checking of the slot numbers programmed in the Tx descriptor with the current reference given in the RSN field. Enable Slot Comparison When set, this bit enables the checking of the slot numbers programmed in the Tx descriptor with the current reference given in the RSN field. The DMA fetches the data from the corresponding buffer only when the slot number is - equal to the reference slot number or

Field	Function
	- ahead of the reference slot number by one slot When reset, this bit disables the checking of the slot numbers. The DMA fetches the data immediately after the descriptor is processed. Note: The UFO (UDP Fragmentation over IPv4)/TSO/USO should not be enabled along with TBS/AVB Slot number check. The UFO/TSO/USO involves multiple packets/segments/fragments transmission for single packet received from application and the slot number check are applicable for fetching of only first segment/fragment. As a result it might be difficult for software to specify slot number for subsequent packets. 0b - Slot Comparison is disabled 1b - Slot Comparison is enabled

61.7.1.561 Channel 4 Current Application Transmit Descriptor (DMA_CH4_CURRENT_APP_TXDESC)

61.7.1.561.1 Offset

Register	Offset
DMA_CH4_CURRENT_APP_TXDESC	1344h

61.7.1.561.2 Function

The Channel 4 Current Application Transmit Descriptor register points to the current Transmit descriptor read by the DMA.

21-19 REB	Rx DMA Error Bits This field indicates the type of error that caused a Bus Error. Rx DMA Error Bits This field indicates the type of error that caused a Bus Error. For example, error response on the AHB or AXI interface. - Bit 21 -- 1'b1: Error during data transfer by Rx DMA -- 1'b0: No Error during data transfer by Rx DMA - Bit 20 -- 1'b1: Error during descriptor access

Table continues on the next page...

Field	Function
	-- 1'b0: Error during data buffer access - Bit 19 -- 1'b1: Error during read transfer -- 1'b0: Error during write transfer This field is valid only when the FBE bit is set. This field does not generate an interrupt.
18-16 TEB	Tx DMA Error Bits This field indicates the type of error that caused a Bus Error. Tx DMA Error Bits This field indicates the type of error that caused a Bus Error. For example, error response on the AHB or AXI interface. - Bit 18 -- 1'b1: Error during data transfer by Tx DMA -- 1'b0: No Error during data transfer by Tx DMA - Bit 17 -- 1'b1: Error during descriptor access -- 1'b0: Error during data buffer access - Bit 16 -- 1'b1: Error during read transfer -- 1'b0: Error during write transfer This field is valid only when the FBE bit is set. This field does not generate an interrupt.
15 NIS	Normal Interrupt Summary Normal Interrupt Summary bit value is the logical OR of the following bits when the corresponding interrupt bits are enabled in the INTERRUPT_ENABLE register: - Bit 0: Transmit Interrupt - Bit 2: Transmit Buffer Unavailable - Bit 6: Receive Interrupt - Bit 11: Early Receive Interrupt Only unmasked bits (interrupts for which interrupt enable is set in INTERRUPT_ENABLE register) affect the Normal Interrupt Summary bit. Normal Interrupt Summary Normal Interrupt Summary bit value is the logical OR of the following bits when the corresponding interrupt bits are enabled in the INTERRUPT_ENABLE register: - Bit 0: Transmit Interrupt - Bit 2: Transmit Buffer Unavailable - Bit 6: Receive Interrupt - Bit 11: Early Receive Interrupt Only unmasked bits (interrupts for which interrupt enable is set in INTERRUPT_ENABLE register) affect the Normal Interrupt Summary bit. This is a sticky bit. You must clear this bit (by writing 1 to this bit) each time a corresponding bit which causes NIS to be set is cleared. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Normal Interrupt Summary status not detected 1b - Normal Interrupt Summary status detected
14 AIS	Abnormal Interrupt Summary Abnormal Interrupt Summary bit value is the logical OR of the following when the corresponding interrupt bits are enabled in the INTERRUPT_ENABLE register: - Bit 1: Transmit Process Stopped - Bit 7: Receive Buffer Unavailable - Bit 8: Receive Process Stopped - Bit 10: Early Transmit Interrupt - Bit 12: Fatal Bus Error - Bit 13: Context Descriptor Error Only unmasked bits affect the Abnormal Interrupt Summary bit.

Table continues on the next page...

Field	Function
	Abnormal Interrupt Summary Abnormal Interrupt Summary bit value is the logical OR of the following when the corresponding interrupt bits are enabled in the INTERRUPT_ENABLE register: - Bit 1: Transmit Process Stopped - Bit 7: Receive Buffer Unavailable - Bit 8: Receive Process Stopped - Bit 10: Early Transmit Interrupt - Bit 12: Fatal Bus Error - Bit 13: Context Descriptor Error Only unmasked bits affect the Abnormal Interrupt Summary bit. This is a sticky bit. You must clear this bit (by writing 1 to this bit) each time a corresponding bit, which causes AIS to be set, is cleared. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Abnormal Interrupt Summary status not detected 1b - Abnormal Interrupt Summary status detected
13 CDE	Context Descriptor Error This bit indicates that the DMA Tx/Rx engine received a descriptor error, which indicates invalid context in the middle of packet flow (intermediate descriptor) or all one's descriptor in Tx case and on Rx side it indicates DMA has read a descriptor with either of the buffer address as ones which is considered to be invalid. Context Descriptor Error This bit indicates that the DMA Tx/Rx engine received a descriptor error, which indicates invalid context in the middle of packet flow (intermediate descriptor) or all one's descriptor in Tx case and on Rx side it indicates DMA has read a descriptor with either of the buffer address as ones which is considered to be invalid. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Context Descriptor Error status not detected 1b - Context Descriptor Error status detected
12 FBE	Fatal Bus Error This bit indicates that a bus error occurred (as described in the EB field). Fatal Bus Error This bit indicates that a bus error occurred (as described in the EB field). When this bit is set, the corresponding DMA channel engine disables all bus accesses. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Fatal Bus Error status not detected 1b - Fatal Bus Error status detected
11 ERI	Early Receive Interrupt This bit when set indicates that the RxDMA has completed the transfer of packet data to the memory. Early Receive Interrupt This bit when set indicates that the RxDMA has completed the transfer of packet data to the memory. In configs supporting ERIC, When ERIC=0, this bit is set only after the Rx DMA has filled up a complete receive buffer with packet data. When ERIC=1, this bit is set after every burst transfer of data from the Rx DMA to the buffer. The setting of RI bit automatically clears this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Early Receive Interrupt status not detected

Table continues on the next page...

Field	Function
	1b - Early Receive Interrupt status detected
10 ETI	Early Transmit Interrupt This bit when set indicates that the TxDMA has completed the transfer of packet data to the MTL TXFIFO memory. Early Transmit Interrupt This bit when set indicates that the TxDMA has completed the transfer of packet data to the MTL TXFIFO memory. In configs supporting ETIC: When ETIC=0, this bit is set only after the Tx DMA has transferred a complete packet to MTL. When ETIC=1, this bit is set after completion of (partial) packet data transfer from buffers in the Transmit descriptor in which IOC=1. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Early Transmit Interrupt status not detected 1b - Early Transmit Interrupt status detected
9 RWT	Receive Watchdog Timeout This bit is asserted when a packet with length greater than 2,048 bytes (10,240 bytes when Jumbo Packet mode is enabled) is received. 0b - Receive Watchdog Timeout status not detected 1b - Receive Watchdog Timeout status detected
8 RPS	Receive Process Stopped This bit is asserted when the Rx process enters the Stopped state. Receive Process Stopped This bit is asserted when the Rx process enters the Stopped state. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Receive Process Stopped status not detected 1b - Receive Process Stopped status detected
7 RBU	Receive Buffer Unavailable This bit indicates that the application owns the next descriptor in the Receive list, and the DMA cannot acquire it. Receive Buffer Unavailable This bit indicates that the application owns the next descriptor in the Receive list, and the DMA cannot acquire it. The Rx process is suspended. To resume processing Rx descriptors, the application should change the ownership of the descriptor and issue a Receive Poll Demand command. If this command is not issued, the Rx process resumes when the next recognized incoming packet is received. In ring mode, the application should advance the Receive Descriptor Tail Pointer register of a channel. This bit is set only when the DMA owns the previous Rx descriptor. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Receive Buffer Unavailable status not detected 1b - Receive Buffer Unavailable status detected
6 RI	Receive Interrupt This bit indicates that the packet reception is complete. Receive Interrupt This bit indicates that the packet reception is complete. When packet reception is complete, Bit 31 of RDES3 is reset in the last descriptor, and the specific packet status information is updated in the descriptor. The reception remains in the Running state. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Receive Interrupt status not detected 1b - Receive Interrupt status detected
5-3 —	Reserved

Table continues on the next page...

Field	Function
2 TBU	Transmit Buffer Unavailable This bit indicates that the application owns the next descriptor in the Transmit list, and the DMA cannot acquire it. Transmit Buffer Unavailable This bit indicates that the application owns the next descriptor in the Transmit list, and the DMA cannot acquire it. Transmission is suspended. The TPS0 field of the DMA_CH4_DEBUG_STATUS0 register explains the Transmit Process state transitions. To resume processing the Transmit descriptors, the application should do the following: 1. Change the ownership of the descriptor by setting Bit 31 of TDES3. 2. Issue a Transmit Poll Demand command. For ring mode, the application should advance the Transmit Descriptor Tail Pointer register of a channel. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Transmit Buffer Unavailable status not detected 1b - Transmit Buffer Unavailable status detected
1 TPS	Transmit Process Stopped This bit is set when the transmission is stopped. Transmit Process Stopped This bit is set when the transmission is stopped. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Transmit Process Stopped status not detected 1b - Transmit Process Stopped status detected
0 TI	Transmit Interrupt This bit indicates that the packet transmission is complete. Transmit Interrupt This bit indicates that the packet transmission is complete. When transmission is complete, Bit 31 of TDES3 is reset in the last descriptor, and the specific packet status information is updated in the descriptor. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Transmit Interrupt status not detected 1b - Transmit Interrupt status detected

61.7.1.566 Channel 4 Missed Frame Counter (DMA_CH4_MISS_FRAME_CNT)

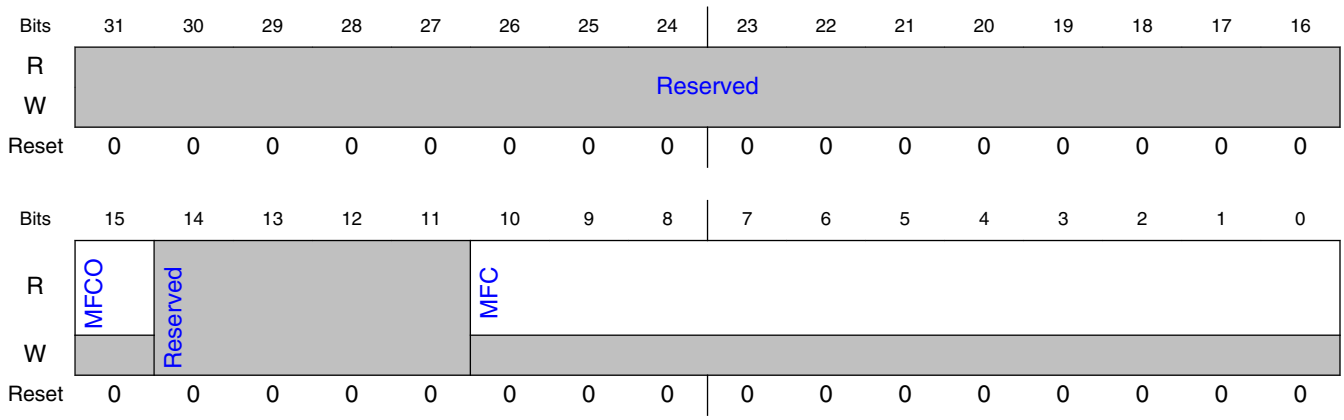
61.7.1.566.1 Offset

Register	Offset
DMA_CH4_MISS_FRAME_CNT	1364h

61.7.1.566.2 Function

This register has the number of packet counter that got dropped by the DMA either due to Bus Error or due to programming RPF field in DMA_CH4_RX_CONTROL register.

61.7.1.566.3 Diagram



61.7.1.566.4 Fields

Field	Function
31-16 —	Reserved
15 MFCO	Overflow status of the MFC Counter When this bit is set then the MFC counter does not get incremented further. Overflow status of the MFC Counter When this bit is set then the MFC counter does not get incremented further. The bit gets cleared when this register is read. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0b - Miss Frame Counter overflow not occurred 1b - Miss Frame Counter overflow occurred
14-11 —	Reserved
10-0 MFC	Dropped Packet Counters This counter indicates the number of packet counters that are dropped by the DMA either because of bus error or because of programming RPF field in RX_CONTROL register. Dropped Packet Counters This counter indicates the number of packet counters that are dropped by the DMA either because of bus error or because of programming RPF field in RX_CONTROL register. The counter gets cleared when this register is read. Access restriction applies. Clears on read. Self-set to 1 on internal event.

61.7.1.567 Channel 4 RXP Frames Accepted Counter (DMA_CH4_RXP_ACCEPT_CNT)

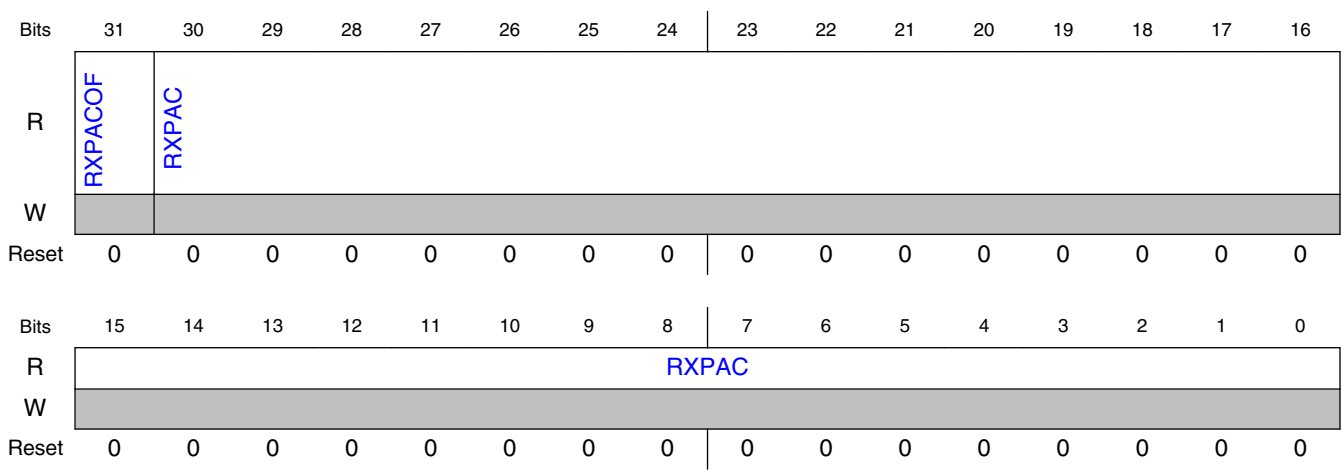
61.7.1.567.1 Offset

Register	Offset
DMA_CH4_RXP_ACCEPT_CNT	1368h

61.7.1.567.2 Function

The DMA_CH4_RXP_Accept_Cnt register provides the count of the number of frames accepted by Rx Parser.

61.7.1.567.3 Diagram



61.7.1.567.4 Fields

Field	Function
31 RXPACOF	Rx Parser Accept Counter Overflow Bit When set, this bit indicates that the RXPAC Counter field crossed the maximum limit. Rx Parser Accept Counter Overflow Bit When set, this bit indicates that the RXPAC Counter field crossed the maximum limit. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0b - Rx Parser Accept Counter overflow not occurred 1b - Rx Parser Accept Counter overflow occurred

Table continues on the next page...

Field	Function
30-0 RXPAC	Rx Parser Accept Counter This 31-bit counter is implemented whenever a Rx Parser Accept a packet due to AF =1. Rx Parser Accept Counter This 31-bit counter is implemented whenever a Rx Parser Accept a packet due to AF =1. The counter is cleared when the register is read.

62.2 Overview

The USB controller block provides high performance USB functionality that conforms to the *Universal Serial Bus Specification*, Rev. 2.0 (Compaq, Hewlett-Packard, Intel, Lucent, Microsoft, NEC, Philips; 2000), and the *On-The-Go and Embedded Host Supplement to the USB Revision* 2.0 Specification (Hewlett-Packard Company, Intel Corporation, LSI Corporation, Microsoft Corporation, Renesas Electronics Corporation, ST-Ericsson; 2012).

The USB controller consists of two independent USB controller cores: two On-The-Go (OTG) controller cores. Each controller core supports UTMI interfaces according to its feature. See Features for more details. Both the controller cores are single-port cores. For the OTG cores, there is only one port. The port can be used as either a downstream or an upstream port.

62.2.1 Block Diagram

The following figure is a block diagram of USB.

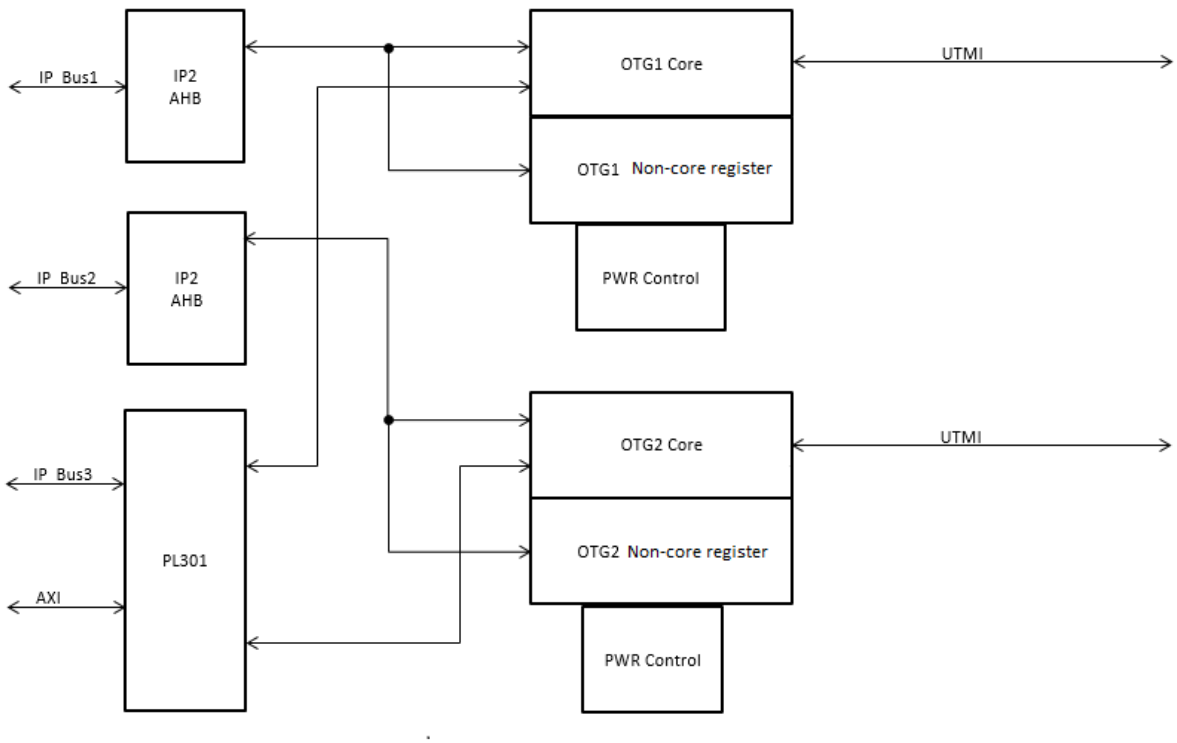

Figure 62-1. USB block diagram

62.2.2 Features

There are two USB 2.0 controller cores in this chip:

- Controller Core 0 is also named 'OTG1 Core'; its connected port is named 'OTG1 port'.
- Controller Core 1 is also named 'OTG2 Core'; its connected port is named 'OTG2 port'.

The following list provides features of each controller core.

- USB 2.0 Controller Core 0
  - High-Speed/Full-Speed/Low-Speed OTG core
  - HS/FS/LS UTMI compliant interface

    - High Speed, Full Speed and Low Speed operation in HOST mode (with UTMI transceiver)
    - High Speed, and Full Speed operation in Peripheral mode (with UTMI transceiver)
    - Hardware support for OTG signaling, session request protocol, and host negotiation protocol
    - 8 bidirectional endpoints
    - Support charger detection
- USB 2.0 Controller Core 1
    - High-Speed/Full-Speed/Low-Speed OTG core
    - HS/FS/LS UTMI compliant interface
    - High Speed, Full Speed and Low Speed operation in Host mode (with UTMI transceiver)
    - High Speed, and Full Speed operation in Peripheral mode (with UTMI transceiver)
    - Hardware support for OTG signaling, session request protocol, and host negotiation protocol
    - 8 bidirectional endpoints
- Low-power mode with local and remote wake-up capability
- Embedded DMA controller in each core

62.3 Functional Description

These sections describe the functionality of the various building blocks of the USB.

62.3.1 USB 2.0 Controller Core 0

The USB 2.0 Controller 0 is an instantiation of an EHCI-compatible core which supports high-, full-, and low-speed operation.

In Host mode, this controller core supports high-, full-, and low-speed operation. In Device mode, it supports high- and full-speed operation.

62.3.1.1 Host Mode

The controller supports direct connection of a HS/FS/LS device with on-chip UTMI transceiver.

Although there is no separate Transaction Translator block in the system, the transaction translator function normally associated with a USB 2.0 high speed hub has been implemented within the DMA and protocol engine blocks to support connection to full and low speed devices.

62.3.1.2 Peripheral (Device) Mode

- 8 bidirectional endpoints
- High/full-speed operation
- Support of HNP, and SRP
- Remote wake-up capability

62.3.2 USB 2.0 Controller Core 1

USB 2.0 Controller Core 1 is an instantiation of EHCI-compatible core which supports High Speed / Full Speed / Low Speed operation

62.3.3 Modes of Operation

The USB has two main modes of operation: normal mode and low power mode .

Each USB OTG controller core can operate in High Speed operation (480 Mbps), Full Speed operation (12 Mbps) and Low Speed operation (1.5 Mbps).

This chapter explains the operation modes.

62.3.3.1 Normal Mode

The OTG controller core can operate in Host mode and Device (Peripheral) mode.

Each USB controller core has its corresponding port, which can work in one or more interface modes.

NOTE

Each controller supports only the interface type listed below. Selecting a different interface type in the PORTSC_PTS field results in unpredictable behavior and may cause the system to hang.

- OTG1 port

    - This port supports on-chip UTMI transceiver only.
- OTG2 port
    - This port supports on-chip UTMI transceiver only.

62.3.3.2 Low-Power Mode

Each USB controller core has a low-power mode (Suspend mode) to save power consumption.

As described in the USB 2.0 specification, the device can go into the Suspend state after it sees a constant Idle state on the upstream facing port. The OTG controller core enters Suspend mode after 3 ms of inactivity on the port when it is in Device Operation mode. Host controllers, including the OTG controller in Host mode, do not suspend automatically but can be placed in Suspend mode by software.

Either the local Arm platform or the remote USB Host/Peripheral can initiate a wake-up sequence to resume USB communication. For details about Suspend/Resume, see Power Control.

62.3.3.2.1 Power Control

The USB controller supports suspend and wake-up functionality.

The power control block allows for placing the transceiver in USB low power mode when USB bus is IDLE, and supports local and remote wake-up to bring the transceiver out of USB low power mode when needed. Additionally, the power control block can wake-up the Arm platform from core sleep mode by generating an interrupt.

62.3.3.2.1.1 Entering Low Power Suspend Mode

In Host operation mode, low power suspend mode is entered as follows:

1. Clear the ASE and PSE bits in USB_USBCMD, and wait until the AS and PS bits in USB_USBSTS become "0".
2. Set the "SUSPEND" bit in USB_PORTSC1
3. Set VBUSVALID_TO_SESSVALID in USBPHYx_USB1_VBUS_DETECT
4. Set the "PHCD" bit in USB_PORTSC1
5. Set all PWD bits in USBPHYx_PWD
6. Set CLKGATE in USBPHYx_CTRL

NOTE

Step 4,5,6 shall be done in atomic operation. That is, interrupt should be disabled during these three steps.

For device operation mode, low power suspend mode is entered as follows:

1. After Host drive is IDLE for 3ms, an SLI interrupt is issued (the "DCSUSPEND" or "SLI" bit in USB_USBSTS)
2. Set VBUSVALID_TO_SESSVALID in USBPHYx_USB1_VBUS_DETECT
3. Set the "PHCD" bit on USB_PORTSC1
4. Set all PWD bits in USBPHYx_PWD
5. Set CLKGATE in USBPHYx_CTRL

NOTE

Step 3,4,5 shall be done in atomic operation. That is, interrupt should be disabled during these three steps.

62.3.3.2.1.2 Wake-Up Events

The power control block monitors the USB bus when the USB core is in the USB suspend state.

Depending on whether the core is on Host or Device mode, a number of wake-up conditions are monitored. Upon detection of a wake-up condition, an interrupt will be generated to Arm platform if the related wake-up interrupt enable bit is set.

USB wake-up interrupt also re-activates the Arm platform clocks if they were stopped during the suspend.

62.3.3.2.1.2.1 Host Mode Events

The host controller wakes up on the following events:

- Remote Wake-up Request

A peripheral can request the host to reactivate the bus by driving wake-up signaling on the DM/DP lines. The power control block sends a wake-up request to the USB core when a J-K transition on DM/DP line is detected.

- Wake-Up On Overcurrent

If Wake-Up On Overcurrent is enabled (WKOC bit in the USB core register PORTSC1 is set '1'), the power control block sends a wake-up request to the USB core when an overcurrent event is detected.

- Wake-Up On Disconnect

If Wake-Up On Disconnect is enabled (WKDC bit in the USB core register PORTSC1 is set '1'), the power control block sends a wake-up request to the USB core when a disconnection event is detected (J-SE0/K-SE0 transition on DM/DP line).

- Wake-Up On Connect

If a Wake-Up On Connect is enabled (WKCN bit in the USB core register PORTSC1 is set '1'), the power control sub-block sends a wake-up request to the USB core when the connection event is detected (SE0-J/SE0-K transition on DM/DP line).

For a detailed description of register bits WKOC, WKDC, WKCN, please see USB_nPORTSC1.

62.3.4 Interrupts

62.3.4.1 USB Core Interrupts

Each USB core uses one dedicated vector in the Interrupt Table. The vector numbers associated with each of the cores can be found in the Interrupt section.

With the exception of the wake-up interrupts, all of the interrupt sources are controlled in the USB Cores. Refer to the USB_nUSBINTR for details.

62.3.4.2 USB Wake-Up Interrupts

Each USB Core has an associated wake-up interrupt. The wake-up interrupts are generated outside of the USB controller cores, but using the same vector as the corresponding USB controller cores interrupt.

These interrupts are generated by the Power Control blocks which run on the 32 KHz standby clock. The wake-up interrupt is designed to work even when the USB and Arm platform clocks are disabled, such that a wake-up condition on the USB bus can re-activate the Arm platform clocks.

Because the wake-up interrupt is generated and cleared on a 32 KHz clock, this interrupt request responds very slowly to clear actions. For this reason, the software must disable the wake-up interrupt to clear the request flag. Disabling the interrupt masks the request instantaneously as this is clocked by the Arm platform clock. The software should wait for at least three 32 KHz clock cycles before re-enabling this interrupt to allow sufficient time for the request flag to clear. Because this interrupt is only used during low power modes of the USB, it is sufficient to enable the wake-up interrupt just prior to entering the USB suspend mode.

62.3.5 Clocks

The following table describes the clock sources for USB. Please see the clock control chapter for clock setting, configuration and gating information.

Table 62-2. USB Clocks

Clock	Description
ipg_ahb_clk	AHB bus clock
ipg_clk_s	Peripheral access clock
ipg_clk_s_pl301	PL301 peripheral clock

62.4 External Signals

The table found here describes the external signals of USB. See the chip-specific information to know the external signals supported by your device.

Table 62-3. USB External Signals

Signal	Description
OTGn_DN	DN OTG Signal
OTGn_DP	DP OTG Signal
OTGn_ID	ID signal
OTGn_OC	OTG External input for VBUS overcurrent detection
OTGn_PWR	To control PMIC to supply VBUS voltage

62.5 USB Operation Model

This section describes the detailed application knowledge for OTG1 and OTG2 ports.

62.5.1 Register Interface

Configuration, control and status registers are divided into three categories, identification, capability and operational registers.

NOTE

USB controller registers support only DWORD (32-bit) access.

- Identification registers are used to declare the slave interface presence along with the complete set of the hardware configuration parameters.
- Static, read only capability registers define the software limits, restrictions, and capabilities of the host/device controller.
- Operational registers are dynamic control or status registers that may be read only, read/write, or read/write-to-clear. The following sections define the use of these registers.

EHCI registers are listed alongside device registers to show the complementary nature of host and device control.

The following table describes the Interface register sets.

Table 62-4. Interface Register Sets

Offset	Register Set	Explanation
000h-07Ch	Identification Registers	Identification registers are used to declare the slave interface presence and include a table of the hardware configuration parameters.
100h-124h	Capability Registers	Capability registers specify the limits, restrictions, and capabilities of a host/device controller implementation. These values are used as parameters to the host/device controller driver.
080h-0FCh 140h-1FCh	Operational Registers	Operational registers are used by the system software to control and monitor the operational state of the host/device controller.

62.5.1.1 Configuration, Control and Status Register Set

The following table describes the Device/Host capability registers.

NOTE

Depending on implementation, "*x*" can have the following values: UOG1, UOG2.

Table 62-5. Device/Host Capability Registers

Offset	Size (Bytes)	Mnemonic	Register Name	Device Mode	Host Mode
000h	4	USB_*x*_ID	Identification Register	O	O
004h	4	USB_*x*_HWGENERAL	General Hardware Parameters	O	O
008h	4	USB_*x*_HWHOST	Host Hardware Parameters	X	O

NOTE

"O" means the register is available in host/device operation mode;

"X" means the register is reserved in host/device operation mode

62.5.1.2 Identification Registers

Identification registers are used to declare the slave interface presence and include a table of the hardware configuration parameters.

62.5.1.3 OTG Operations

62.5.1.3.1 Register Bits

In the previous section, the Register interface has behaviors described for device mode and behaviors described for host mode. However, for OTG operations it is necessary to perform tasks independent of the controller mode.

NOTE

The only way to transit the controller mode out of host or device mode is with the controller reset bit. Therefore, it is also

necessary for the OTG tasks to be performed independent of a controller reset as well as independent of the controller mode.

The following figure shows the controller mode.

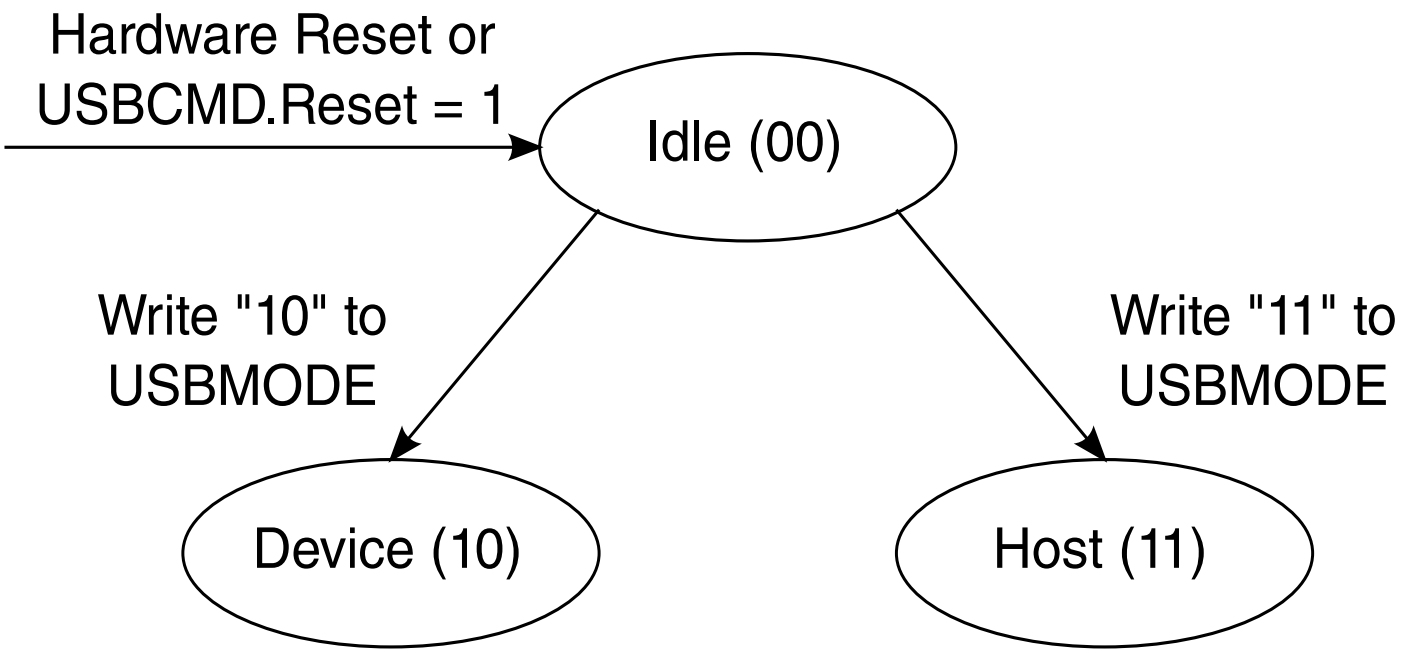

Figure 62-2. Controller Mode

To this end, listed below are the register bits that are used for OTG operations, which are independent of the controller mode and are also not affected by a write to the reset bit in the USBCMD register:

All Identification Registers

All Device/Host Capability Registers

OTGSC: All bits

PORTSC1:

- Physical Interface Select
- Physical Interface Serial Select
- Physical Interface Data Width
- Physical Interface Low Power
- Physical Interface Wake Signals
- Port Indicators
- Port Power

62.5.2 Host Data Structures

This section defines the interface data structures used to communicate control, status, and data between Host Controller Driver (HCD) (software) and the Enhanced Host Controller (hardware).

The data structure definitions in this chapter support a 32-bit memory buffer address space. The interface consists of a Periodic Schedule, Periodic Frame List, Asynchronous Schedule, Isochronous Transaction Descriptors, Split-transaction Isochronous Transfer Descriptors, Queue Heads, and Queue Element Transfer Descriptors.

The periodic frame list is the root of all periodic (isochronous and interrupt transfer type) transfers for the host controller. The asynchronous list is the root for all the bulk and control transfers. Isochronous data streams are managed using Isochronous Transaction Descriptors. Isochronous split-transaction data streams are managed with Split-transaction Isochronous Transfer Descriptors. All Interrupt, Control, and Bulk data streams are managed via queue heads and Queue Element Transfer Descriptors. These data structures are optimized to reduce the total memory footprint of the schedule and to reduce (on average) the number of memory accesses needed to execute a USB transaction.

Note that software must ensure that no interface data structure reachable by the EHCI host controller spans a 4 K-page boundary.

The data structures defined in this section are (from the host controller's perspective) a mix of read-only and read/writeable fields. The host controller must preserve the read-only fields on all data structure writes.

62.5.2.1 Periodic Frame List

This schedule is for all periodic transfers (isochronous and interrupt). The periodic schedule is referenced from the operational registers space using the USB_PERIODICLISTBASE address register and the USB_FRINDEX register.

The periodic schedule is based on an array of pointers called the Periodic Frame List.

The USB_PERIODICLISTBASE address register is combined with the USB_FRINDEX register to produce a memory pointer into the frame list. The Periodic Frame List implements a sliding (1 msec) window of work over time.

The following figure shows the organization of periodic schedule.

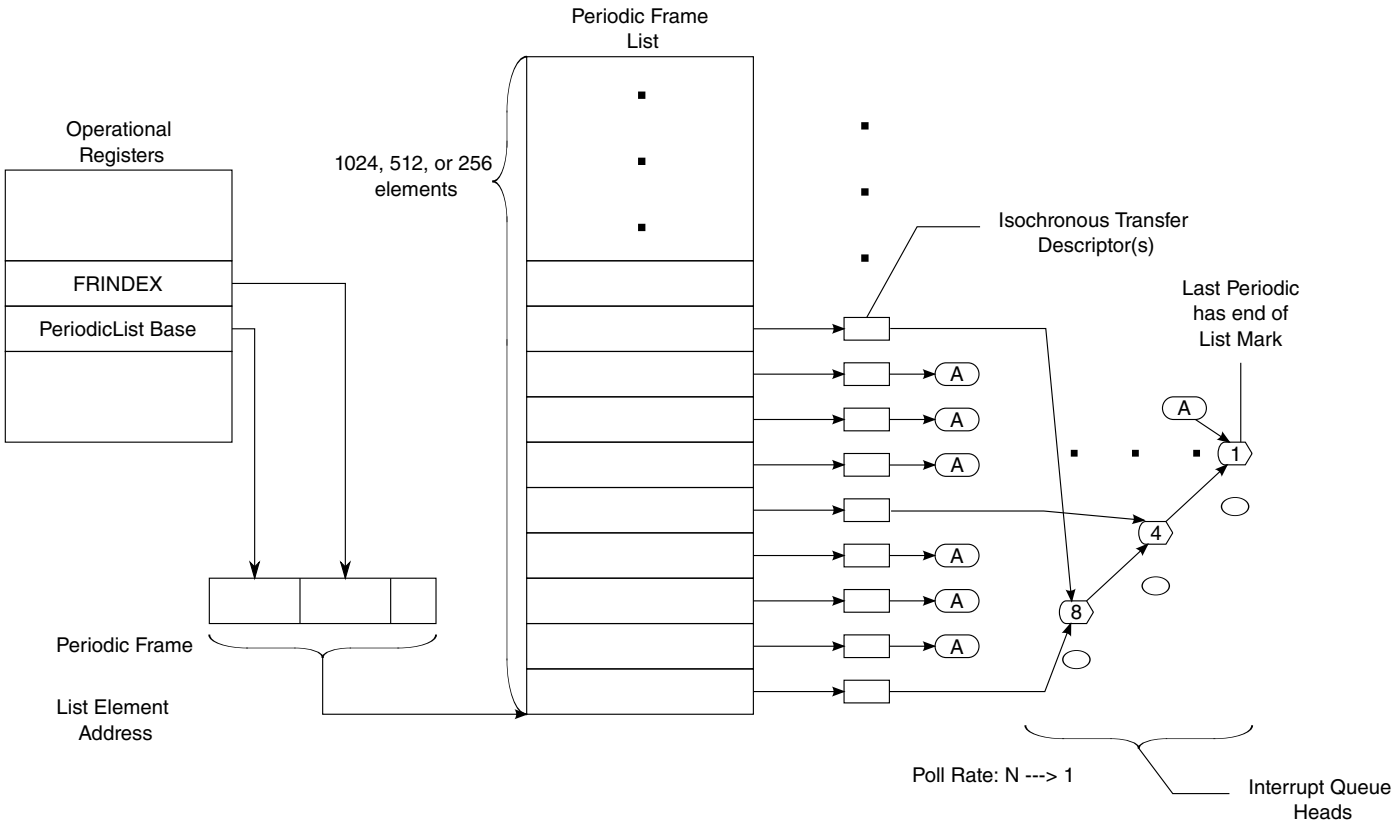

Figure 62-3. Periodic Schedule Organization

Split transaction Interrupt, Bulk and Control are also managed using queue heads and queue element transfer descriptors.

The periodic frame list is a 4 K-page aligned array of Frame List Link pointers. The length of the frame list may be programmable. The programmability of the periodic frame list is exported to system software via the USB_HCCPARAMS register. If non-programmable, the length is 1024 elements. If programmable, the length can be selected by system software as one of 8, 16, 32, 64, 128, 256, 512, or 1024 elements. An implementation must support all three sizes. Programming the size (that is, the number of elements) is accomplished by system software writing the appropriate value into Frame List Size field in the USB_USBCMD register.

Frame List Link pointers direct the host controller to the first work item in the frame's periodic schedule for the current micro-frame. The link pointers are aligned on DWord boundaries within the Frame List.

The table below illustrates the format of the Frame list element pointer.

Table 62-6. Format of Frame List Element Pointer

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	

Table continues on the next page...

Table 62-6. Format of Frame List Element Pointer (continued)

Frame List Link Pointer	0	Typ		03-00H

Frame List Link pointers always reference memory objects that are 32-byte aligned. The referenced object may be an isochronous transfer descriptor for high-speed devices, a split-transaction isochronous transfer descriptor (for full-speed isochronous endpoints), or a queue head (used to support high-, full- and low-speed interrupt). System software should not place non-periodic schedule items into the periodic schedule. The least significant bits in a frame list pointer are used to key the host controller as to the type of object the pointer is referencing.

The least significant bit is the T-Bit (bit 0). When this bit is set to a one, the host controller never uses the value of the frame list pointer as a physical memory pointer. The Typ field is used to indicate the exact type of data structure being referenced by this pointer. The value encodings are.

Table 62-7. Typ Field Value Definitions

Value	Meaning
00b	Isochronous Transfer Descriptor
01b	Queue Head
10b	Split Transaction Isochronous Transfer Descriptor.
11b	Frame Span Traversal Node.

62.5.2.2 Asynchronous List Queue Head Pointer

The Asynchronous Transfer List (based at the USB_ASYNCLISTADDR register) is where all of the control and bulk transfers are managed.

Host controllers use this list only when it reaches the end of the periodic list, the periodic list is disabled, or the periodic list is empty.

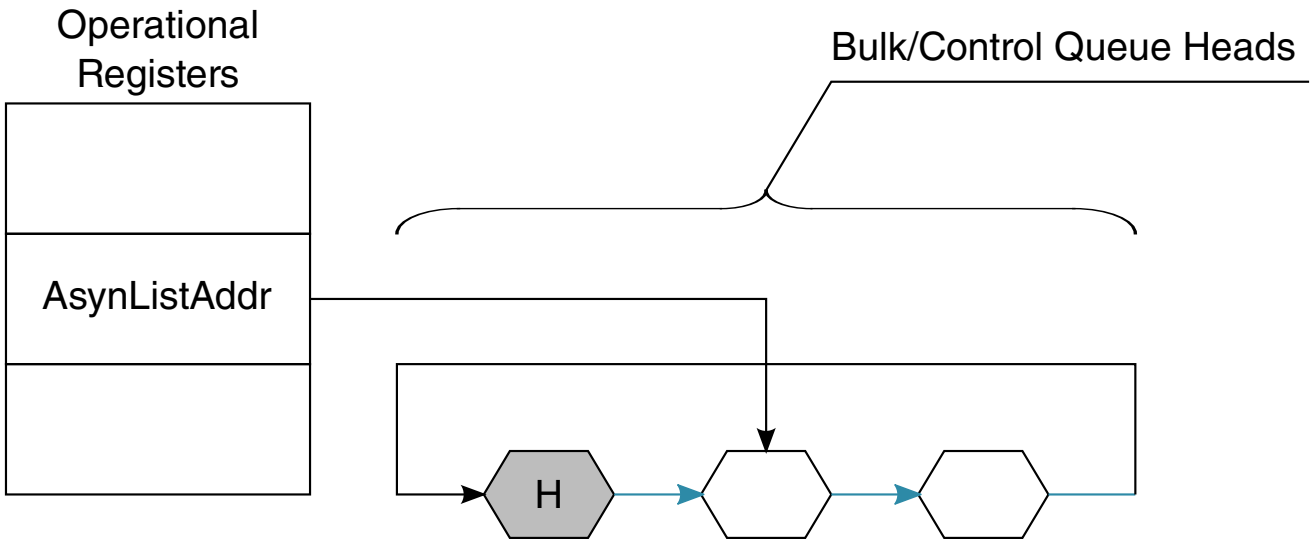

Figure 62-4. Asynchronous Schedule Organization

The Asynchronous list is a simple circular list of queue heads. The USB_ASYNCLISTADDR register is simply a pointer to the next queue head. This implements a pure round-robin service for all queue heads linked into the asynchronous list.

62.5.2.3 Isochronous (High-Speed) Transfer Descriptor (iTD)

The format of an isochronous transfer descriptor is shown in the table below.

This structure is used only for high-speed isochronous endpoints. All other transfer types should use queue structures. Isochronous TDs must be aligned on a 32-byte boundary.

Table 62-8. Isochronous Transaction Descriptor (iTD)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Next Link Pointer																											0		Typ		T	03-00 H
Status				Transaction 0 Length												IOC	PG*			Transaction 0 Offset*													07-04 H
Status				Transaction 1 Length												IOC	PG*			Transaction 1 Offset*													0B-08H
Status				Transaction 2 Length												IOC	PG*			Transaction 2 Offset*													0F-0CH
Status				Transaction 3 Length												IOC	PG*			Transaction 3 Offset*													13-10 H

Table continues on the next page...

Table 62-8. Isochronous Transaction Descriptor (iTD) (continued)

| | | |

Table 62-9. Next Schedule Element Pointer (continued)

Reserved	
2-1 QH/(s)iTD Select (Typ)	This field indicates to the Host Controller whether the item referenced is an iTD, siTD or a QH. This allows the Host Controller to perform the proper type of processing on the item after it is fetched. Value encodings are: Value Meaning 00b iTD (isochronous transfer descriptor) 01b QH (queue head) 10b siTD (split transaction isochronous transfer descriptor 11b FSTN (frame span traversal node)
0 Terminate (T)	1= Link Pointer field is not valid. 0= Link Pointer field is valid.

62.5.2.3.2 iTD Transaction Status and Control List

DWords 1 through 8 are eight slots of transaction control and status.

Each transaction description includes:

- Status results field
- Transaction length (bytes to send for OUT transactions and bytes received for IN transactions).
- Buffer offset. The PG and Transaction X Offset fields are used with the buffer pointer list to construct the starting buffer address for the transaction.

The host controller uses the information in each transaction description plus the endpoint information contained in the first three DWords of the Buffer Page Pointer list, to execute a transaction on the USB.

The following table describes iTD Transaction Status and Control fields.

Table 62-10. iTD Transaction Status and Control

Bit	Description	
31-28 Status	This field records the status of the transaction executed by the host controller for this slot. This field is a bit vector with the following encoding:	
	Bit	Definition
	31	Active. Set to one by software to enable the execution of an isochronous transaction by the Host Controller. When the transaction associated with this descriptor is completed, the Host Controller sets this bit to zero indicating that a transaction for this element should not be executed when it is next encountered in the schedule.
	30	Data Buffer Error. Set to a one by the Host Controller during status update to indicate that the Host Controller is unable to keep up with the reception of incoming data (overrun) or is unable to supply data fast enough during transmission (under run). If an overrun condition occurs, no action is necessary.
	29	Babble Detected. Set to one by the Host Controller during status update when" babble" is detected during the transaction generated by this descriptor.

Table continues on the next page...

Table 62-10. iTD Transaction Status and Control (continued)

Bit	Description	
	28	Transaction Error (XactErr). Set to one by the Host Controller during status update in the case where the host did not receive a valid response from the device (Timeout, CRC, Bad PID, etc.). This bit may only be set for isochronous IN transactions.
27-16 Transaction X Length	For an OUT, this field is the number of data bytes the host controller sends during the transaction. The host controller is not required to update this field to reflect the actual number of bytes transferred during the transfer. For an IN, the initial value of the endpoint to deliver. During the status update, the host controller writes back the field is the number of bytes the host expects the number of bytes successfully received. The value in this register is the actual byte count (0‡zero length data, 1‡one byte, 2‡two bytes, etc.). The maximum value this field may contain is 0xC00 (3072).	
15 Interrupt On Complete (IOC)	If this bit is set to one, it specifies that when this transaction completes, the Host Controller should issue an interrupt at the next interrupt threshold.	
14-12 Page Select (PG)	These bits are set by software to indicate which of the buffer page pointers the offset field in this slot should be concatenated to produce the starting memory address for this transaction. The valid range of values for this field is 0 to 6.	
11-0 Transaction X Offset	This field is a value that is an offset, expressed in bytes, from the beginning of a buffer. This field is concatenated onto the buffer page pointer indicated in the adjacent *PG* field to produce the starting buffer address for this transaction.	

62.5.2.3.3 iTD Buffer Page Pointer List (Plus)

DWords 9-15 of an isochronous transaction descriptor are nominally page pointers (4 K aligned) to the data buffer for this transfer descriptor. This data structure requires the associated data buffer to be contiguous (relative to virtual memory), but allows the physical memory pages to be non-contiguous.

Seven page pointers are provided to support the expression of eight isochronous transfers. The seven pointers allow for 3 (transactions) * 1024 (maximum packet size) * 8 (transaction records) (24576 bytes) to be moved with this data structure, regardless of the alignment offset of the first page.

Because each pointer is a 4 K aligned page pointer, the least significant 12 bits in several of the page pointers are used for other purposes.

The tables below illustrate the field descriptions.

Table 62-11. iTD Buffer Pointer Page 0 (Plus)

Bit	Description
31-12 Buffer Pointer (Page 0)	This is a 4 K aligned pointer to physical memory. Corresponds to memory address bits [31:12].
11-8 Endpoint Number (Endpt)	This 4-bit field selects the particular endpoint number on the device serving as the data source or sink.

Table continues on the next page...

Table 62-11. iTD Buffer Pointer Page 0 (Plus) (continued)

Bit	Description
7 Reserved	Bit reserved for future use and should be initialized by software to zero.
6-0 Device Address	This field selects the specific device serving as the data source or sink.

Table 62-12. iTD Buffer Pointer Page 1 (Plus)

Bit	Description
31-12 Buffer Pointer (Page 1)	This is a 4K aligned pointer to physical memory. Corresponds to memory address bits [31:12].
11 Direction (I/O)	0 = OUT; 1 = IN. This field encodes whether the high-speed transaction should use an IN or OUT PID.
10-0 Maximum Packet Size	This directly corresponds to the maximum packet size of the associated endpoint *(wMaxPacketSize)*. This field is used for high-bandwidth endpoints where more than one transaction is issued per transaction description (per micro-frame). This field is used with the *Multi* field to support high-bandwidth pipes. This field is also used for all IN transfers to detect packet babble. Software should not set a value larger than 1024 (400h). Any value larger yields undefined results.

Table 62-13. iTD Buffer Pointer Page 2 (Plus)

Bit	Description
31-12 Buffer Pointer	This is a 4K aligned pointer to physical memory. Corresponds to memory address bits [31:12].
11-2 Reserved	This bit reserved for future use and should be set to zero.
1-0 Multi	This field is used to indicate to the host controller the number of transactions that should be executed per transaction description (per micro-frame). The valid values are: Value Meaning 00b Reserved. A zero in this field yields undefined results. 01b One transaction to be issued for this endpoint per micro- frame. 10b Two transactions to be issued for this endpoint per micro- frame. 11b Three transactions to be issued for this endpoint per micro- frame.

Table 62-14. iTD Buffer Pointer Page 3-6

Bit	Description
31-12 Buffer Pointer	This is a 4 K aligned pointer to physical memory. Corresponds to memory address bits [31:12].
11-0 Reserved	These bits reserved for future use and should be set to zero.

62.5.2.4 Split Transaction Isochronous Transfer Descriptor (siTD)

All Full-speed isochronous transfers through the internal transaction translator are managed using the siTD data structure. This data structure satisfies the operational requirements for managing the split transaction protocol.

The following table shows the Split Transaction Isochronous Transfer Descriptor (siTD).

Table 62-15. Split Transaction Isochronous Transfer Descriptor

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Addr

Host Controller Read/Write

Host Controller Read Only

62.5.2.4.1 Next Link Pointer

DWord0 of a siTD is a pointer to the next schedule data structure.

The following table describes the Next Link Pointer fields.

Table 62-16. Next Link Pointer

Bit	Description
31-5	Next Link Pointer (LP). This field contains the address of the next data object to be processed in the periodic list and corresponds to memory address signals [31:5], respectively.

Table continues on the next page...

Table 62-16. Next Link Pointer (continued)

Bit	Description
4-3	Reserved. These bits must be written as zeros.
2-1	QH/(s)iTD Select (Typ). This field indicates to the Host Controller whether the item referenced is an iTD/siTD or a QH. This allows the Host Controller to perform the proper type of processing on the item after it is fetched. Value encodings are: Value Meaning 00b iTD (isochronous transfer descriptor) 01b QH (queue head) 10b siTD (split transaction isochronous transfer descriptor 11b FSTN (frame span traversal node)
0	Terminate (T). 1 = Link Pointer field is not valid. 0 = Link Pointer is valid.

62.5.2.4.2 siTD Endpoint Capabilities/Characteristics

DWords 1 and 2 specify static information about the full-speed endpoint, the addressing of the parent Companion Controller, and micro-frame scheduling control.

The tables below describe the Endpoint and transaction translator characteristics and micro-frame schedule control fields.

Table 62-17. Endpoint and Transaction Translator Characteristics

Bit	Description
31	Direction (I/O).0 = OUT; 1 = IN. This field encodes whether the full-speed transaction should be an IN or OUT.
30-24	Port Number. This field is the port number of the recipient Transaction Translator.
23	Reserved. Bit reserved and should be set to zero.
22-16	Hub Address. This field holds the device address of the Companion Controllers' hub.
15-12	Reserved. Field reserved and should be set to zero.
11-8	Endpoint Number (Endpt). This 4-bit field selects the particular endpoint number on the device serving as the data source or sink.
7	Reserved. Bit is reserved for future use. It should be set to zero.
6-0	Device Address. This field selects the specific device serving as the data source or sink.

Table 62-18. Micro-frame Schedule Control

Bit	Description
31-16	Reserved. This field reserved for future use. It should be set to zero.
15-8	Split Completion Mask (mFrame C-Mask). This field (along with the *Active* and *SplitX- state* fields in the *Status* byte) is used to determine during which micro-frames the host controller should execute complete-split transactions. When the criteria for using this field is met, an all zeros value has undefined behavior. The host

Table continues on the next page...

Table 62-18. Micro-frame Schedule Control (continued)

Bit	Description
	controller uses the value of the three low-order bits of the FRINDEX register to index into this bit field. If the FRINDEX register value indexes to a position where the m*Frame C-Mask* field is a one, then this siTD is a candidate for transaction execution. There may be more than one bit in this mask set.
7-0	Split Start Mask (mFrame S-mask). This field (along with the *Active* and *SplitX-state* fields in the *Status* byte) is used to determine during which micro-frames the host controller should execute start-split transactions. The host controller uses the value of the three low-order bits of the FRINDEX register to index into this bit field. If the FRINDEX register value indexes to a position where the m*Frame S-mask* field is a one, then this siTD is a candidate for transaction execution. An all zeros value in this field, in combination with existing periodic frame list has undefined results.

62.5.2.4.3 siTD Transfer State

DWords 3-6 are used to manage the state of the transfer.

The following table describes siTD transfer state fields.

Table 62-19. siTD Transfer Status and Control

Bit	Description
31	Interrupt On Complete (ioc). 0 = Do not interrupt when transaction is complete. 1 = Do interrupt when transaction is complete. When the host controller determines that the split transaction has completed it asserts a hardware interrupt at the next interrupt threshold.
30	Page Select (P). Used to indicate which data page pointer should be concatenated with the *CurrentOffset* field to construct a data buffer pointer (0 selects *Page 0* pointer and 1 selects *Page 1*). The host controller is not required to write this field back when the siTD is retired (*Active* bit transitioned from a one to a zero).
29-26	Reserved. This field reserved for future use and should be set to zero.
25-16	Total Bytes To Transfer. This field is initialized by software to the total number of bytes expected in this transfer. Maximum value is 1023 (3FFh)
15-8	µFrame Complete-split Progress Mask (C-prog-Mask). This field is used by the host controller to record which split-completes has been executed.
7-0: Status—This field records the status of the transaction executed by the host controller for this slot. It is a bit vector with the encoding shown in the following rows.	
7	Active. Set to one by software to enable the execution of an isochronous split transaction by the Host Controller.
6	ERR. Set to a one by the Host Controller when an ERR response is received from the Companion Controller.
5	Data Buffer Error. Set to a one by the Host Controller during status update to indicate that the Host Controller is unable to keep up with the reception of incoming data (overrun) or is unable to supply data fast enough during transmission (under run). In the case of an under run, the Host Controller transmits an incorrect CRC (thus invalidating the data at the endpoint). If an overrun condition occurs, no action is necessary.
4	Babble Detected. Set to a one by the Host Controller during status update when" babble" is detected during the transaction generated by this descriptor.
3	Transaction Error (XactErr). Set to a one by the Host Controller during status update in the case where the host did not receive a valid response from the device (Timeout, CRC, Bad PID, etc.). This bit is set only for IN transactions.
2	Missed Micro-Frame. The host controller detected that a host-induced hold- off caused the host controller to miss a required complete-split transaction.
1	Split Transaction State (SplitXstate). The bit encodings are:

Table continues on the next page...

Table 62-19. siTD Transfer Status and Control (continued)

Bit	Description
	Value Meaning 00b Do Start Split. This value directs the host controller to issue a Start split transaction to the endpoint when a match is encountered in the S-mask. 01b Do Complete Split. This value directs the host controller to issue a Complete split transaction to the endpoint when a match is encountered in the C-mask.
0	Reserved. Bit reserved for future use and should be set to zero.

62.5.2.4.4 siTD Buffer Pointer List (plus)

DWords 4 and 5 are the data buffer page pointers for the transfer. This structure supports one physical page cross. The most significant 20 bits of each DWord in this section are the 4 K (page) aligned buffer pointers.

The least significant 12 bits of each DWord are used as additional transfer state. The following table describes the siTD buffer pointer fields.

Table 62-20. Buffer Page Pointer List (plus)

Bit	Description
31-12	Buffer Pointer List. Bits [31:12] of DWords 4 and 5 are 4 K page aligned physical memory addresses. These bits correspond to physical address bits [31:12] respectively. The lower 12 bits in each pointer are defined and used as specified below. The field *P* (see siTD Transfer State) specifies the *current* active pointer.
Bits 11-0 (Page 0)	Current Offset—The 12 least significant bits of the Page 0 pointer are the current byte offset for the current page pointer (as selected with the page indicator bit (*P* field). The host controller is not required to write this field back when the siTD is retired (*Active* bit transitioned from a one to a zero).
Bits 11-0 (Page 1)—The least significant bits of the Page 1 pointer are split into three subfields as shown in the following rows.	
11-5 (Page 1)	Reserved
4-3 (Page 1)	Transaction position (TP). This field is used with T-count to determine whether to send *all*, *first*, *middle*, or *last* with each outbound transaction payload. System software must initialize this field with the appropriate starting value. The host controller must correctly manage this state during the lifetime of the transfer. The bit encodings are: Value Meaning 00b All. The entire full-speed transaction data payload is in this transaction (that is, less than or equal to 188 bytes). 01b Begin. This is the first data payload for a full- speed that is greater than 188 bytes. 10B Mid. This is the *middle* payload for a full-speed OUT transaction that is larger than 188 bytes. 11b End. This is the *last* payload for a full-speed OUT transaction that was larger than 188 bytes.
2-0 (Page 1)	Transaction count (T-Count). Software initializes this field with the number of OUT start-splits this transfer requires. Any value larger than 6 is undefined.

62.5.2.4.5 siTD Back Link Pointer

DWord 6 of a siTD is simply another schedule link pointer. This pointer is always zero, or references a siTD, and it cannot reference any other schedule data structure.

The following table describes the siTD back link pointer fields.

Table 62-21. siTD Back Link Pointer

Bit	Description
31-5	siTD Back Pointer. This field is a physical memory pointer to a siTD.
4-1	Reserved. This field is reserved for future use. It should be set to zero.
0	Terminate (T). 1 = siTD Back Pointer field is not valid. 0 = siTD Back Pointer field is valid.

62.5.2.5 Queue element transfer descriptor (qTD)

This data structure is only used with a queue head. It describes one or more USB transactions to transfer up to 20480 (5*4096) bytes.

The structure contains two structure pointers used for queue advancement, a DWord of transfer state, and a five-element array of data buffer pointers.

It is 32 bytes and must be physically contiguous.

The buffer associated with this transfer must be virtually contiguous. The buffer may start on any byte boundary; however, for optimal utilization of on-chip busses it is recommended to align the buffers on a 32-byte boundary. A separate buffer pointer list element must be used for each physical page in the buffer, regardless of whether the buffer is physically contiguous.

Host controller updates (host controller writes) to stand-alone qTDs only occur during transfer retirement. References in the following bit field definitions of updates to the qTD are to the qTD portion of a queue head.

The following table shows the queue element transfer descriptor data structure.

Table 62-22. Queue element transfer descriptor data structure

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Addr

1. 08-0F: Transfer Results

Host Controller Read/Write

Host Controller Read Only

Queue Element Transfer Descriptors must be aligned on 32-byte boundaries.

62.5.2.5.1 Next qTD Pointer

The first DWord of an element transfer descriptor is a pointer to another transfer element descriptor.

The following table describes Next qTD pointer fields.

Table 62-23. qTD Next Element Transfer Pointer (DWord 0)

Bit	Description
31-5	Next Transfer Element Pointer. This field contains the physical memory address of the next qTD to be processed. The field corresponds to memory address signals[31:5], respectively.
4-1	Reserved
0	Terminate (T). 1= pointer is invalid. 0=Pointer is valid (points to a valid Transfer Element Descriptor). This bit indicates to the Host Controller that there are no more valid entries in the queue.

62.5.2.5.2 Alternate Next qTD Pointer

The second DWord of a queue element transfer descriptor is used to support hardware-only advance of the data stream to the next transfer descriptor on short packet. To be more explicit the host controller always uses this pointer when the current qTD is retired due to short packet.

The following table describes the TD Alternate Next Element Transfer Pointer field descriptions.

Table 62-24. TD Alternate Next Element Transfer Pointer (DWord 1)

Bit	Description
31-5	Alternate Next Transfer Element Pointer. This field contains the physical memory address of the next qTD to be processed in the event that the current qTD execution encounters a short packet (for an IN transaction). The field corresponds to memory address signals [31:5], respectively.
4-1	Reserved
0	Terminate (T). 1= pointer is invalid. 0=Pointer is valid (points to a valid Transfer Element Descriptor). This bit indicates to the Host Controller that there are no more valid entries in the queue.

62.5.2.5.3 qTD Token

The third DWord of a queue element transfer descriptor contains most of the information the host controller requires to execute a USB transaction (the remaining endpoint-addressing information is specified in the queue head).

NOTE

The field descriptions forward reference fields defined in the queue head. Where necessary, these forward references are preceded with a QH notation.

The following table describes the TD Token fields.

Table 62-25. TD Token (DWord 2)

Bit	Description
31 Data Toggle	This is the data toggle sequence bit. The use of this bit depends on the setting of the *Data Toggle Control* bit in the queue head.
30-16 Total Bytes to Transfer	This field specifies the total number of bytes to be moved with this transfer descriptor. This field is decremented by the number of bytes actually moved during the transaction, only on the successful completion of the transaction. The maximum value software may store in this field is 5 * 4K (5000H). This is the maximum number of bytes 5 page pointers can access. If the value of this field is zero when the host controller fetches this transfer descriptor (and the active bit is set), the host controller executes a zero-length transaction and retires the transfer descriptor. It is not a requirement for OUT transfers that *Total Bytes To Transfer* be an even multiple of QHD.Maximum Packet Length. If software builds such a transfer descriptor for an OUT transfer, the last transaction is always less than QHD.Maximum Packet Length.

Table continues on the next page...

Table 62-25. TD Token (DWord 2) (continued)

<table>
<tr><th>Bit</th><th colspan="2">Description</th></tr>
<tr><td></td><td colspan="2">Although it is possible to create a transfer up to 20K this assumes the 1st offset into the first page is 0. When the offset cannot be predetermined, crossing past the 5th page can be guaranteed by limiting the total bytes to 16K**. Therefore, the maximum recommended transfer is 16 K(4000H).</td></tr>
<tr><td>15
Interrupt On Complete (IOC)</td><td colspan="2">If this bit is set to a one, it specifies that when this qTD is completed, the Host Controller should issue an interrupt at the next interrupt threshold.</td></tr>
<tr><td>14-12
Current Page (C_Page)</td><td colspan="2">This field is used as an index into the qTD buffer pointer list. Valid values are in the range 0H to 4H. The host controller is not required to write this field back when the qTD is retired.</td></tr>
<tr><td>11-10
Error Counter (CERR)</td><td colspan="2">This field is a 2-bit down counter that keeps track of the number of consecutive Errors detected while executing this qTD. If this field is programmed with a non-zero value during set-up, the Host Controller decrements the count and writes it back to the qTD if the transaction fails. If the counter counts from one to zero, the Host Controller marks the qTD inactive, sets the Halted bit to a one, and error status bit for the error that caused CERR to decrement to zero. An interrupt is generated if the USB Error Interrupt Enable bit in the USBINTR register is set to a one. If HCD programs this field to zero during set-up, the Host Controller does not count errors for this qTD and there is no limit on the retries of this qTD. Note that write-backs of intermediate execution state are to the queue head overlay area, not the qTD.
Transaction Error - Decrement
Data Buffer Error - No Decrement[3]
Stalled - No Decrement[1]
Babble Detected - No Decrement[1]
No Error - No Decrement[2]
<table>
<tr><td>Error</td><td>Decrement Counter</td></tr>
<tr><td>1</td><td>Detection of Babble or Stall automatically halts the queue head. Thus, count is not decremented</td></tr>
<tr><td>2</td><td>If the EPS field indicates a HS device or the queue head is in the Asynchronous Schedule (and PIDCode indicates an IN or OUT) and a bus transaction completes and the host controller does not detect a transaction error, then the host controller should reset CERR to extend the total number of errors for this transaction. For example, CERR should be reset with maximum value (3) on each successful completion of a transaction. The host controller must never reset this field if the value at the start of the transaction is 00b.
See Split Transaction Interrupt for CERR adjustment rules when the EPS field indicates a FS or LS device and the queue head is in the Periodic Schedule. See Asynchronous - Do Complete Split for CERR adjustment rules when the EPS field indicates a FS or LS device, the queue head is in the Asynchronous schedule and the PIDCode indicates a SETUP.</td></tr>
<tr><td>3</td><td>Data buffer errors are host problems. They don't count against the device's retries.</td></tr>
<tr><td colspan="2">NOTE: Software must not program CERR to a value of zero when the EPS field is programmed with a value indicating a Full- or Low-speed device. This combination could result in undefined behavior.</td></tr>
</table></td></tr>
<tr><td>9-8
PID Code</td><td colspan="2">This field is an encoding of the token, which should be used for transactions associated with this transfer descriptor. Encodings are:
<table>
<tr><td>00b</td><td>OUT Token generates token (E1H)</td></tr>
<tr><td>01b</td><td>IN Token generates token (69H)</td></tr>
</table></td></tr>
</table>

Table continues on the next page...

Table 62-25. TD Token (DWord 2) (continued)

Bit	Description	
	10b	SETUP Token generates token (2DH) (undefined if endpoint is an interrupt, the queue head is non-zero) transfer type, for example, µ*Frame S-mask* field in.
	11b	Reserved
7-0 Status	This field is used by the Host Controller to communicate individual command execution states back to HCD. This field contains the status of the last transaction performed on this qTD. The bit encodings are:	
	Bit	Status Field Description
	7	Active. Set to one by software to enable the execution of transactions by the Host Controller.
	6	Halted. Set to one by the Host Controller during status updates to indicate that a serious error has occurred at the device/endpoint addressed by this qTD. This can be caused by babble, the error counter counting down to zero, or reception of the STALL handshake from the device during a transaction. Any time that a transaction results in the Halted bit being set to a one, the Active bit is also set to zero.
	5	Data Buffer Error. Set to a one by the Host Controller during status update to indicate that the Host Controller is unable to keep up with the reception of incoming data (overrun) or is unable to supply data fast enough during transmission (under run). If an overrun condition occurs, the Host Controller forces a timeout condition on the USB, invalidating the transaction at the source. If the host controller sets this bit to a one, then it remains a one for the duration of the transfer.
	4	Babble Detected. Set to a one by the Host Controller during status update when" babble" is detected during the transaction. In addition to setting this bit, the Host Controller also sets the *Halted* bit to a one. Because "babble" is considered a fatal error for the transfer, setting the Halted bit to a one insures that no more transactions occur because of this descriptor.
	3	Transaction Error (XactErr). Set to a one by the Host Controller during status update in the case where the host did not receive a valid response from the device (Timeout, CRC, Bad PID, etc.). If the host controller sets this bit to a one, then it remains a one for the duration of the transfer.
	2	Missed Micro-Frame. This bit is ignored unless the *QH.EPS* field indicates a full- or low-speed endpoint and the queue head is in the periodic list. This bit is set when the host controller detected that a host-induced hold-off caused the host controller to miss a required complete-split transaction. If the host controller sets this bit to a one, then it remains a one for the duration of the transfer.
	1	Split Transaction State (SplitXstate). This bit is ignored by the host controller unless the *QH.EPS* field indicates a full- or low-speed endpoint. When a Full- or Low-speed device, the host controller uses this bit to track the state of the split-transaction. The functional requirements of the host controller for managing this state bit and the split transaction protocol depends on whether the endpoint is in the periodic or asynchronous schedule. The bit encodings are: Value Meaning 0b Do Start Split. This value directs the host controller to issue a Start split transaction to the endpoint. 1b Do Complete Split. This value directs the host controller to issue a Complete split transaction to the endpoint.

Table continues on the next page...

Table 62-25. TD Token (DWord 2) (continued)

Bit	Description	
	0	Ping State (P)/ERR. If the *QH.EPS* field indicates a High-speed device and the *PID_Code* indicates an OUT endpoint, then this is the state bit for the Ping protocol. The bit encodings are: Value Meaning 0b Do OUT. This value directs the host controller to issue an OUT PID to the endpoint. 1b Do Ping. This value directs the host controller to issue a PING PID to the endpoint. If the *QH.EPS* field does not indicate a High-speed device, then this field is used as an error indicator bit. It is set to a one by the host controller whenever a periodic split-transaction receives an ERR handshake.

62.5.2.5.4 qTD Buffer Page Pointer List

The last five DWords of a queue element transfer descriptor is an array of physical memory address pointers. These pointers reference the individual pages of a data buffer.

System software initializes Current Offset field to the starting offset into the current page, where current page is selected through the value in the C_Page field.

The following table describes the qTD Buffer Pointer(s) (DWords 3-7) fields.

Table 62-26. qTD Buffer Pointer(s) (DWords 3-7)

Bit	Description
31-12	Buffer Pointer List. Each element in the list is a 4 K page aligned physical memory address. The lower 12 bits in each pointer are reserved (except for the first one), as each memory pointer must reference the start of a 4 K page. The field C_Page specifies the current active pointer. When the transfer element descriptor is fetched, the starting buffer address is selected using C_Page (similar to an array index to select an array element). If a transaction spans a 4K buffer boundary, the host controller must detect the page-span boundary in the data stream, increment C_Page and advance to the next buffer pointer in the list, and conclude the transaction through the new buffer pointer.
11-0	Current Offset (Reserved). This field is reserved in all pointers except the first one (for example Page 0). The host controller should ignore all reserved bits. For the page 0 current offset interpretation, this field is the byte offset into the current page (as selected by C_Page). The host controller is not required to write this field back when the qTD is retired. Software should ensure the Reserved fields are initialized to zero.

62.5.2.6 Queue Head

The table located in this section shows the Queue Head structure layout.

The following table shows the queue head structure layout.

Table 62-27. Queue Head Structure Layout

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Addr

Buffer Pointer (Page 4)																				Reserved												2F-2C[3]

1. 04-0B: Static endpoint state.
2. These fields are used exclusively to support split transactions to USB 2.0 hubs
3. 10-2F: Transfer overlay.
4. 14-27: Transfer results.

Host Controller Read/Write

Host Controller Read Only

62.5.2.6.1 Queue Head Horizontal Link Pointer

The first DWord of a Queue Head contains a link pointer to the next data object to be processed after any required processing in this queue has been completed, as well as the control bits defined below.

This pointer may reference a queue head or one of the isochronous transfer descriptors. It must not reference a queue element transfer descriptor.

The following table describes the Queue head DWord 0 fields.

Table 62-28. Queue Head DWord 0

Bit	Description
31-5	Queue Head Horizontal Link Pointer (QHLP). This field contains the address of the next data object to be processed in the horizontal list and corresponds to memory address signals [31:5], respectively.
4-3	Reserved
2-1	QH/(s)iTD Select (Typ). This field indicates to the hardware whether the item referenced by the link pointer is an iTD, siTD or a QH. This allows the Host Controller to perform the proper type of processing on the item after it is fetched. Value encodings are: Value Meaning 00b iTD (isochronous transfer descriptor) 01b QH (queue head) 10b siTD (split transaction isochronous transfer descriptor) 11b FSTN (frame span traversal node)
0	Terminate (T). 1=Last QH (pointer is invalid). 0=Pointer is valid. If the queue head is in the context of the periodic list, a one bit in this field indicates to the host controller that this is the end of the periodic list. This bit is ignored by the host controller when the queue head is in the Asynchronous schedule. Software must ensure that queue heads reachable by the host controller always have valid horizontal link pointers.

62.5.2.6.2 Queue Head Endpoint Capabilities/Characteristics

The second and third DWords of a Queue Head specifies static information about the endpoint. This information does not change over the lifetime of the endpoint.

There are three types of information in this region:

- Endpoint Characteristics. These are the USB endpoint characteristics including addressing, maximum packet size, and endpoint speed.
- Endpoint Capabilities. These are adjustable parameters of the endpoint. They effect how the endpoint data stream is managed by the host controller.
- Split Transaction Characteristics. This data structure is used to manage full- and low-speed data streams for bulk, control, and interrupt via split transactions to USB2.0 Hub Transaction Translator. There are additional fields used for addressing the hub and scheduling the protocol transactions (for periodic).

The host controller must not modify the bits in this region.

The following table describes the Endpoint characteristics: Queue head DWord 1 fields.

Table 62-29. Endpoint Characteristics: Queue Head DWord 1

Bit	Description
31-28	Nak Count Reload (RL). This field contains a value, which is used by the host controller to reload the Nak Counter field.

Table continues on the next page...

Table 62-29. Endpoint Characteristics: Queue Head DWord 1 (continued)

27	Control Endpoint Flag (C). If the *QH.EPS* field indicates the endpoint is not a high-speed device, and the endpoint is a control endpoint, then software must set this bit to a one. Otherwise, it should always set this bit to zero.	
26-16	Maximum Packet Length. This directly corresponds to the maximum packet size of the associated endpoint (*wMaxPacketSize*). The maximum value this field may contain is 0x400 (1024).	
15	Head of Reclamation List Flag (H). This bit is set by System Software to mark a queue head as being the head of the reclamation list.	
14	Data Toggle Control (DTC). This bit specifies where the host controller should get the initial data toggle on an overlay transition. 0b Ignore DT bit from incoming qTD. Host controller preserves DT bit in the queue head. 1b Initial data toggle comes from incoming qTD DT bit. Host controller replaces DT bit in the queue head from the DT bit in the qTD.	
13-12	Endpoint Speed (EPS). This is the speed of the associated endpoint. Bit combinations are:	
	Value	Meaning
	00b	Full-Speed (12 Mbits/sec)
	01b	Low-Speed (1.5 Mbits/sec)
	10b	High-Speed (480 Mbits/sec)
	11b	Reserved
	This field must not be modified by the host controller.	
11-8	Endpoint Number (Endpt). This 4-bit field selects the particular endpoint number on the device serving as the data source or sink.	
7	Inactivate on Next Transaction (I). This bit is used by system software to request that the host controller set the Active bit to zero. See Rebalancing the periodic schedule , for full operational details. This field is only valid when the queue head is in the Periodic Schedule and the *EPS* field indicates a Full or Low-speed endpoint. Setting this bit to one when the queue head is in the Asynchronous Schedule or the *EPS* field indicates a high-speed device yields undefined results.	
6-0	Device Address. This field selects the specific device serving as the data source or sink.	

The table below describes the Endpoint capabilities: Queue head DWord 2 field descriptions.

Table 62-30. Endpoint Capabilities: Queue Head DWord 2

Bit	Description
31-30	High-Bandwidth Pipe Multiplier (Mult). This field is a multiplier used to key the host controller as the number of successive packets the host controller may submit to the endpoint in the current execution. The host controller makes the simplifying assumption that software properly initializes this field (regardless of location of queue head in the schedules or other run time parameters). The valid values are: Value Meaning 00b Reserved. A zero in this field yields undefined results. 01b One transaction to be issued for this endpoint per micro-frame. 10b Two transactions to be issued for this endpoint per micro-frame. 11b Three transactions to be issued for this endpoint per micro-frame.

Table continues on the next page...

Table 62-30. Endpoint Capabilities: Queue Head DWord 2 (continued)

29-23	Port Number. This field is ignored by the host controller unless the *EPS* field indicates a full- or low-speed device. The value is the port number identifier on the USB 2.0 Hub (for hub at device address *Hub Addr* below), below which the full- or low-speed device associated with this endpoint is attached. This information is used in the split-transaction protocol.
22-16	Hub Addr. This field is ignored by the host controller unless the *EPS* field indicates a full-or low-speed device. The value is the USB device address of the USB 2.0 Hub below which the full- or low-speed device associated with this endpoint is attached. This field is used in the split-transaction protocol.
15-8	Split Completion Mask (µFrame C-Mask). This field is ignored by the host controller unless the *EPS* field indicates this device is a low- or full-speed device and this queue head is in the periodic list. This field (along with the *Active* and *SplitX-state* fields) is used to determine during which micro-frames the host controller should execute a complete-split transaction. When the criteria for using this field are met, a zero value in this field has undefined behavior. This field is used by the host controller to match against the three low-order bits of the FRINDEX register. If the FRINDEX register bits decode to a position where the µ*Frame C- Mask* field is a one, then this queue head is a candidate for transaction execution. There may be more than one bit in this mask set.
7-0	Interrupt Schedule Mask (µFrame S-mask). This field is used for all endpoint speeds. Software should set this field to a zero when the queue head is on the asynchronous schedule. A non-zero value in this field indicates an interrupt endpoint. The host controller uses the value of the three low-order bits of the FRINDEX register as an index into a bit position in this bit vector. If the µ*Frame S-mask* field has a one at the indexed bit position then this queue head is a candidate for transaction execution. If the *EPS* field indicates the endpoint is a high-speed endpoint, then the transaction executed is determined by the *PID_Code* field contained in the execution area. This field is also used to support split transaction types: Interrupt (IN/OUT). This condition is true when this field is non-zero and the *EPS* field indicates this is either a full- or low-speed device. A zero value in this field, in combination with existing in the periodic frame list has undefined results.

62.5.2.6.3 Transfer Overlay-Queue Head

The nine DWords in this area represent a transaction working space for the host controller. The general operational model is that the host controller can detect whether the overlay area contains a description of an active transfer. If it does not contain an active transfer, then it follows the Queue Head Horizontal Link Pointer to the next queue head. The host controller will never follow the Next Transfer Queue Element or Alternate Queue Element pointers unless it is actively attempting to advance the queue. For the duration of the transfer, the host controller keeps the incremental status of the transfer in the overlay area. When the transfer is complete, the results are written back to the original queue element.

The DWord3 of a Queue Head contains a pointer to the source qTD currently associated with the overlay. The host controller uses this pointer to write back the overlay area into the source qTD after the transfer is complete.

The following table describes the current qTD link pointer field descriptions.

Table 62-31. Current qTD Link Pointer

Bit	Description

Table continues on the next page...

Table 62-31. Current qTD Link Pointer (continued)

31-5	Current Element Transaction Descriptor Link Pointer. This field contains the address Of the current transaction being processed in this queue and corresponds to memory address signals [31:5], respectively.
4-0	Reserved (R). These bits are ignored by the host controller when using the value as an address to write data. The actual value may vary depending on the usage.

The DWords 4-11 of a queue head are the transaction overlay area. This area has the same base structure as a Queue Element Transfer Descriptor. The queue head utilizes the reserved fields of the page pointers to implement tracking the state of split transactions.

This area is characterized as an overlay because when the queue is advanced to the next queue element, the source queue element is merged onto this area. This area serves as execution cache for the transfer.

The table below describes the Host-controller rules for bits in overlay.

Table 62-32. Host-Controller Rules for Bits in Overlay (DWords 5, 6, 8 and 9)

DWord	Bit	Description
5	4-1	Nak Counter (NakCnt)µRW. This field is a counter the host controller decrements whenever a transaction for the endpoint associated with this queue head results in a Nak or Nyet response. This counter is reloaded from *RL* before a transaction is executed during the first pass of the reclamation list (relative to an Asynchronous List Restart condition). It is also loaded from RL during an overlay.
6	31	Data Toggle. The *Data Toggle Control* controls whether the host controller preserves this bit when an overlay operation is performed.
6	15	Interrupt On Complete (IOC). The IOC control bit is always inherited from the source qTD when the overlay operation is performed.
6	11-10	Error Counter (C_ERR). This two-bit field is copied from the qTD during the overlay and written back during queue advancement.
6	0	Ping State (P)/ERR. If the *EPS* field indicates a high-speed endpoint, then this field should be preserved during the overlay operation.
8	7-0	Split-transaction Complete-split Progress (C-prog-mask). This field is initialized to zero during any overlay. This field is used to track the progress of an interrupt split-transaction.
9	4-0	Split-transaction Frame Tag (Frame Tag). This field is initialized to zero during any overlay. This field is used to track the progress of an interrupt split-transaction.
9	11-5	S-bytes. Software must ensure that the *S-bytes* field in a *qTD* is zero before activating the *qTD*. This field is used to keep track of the number of bytes sent or received during an IN or OUT split transaction.

62.5.2.7 Periodic Frame Span Traversal Node (FSTN)

This data structure is to be used only for managing Full- and Low-speed transactions that span a Host-frame boundary.

See Host Controller Operational Model for FSTNs for full operational details. Software must not use an FSTN in the Asynchronous Schedule. An FSTN in the Asynchronous schedule results in undefined behavior. Software must not use the FSTN feature with a host controller whose USB_HCIVERSION register indicates a revision implementation below 0096h. FSTNs are not defined for implementations before 0.96 and their use yields undefined results.

Table 62-33. Frame Span Traversal Node Structure Layout

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Addr
Normal Path Link Pointer																											0		Typ		T	03-00
Back Path Link Pointer																											0		Typ[1]		T	07-04

1. Must be set to indicate a queue head

Host Controller Read/Write

Host Controller Read Only

62.5.2.7.1 FSTN Normal Path Pointer

The first DWord of an FSTN contains a link pointer to the next schedule object. This object can be of any valid periodic schedule data type.

The following table describes the FSTN normal path pointer fields.

Table 62-34. FSTN Normal Path Pointer Field Descriptions

Bit	Description
31-5	Normal Path Link Pointer (NPLP). This field contains the address of the next data object to be processed in the periodic list and corresponds to memory address signals [31:5], respectively.
4-3	Reserved
2-1	QH/(s)iTD/FSTN Select (Typ). This field indicates to the Host Controller whether the item referenced is a iTD/siTD, a QH or an FSTN. This allows the Host Controller to perform the proper type of processing on the item after it is fetched. Value encodings are: Value Meaning 00b iTD (isochronous transfer descriptor) 01b QH (queue head) 10b siTD (split transaction isochronous transfer descriptor) 11b FSTN (Frame Span Traversal Node)
0	Terminate (T). 1 = Link Pointer field is not valid. 0 = Link Pointer is valid.

62.5.2.7.2 FSTN Back Path Link Pointer

The second DWord of an FTSN node contains a link pointer to a queue head.

If the T-bit in this pointer is zero, then this FSTN is a Save-Place indicator. Its Typ field must be set by software to indicate the target data structure is a queue head. If the T-bit in this pointer is set to one, then this FSTN is the Restore indicator. When the T-bit is one, the host controller ignores the Typ field.

The following table describes the FSTN back path link pointer fields.

Table 62-35. FSTN Back Path Link Pointer Field Descriptions

Bit	Description
31-5	Back Path Link Pointer (BPLP). This field contains the address of a Queue Head. This field corresponds to memory address signals [31:5], respectively.
4-3	Reserved
2-1	Typ. Software must ensure this field is set to indicate the target data structure is a Queue Head. Any other value in this field yields undefined results.
0	Terminate (T). 1=Link Pointer field is not valid (that is the host controller must not use bits [31:5] as a valid memory address). This value also indicates that this FSTN is a Restore indicator. 0=Link Pointer is valid (that is the host controller may use bits [31:5] (in combination with the CTRLDSSEGMENT register if applicable) as a valid memory address). This value also indicates that this FSTN is a Save-Place indicator.

62.5.3 Host Operational Model

The general operational model is for the enhanced interface host controller hardware and enhanced interface host controller driver (generally referred to as system software).

Each significant operational feature of the EHCI host controller is discussed in a separate section. Each section presents the operational model requirements for the host controller hardware. Where appropriate, recommended system software operational models for features are also presented.

62.5.3.1 Host Controller Initialization

After initial power-on or HCReset (hardware or through HCReset bit in the USB_USBCMD register), all of the operational registers are at their default values. After a hardware reset, only the operational registers not contained in the Auxiliary power well are at their default values.

The following table describes the default values of operational registers.

Table 62-36. Default Values of Operational Register Space

Operational Register	Default Value (after Reset)
USB_USBCMD	00080000h (00080B00h, if *Asynchronous Schedule Park Capability is one*)
USB_USBSTS	00001000h
USB_USBINTR	00000000h
USB_FRINDEX	00000000h
USB_CTRLDSSEGMENT	00000000h
USB_PERIODICLISTBASE	Undefined
USB_ASYNCLISTADDR	Undefined
USB_CONFIGFLAG	00000000h
USB_PORTSC1	00002000h (w/*PPC* set to one); 00003000h (w/*PPC* set to zero)

To initialize the host controller, software should perform the following steps:

- Write the appropriate value to the USB_USBINTR register to enable the appropriate interrupts.
- Write the base address of the Periodic Frame List to the USB_PERIODICLIST BASE register. If no work items are in the periodic schedule, all elements of the Periodic Frame List should have their T-Bits set to one.
- Write the USB_USBCMD register to set the desired interrupt threshold, frame list size (if applicable) and turn the host controller ON through setting the Run/Stop bit.

At this point, the host controller is up and running and the port registers begin reporting device connects, and so on. System software can enumerate a port through the reset process (where the port is in the enabled state). At this point, the port is active with SOFs occurring down the enabled ports, but the schedules have not enabled. To communicate with devices through the asynchronous schedule, system software must write the USB_ASYNCLISTADDR register with the address of a control or bulk queue head. Software must then enable the asynchronous schedule by writing one to the Asynchronous Schedule Enable bit in the USB_USBCMD register. To communicate with devices through the periodic schedule, system software must enable the periodic schedule by writing one to the Periodic Schedule Enable bit in the USB_USBCMD register.

NOTE

The schedules can be turned on before the first port is reset (and enabled).

When the USB_USBCMD register is written, system software must ensure the appropriate bits are preserved, depending on the intended operation.

62.5.3.2 Port Routing and Control

The EHCI specification defines that a USB 2.0 Host controller is comprised of one high-speed host controller, which implements the EHCI programming interface and 0 to N USB 1.1 companion host controllers.

Companion host controllers (cHCs) may be implementations of either Universal or Open host controller specifications. This configuration is used to deliver the required full USB 2.0-defined port capability; for example, Low-, Full-, and High-speed capability for every port.

NOTE

The USB controllers on do not require nor support companion controllers to support Full and Low Speed device. Full and Low Speed devices are supported within the USB controller by emulating the functionality of a high-speed HUB. Therefore, no port routing is present in the controller. Please refer to Embedded Transaction Translator Function for details.

The following figure illustrates a simple block diagram of the port routing logic and its relationship to the high-speed and companion host controllers within a USB 2.0 host controller.

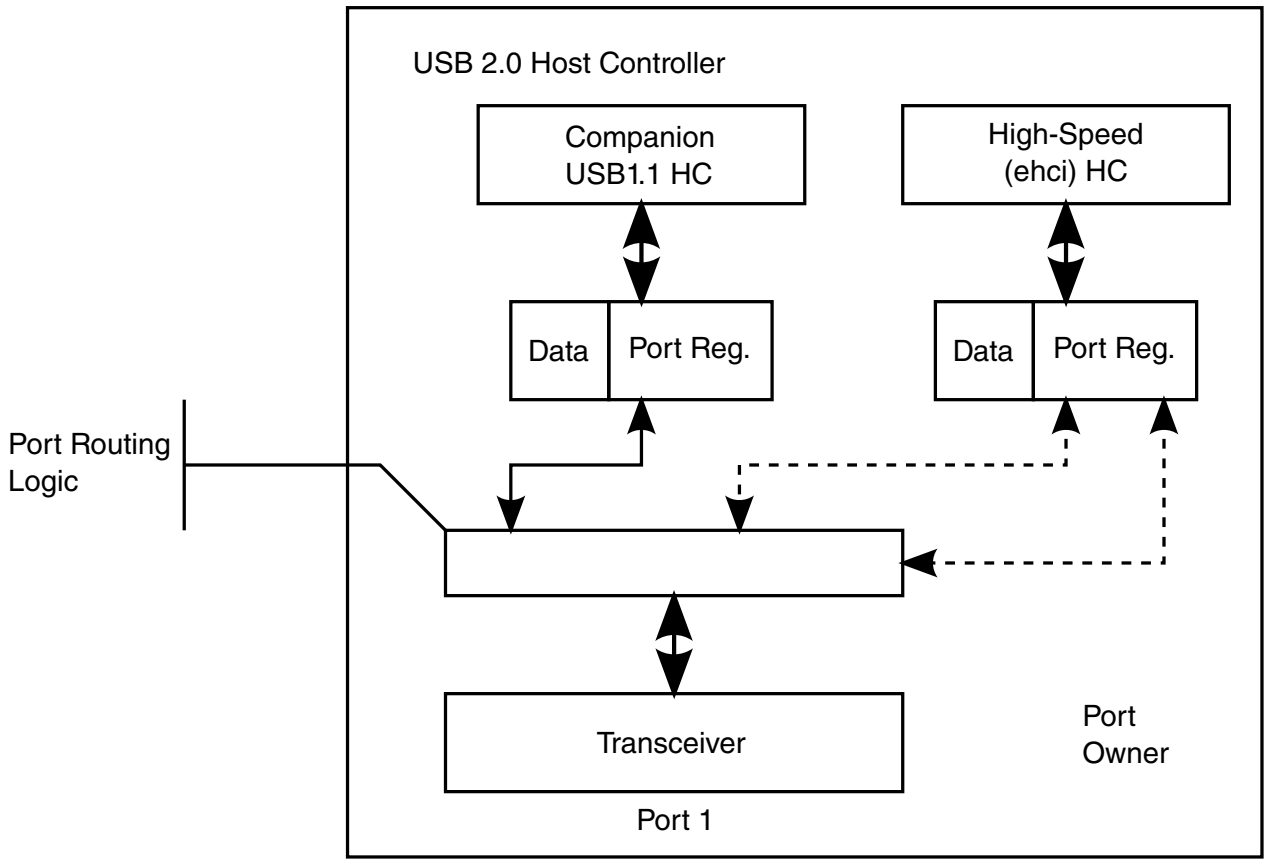

Figure 62-5. Example USB 2.0 Host Controller Port Routing Block Diagram

There exists one transceiver per physical port and each host controller block has its own port status and control registers. The EHCI controller has port status and control registers for every port. Each companion host controller has only the port control and status registers it is required to operate. Either the EHCI host controller or one companion host controller controls each transceiver. Routing logic lies between the transceiver, the port status and control registers.[1]

The port routing logic is controlled from signals originating in the EHCI host controller. The EHCI host controller has a global routing policy control field and per-port ownership control fields. The Configured Flag (CF) bit is the global routing policy control. At power-on or reset, the default routing policy is to the companion controllers (if they exist). If the system does not include a driver for the EHCI host controller and the host controller includes Companion Controllers, then the ports still work in Full- and Low-speed mode (assuming the system includes a driver for the companion controllers). In general, when the EHCI owns the ports, the companion host controllers' port registers do not see a connect indication from the transceiver. Similarly, when a companion host controller owns a port, the EHCI controller's port registers do not see a connect indication

1. The routing logic should not be implemented in the 480 MHz clock domain of the transceiver.

from the transceiver. The details on the rules for the port routing logic are described in the following sections. The USB 2.0 host controller must be implemented as a multi-function PCI device if the implementation includes companion controllers. The companion host controllers' function numbers must be less than the EHCI host controller function number. The EHCI host controller must be a larger function number with respect to the companion host controllers associated with this EHCI host controller. If a PCI device implementation contains only an EHCI controller (that is no companion controllers or other PCI functions), then the EHCI host controller must be function zero, in accordance with the PCI Specification. The N_CC field in the Structural Parameter register (HCSPARAMS) indicates whether the controller implementation includes companion host controllers. When N_CC has a non-zero value there exists companion host controllers. If N_CC has a value of zero, then the host controller implementation does not include companion host controllers. If the host controller root ports are exposed to attachment of full- or low-speed devices, the ports always fails the high-speed chirp during reset and the ports are not enabled. System software can notify the user of the illegal condition. This type of implementation requires a USB 2.0 hub be connected to a root port to provide full and low-speed device connectivity.

System software uses information in the host controller capability registers to determine how the ports are routed to the companion host controllers. See USB_nHCSPARAMS

62.5.3.2.1 Port Routing Control through EHCI Configured (CF) Bit

Each port in the USB 2.0 host controller are routed either to a single companion host controller or to the EHCI host controller.

The port routing logic is controlled by two mechanisms in the EHCI HC: a host controller global flag and per-port control. The Configured Flag (CF) bit, is used to globally set the policy of the routing logic. Each port register has a Port Owner control bit which allows the EHCI Driver to explicitly control the routing of individual ports. Whenever the CF bit transitions from zero to one (this transition is only available under program control) the port routing unconditionally routes all of the port registers to the EHCI HC (all Port Owner bits go to zero). While the CF-bit is one, the EHCI Driver controls individual ports' routing through the Port Owner control bit. Likewise, whenever the CF bit transitions from one to zero (as a result of Aux power application, HCRESET, or software writing zero to CF-bit), the port routing unconditionally routes all of the port registers to the appropriate companion HC. The default value for the EHCI HC's CF bit (after Aux power application or HCRESET) is zero.

The *view* of the port depends on the current owner. A Universal or Open companion host controller will see port register bits consistent with the appropriate specification. Port bit definitions that are required for EHCI host controllers are not visible to companion host controllers.

The following table summarizes the default routing for all the ports, based on the value of the EHCI HC's CF bit.

Table 62-37. Default Port Routing Depending on EHCI HC CF Bit

HS CF Bit	Default Port Ownership	Explanation
0B	Companion HCs	The companion host controllers own the ports and only Full- and Low-speed devices are supported in the system. The exact port assignments are implementation dependent. The ports behave only as Full- and Low-speed ports in this configuration
1B	EHCI HC	The EHCI host controller has default ownership over all of the ports. The routing logic inhibits device connect events from reaching the companion HCs' port status and control registers when the port owner is the EHCI HC.The EHCI HC has access to the additional port status and control bits defined in this specification (see PORTSC1 register). The EHCI HC can temporarily release control of the port to a companion HC by setting the *PortOwner* bit in the PORTSC1 register to one.

62.5.3.2.2 Port Routing Control through PortOwner and Disconnect Event

Manipulating the port routing through the CF-bit is an extreme process and not intended to be used during normal operation.

The normal mode of port ownership transferal is on the granularity of individual ports using the Port Owner bit in the EHCI HC's USB_PORTSC1 register (for hand-offs from EHCI to companion host controllers). Individual port ownership is returned to the EHCI controller when the port registers a device disconnect. When the disconnect is detected, the port routing logic immediately returns the port ownership to the EHCI controller. The companion host controller port register detects the device disconnect and operates normally.

Under normal operating conditions (assuming all HC drivers loaded and operational and the EHCI *CF-bit* is set to one), the typical port enumeration sequence proceeds as illustrated below:

- Initial condition is that EHCI is port owner. A device is connected causing the port to detect a connect, set the port connect change bit and issue a port-change interrupt (if enabled).
- EHCI Driver identifies the port with the new connect change bit asserted and sends a change report to the hub driver. Hub driver issues a GetPortStatus() request and identifies the connect change. It then issues a request to clear the connect change, followed by a request to reset and enable the port.
- When the EHCI Driver receives the request to reset and enable the port, it first checks the value reported by the LineStatus bits in the USB_PORTSC1 register. If they indicate the attached device is a full-speed device (for example, D+ is asserted), then the EHCI Driver sets the PortReset control bit to one (and sets the PortEnable

bit to zero) which begins the reset-process. Software times the duration of the reset, then terminates reset signaling by writing zero to the port reset bit. The reset process is actually complete when software reads zero in the PortReset bit. The EHCI Driver checks the PortOwner bit in the USB_PORTSC1 register. If set to one, the connected device is a high-speed device and EHCI Driver (root hub emulator) issues a change report to the hub driver and the hub driver continues to enumerate the attached device.

- At the time the EHCI Driver receives the port reset and enable request the LineStatus bits might indicate a low-speed device. Additionally, when the port reset process is complete, the PortEnable field may indicate that a full-speed device is attached. In either case the EHCI driver sets the PortOwner bit in the USB_PORTSC1 register to one to release port ownership to a companion host controller.
- When the EHCI Driver sets PortOwner bit to one, the port routing logic makes the connection state of the transceiver available to the companion host controller port register and removes the connection state from the EHCI HC port. The EHCI USB_PORTSC1 register observes and reports a disconnect event through the disconnect change bit. The EHCI Driver detects the connection status change (either by polling or by port change interrupt) and then sends a change report to the hub driver. When the hub driver requests that port-state, the EHCI Driver responds with a reset complete change set to one, a connect change set to one and a connect status set to zero. This information is derived directly from the EHCI port register. This allows the hub driver to assume the device was disconnected during reset. It acknowledges the change bits and wait for the next change event. While the EHCI controller does not own the port, it simply remains in a state where the port reports no device connected. The device-connect evaluation circuitry of the companion HC activates and detects the device, the companion Driver detects the connection and enumerates the port.

When a port is routed to a companion HC, it remains under the control of the companion HC until the device is disconnected from the root port (ignoring for now the scenario where EHCI's CF-bit transitions from1b to 0b). When a disconnect occurs, the disconnect event is detected by both the companion HC port control and the EHCI port ownership control. On the event, the port ownership is returned immediately to the EHCI controller. The companion HC stack detects the disconnect and acknowledges as it would in an ordinary standalone implementation. Subsequent connects is detected by the EHCI port register and the process repeats.

62.5.3.2.3 Example Port Routing State Machine

The following figure illustrates an example of how the port ownership should be managed. The following sections describe the entry conditions to each state.

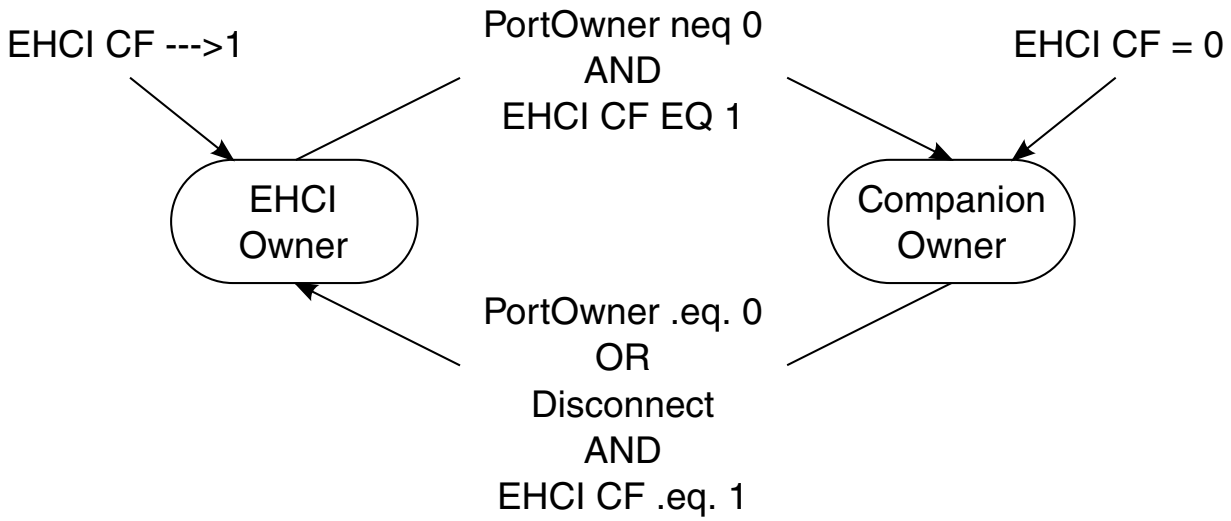

Figure 62-6. Port Owner Handoff State Machine

62.5.3.2.3.1 EHCI HC Owner

Entry to this state occurs when one of the following events occur:

- When the EHCI HC's Configure Flag (CF) bit in the USB_CONFIGFLAG register transitions from zero to one. This signals the fact that the system has a host controller driver for the EHCI HC and that all ports in the USB 2.0 host controller must default route to the EHCI controller.
- When the port is owned by a companion HC and the device is disconnected from the port. The EHCI port routing control logic is notified of the disconnect, and returns port routing to the EHCI controller. The connection state of the companion HC goes immediately to the disconnected state (with appropriate side effect to connect change, enable and enable change). The companion HC driver acknowledges the disconnect by setting the connect status change bit to zero. This allows the companion HC's driver to interact with the port completely through the disconnect process.
- When system software writes zero to the PortOwner bit in the USB_PORTSC1 register. This allows software to take ownership of a port from a companion host controller. When this occurs, the routing logic to the companion HC effectively signals a disconnect to the companion HC's port status and control register.

62.5.3.2.3.2 Companion HC Owner

Entry to this state occurs whenever one of the following events occur:

- When the PortOwner field transitions from zero to one.
- When the HS-mode HC's Configure Flag (CF) is equal to zero.

On entry to this state, the routing logic allows the companion HC port register to detect a device connect. Normal port enumeration proceeds.

62.5.3.2.4 Port Power

The Port Power Control (PPC) bit in the USB_HCSPARAMS register indicates whether the USB 2.0 host controller has port power control (see HCSPARAMS register). When this bit is zero, then the host controller does not support software control of port power switches. When in this configuration, the port power is always available and the companion host controllers must implement functionality consistent with port power always on. When the *PPC* bit is one, then the host controller implementation includes port power switches. Each available switch has an output enable, which is referred to in this discussion as PortPowerOutputEnable (PPE). PPE is controlled based on the state of the combination bits PPC bit, EHCI Configured (CF)-bit and individual Port Power (PP) bits.

The following table describes the summary behavioral model.

Table 62-38. Port Power Enable Control Rules

CF	CHC[1] (PP)	EHC[2] (PP)	Owner	PPE[3]	Description
0	0	X	CHC	0	When the EHCI controller is not configured, the port is owned by the companion host controller. When the companion HC's port power select is off, then the port power is off.
0	1	X	CHC	1	Similar to previous entry. When the companion HC's port power select is on, then the port power is on.
1	0	0	CHC	0	Port owner has port power turned off, the power to port is off.
1	0	0	EHC	0	Port owner has port power turned off, the power to port is off.
1	0	1	EHC	1	Port owner has port power on, so power to port is on.
1	0	1	CHC	1	If either HC has port power turned on, the power to the port is on.
1	1	0	EHC	1	If either HC has port power turned on, the power to the port is on.
1	1	0	CHC	1	Port owner has port power on, so power to port is on.
1	1	1	CHC	1	Port owner has port power on, so power to port is on.
1	1	1	EHC	1	Port owner has port power on, so power to port is on.

1. CHC (Companion Host Controller).
2. EHC (EHCI Host Controller).
3. PPE (Port Power Enable). This bit actually turns on the port power switch (if one exists).

62.5.3.2.5 Port Reporting Over-Current

Host controllers are by definition power providers on USB. Whether the ports are considered high- or low-powered is a platform implementation issue. Each EHCI USB_PORTSC1 register has an over-current status and over-current change bit.

The functionality of these bits are specified in the USB Specification Revision 2.0.

The over current detection and limiting logic usually resides outside the host controller logic. This logic may be associated with one or more ports. When this logic detects an over-current condition it is made available to both the companion and EHCI ports. The effect of an over-current status on a companion host controller port is beyond the scope of this document.

The over-current condition effects the following bits in the USB_PORTSC1 register on the EHCI port:

- Over-current Active bits are set to one. When the over-current condition goes away, the Over-current Active bit transitions from one to zero.
- Over-current Change bits are set to one. On every transition of the Over-current Active bit the host controller sets the Over-current Change bit to one. Software sets the Over-current Change bit to zero by writing one to this bit.
- Port Enabled/Disabled bit is set to zero. When this change bit gets set to one, then the Port Change Detect bit in the USB_USBSTS register is set to one.
- Port Power (PP) bits may optionally be set to zero. There is no requirement in USB that a power provider shut off power in an over current condition. It is sufficient to limit the current and leave power applied. When the Over-current Change bit transitions from zero to one, the host controller also sets the Port Change Detect bit in the USB_USBSTS register to one. In addition, if the Port Change Interrupt Enable bit in the USB_USBINTR register is one, then the host controller issues an interrupt to the system. Refer to Table 62-39 for summary behavior for over-current detection when the host controller is halted (suspended from a device component point of view).

62.5.3.3 Suspend/Resume-Host Operational Model

The EHCI host controller provides an equivalent suspend and resume model as that defined for individual ports in a USB 2.0 Hub.

Control mechanisms are provided to allow system software to suspend and resume individual ports. The mechanisms allow the individual ports to be resumed completely through software initiation. Other control mechanisms are provided to parameterize the host controller's response (or sensitivity) to external resume events. In this discussion, host-initiated, or software initiated resumes are called Resume Events/Actions. Bus-initiated resume events are called wake-up events. The classes of wake-up events are:

- Remote-wake-up enabled device asserts resume signaling. In similar kind to USB 2.0 Hubs, EHCI controllers must always respond to explicit device resume signaling and wake-up the system (if necessary).
- Port connect and disconnect and over-current events. Sensitivity to these events can be turned on or off by using the per-port control bits in the USB_PORTSC1 registers.

Selective suspend is a feature supported by every USB_PORTSC1 register. It is used to place specific ports into a suspend mode. This feature is used as a functional component for implementing the appropriate power management policy implemented in a particular operating system. When system software intends to suspend the entire bus, it should selectively suspend all enabled ports, then shut off the host controller by setting the Run/Stop bit in the USB_USBCMD register to zero. The EHCI sub-block can then be placed into a lower device state through the PCI power management interface (see Appendix A, Enhanced Host Controller Interface Specification for Universal Serial Bus, Revision 0.95, November 2000, Intel Corporation. http://www.intel.com).

When a wake event occurs, the system resumes operation and system software eventually set the Run/Stop bit to one and resume the suspended ports. Software must not set the Run/Stop bit to one until it is confirmed that the clock to the host controller is stable. This is usually confirmed in a system implementation in that all of the clocks in the system are stable before the Arm platform is restarted. So, by definition, if software is running, clocks in the system are stable and the Run/Stop bit in the USB_USBCMD register can be set to one. Minimum system software delays are also defined in the PCI Power Management Specification. Refer to PCI Power Management Specification for more information.

62.5.3.3.1 Port Suspend/Resume

System software places individual ports into suspend mode by writing one into the appropriate USB_PORTSC1 Suspend bit. Software must only set the Suspend bit when the port is in the enabled state (Port Enabled bit is one) and the EHCI is the port owner (PortOwner bit is zero).

The host controller may evaluate the Suspend bit immediately or wait until a micro-frame or frame boundary occurs. If evaluated immediately, the port is not suspended until the current transaction (if one is executing) completes. Therefore, there may be several micro-frames of activity on the port until the host controller evaluates the Suspend bit. The host controller must evaluate the Suspend bit at least every frame boundary.

System software can initiate a resume on a selectively suspended port by writing one to the Force Port Resume bit. Software should not attempt to resume a port unless the port reports that it is in the suspended state (see USB_nPORTSC1). If system software sets Force Port Resume bit to one when the port is not in the suspended state, the resulting behavior is undefined. In order to assure proper USB device operation, software must wait for at least 10 ms after a port indicates that it is suspended (Suspend bit is one) before initiating a port resume through the Force Port Resume bit. When Force Port Resume bit is one, the host controller sends resume signaling down the port. System software times the duration of the resume (nominally 20 ms) then sets the Force Port Resume bit to zero. When the host controller receives the write to transition Force Port Resume to zero, it completes the resume sequence as defined in the USB specification, and sets both the Force Port Resume and Suspend bits to zero. Software-initiated port resumes do not affect the Port Change Detect bit in the USB_USBSTS register nor do they cause an interrupt if the Port Change Interrupt Enable bit in the USB_USBINTR register is one. An external USB event may also initiate a resume. The wake events are defined above. When a wake event occurs on a suspended port, the resume signaling is detected by the port and the resume is reflected downstream within 100 µsec. The port's Force Port Resume bit is set to one and the Port Change Detect bit in the USB_USBSTS register is set to one. If the Port Change Interrupt Enable bit in the USB_USBINTR register is one the host controller issues a hardware interrupt.

System software observes the resume event on the port, delays a port resume time (nominally 20 ms), then terminates the resume sequence by writing zero to the Force Port Resume bit in the port. The host controller receives the write of zero to Force Port Resume, terminates the resume sequence and sets Force Port Resume and Suspend port bits to zero. Software can determine that the port is enabled (not suspended) by sampling the USB_PORTSC1 register and observing that the Suspend and Force Port Resume bits are zero. Software must ensure that the host controller is running (that is HCHalted bit in the USB_USBSTS register is zero), before terminating a resume by writing zero to a port's Force Port Resume bit. If HCHalted is one when Force Port Resume is set to zero, then SOFs do not occur down the enabled port and the device returns to suspend mode in a maximum of 10 msec.

The table below summarizes the wake-up events. Whenever a resume event is detected, the Port Change Detect bit in the USB_USBSTS register is set to one. If the Port Change Interrupt Enable bit is one in the USB_USBINTR register, the host controller generates an interrupt on the resume event. Software acknowledges the resume event interrupt by clearing the Port Change Detect status bit in the USB_USBSTS register.

Table 62-39. Behavior During Wake-up Events

Port Status and Signaling Type	Signaled Port Response	Device State	
		D0	Not D0
Port disabled, resume K-State received	No Effect	N/A	N/A
Port suspended, resume K-State received	Resume reflected downstream on signaled port. Force Port Resume status bit in USB_PORTSC1 register is set to one. Port Change Detect bit in USB_USBSTS register set to one.	[1], [2]	[2]
Port is enabled, disabled or suspended, and the port's WKDSCNNT_E bit is one. A disconnect is detected.	Depending in the initial port state, theUSB_ PORTSC1 Connected Enable status bits are set to zero, and the Connect Change status bit is set to one. Port Change Detect bit in the USB_USBSTS register is set to one.	[1], [2]	[2]
Port is enabled, disabled or suspended, and the port's WKDSCNNT_E bit is zero. A disconnect is detected.	Depending on the initial port state, the USB_PORTSC1 Connect and Enable status bits are set to zero, and the Connect Change status bit is set to one. Port Change Detect bit in the USB_USBSTS register is set to one.	[1], [3]	[3]
Port is not connected and the port's WKCNNT_E bit is one. A connect is detected.	USB_PORTSC1 Connect Status and Connect Status Change bits are set to one. Port Change Detect bit in the USB_USBSTS register is set to one.	[1], [2]	[2]
Port is not connected and the port's WKCNNT_E bit is zero. A connect is detected.	USB_PORTSC1 Connect Status and Connect Status Change bits are set to one. Port Change Detect bit in the USB_USBSTS register is set to one.	[1], [3]	[3]
Port is connected and the port's WKOC_E bit is one. An over-current condition occurs.	USB_PORTSC1 Over-current Active, Over-current Change bits are set to one. If Port Enable/Disable bit is one, it is set to zero. Port Change Detect bit in the USB_USBSTS register is set to one	[1], [2]	[2]
Port is connected and the port's WKOC_E bit is zero. An over-current condition occurs.	USB_PORTSC1 Over-current Active, Over-current Change bits are set to one. If Port Enable/Disable bit is one, it is set to zero. Port Change Detect bit in the USB_USBSTS register is set to one.	[1], [3]	[3]

[1] Hardware interrupt issued if Port Change Interrupt Enable bit in the USB_USBINTR register is one.

[2] PME# asserted if enabled (Note: PME Status must always be set to one).

[3] PME# not asserted.

62.5.3.4 Schedule Traversal Rules

The host controller executes transactions for devices using a simple, shared-memory schedule.

The schedule is comprised of a few data structures, organized into two distinct lists. The data structures are designed to provide the maximum flexibility required by USB, minimize memory traffic and hardware / software complexity.

System software maintains two schedules for the host controller: a periodic schedule and an asynchronous schedule. The root of the periodic schedule is the USB_PERIODICLISTBASE register (see USB_nPERIODICLISTBASE) DEVICEADDR. The USB_PERIODICLISTBASE register is the physical memory base address of the periodic frame list. The periodic frame list is an array of physical memory pointers. The objects referenced from the frame list must be valid schedule data structures as defined in Host Data Structures. In each micro-frame, if the periodic schedule is enabled (see Periodic scheduling threshold) then the host controller must execute from the periodic schedule before executing from the asynchronous schedule. It only executes from the asynchronous schedule after it encounters the end of the periodic schedule. The host controller traverses the periodic schedule by constructing an array offset reference from the USB_PERIODICLISTBASE and the USB_FRINDEX registers (see the following figure). It fetches the element and begins traversing the graph of linked schedule data structures.

The end of the periodic schedule is identified by a next link pointer of a schedule data structure having its T-bit set to one. When the host controller encounters a T-Bit set to one during a horizontal traversal of the periodic list, it interprets this as an End-Of-Periodic-List mark. This causes the host controller to cease working on the periodic schedule and transitions immediately to traversing the asynchronous schedule. After the transition, the host controller executes from the asynchronous schedule until the end of the micro-frame.

The following figure illustrates the derivation of pointer into frame list array.

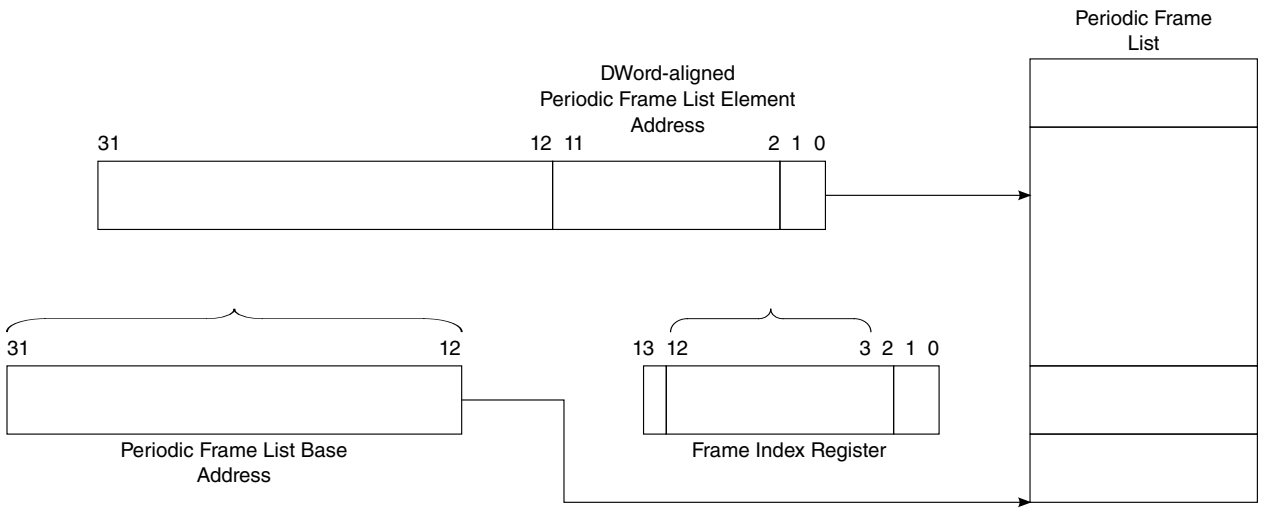

Figure 62-7. Derivation of Pointer into Frame List Array

When the host controller determines that it is the time to execute from the asynchronous list, it uses the operational register USB_ASYNCLISTADDR to access the asynchronous schedule, see the figure below.

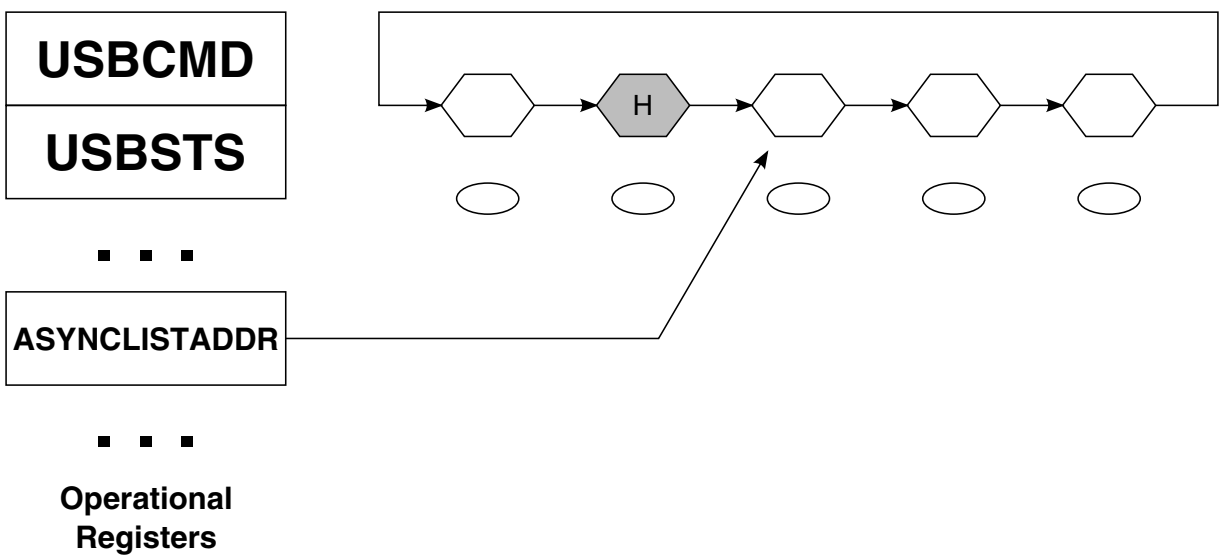

Figure 62-8. General Format of Asynchronous Schedule List

The USB_ASYNCLISTADDR register contains a physical memory pointer to the next queue head. When the host controller makes a transition to executing the asynchronous schedule, it begins by reading the queue head referenced by the USB_ASYNCLISTADDR register. Software must set queue head horizontal pointer T-bits to zero for queue heads in the asynchronous schedule. See Asynchronous Schedule for complete operational details.

62.5.3.4.1 Example - Preserving Micro-Frame Integrity

One of the requirements of a USB host controller is to maintain Frame Integrity. This means that the HC must preserve the micro-frame boundaries.

For example, SOF packets must be generated on time (within the specified allowable jitter), and High-speed EOF1,2 thresholds must be enforced. The end of micro-frame timing points EOF1 and EOF2 are clearly defined in the USB Specification Revision 2.0. One implication of this responsibility is that the HC must ensure that it does not start transactions that do not complete before the end of the micro-frame. More precisely, no transactions should be started by the host controller, which do not complete in their entirety before the EOF1 point. In order to enforce this rule, the host controller must check each transaction before it starts to ensure that it completes before the end of the micro-frame.

So, what exactly needs to be involved in this check? Fundamentally, the transaction data payload, plus bit stuffing, plus transaction overhead must be taken into consideration. It is possible to be extremely accurate on how much time the next transaction takes. Take OUTs for an example. The host controller must fetch all of the OUT data from memory in order to send it onto the USB bus. A host controller implementation could pre-fetch all of the OUT data, and pre-compute the actual number of bits in the token and data packets. In addition, the system knows the depth of the target endpoint, so it could closely estimate turnaround time for handshake. In addition, the host controller knows the size of a handshake packet. Pre-computing effects of bit stuffing and summing up the other overhead numbers can allow the host controller to know exactly whether there is enough bus time, before EOF1 to complete the OUT transaction. To accomplish this particular approach takes an inordinate amount of time and hardware complexity.

The alternative is to make a reasonable guess whether the next transaction can be started. An example approximation algorithm is described below. This example algorithm relies on the EHCI policy that periodic transactions are scheduled first in the micro-frame. It is a reasonable assumption that software never over-commits the micro-frame to periodic transactions greater than the specification allowable 80%. In the available remaining 20% bandwidth, the host controller has some ability (in this example) to decide whether or not to execute a transaction. The result of this algorithm is that sometimes, under some circumstances a transaction is not executed that could have been executed. However, under all circumstances, a transaction is never started unless there is enough time in the frame to complete the transaction.

62.5.3.4.1.1 Transaction Fit - A Best-Fit Approximation Algorithm

A curve is calculated which represents the latest start time for every packet size, at which software schedules the start of a periodic transaction.

This curve is the 80% bandwidth curve. Another curve is calculated which is the absolute, latest permitted start time for every packet size. This curve represents the absolute latest time, that a transaction of each packet size can be started and completed, in the micro-frame. A plot of these two curves are illustrated in Figure 62-9. The plot Y-axis represents the number of byte-times left in a frame.

The space between the 80% and the Last Start plots is bandwidth reclamation area. In this algorithm the host controller may skip transactions during this time if it is prudent.

The Best-Fit Approximation method plots a function ($f(x)$) between the 80% and Last Start curves. The function $f(x)$ adds a constant to every transaction's maximum packet size and the result compared with the number of bytes left in the frame. The constant represents an approximation of the effects of bit stuffing and protocol overhead. The host controller starts transactions whose results land above the function curve. The host controller will not start transactions whose results land below the function curve.

The following figure illustrates the Best-Fit Approximation.

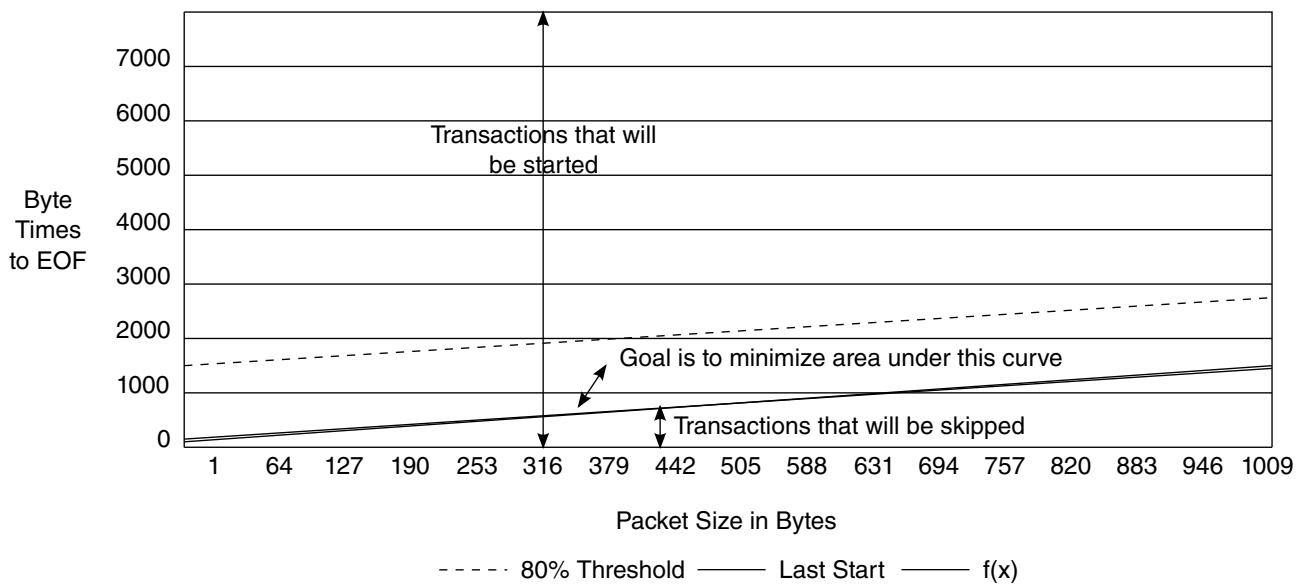

Figure 62-9. Best Fit Approximation

The LastStart line was calculated in this example to assume the absolute worst-case bus overhead per transaction. The particular transaction used is a start-split, zero-length OUT transaction with a handshake. Summaries of the component parts are listed in the table below. The component times were derived from the protocol timings defined in the USB Specification Revision 2.0.

Table 62-40. Example Worse-case Transaction Timing Components

Component	Bit time	Byte Time	Explanation

Table continues on the next page...

Table 62-40. Example Worse-case Transaction Timing Components (continued)

Split Token	76	9.5	Split token as defined in USB core specification. Includes sync, token, eop, and so on.
Host 2 Host IPG	88	11	Number of bit times required between consecutive host packets.
Token	67	8.375	Token as defined in USB core specification. Includes sync, token, eop, and so on.
Host 2 Host IPG	88	11	Token as defined in USB core specification. Includessync, token, eop, and so on.
Data Packet (0 data bytes)	66.7	8.34	Zero-length data packet. Includes sync, PID, crc16, eop, and so on.
Turnaround time	721	90.125	Time for packet initiator (Host) to see the beginning of a response to a transmitted packet.
Handshake packet	48	6	Handshake packet as defined in USB core specification. Includes sync, PID, eop, and so on.
		144	Total

The exact details of the function (f(x)) are up to the particular implementation. However, it should be obvious that the goal is to minimize the area under the curve between the approximation function and the Last Start curve, without dipping below the LastStart line, while at the same time keeping the check as simple as possible for hardware implementation. The f(x) in Figure 62-9 was constructed using the following pseudo-code test on each transaction size data point. This algorithm assumes that the host controller keeps track of the remaining bits in the frame.

```
Alorithm CheckTransactionWillFit (MaximumPacketSize, HC_BytesLeftInFrame)
Begin
Local Temp = MaximumPacketSize + 192
Local rvalue = TRUE
If MaximumPacketSize >= 128 then
     Temp += 128
End If
If Temp > HC_BytesLeftInFrame then
     Rvalue = FALSE
End If
Return rvalue
End
```

This algorithm takes two inputs, the current maximum packet size of the transaction and the hardware counter of the number of bytes left in the current micro-frame. It unconditionally adds a simple constant of 192 to the maximum packet size to account for a first-order effect of transaction overhead and bit stuffing. If the transaction size is greater than or equal to 128 bytes, then an additional constant of 128 is added to the running sum to account for the additional worst-case bit stuffing of payloads larger than 128. An inflection point was inserted at 128 because the $f(x)$ plot was getting close to the LastStart line.

62.5.3.5 Periodic Schedule Frame Boundaries vs Bus Frame Boundaries

The USB Specification Revision 2.0 requires that the frame boundaries (SOF frame number changes) of the high-speed bus and the full- and low-speed bus(s) below USB 2.0 Hubs be strictly aligned.

Super-imposed on this requirement is that USB 2.0 Hubs manage full- and low-speed transactions through a micro-frame pipeline (see start- (SS) and complete- (CS) splits illustrated in the following figure). A simple, direct projection of the frame boundary model into the host controller interface schedule architecture creates tension (complexity for both hardware and software) between the frame boundaries and the scheduling mechanisms required to service the full- and low-speed transaction translator periodic pipelines.

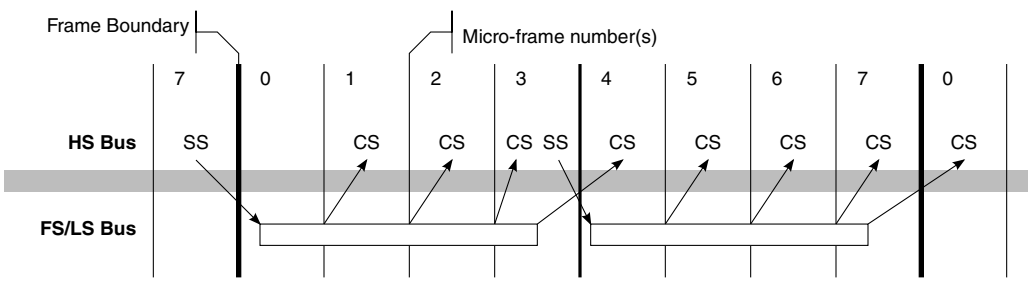

Figure 62-10. Frame Boundary Relationship between HS bus and FS/LS Bus

The simple projection, as the above figure illustrates, introduces frame-boundary wrap conditions for scheduling on both the beginning and end of a frame. In order to reduce the complexity for hardware and software, the host controller is required to implement one micro-frame phase shift for its view of frame boundaries. The phase shift eliminates the beginning of frame and frame-wrap scheduling boundary conditions.

The implementation of this phase shift requires that the host controller use one register value for accessing the periodic frame list and another value for the frame number value included in the SOF token. These two values are separate, but tightly coupled. The periodic frame list is accessed through the Frame List Index Register (USB_FRINDEX) documented in FRINDEX and initially illustrated in Schedule Traversal Rules. Bits FRINDEX[2:0], represent the micro-frame number. The SOF value is coupled to the value of FRINDEX[13:3]. Both FRINDEX[13:3] and the SOF value are increment based on FRINDEX[2:0]. It is required that the SOF value be delayed from the FRINDEX value by one micro-frame. The one micro-frame delay yields host controller periodic schedule and bus frame boundary relationship as illustrated in the following figure. This adjustment allows software to trivially schedule the periodic start and complete-split

transactions for full-and low-speed periodic endpoints, using the natural alignment of the periodic schedule interface. The reasons for selecting this phase-shift are beyond the scope of this specification.

The following figure illustrates how periodic schedule data structures relate to schedule frame boundaries and bus frame boundaries. To aid the presentation, two terms are defined: The host controller's view of the 1 msec boundaries is called H-Frames. The high-speed bus's view of the 1 msec boundaries is called B-Frames.

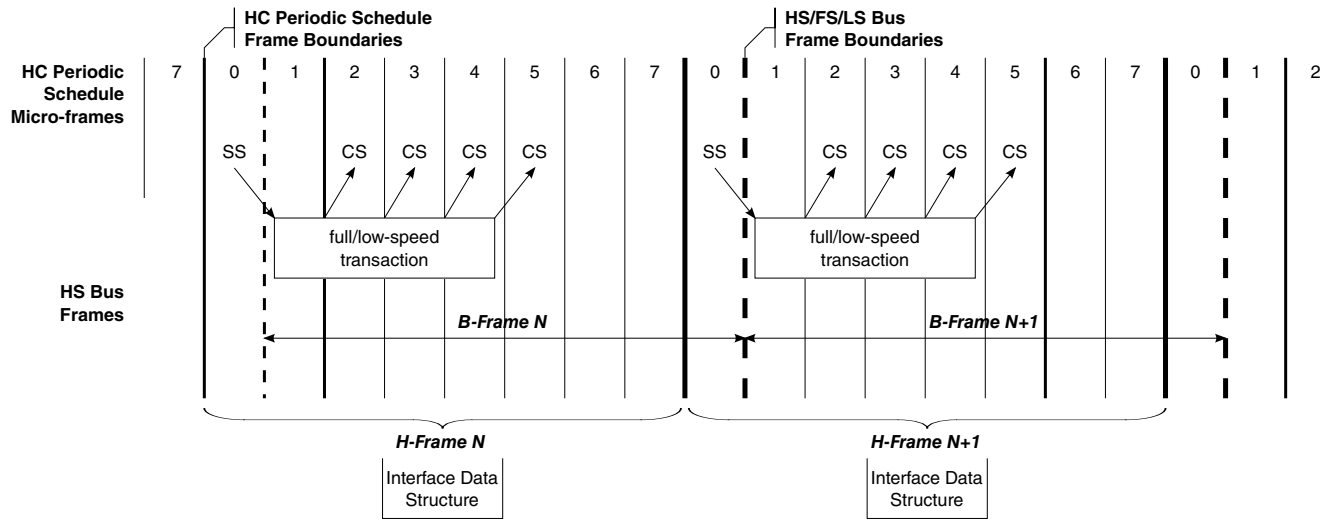

Figure 62-11. Relationship of Periodic Schedule Frame Boundaries to Bus Frame Boundaries

H-Frame boundaries for the host controller correspond to increments of FRINDEX[13:3]. Micro-frame numbers for the H-Frame are tracked by FRINDEX[2:0]. B-Frame boundaries are visible on the high-speed bus through changes in the SOF token's frame number. Micro-frame numbers on the high-speed bus are only derived from the SOF token's frame number (that is the high-speed bus sees eight SOFs with the same frame number value). H-Frames and B-Frames have the fixed relationship (that is B-Frames lag H-Frames by one micro-frame time) illustrated in the figure above. The host controller's periodic schedule is naturally aligned to H-Frames. Software schedules transactions for full- and low-speed periodic endpoints relative the H-Frames. The result is these transactions execute on the high-speed bus at exactly the right time for the USB 2.0 Hub periodic pipeline. As described in FRINDEX, the SOF Value can be implemented as a shadow register (in this example, called SOFV), which lags the FRINDEX register bits [13:3] by one micro-frame count. This lag behavior can be accomplished by incrementing FRINDEX[13:3] based on carry-out on the 7 to 0 increment of FRINDEX[2:0] and incrementing SOFV based on the transition of 0 to 1 of FRINDEX[2:0].

Software is allowed to write to FRINDEX. FRINDEX provides the requirements that software should adhere when writing a new value in FRINDEX.

The table below illustrates the required relationship between the value of FRINDEX and the value of SOFV.

Table 62-41. Operation of FRINDEX and SOFV (SOF Value Register)

Current			Next		
FRINDEX[F]	SOFV	FRINDEX[mF]	FRINDEX[F]	SOFV	FRINDEX[mF]
N	N	111b	N+1	N	000b
N+1	N	000b	N+1	N+1	001b
N+1	N+1	001b	N+1	N+1	010b
N+1	N+1	010b	N+1	N+1	011b
N+1	N+1	011b	N+1	N+1	100b
N+1	N+1	100b	N+1	N+1	101b
N+1	N+1	101b	N+1	N+1	110b
N+1	N+1	110b	N+1	N+1	111b

NOTE

Where [F] = [13:3]; [μF] = [2:0]

62.5.3.6 Periodic Schedule

The periodic schedule traversal is enabled or disabled through the Periodic Schedule Enable bit in the USB_USBCMD register. If the Periodic Schedule Enable bit is set to zero, then the host controller simply does not try to access the periodic frame list through the USB_PERIODICLISTBASE register. Likewise, when the Periodic Schedule Enable bit is one, then the host controller does use the USB_PERIODICLISTBASE register to traverse the periodic schedule.

The host controller will not react to modifications to the Periodic Schedule Enable immediately. In order to eliminate conflicts with split transactions, the host controller evaluates the Periodic Schedule Enable bit only when FRINDEX[2:0] is zero. System software must not disable the periodic schedule if the schedule contains an active split transaction work item that spans the 000b micro-frame. These work items must be removed from the schedule before the Periodic Schedule Enable bit is written to zero.

The Periodic Schedule Status bit in the USB_USBSTS register indicates status of the periodic schedule. System software enables (or disables) the periodic schedule by writing one (or zero) to the Periodic Schedule Enable bit in the USB_USBCMD register. Software then can poll the Periodic Schedule Status bit to determine when the periodic schedule has made the desired transition. Software must not modify the Periodic Schedule Enable bit unless the value of the Periodic Schedule Enable bit equals that of the Periodic Schedule Status bit.

The periodic schedule is used to manage all isochronous and interrupt transfer streams. The base of the periodic schedule is the periodic frame list. Software links schedule data structures to the periodic frame list to produce a graph of scheduled data structures. The graph represents an appropriate sequence of transactions.

The following figure illustrates isochronous transfers (using iTDs and siTDs) with a period of one are linked directly to the periodic frame list. Interrupt transfers (are managed with queue heads) and isochronous streams with periods other than one are linked following the period-one iTD/siTDs. Interrupt queue heads are linked into the frame list ordered by poll rate. Longer poll rates are linked first (for example, closest to the periodic frame list), followed by shorter poll rates, with queue heads with a poll rate of one, on the very end.

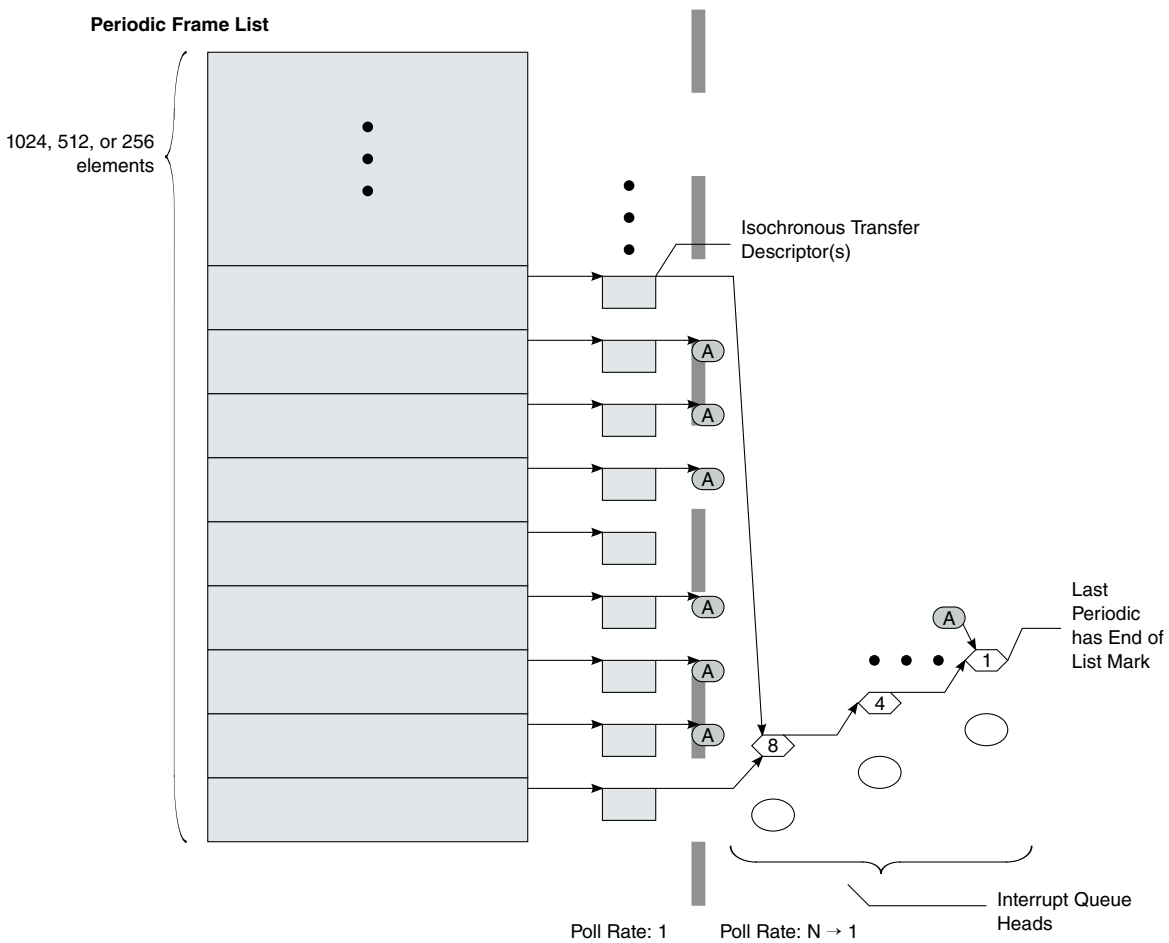

Figure 62-12. Example Periodic Schedule

62.5.3.7 Managing Isochronous Transfers Using iTDs

The structure of an iTD is presented in Isochronous (High-Speed) Transfer Descriptor (iTD). The four distinct sections to an iTD:

- The first field is the Next Link Pointer. This field is for schedule linkage purposes only.
- Transaction description array. This area is an eight-element array. Each element represents control and status information for one micro-frame's worth of transactions for a single high-speed isochronous endpoint.
- The buffer page pointer array is a 7-element array of physical memory pointers to data buffers. These are 4 K aligned pointers to physical memory.
- Endpoint capabilities. This area utilizes the unused low-order 12 bits of the buffer page pointer array. The fields in this area are used across all transactions executed for this iTD, including endpoint addressing, transfer direction, maximum packet size and high-bandwidth multiplier.

62.5.3.7.1 Host Controller Operational Model for iTDs

The host controller uses FRINDEX register bits [12:3] to index into the periodic frame list. This means that the host controller visits each frame list element eight consecutive times before incrementing to the next periodic frame list element. Each iTD contains eight transaction descriptions, which map directly to FRINDEX register bits [2:0]. Therefore, each transaction descriptor corresponds to one micro-frame. Each iTD can span 8 micro-frames worth of transactions.

When the host controller fetches an iTD, it uses FRINDEX register bits [2:0] to index into the transaction description array.

If the active bit in the Status field of the indexed transaction description is set to zero, the host controller ignores the iTD and follows the Next pointer to the next schedule data structure.

When the indexed active bit is one, the host controller continues to parse the iTD. It stores the indexed transaction description and the general endpoint information (device address, endpoint number, maximum packet size, and so on.). It also uses the Page Select (PG) field to index the buffer pointer array, storing the selected buffer pointer and the next sequential buffer pointer. For example, if PG field is 0, then the host controller stores Page 0 and Page 1.

The host controller constructs a physical data buffer address by concatenating the current buffer pointer (as selected using the current transaction description's PG field) and the transaction description's Transaction Offset field. The host controller uses the endpoint addressing information and I/O-bit to execute a transaction to the appropriate endpoint.

When the transaction is complete, the host controller clears the active bit and writes back any additional status information to the Status field in the currently selected transaction description.

The data buffer associated with the iTD must be virtually contiguous memory. Seven page pointers are provided to support eight high-bandwidth transactions regardless of the starting packet's offset alignment into the first page. A starting buffer pointer (physical memory address) is constructed by concatenating the page pointer (for example, page 0 pointer) selected by the active transaction descriptions' PG (for example, value: 00B) field with the transaction offset field. As the transaction moves data, the host controller must detect when an increment of the current buffer pointer crosses a page boundary. When this occurs the host controller simply replaces the current buffer pointer's page portion with the next page pointer (for example, page 1 pointer) and continues to move data. The size of each bus transaction is determined by the value in the Maximum Packet Size field. An iTD supports high-bandwidth pipes through the Mult (multiplier) field. When the Mult field is 1, 2, or 3, the host controller executes the specified number of Maximum Packet sized bus transactions for the endpoint in the current micro-frame. In other words, the Mult field represents a transaction count for the endpoint in the current micro-frame. If the Mult field is zero, the operation of the host controller is undefined. The transfer description is used to service all transactions indicated by the Mult field.

For OUT transfers, the value of the Transaction X Length field represents the total bytes to be sent during the micro-frame. The Mult field must be set by software to be consistent with Transaction X Length and Maximum Packet Sixe. The host controller sends the bytes in Maximum Packet Size'd portions. After each transaction, the host controller decrements its local copy of Transaction X Length by Maximum Packet Size. The number of bytes the host controller sends is always Maximum Packet Size or Transaction X Length, whichever is less. The host controller advances the transfer state in the transfer description, updates the appropriate record in the iTD and moves to the next schedule data structure. The maximum sized transaction supported is 3 x 1024 bytes.

For IN transfers, the host controller issues Mult transactions. It is assumed that software has properly initialized the iTD to accommodate all of the possible data. During each IN transaction, the host controller must use Maximum Packet Size to detect packet babble errors. The host controller keeps the sum of bytes received in the Transaction X Length field. After all transactions for the endpoint have completed for the micro-frame, Transaction X Length contains the total bytes received. If the final value of Transaction X Length is less than the value of Maximum Packet Size, then less data than was allowed for was received from the associated endpoint. This short packet condition does not set the USBINT bit in the USB_USBSTS register to one. The host controller will not detect this condition. If the device sends more than Transaction X Length or Maximum Packet Size bytes (whichever is less), then the host controller sets the Babble Detected bit to one and set the Active bit to zero. Note, that the host controller is not required to update the

iTD field Transaction X Length in this error scenario. If the Mult field is greater than one, then the host controller automatically executes the value of Mult transactions. The host controller will not execute all Mult transactions if:

- The endpoint is an OUT and Transaction X Length goes to zero before all the Mult transactions have executed (ran out of data), or
- The endpoint is an IN and the endpoint delivers a short packet, or an error occurs on a transaction before Mult transactions have been executed. The end of micro-frame may occur before all of the transaction opportunities have been executed. When this happens, the transfer state of the transfer description is advanced to reflect the progress that was made, the result written back to the iTD and the host controller proceeds to processing the next micro-frame. Refer to Appendix D for a table summary of the host controller required behavior for all the high-bandwidth transaction cases.

62.5.3.7.2 Software Operational Model for iTDs

A client buffer request to an isochronous endpoint may span 1 to N micro-frames. When N is larger than one, system software may have to use multiple iTDs to read or write data with the buffer (if N is larger than eight, it must use more than one iTD).

The following figure illustrates the simple model of how a client buffer is mapped by system software to the periodic schedule (that is the periodic frame list and a set of iTDs). On the right is the client description of its request. The description includes a buffer base address plus additional annotations to identify which portions of the buffer should be used with each bus transaction. In the middle is the iTD data structures used by the system software to service the client request. Each iTD can be initialized to service up to 24 transactions, organized into eight groups of up to three transactions each. Each group maps to one micro-frame's worth of transactions. The EHCI controller does not provide per-transaction results within a micro-frame. It treats the per-micro-frame transactions as a single logical transfer. On the left is the host controller's frame list. System software establishes references from the appropriate locations in the frame list to each of the appropriate iTDs. If the buffer is large, then system software can use a small set of iTDs to service the entire buffer. System software can activate the transaction description records (contained in each iTD) in any pattern required for the particular data stream.

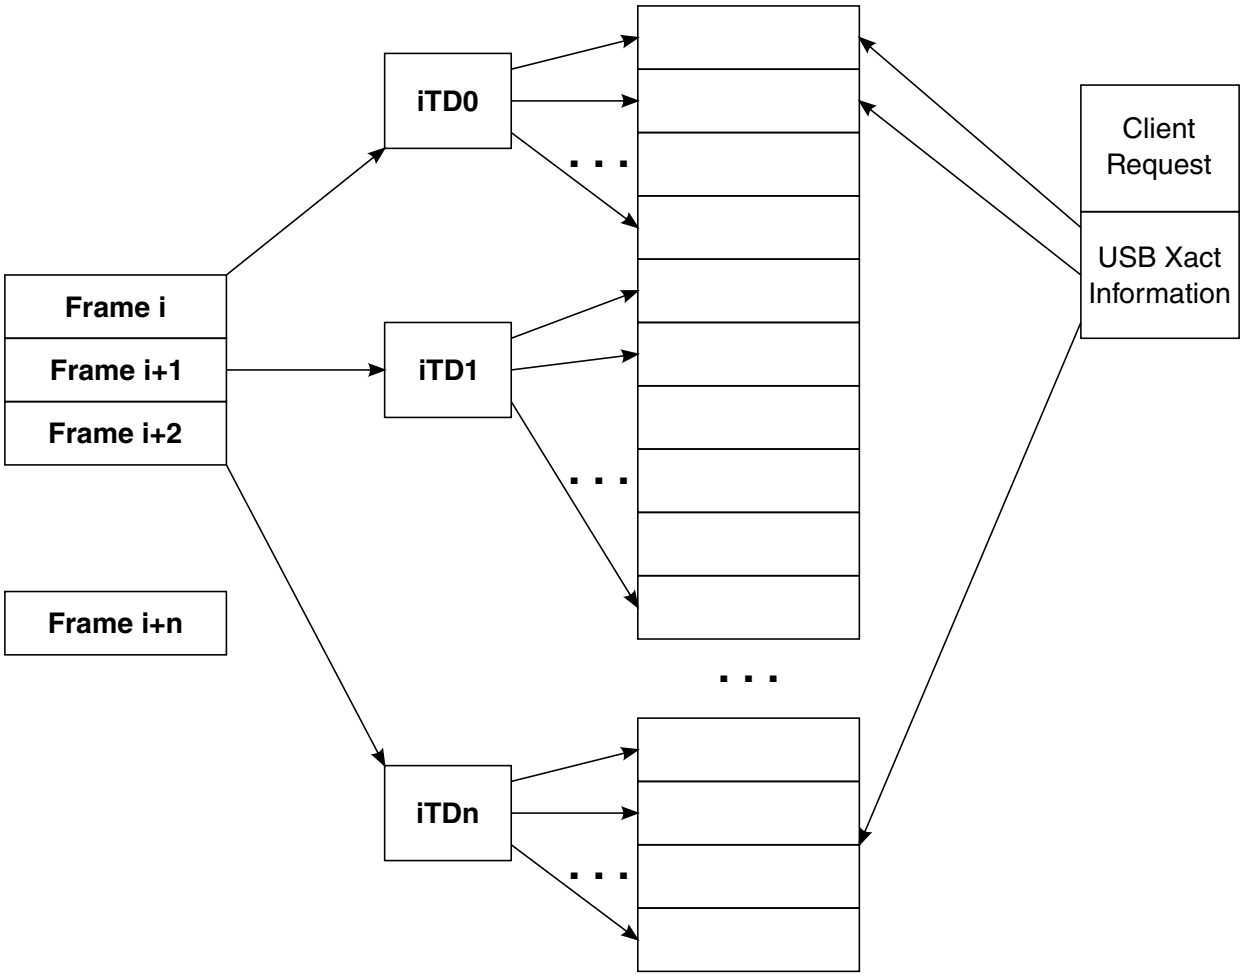

Figure 62-13. Example Association of iTDs to Client Request Buffer

As noted above, the client request includes a pointer to the base of the buffer and offsets into the buffer to annotate which buffer sections are to be used on each bus transaction that occurs on this endpoint. System software must initialize each transaction description in an iTD to ensure it uses the correct portion of the client buffer. For example, for each transaction description, the PG field is set to index the correct physical buffer page pointer and the Transaction Offset field is set relative to the correct buffer pointer page (for example, the same one referenced by the PG field). When the host controller executes a transaction it selects a transaction description record based on FRINDEX[2:0]. It then uses the current Page Buffer Pointer (as selected by the PG field) and concatenates to the transaction offset field. The result is a starting buffer address for the transaction. As the host controller moves data for the transaction, it must watch for a page wrap condition and properly advance to the next available Page Buffer Pointer. System software must not use the Page 6 buffer pointer in a transaction description where the length of the transfer wraps a page boundary. Doing so yields undefined behavior. The host controller hardware is not required to 'alias' the page selector to Page zero. USB 2.0 isochronous

endpoints can specify a period greater than one. Software can achieve the appropriate scheduling by linking iTDs into the appropriate frames (relative to the frame list) and by setting appropriate transaction description elements active bits to one.

62.5.3.7.2.1 Periodic scheduling threshold

The Isochronous Scheduling Threshold field in the USB_HCCPARAMS capability register is an indicator to system software as to how the host controller pre-fetches and effectively caches schedule data structures.

It is used by system software when adding isochronous work items to the periodic schedule. The value of this field indicates to system software the minimum distance it can update isochronous data (relative to the current location of the host controller execution in the periodic list) and still have the host controller process them.

The iTD and siTD data structures each describe 8 micro-frames worth of transactions. The host controller is allowed to cache one (or more) of these data structures in order to reduce memory traffic. Three basic caching models that account for the fact the isochronous data structures span 8 micro-frames. The three caching models are: no caching, micro-frame caching and frame caching.

When software is adding new isochronous transactions to the schedule, it always performs a read of the USB_FRINDEX register to determine the current frame and micro-frame the host controller is currently executing. Of course, there is no information about where in the micro-frame the host controller is, so a constant uncertainty-factor of one micro-frame has to be assumed. Combining the knowledge of where the host controller is executing with the knowledge of the caching model allows the definition of simple algorithms for how closely software can reliably work to the executing host controller.

No caching is indicated with a value of zero in the Isochronous Scheduling Threshold field. The host controller may pre-fetch data structures during a periodic schedule traversal (per micro-frame) but always dumps any accumulated schedule state at the end of the micro-frame. At the appropriate time relative to the beginning of every micro-frame, the host controller always begins schedule traversal from the frame list. Software can use the value of the USB_FRINDEX register (plus the constant 1 uncertainty-factor) to determine the approximate position of the executing host controller. When no caching is selected, software can add an isochronous transaction as near as 2 micro-frames in front of the current executing position of the host controller.

Frame caching is indicated with a non-zero value in bit [7] of the Isochronous Scheduling Threshold field. In the frame-caching model, system software assumes that the host controller caches one (or more) isochronous data structures for an entire frame (8 micro-frames). Software uses the value of the USB_FRINDEX register (plus the constant 1

uncertainty) to determine the current micro-frame/frame (assume modulo 8 arithmetic in adding the constant 1 to the micro-frame number). For any current frame N, if the current micro-frame is 0 to 6, then software can safely add isochronous transactions to Frame N + 1. If the current micro-frame is 7, then software can add isochronous transactions to Frame N + 2.

Micro-frame caching is indicated with a non-zero value in the least-significant 3 bits of the Isochronous Scheduling Threshold field. System software assumes the host controller caches one or more periodic data structures for the number of micro-frames indicated in the Isochronous Scheduling Threshold field. For example, if the count value were 2, then the host controller keeps a window of 2 micro-frames worth of state (current micro-frame, plus the next) on-chip. On each micro-frame boundary, the host controller releases the current micro-frame state and begins accumulating the next micro-frame state.

62.5.3.8 Asynchronous Schedule

The Asynchronous schedule traversal is enabled or disabled through the Asynchronous Schedule Enable bit in the USB_USBCMD register.

If the Asynchronous Schedule Enable bit is set to zero, then the host controller simply does not try to access the asynchronous schedule through the USB_ASYNCLISTADDR register. Likewise, when the Asynchronous Schedule Enable bit is one, then the host controller does use the USB_ASYNCLISTADDR register to traverse the asynchronous schedule. Modifications to the Asynchronous Schedule Enable bit are not necessarily immediate. Rather the new value of the bit is taken into consideration the next time the host controller needs to use the value of the USB_ASYNCLISTADDR register to get the next queue head.

The Asynchronous Schedule Status bit in the USB_USBSTS register indicates status of the asynchronous schedule. System software enables (or disables) the asynchronous schedule by writing one (or zero) to the Asynchronous Schedule Enable bit in the USB_USBCMD register. Software then can poll the Asynchronous Schedule Status bit to determine when the asynchronous schedule has made the desired transition. Software must not modify the Asynchronous Schedule Enable bit unless the value of the Asynchronous Schedule Enable bit equals that of the Asynchronous Schedule Status bit.

The asynchronous schedule is used to manage all Control and Bulk transfers. Control and Bulk transfers are managed using queue head data structures. The asynchronous schedule is based at the USB_ASYNCLISTADDR register. The default value of the USB_ASYNCLISTADDR register after reset is undefined and the schedule is disabled when the Asynchronous Schedule Enable bit is zero.

Software may only write this register with defined results when the schedule is disabled. For example, Asynchronous Schedule Enable bit in the USB_USBCMD and the Asynchronous Schedule Status bit in the USB_USBSTS register are zero. System software enables execution from the asynchronous schedule by writing a valid memory address (of a queue head) into this register. Then software enables the asynchronous schedule by setting the Asynchronous Schedule Enable bit to one. The asynchronous schedule is actually enabled when the Asynchronous Schedule Status bit is one.

When the host controller begins servicing the asynchronous schedule, it begins by using the value of the USB_ASYNCLISTADDR register. It reads the first referenced data structure and begins executing transactions and traversing the linked list as appropriate. When the host controller completes processing the asynchronous schedule, it retains the value of the last accessed queue head's horizontal pointer in the USB_ASYNCLISTADDR register. Next time the asynchronous schedule is accessed, this is the first data structure that is serviced. This provides round-robin fairness for processing the asynchronous schedule.

A host controller completes processing the asynchronous schedule when one of the following events occur:

- The end of a micro-frame occurs.
- The host controller detects an empty list condition (see Empty Asynchronous Schedule Detection)
- The schedule has been disabled through the Asynchronous Schedule Enable bit in the USB_USBCMD register.

The queue heads in the asynchronous list are linked into a simple circular list as shown in Figure 62-8. Queue head data structures are the only valid data structures that may be linked into the asynchronous schedule. An isochronous transfer descriptor (iTD or siTD) in the asynchronous schedule yields undefined results.

The maximum packet size field in a queue head is sized to accommodate the use of this data structure for all non-isochronous transfer types. The USB Specification, Revision 2.0 specifies the maximum packet sizes for all transfer types and transfer speeds. System software should always parameterize the queue head data structures according to the core specification requirements.

62.5.3.8.1 Adding Queue Heads to Asynchronous Schedule

This is a software requirement section.

There are two independent events for adding queue heads to the asynchronous schedule. The first is the initial activation of the asynchronous list. The second is inserting a new queue head into an activated asynchronous list.

Activation of the list is simple. System software writes the physical memory address of a queue head into the USB_ASYNCLISTADDR register, then enables the list by setting the Asynchronous Schedule Enable bit in the USB_USBCMD register to one.

When inserting a queue head into an active list, software must ensure that the schedule is always coherent from the host controllers' point of view. This means that the system software must ensure that all queue head pointer fields are valid. For example, qTD pointers have T-Bits set to one or reference valid qTDs and the Horizontal Pointer references a valid queue head data structure. The following algorithm represents the functional requirements:

```
InsertQueueHead (pQHeadCurrent, pQueueHeadNew)
          --
          -- Requirement: all inputs must be properly initialized.
          --
          -- pQHeadCurrent is a pointer to a queue head that is
          -- already in the active list
          -- pQHeadNew is a pointer to the queue head to be added
          --
          -- This algorithm links a new queue head into a existing
          -- list
          --
          pQueueHeadNew.HorizontalPointer  =  pQueueHeadCurrent.HorizontalPointer
          pQueueHeadCurrent.HorizontalPointer =  physicalAddressOf(pQueueHeadNew)
End InsertQueueHead
```

62.5.3.8.2 Removing Queue Heads from Asynchronous Schedule

This is a software requirement section.

There are two independent events for removing queue heads from the asynchronous schedule. The first is shutting down (deactivating) the asynchronous list. The second is extracting a single queue head from an activated list.

Software deactivates the asynchronous schedule by setting the Asynchronous Schedule Enable bit in the USB_USBCMD register to zero. Software can determine when the list is idle when the Asynchronous Schedule Status bit in the USB_USBSTS register is zero. The normal mode of operation is that software removes queue heads from the asynchronous schedule without shutting it down. Software must not remove an active queue head from the schedule. Software should first deactivate all active qTDs, wait for the queue head to go inactive, then remove the queue head from the asynchronous list. Software removes a queue head from the asynchronous list through the following algorithm. As illustrated, the unlinking is quite easy. Software merely must ensure all of the link pointers reachable by the host controller are kept consistent.

```
UnlinkQueueHead (pQHeadPrevious, pQueueHeadToUnlink, pQHeadNext)
          --
          -- Requirement: all inputs must be properly initialized.
          --
          -- pQHeadPrevious is a pointer to a queue head that
          -- references the queue head to remove
          -- pQHeadToUnlink is a pointer to the queue head to be
```

```
        -- removed
        -- pQheadNext is a pointer to a queue head still in the
        -- schedule. Software provides this pointer with the
        -- following strict rules:
        --          if the host software is one queue head, then
        --          pQHeadNext must be the same as
        --          QueueheadToUnlink.HorizontalPointer. If the host
        --          software is unlinking a consecutive series of
        --          queue heads, QHeadNext must be set by software to
        --          the  queue head remaining in the schedule.
        --
        -- This algorithm unlinks a queue head from a circular list
        --
        pQueueHeadPrevious.HorizontalPointer =  pQueueHeadToUnlink.HorizontalPointer
                            pQueueHeadToUnlink.HorizontalPointer = pQHeadNext
End UnlinkQueueHead
```

If software removes the queue head with the H-bit set to one, it must select another queue head still linked into the schedule and set its H-bit to one. This should be completed before removing the queue head. The requirement is that software keep one queue head in the asynchronous schedule, with its H-bit set to one. At the point software has removed one or more queue heads from the asynchronous schedule, it is unknown whether the host controller has a cached pointer to them. Similarly, it is unknown how long the host controller might retain the cached information, as it is implementation dependent and may be affected by the actual dynamics of the schedule load. Therefore, once software has removed a queue head from the asynchronous list, it must retain the coherency of the queue head (link pointers, and so on). It cannot disturb the removed queue heads until it knows that the host controller does not have a local copy of a pointer to any of the removed data structures.

The method software uses to determine when it is safe to modify a removed queue head is to handshake with the host controller. The handshake mechanism allows software to remove items from the asynchronous schedule, then execute a simple, lightweight handshake that is used by software as a key that it can free (or reuse) the memory associated the data structures it has removed from the asynchronous schedule.

The handshake is implemented with three bits in the host controller. The first bit is a command bit (Interrupt on Async Advance Doorbell bit in the USB_USBCMD register) that allows software to inform the host controller that something has been removed from its asynchronous schedule. The second bit is a status bit (Interrupt on Async Advance bit in the USB_USBSTS register) that the host controller sets after it has released all on-chip state that may potentially reference one of the data structures just removed. When the host controller sets this status bit to one, it also sets the command bit to zero. The third bit is an interrupt enable (Interrupt on Async Advance bit in the USB_USBINTR register) that is matched with the status bit. If the status bit is one and the interrupt enable bit is one, then the host controller asserts a hardware interrupt.

The figure below illustrates a general example. In this example, consecutive queue heads (B and C) are unlinked from the schedule using the algorithm above. Before the unlink operation, the host controller has a copy of queue head A.

The unlink algorithm requires that as software unlinks each queue head, the unlinked queue head is loaded with the address of a queue head that remains in the asynchronous schedule.

When the host controller observes that doorbell bit being set to one, it makes a note of the local reachable schedule information. In this example, the local reachable schedule information includes both queue heads (A and B). It is sufficient that the host controller can set the status bit (and clear the doorbell bit) as soon as it has traversed beyond current reachable schedule information (that is traversed beyond queue head (B) in this example). The following figure illustrates the generic queue head unlink scenario.

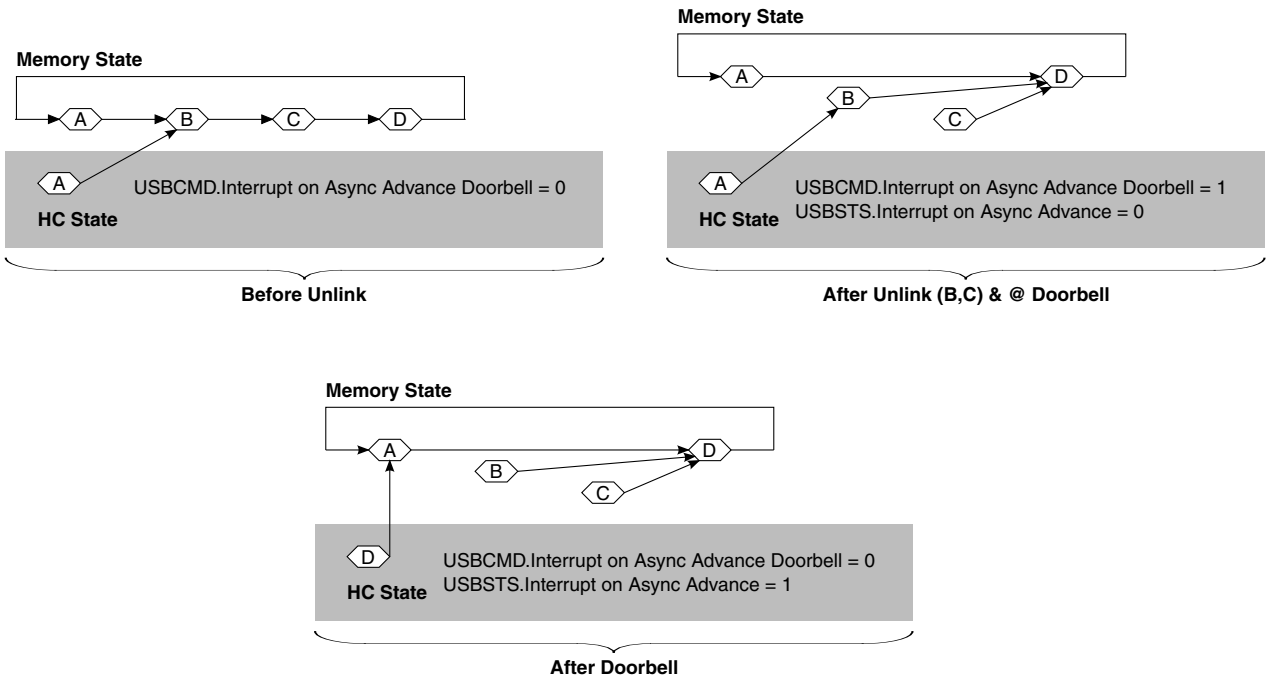

Figure 62-14. Generic Queue Head Unlink Scenario

Alternatively, a host controller implementation is allowed to traverse the entire asynchronous schedule list (for example, observed the head of the queue (twice)) before setting the Advance on Async status bit to one.

Software may re-use the memory associated with the removed queue heads after it observes the Interrupt on Async Advance status bit is set to one, following assertion of the doorbell. Software should acknowledge the Interrupt on Async Advance status as indicated in the USB_USBSTS register, before using the doorbell handshake again.

62.5.3.8.3 Empty Asynchronous Schedule Detection

The Enhanced Host Controller Interface uses two bits to detect when the asynchronous schedule is empty.

The queue head data structure (see Queue Head) defines an *H-bit* in the queue head, which allows software to mark a queue head as being the *head* of the reclaim list. The Enhanced Host Controller Interface also keeps a 1-bit flag in the USB_USBSTS register (*Reclamation*) that is set to zero when the Enhanced Interface Host Controller observes a queue head with the H-bit set to one. The reclamation flag in the status register is set to one when any USB transaction from the asynchronous schedule is executed (or whenever the asynchronous schedule starts, see Asynchronous schedule traversal: *Start Event*).

If the Enhanced Host Controller Interface ever encounters an *H-bit* of one and a *Reclamation* bit of zero, the EHCI controller simply stops traversal of the asynchronous schedule.

An example illustrating the H-bit in a schedule is shown in the following figure.

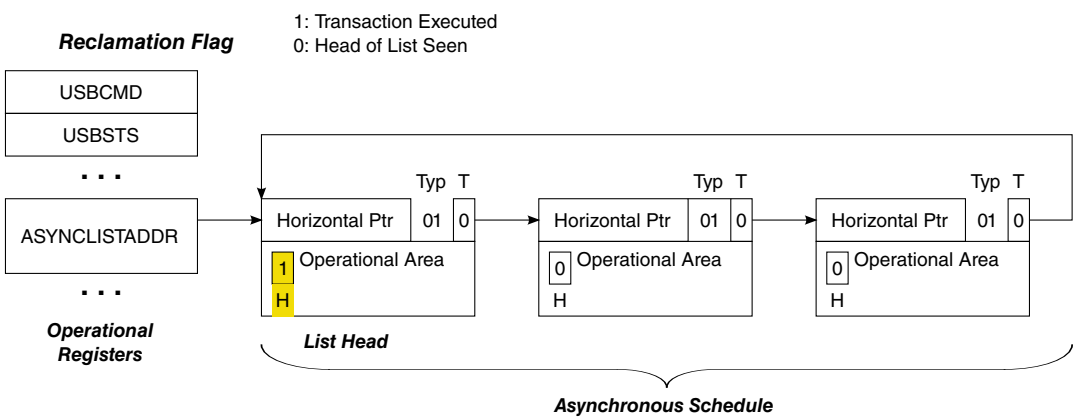

Figure 62-15. Asynchronous Schedule List w/Annotation to Mark Head of List

Software must ensure there is at most one queue head with the *H-bit* set to one, and that it is always coherent with respect to the schedule.

62.5.3.8.4 Restarting Asynchronous Schedule Before EOF

There are many situations where the host controller will detect an empty list *long* before the end of the micro-frame.

It is important to remember that under many circumstances the schedule traversal has stopped due to Nak/Nyet responses from all endpoints.

An example of particular interest is when a start-split for a bulk endpoint occurs early in the micro-frame. Given the EHCI simple traversal rules, the complete-split for that transaction may Nak/Nyet out very quickly. If it is the only item in the schedule, then the host controller ceases traversal of the Asynchronous schedule very early in the micro-frame. In order to provide reasonable service to this endpoint, the host controller should issue the complete-split before the end of the current micro-frame, instead of waiting

until the next micro-frame. When the reason for host controller idling asynchronous schedule traversal is because of empty list detection, it is mandatory the host controller implement a 'waking' method to resume traversal of the asynchronous schedule. An example method is described below.

62.5.3.8.4.1 Example Method for Restarting Asynchronous Schedule Traversal

The reason for idling the host controller when the list is empty is to keep the host controller from unnecessarily occupying too much memory bandwidth. The question is: *how long should the host controller stay idle before restarting*?

The answer in this example is based on deriving a manifest constant, which is the amount of time the host controller will stay idle before restarting traversal. In this example, the manifest constant is called *AsyncSchedSleepTime*, and has a value of 10 µsec. The value is derived based on the analysis in Example Derivation for *AsyncSchedSleepTime*, The traversal algorithm is simple:

- Traverse the Asynchronous schedule until the either an End-Of-micro-Frame event occurs, or an empty list is detected. If the event is an End-of-micro-Frame, go attempt to traverse the Periodic schedule. If the event is an empty list, then set a sleep timer and go to a *schedule sleep* state.
- When the sleep timer expires, set working context to the Asynchronous Schedule start condition and go to *schedule active* state. The start context allows the HC to reload *Nakcnt* fields, and so on. So the HC has a chance to run for more than one iteration through the schedule.

This process simply repeats itself each micro-frame. The figure below illustrates a sample state machine to manage the active and sleep states of the Asynchronous Schedule traversal policy. There are three states: Actively traversing the Asynchronous schedule, Sleeping, and Not Active. The last two are similar in terms of interaction with the Asynchronous schedule, but the Not Active state means that the host controller is busy with the Periodic schedule or the Asynchronous schedule is not enabled. The Sleeping state is specifically a special state where the host controller is just waiting for a period of time before resuming execution of the Asynchronous schedule.

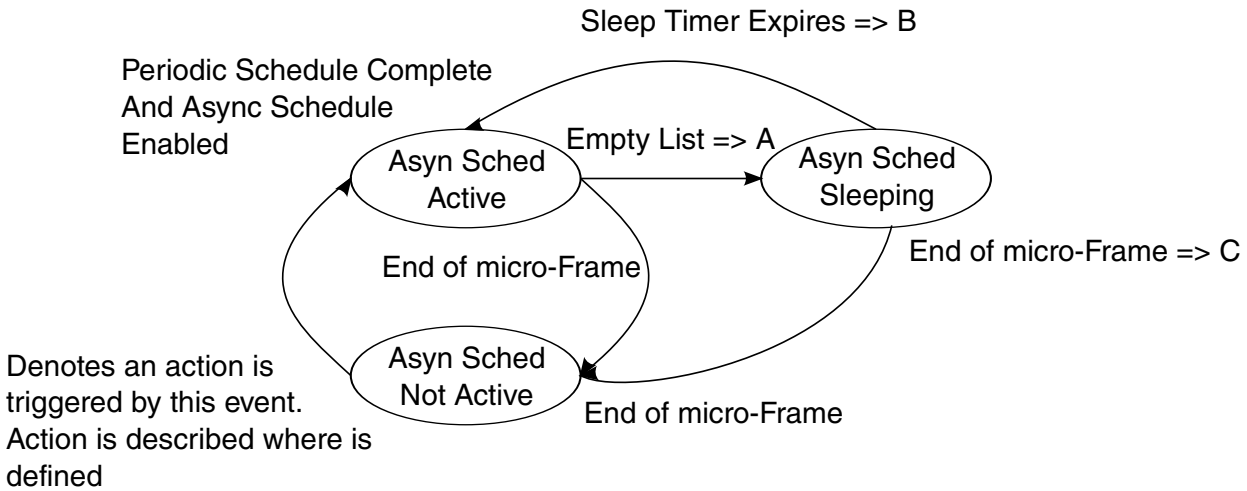

Figure 62-16. Example State Machine for Managing Asynchronous Schedule Traversal

The actions referred to in the figure above are defined in the following table.

Table 62-42. Asynchronous Schedule SM Transition Actions

Action	Action Description Label
A	On detection of the empty list, the host controller sets the *AsynchronousTraversalSleepTimer* to *AsyncSchedSleepTime*.
B	When the *AsynchronousTraversalSleepTimer* expires, the host controller sets the *Reclamation* bit in the USBSTS register to one and moves the Nak Counter reload state machine to WaitForListHead (see Nak Count Reload Control).
C	The host controller cancels the sleep timer (*AsynchronousTraversalSleepTimer*).

62.5.3.8.4.2 Async Sched Not Active

This is the initial state of the traversal state machine after a host controller reset. The traversal state machine does not leave this state when the *Asynchronous Schedule Enable* bit in the USB_USBCMD register is zero.

This state is entered from Async Sched Active or Async Sched Sleeping states when the end-of-micro-frame event is detected.

62.5.3.8.4.3 Async Sched Active

This state is entered from the Async Sched Not Active state when the periodic schedule is not active. It is also entered from the Async Sched Sleeping states when the *AsyncrhonousTraversalSleepTimer* expires. On every transition into this state, the host controller sets the *Reclamation* bit in the USB_USBSTS register to one.

While in this state, the host controller continually traverses the asynchronous schedule until either the end of micro-frame or an empty list condition is detected.

62.5.3.8.4.4 Async Sched Sleeping

The state is entered from the Async Sched Active state when a schedule empty condition is detected. On entry to this state, the host controller sets the *AsynchronousTraversalSleepTimer* to *AsyncSchedSleepTime*.

62.5.3.8.4.5 Example Derivation for *AsyncSchedSleepTime*

The derivation is based on analysis of what work the host controller could be doing next.

It assumes the host controller does not keep any state about what work is possibly pending in the asynchronous schedule. The schedule could contain any mix of the possible combinations of high- full- or low-speed control and bulk requests.

The table below summarizes some of the typical 'next transactions' that could be in the schedule, and the amount of time (for example *footprint*, or *wall clock*) the transaction takes to complete.

Table 62-43. Typical Low-/Full-speed Transaction Times

Transaction Attributes		Footprint (time)	Description
Speed	HS	11.9 ms	Maximum foot print for a worst-case, full-sized bulk data transaction.
Size	512	9.45 ms	Maximum footprint for an approximate best-case, full-sized bulk data transaction.
Type	Bulk		
Speed	FS	~50 ms	Approximate typical for full-sized bulk data. An 8-byte low-speed is about 2x, or between 90 and 100 ms.
Size	64		
Type	Bulk		
Speed	FS	~12 ms	Approximate typical for 8-byte bulk/control (that is setup)
Size	8		
Type	Cntrl		

A *AsyncSchedSleepTime* value of 10 µs provides a reasonable relaxation of the system memory load and still provides a good level of service for the various transfer types and payload sizes. For example, say we detect an empty list after issuing a start-split for a 64-byte full-speed bulk request. Assuming this is the only thing in the list, the host controller gets the results of the full-speed transaction from the hub during the fifth complete-split request. If the full-speed transaction was an IN and it nak'd, the 10 µs sleep period would allow the host controller to get the NAK results on the first complete-split.

62.5.3.8.5 Asynchronous schedule traversal: *Start Event*

Once the HC has *idled* itself through the empty schedule detection (Section 0), it will naturally *activate* and begin processing from the Periodic Schedule at the beginning of each micro-frame.

In addition, it may have idled itself early in a micro-frame. When this occurs (idles early in the micro-frame) the HC must occasionally *re-activate* during the micro-frame and traverse the asynchronous schedule to determine whether any progress can be made. The requirements and method for this restart are described in Restarting Asynchronous Schedule Before EOF . Asynchronous schedule *Start Event*s are defined to be:

- Whenever the host controller transitions from the periodic schedule to the asynchronous schedule. If the periodic schedule is disabled and the asynchronous schedule is enabled, then the beginning of the micro-frame is equivalent to the transition from the periodic schedule, or
- The asynchronous schedule traversal restarts from a sleeping state (see Restarting Asynchronous Schedule Before EOF).

62.5.3.8.6 Reclamation Status Bit (USBSTS Register)

The operation of the empty asynchronous schedule detection feature (see Empty Asynchronous Schedule Detection) depends on the proper management of the *Reclamation* bit in the USB_USBSTS register. The host controller tests for an empty schedule just after it fetches a new queue head while traversing the asynchronous schedule (see Fetch Queue Head).

The host controller is required to set the *Reclamation* bit to one whenever an asynchronous schedule traversal *Start Event*, as documented in Asynchronous schedule traversal: *Start Event*, occurs. The *Reclamation* bit is also set to one whenever the host controller executes a transaction while traversing the asynchronous schedule (see Execute Transaction). The host controller sets the *Reclamation* bit to zero whenever it finds a queue head with its *H-bit* set to one. Software should only set a queue head's *H-bit* if the queue head is in the asynchronous schedule. If software sets the *H-bit* in an interrupt queue head to one, the resulting behavior is undefined. The host controller may set the *Reclamation* bit to zero when executing from the periodic schedule.

62.5.3.9 Operational Model for Nak Counter

This section describes the operational model for the *NakCnt* field defined in a queue head.

See Queue Head Initialization for more information. Software should not use this feature for interrupt queue heads. This rule is not required to be enforced by the host controller.

USB protocol has built-in flow control through the Nak response by a device. There are several scenarios, beyond the Ping feature, where an endpoint may naturally Nak or Nyet the majority of the time. An example is the host controller management of the split transaction protocol for control and bulk endpoints. All bulk endpoints (High- or Full-speed) are serviced through the same asynchronous schedule. The time between the *Start-split* transaction and the first *Complete-split* transaction could be very short (that is like when the endpoint is the only one in the asynchronous schedule). The hub NYETs (effectively Naks) the *Complete-split* transaction until the classic transaction is complete. This could result in the host controller thrashing memory, repeatedly fetching the queue head and executing the transaction to the Hub, which does not complete until after the transaction on the classic bus completes.

The two component fields in a queue head to support the throttling feature: a counter field (*NakCnt*), and a counter reload field (*RL*). *NakCnt* is used by the host controller as one of the criteria to determine whether or not to execute a transaction to the endpoint. The two operational modes associated with this counter:

- Not Used- This mode is set when the *RL* field is zero. The host controller ignores the *NakCnt* field for any execution of transactions through a queue head with an *RL* field of zero. Software must use this selection for interrupt endpoints.
- Nak Throttle Mode- This mode is selected when the *RL* field is non-zero. In this mode, the value in the *NakCnt* field represents the maximum number of Nak or Nyet responses the host controller tolerates on each endpoint. In this mode, the HC decrements the *NakCnt* field based on the token/handshake criteria listed in the table below. The host controller must reload *NakCnt* when the endpoint successfully moves data (for example, policy to reward device for moving data).

The following table describes the NakCnt field adjustment rules.

Table 62-44. NakCnt Field Adjustment Rules

Token	Handshake	
	Handshake NAK	NYET
IN/PING	decrement *NakCnt*	N/A (protocol error)
OUT	decrement *NakCnt*	No Action[1] Start
Split	decrement *NakCnt*	N/A (protocol error)
Complete Split	No Action	Decrement *NakCnt*

1. Recommended behavior on this response is to reload *NakCnt*

In summary, system software enables the counter by setting the reload field (*RL*) to a non-zero value. The host controller may execute a transaction if *NakCnt* is non-zero. The host controller does not execute a transaction if *NakCnt* is zero. The reload mechanism is described in detail in Nak Count Reload Control .

NOTE

When all queue heads in the Asynchronous Schedule either exhausts all transfers or all NakCnt's go to zero, then the host controller detects an empty Asynchronous Schedule and idle schedule traversal (see Empty Asynchronous Schedule Detection).

Any time the host controller begins a new traversal of the Asynchronous Schedule, a *Start Event* is assumed, see Asynchronous schedule traversal: *Start Event*. Every time a Start-Event occurs, the Nak Count reload procedure is enabled.

62.5.3.9.1 Nak Count Reload Control

When the host controller reaches the *Execute Transaction* state for a queue head (meaning that it has an active operational state), it checks to determine whether the *NakCnt* field should be reloaded from *RL* (see Execute Transaction). If the answer is yes, then *RL* is copied into *NakCnt*. After the reload or if the reload is not active, the host controller evaluates whether to execute the transaction.

The host controller must reload nak counters (*NakCnt* see Queue Head) in queue heads during the first pass through the reclamation list after an asynchronous schedule Start Event (see Asynchronous schedule traversal: *Start Event* for the definition of the Start Event). The Asynchronous Schedule should have at most one queue head marked as the head (see Figure 62-15).

The following figure illustrates an example state machine that satisfies the operational requirements of the host controller detecting the first pass through the Asynchronous Schedule. This state machine is maintained internal to the host controller and is only used to gate reloading of the nak counter during the queue head traversal state: Execute Transaction (see the figure below). The host controller does not perform the nak counter reload operation if the RL field (see Queue Head) is set to zero.

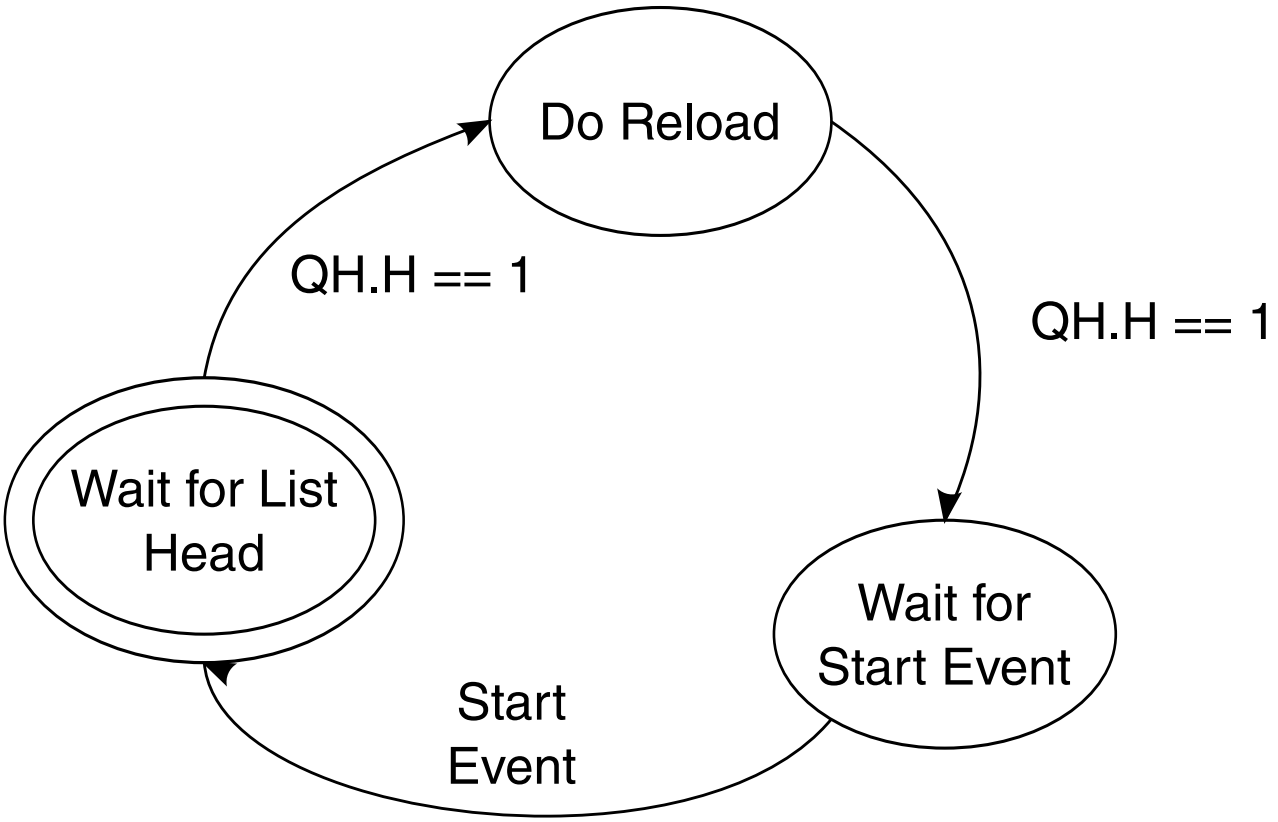

Figure 62-17. Example HC State Machine for Controlling Nak Counter Reloads

62.5.3.9.1.1 Wait for List Head

This is the initial state.

The state machine enters this state from Wait for Start Event when a start event as defined in Asynchronous schedule traversal: *Start Event* occurs.

The purpose of this state is to wait for the first observation of the head of the Asynchronous Schedule.

This occurs when the host controller fetches a queue head whose *H-bit* is set to one.

62.5.3.9.1.2 Do Reload

This state is entered from the Wait for List Head state when the host controller fetches a queue head with the *H-bit* set to one. While in this state, the host controller performs nak counter reloads for every queue head visited that has a non-zero nak reload value (*RL*) field.

62.5.3.9.1.3 Wait for Start Event

This state is entered from the *Do Reload* state when a queue head with the *H-bit* set to one is fetched. While in this state, the host controller does not perform nak counter reloads.

62.5.3.10 Managing Control/Bulk/Interrupt Transfers through Queue Heads

This section presents an overview of how the host controller interacts with queuing data structures.

Queue heads use the Queue Element Transfer Descriptor (qTD) structure. One queue head is used to manage the data stream for one endpoint. The queue head structure contains static endpoint characteristics and capabilities. It also contains a working area from where individual bus transactions for an endpoint are executed (see Overlay area defined in Table 62-27). Each qTD represents one or more bus transactions, which is defined in the context of this specification as a *transfer*.

The general processing model for the host controller's use of a queue head is simple:

- read a queue head,
- execute a transaction from the overlay area,
- write back the results of the transaction to the overlay area,
- move to the next queue head.

If the host controller encounters errors during a transaction, the host controller sets one (or more) of the error reporting bits in the queue head's *Status* field. The *Status* field accumulates all errors encountered during the execution of a qTD (for example, the error bits in the queue head *Status* field are 'sticky' until the transfer (qTD) has completed). This state is always written back to the source qTD when the transfer is complete. On transfer (for example, buffer or halt conditions) boundaries, the host controller must auto-advance (without software intervention) to the next qTD. Additionally, the hardware must be able to halt the queue so no additional bus transactions occurs for the endpoint and the host controller does not advance the queue.

An example host controller operational state machine of a queue head traversal is illustrated in the following figure. This state machine is a model for how a host controller should traverse a queue head. The host controller must be able to advance the queue from the *Fetch QH* state in order to avoid all hardware/software race conditions. This simple mechanism allows software to simply link qTDs to the queue head and *activate* them, then the host controller always *find* them if/when they are reachable. The figure below illustrates the Host Controller Queue Head Traversal State Machine.

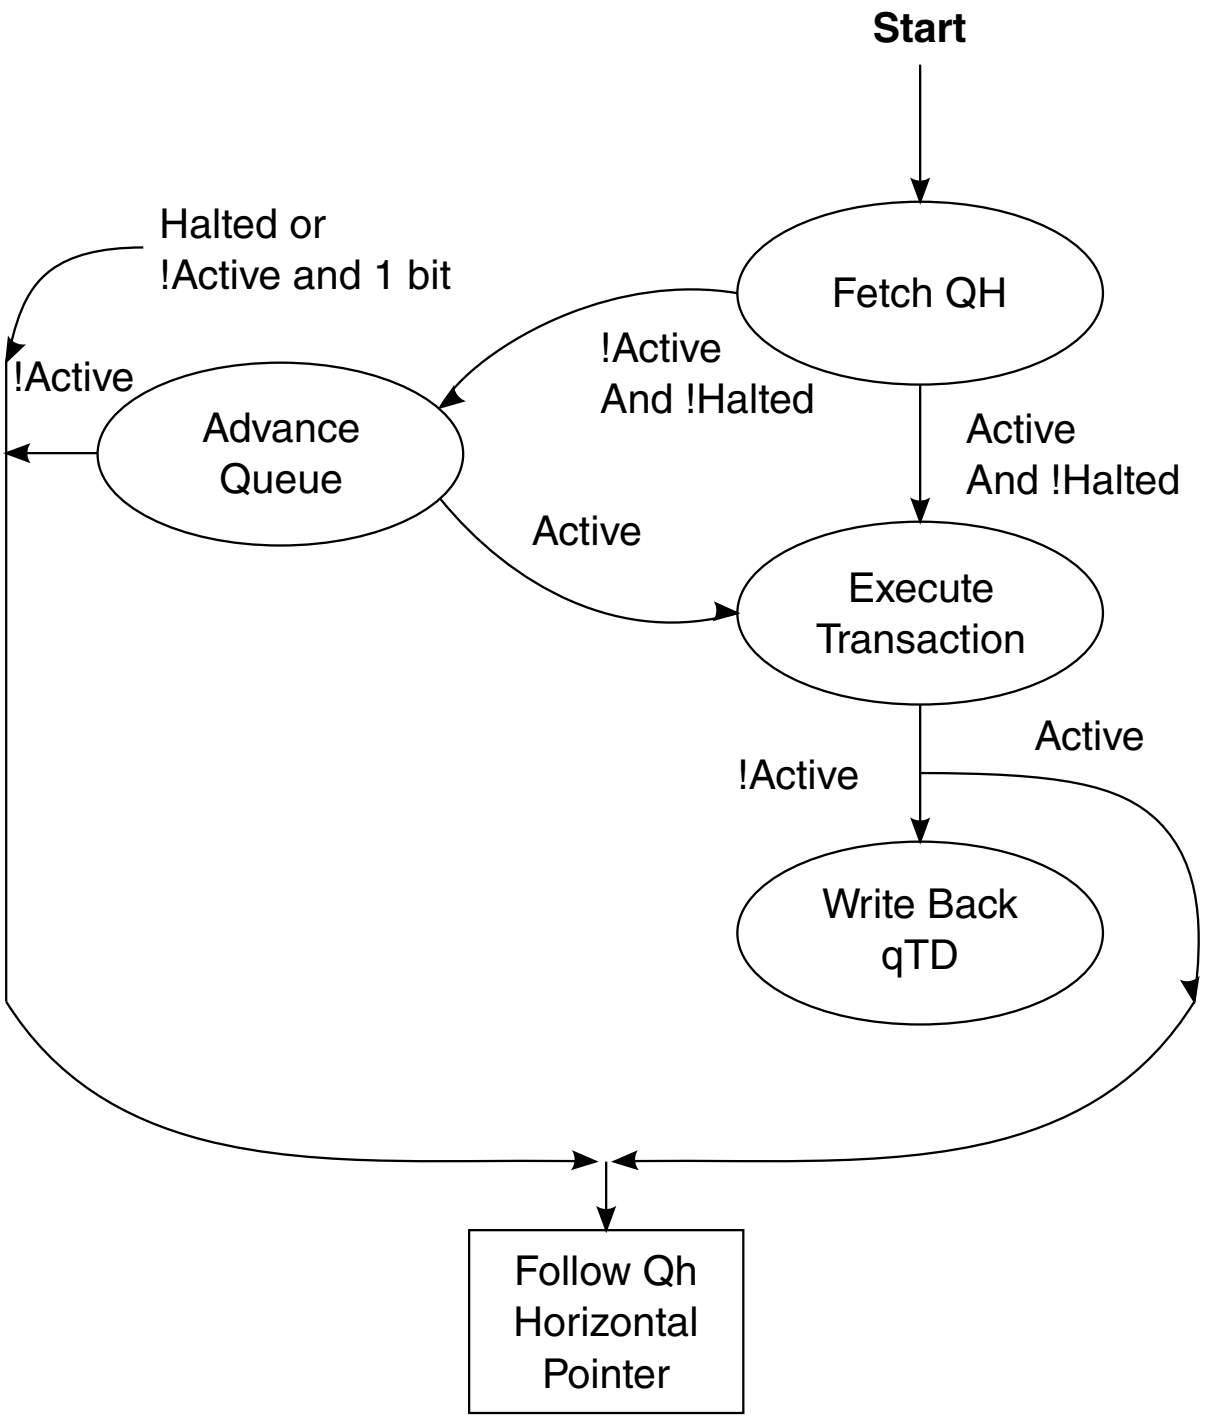

Figure 62-18. Host Controller Queue Head Traversal State Machine

This traversal state machine applies to all queue heads, regardless of transfer type or whether split transactions are required. The following sections describe each state. Each state description describes the entry criteria. The Execute Transaction state (see Execute

Transaction) describes the basic requirements for all endpoints. Split Transactions for Asynchronous Transfers and Split Transaction Interrupt describe details of the required extensions to the Execute Transaction state for endpoints requiring split transactions.

NOTE

Prior to software placing a queue head into either the periodic or asynchronous list, software must ensure the queue head is properly initialized. Minimally, the queue head should be initialized to the following (see Section Queue Head for layout of a queue head):

Valid static endpoint state.

- For the very first use of a queue head, software may zero-out the queue head transfer overlay, then set the *Next qTD Pointer* field value to reference a valid qTD.

62.5.3.10.1 Fetch Queue Head

A queue head can be referenced from the physical address stored in the ASYNCLISTADDR Register. Additionally, it may be referenced from the *Next LinkPointer* field of an iTD, siTD, FSTN or another Queue Head. If the referencing link pointer has the *Typ* field set to indicate a queue head, it is assumed to reference a queue head structure as defined in Queue Head.

While in this state, the host controller performs operations to implement empty schedule detection (see Empty Asynchronous Schedule Detection) and Nak Counter reloads (see Operational Model for Nak Counter). After the queue head has been fetched, the host controller conducts the following queries for empty schedule detection:

- If queue head is not an interrupt queue head (that is *S-mask* is zero), and
- The *H-bit* is one, and
- The *Reclamation* bit in the USBSTS register is zero.

When these criteria are met, the host controller stops traversing the asynchronous list (as described in Empty Asynchronous Schedule Detection). When the criteria are not met, the host controller continues schedule traversal. If the queue head is not an interrupt and the *H-bit* is one and the *Reclamation* bit is one, then the host controller sets the *Reclamation* bit in the USBSTS register to zero before completing this state. The operations for reloading of the Nak Counter are described in detail in Operational Model for Nak Counter.

This state is complete when the queue head has been read on-chip.

62.5.3.10.2 Advance Queue

To advance the queue, the host controller must find the next qTD, adjust pointers, perform the overlay and write back the results to the queue head.

This state is entered from the FetchQHD state if the overlay *Active* and *Halt* bits are set to zero. On entry to this state, the host controller determines which next pointer to use to fetch a qTD, fetches a qTD and determines whether or not to perform an overlay.

NOTE

If the *I-bit* is one and the *Active* bit is zero, the host controller immediately skips processing of this queue head, exits this state and uses the horizontal pointer to the next schedule data structure. If the field *Bytes to Transfer* is not zero and the *T-bit* in the *Alternate Next qTD Pointer* is set to zero, then the host controller uses the *Alternate Next qTD Pointer*. Otherwise, the host controller uses the *NextqTD Pointer*. If *NextqTD Pointer's T-bit* is set to one, then the host controller exits this state and uses the horizontal pointer to the next schedule data structure.

Using the selected pointer the host controller fetches the referenced qTD. If the fetched qTD has its *Active* bit set to one, the host controller moves the pointer value used to reach the qTD (*Next* or *Alternate Next*) to the *Current qTD Pointer* field, then performs the overlay. If the fetched qTD has its *Active* bit set to zero, the host controller aborts the queue advance and follows the queue head's horizontal pointer to the next schedule data structure.

The host controller performs the overlay based on the following rules:

- The value of the data toggle (*dt*) field in the overlay area depends on the value of the *data toggle control* (*dtc*) bit (see Table 62-29).
- If the *EPS* field indicates the endpoint is a high-speed endpoint, the *Ping* state field is preserved by the host controller. The value of this field is not changed as a result of the overlay.
- *C-prog-mask* field is set to zero (field from incoming qTD is ignored, as is the current contents of the overlay area).
- *Frame Tag* field is set to zero (field from incoming qTD is ignored, as is the current contents of the overlay area).
- *NakCnt* field in the overlay area is loaded from the *RL* field in the queue head's Static Endpoint State.
- All other areas of the overlay are set by the incoming qTD.

The host controller exits this state when it has committed the write to the queue head.

62.5.3.10.3 Execute Transaction

The host controller enters this state from the Fetch Queue Head state only if the *Active* bit in *Status* field of the queue head is set to one.

On entry to this state, the host controller executes a few pre-operations, then checks some pre-condition criteria before committing to executing a transaction for the queue head.

The pre-operations performed and the pre-condition criteria depend on whether the queue head is an interrupt endpoint. The host controller can determine that a queue head is an interrupt queue head when the queue head's *S-mask* field contains a non-zero value. It is the responsibility of software to ensure the *S-mask* field is appropriately initialized based on the transfer type. There are other criteria that must be met if the *EPS* field indicates that the endpoint is a low- or full-speed endpoint, see Split Transactions for Asynchronous Transfers and Split Transaction Interrupt .

62.5.3.10.3.1 Interrupt Transfer Pre-condition Criteria

If the queue head is for an interrupt endpoint (for example, non-zero *S-mask* field), then the FRINDEX[2:0] field must identify a bit in the *S-mask* field that has one in it.

For example, an *S-mask* value of 00100000b would evaluate to true only when FRINDEX[2:0] is equal to 101b. If this condition is met then the host controller considers this queue head for a transaction.

62.5.3.10.3.2 Asynchronous Transfer Pre-operations and Pre-condition Criteria

If the queue head is not for an interrupt endpoint (for example, zero *S-mask* field), then the host controller performs one pre-operation and then evaluates one pre-condition criteria.

The pre-operation is:

Checks the Nak counter reload state (Operational Model for Nak Counter). It may be necessary for the host controller to reload the Nak Counter field. The reload is performed at this time.

The pre-condition evaluated is:

- Whether or not the *NakCnt* field has been reloaded, the host controller checks the value of the *NakCnt* field in the queue head. If *NakCnt* is non-zero, or if the *Reload Nak Counter* field is zero, then the host controller considers this queue head for a transaction.

62.5.3.10.3.3 Transfer Type Independent Pre-operations

Regardless of the transfer type, the host controller always performs at least one pre-operation and evaluates one pre-condition. The pre-operation is:

- A host controller internal transaction (down) counter *qHTransactionCounter* is loaded from the queue head's *Mult* field. A host controller implementation is allowed to ignore this for queue heads on the asynchronous list. It is mandatory for interrupt queue heads. Software should ensure that the *Mult* field is set appropriately for the transfer type.

The pre-conditions evaluated are:

- The host controller determines whether there is enough time in the micro-frame to complete this transaction (see Transaction Fit - A Best-Fit Approximation Algorithm for an example evaluation method). If there is not enough time to complete the transaction, the host controller exits this state.
- If the value of *qHTransactionCounter* for an interrupt endpoint is zero, then the host controller exits this state.

When the pre-operations are complete and pre-conditions are met, the host controller sets the *Reclamation* bit in the USBSTS register to one and then begins executing one or more transactions using the endpoint information in the queue head. The host controller iterates *qHTransactionCounter* times in this state executing transactions. After each transaction is executed, *qHTransactionCounter* is decremented by one. The host controller exits this state when one of the following events occurs:

- The *qHTransactionCounter* decrements to zero, or
- The endpoint responds to the transaction with any handshake other than an ACK,[4] or
- The transaction experiences a transaction error, or
- The *Active* bit in the queue head goes to zero, or
- There is not enough time in the micro-frame left to execute the next transaction(see Transaction Fit - A Best-Fit Approximation Algorithm) for example method for implementing the frame boundary test).

NOTE

For a high-bandwidth interrupt OUT endpoint, the host controller may optionally immediately retry the transaction if it fails.

The results of each transaction is recorded in the on-chip overlay area. If data was successfully moved during the transaction, the transfer state in the overlay area is advanced. To advance queue head's transfer state, the *Total Bytes to Transfer* field is decremented by the number of bytes moved in the transaction, the data toggle bit (*dt*) is toggled, the current page offset is advanced to the next appropriate value (for example,

advanced by the number of bytes successfully moved), and the *C_Page* field is updated to the appropriate value (if necessary). See Buffer Pointer List Use for Data Streaming with qTDs .

NOTE

The *Total Bytes To Transfer* field may be zero when all the other criteria for executing a transaction are met. When this occurs, the host controller executes zero-length transaction to the endpoint. If the *PID_Code* field indicates an IN transaction and the device delivers data, the host controller detects a packet babble condition, set the *babble* and *halted* bits in the *Status* field, set the *Active* bit to zero, write back the results to the source qTD, then exit this state.

In the event an IN token receives a data PID mismatch response, the host controller must ignore the received data (for example not advance the transfer state for the bytes received). Additionally, if the endpoint is an interrupt IN, then the host controller must record that the transaction occurred (for example, decrement *qHTransactionCounter*). It is recommended (but not required) the host controller continue executing transactions for this endpoint if the resultant value of *qHTransactionCounter* is greater than one.

If the response to the IN bus transaction is a Nak (or Nyet) and *RL* is non-zero, *NakCnt* is decremented by one. If *RL* is zero, then no write-back by the host controller is required (for a transaction receiving a Nak or Nyet response and the value of *CErr* did not change). Software should set the *RL* field to zero if the queue head is an interrupt endpoint. Host controller hardware is not required to enforce this rule or operation.

After the transaction has finished and the host controller has completed the post processing of the results (advancing the transfer state and possibly *NakCnt*, the host controller writes back the results of the transaction to the queue head's overlay area in main memory).

The number of bytes moved during an IN transaction depends on how much data the device endpoint delivers. The maximum number of bytes a device can send is *MaximumPacket Size*. The number of bytes moved during an OUT transaction is either *Maximum Packet Length* bytes or *Total Bytes to Transfer*, whichever is less.

If there was a transaction error during the transaction, the transfer state (as defined above) is not advanced by the host controller. The *CErr* field is decremented by one and the status field is updated to reflect the type of error observed. Transaction errors are summarized in Transaction Error .

The following events causes the host controller to clear the *Active* bit in the queue head's overlay status field. When the *Active* bit transitions from one to zero, the transfer in the overlay is considered complete. The reason for the transfer completion (clearing the *Active* bit) determines the next state.

- *CErr* field decrements to zero. When this occurs the *Halted* bit is set to one and *Active* is set to zero. This results in the hardware not advancing the queue and the pipe halts. Software must intercede to recover.
- The device responds to the transaction with a STALL PID. When this occurs, the *Halted* bit is set to one and the *Active* bit is set to zero. This results in the hardware not advancing the queue and the pipe halts. Software must intercede to recover.
- The *Total Bytes to Transfer* field is zero after the transaction completes.
  - For a zero length transaction, it was zero before the transaction was started. When this condition occurs, the *Active* bit is set to zero.
- The PID code is an IN, and the number of bytes moved during the transaction is less than the *Maximum Packet Length*. When this occurs, the *Active* bit is set to zero and a short packet condition exists. The short-packet condition is detected during the Advance Queue state. Refer to Split Transactions for additional rules for managing low- and full-speed transactions.

With the exception of a NAK response (when *RL* field is zero), the host controller always writes the results of the transaction back to the overlay area in main memory. This includes when the transfer completes. For a high-speed endpoint, the queue head information written back includes minimally the following fields: The *PID Code* field indicates an IN and the device sends more than the expected number of bytes (for example *Maximum Packet Length* or *Total Bytes to Transfer* bytes, whichever is less) (for example a packet babble). This results in the host controller setting the *Halted* bit to one.

- NakCnt, dt, Total Bytes to Transfer, C_Page, Status, CERR, and Current Offset

For a low- or full-speed device the queue head information written back also includes the fields:

- C-prog-mask, FrameTag and S-bytes.

The duration of this state depends on the time it takes to complete the transaction(s) and the status write to the overlay is committed.

62.5.3.10.3.4 Halting a Queue Head

A halted endpoint is defined only for the transfer types that are managed through queue heads (control, bulk and interrupt).

The following events indicate that the endpoint has reached a condition where no more activity can occur without intervention from the driver:

- An endpoint may return a STALL handshake during a transaction,
- A transaction had three consecutive error conditions, or
- A Packet Babble error occurs on the endpoint.

When any of these events occur (for a queue head) the Host Controller halts the queue head and set the USBERRINT status bit in the USB_n_USBSTS register to one. To halt the queue head, the *Active* bit is set to zero and the *Halted* bit is set to one. There may be other error status bits that are set when a queue is halted. The host controller always writes back the overlay area to the source qTD when the transfer is complete, regardless of the reason (normal completion, short packet or halt). The host controller does not advance the transfer state on a transaction that results in a *Halt* condition (for example no updates necessary for *Total Bytes to Transfer*, *C_Page*, *Current Offset,* and *dt*). The host controller must update *CErr* as appropriate. When a queue head is halted, the *USB Error Interrupt* bit in the USB_n_USBSTS register is set to one. If the *USB Error Interrupt Enable* bit in the USB_n_USBINTR register is set to one, a hardware interrupt is generated at the next interrupt threshold.

62.5.3.10.3.5 Asynchronous Schedule Park Mode

Asynchronous Schedule Park mode is a special execution mode that can be enabled by system software, where the host controller is permitted to execute more than one bus transaction from a high-speed queue head in the Asynchronous schedule before continuing horizontal traversal of the Asynchronous schedule.

This feature has no effect on queue heads or other data structures in the Periodic schedule. This feature is similar in intent as the *Mult* feature that is used in the Periodic schedule. Where-as the *Mult* feature is a characteristic that is tunable for each endpoint; park-mode is a policy that is applied to all high-speed queue heads in the asynchronous schedule. It is essentially the specification of an iterator for consecutive bus transactions to the same endpoint. All of the rules for managing bus transactions and the results of those as defined in Execute Transaction apply. This feature merely specifies how many consecutive times the host controller is permitted to execute from the same queue head before moving to the next queue head in the Asynchronous List. This feature should allow the host controller to attain better bus utilization for those devices that are capable of moving data at maximum rate, while at the same time providing a fair service to all endpoints.

A host controller exports its capability to support this feature to system software by setting the *Asynchronous Schedule Park Capability* bit in the USB_n_HCCPARAMs register to one. This information keys system software that the *Asynchronous Schedule Park Mode Enable* and *Asynchronous Schedule Park Mode Count* fields in the USB_n_USBCMD register are modifiable. System software enables the feature by writing a one to the *Asynchronous Schedule Park Mode Enable* bit.

When park-mode is not enabled (for example *Asynchronous Schedule Park Mode Enable* bit in the USB_n_USBCMD register is zero), the host controller must not execute more than one bus transaction per high-speed queue head, per traversal of the asynchronous schedule. When park-mode is enabled, the host controller must not apply the feature to a queue head whose *EPS* field indicates a Low/Full-speed device (for example only one bus transaction is allowed from each Low/Full-speed queue head per traversal of the asynchronous schedule). Park-mode may only be applied to queue heads in the Asynchronous schedule whose *EPS* field indicates that it is a high-speed device.

The host controller must apply park mode to queue heads whose *EPS* field indicates a high-speed endpoint. The maximum number of consecutive bus transactions a host controller may execute on a high-speed queue head is determined by the value in the *Asynchronous Schedule Park Mode Count* field in the USB_n_USBCMD register. Software must not set *Asynchronous Schedule Park Mode Enable* bit to one and also set *Asynchronous Schedule Park Mode Count* field to zero. The resulting behavior is not defined. An example behavioral example describes the operational requirements for the host controller implementing park-mode. This feature does not affect how the host controller handles the bus transaction as defined in Execute Transaction . It only effects how many consecutive bus transactions for the current queue head can be executed. All boundary conditions, error detection and reporting applies as usual. This feature is similar in concept to the use of the *Mult* field for high-bandwidth Interrupt for queue heads in the Periodic Schedule.

The host controller effectively loads an internal down-counter *PM-Count* from *Asynchronous Schedule Park Mode Count* when *Asyncrhonous Schedule Park Mode Enable* bit is one, and a high-speed queue head is first fetched and meets all the criteria for executing a bus transaction. After the bus transaction, *PM-Count* is decremented. The host controller may continue to execute bus transactions from the current queue head until *PM-Count* goes to zero, an error is detected, the buffer for the current transfer is exhausted or the endpoint responds with a flow-control or STALL handshake.

The following table summarizes the responses that effect whether the host controller continues with another bus transaction for the current queue head.

Table 62-45. Actions for Park Mode, based on Endpoint Response and Residual Transfer State

PID	Endpoint Response	Transfer State after Transaction		Action
		PM-Count	Bytes to Transfer	
IN	DATA[0,1] w/Maximum Packet sized data	Not zero	Not Zero	Allowed to perform another bus transaction.[1, 2]
		Not zero	Zero	Retire qTD and move to next QH
		Zero	Don't care	Move to next QH.

Table continues on the next page...

Table 62-45. Actions for Park Mode, based on Endpoint Response and Residual Transfer State (continued)

	DATA[0,1] w/short packet	Don't care	Don't care	Retire qTD and move to next QH.
	NAK	Don't care	Don't care	Move to next QH.
	STALL, XactErr	Don't care	Don't care	Move to next QH.
OUT	ACK	Not zero	Not Zero	Allowed to perform another bus transaction.[2]
		Not zero	Zero	Retire qTD and move to next QH
		Zero	Don't' care	Move to next QH.
	NYET, NAK	Don't care	Don't care	Move to next QH.
	STALL, XactErr	Don't care	Don't care	Move to next QH
PING	ACK	Not Zero	Not Zero	Allowed to perform another bus transaction. [2]
	NAK	Don't care	Don't care	Move to next QH
	STALL, XactErr	Don't care	Don't care	Move to next QH

1. The host controller may continue to execute bus transactions from the current high-speed queue head (if *PM-Count* is not equal to zero), if a PID mismatch is detected (for example expected DATA1 and received DATA0, or visa-versa).
2. This specification does not *require* that the host controller execute another bus transaction when *PM-Count* is non-zero. Implementations are encouraged to make appropriate complexity and performance trade-offs.

62.5.3.10.4 Write Back qTD

This state is entered from the Execute Transaction state when the *Active* bit is set to zero.

The source data for the write-back is the transfer results area of the queue head overlay area (see Table 62-45).

The host controller uses the *Current qTD Pointer* field as the target address for the qTD.

The queue head transfer result area is written back to the transfer result area of the target qTD. This state is also referred to as: qTD retirement. The fields that must be written back to the source qTD include *Total Bytes to Transfer*, *Cerr*, and *Status*.

The duration of this state depends on when the qTD write-back is committed.

62.5.3.10.5 Follow Queue Head Horizontal Pointer

The host controller must use the horizontal pointer in the queue head to the next schedule data structure when any of the following conditions exist:

- If the *Active* bit is one on exit from the Execute Transaction state, or
- When the host controller exits the Write Back qTD state, or
- If the Advance Queue state fails to advance the queue because the target qTD is not active, or
- If the *Halted* bit is one on exit from the Fetch QH state.

There is no functional requirement that the host controller wait until the current transaction is complete before using the horizontal pointer to read the next linked data structure. However, it must wait until the current transaction is complete before executing the next data structure.

62.5.3.10.6 Buffer Pointer List Use for Data Streaming with qTDs

A qTD has an array of buffer pointers, which is used to reference the data buffer for a transfer. This specification requires that the buffer associated with the transfer be *virtually contiguous*.

This means: if the buffer spans more than one physical page, it must obey the following rules (the figure below illustrates an example):

- The first portion of the buffer must begin at some offset in a page and extend through the end of the page.
- The remaining buffer cannot be allocated in small chunks scattered around memory. For each 4 K chunk beyond the first page, each buffer portion matches to a full 4 K page. The final portion, which may only be large enough to occupy a portion of a page, must start at the top of the page and be contiguous within that page.

The buffer pointer list in the qTD is long enough to support a maximum transfer size of 20 K bytes. This case occurs when all five buffer pointers are used and the first offset is zero. A qTD handles a 16 Kbyte buffer with any starting buffer alignment.

The host controller uses the field *C_Page* field as an index value to determine which buffer pointer in the list should be used to start the current transaction. The host controller uses a different buffer pointer for each physical page of the buffer. This is always true, even if the buffer is physically contiguous.

The host controller must detect when the current transaction spans a page boundary and automatically move to the next available buffer pointer in the page pointer list. The next available pointer is reached by incrementing *C_Page* and pulling the next page pointer from the list. Software must ensure there are sufficient buffer pointers to move the amount of data specified in the *Bytes to Transfer* field.

The following figure illustrates a nominal example of how System software would initialize the buffer pointers list and the *C_Page* field for a transfer size of 16383 bytes. *C_Page* is set to zero. The upper 20-bits of Page 0 references the start of the physical page. *Current Offset* (the lower 12-bits of queue head Dword 7) holds the offset in the page for example 2049 (for example 4096-2047). The remaining page pointers are set to reference the beginning of each subsequent 4 K page.

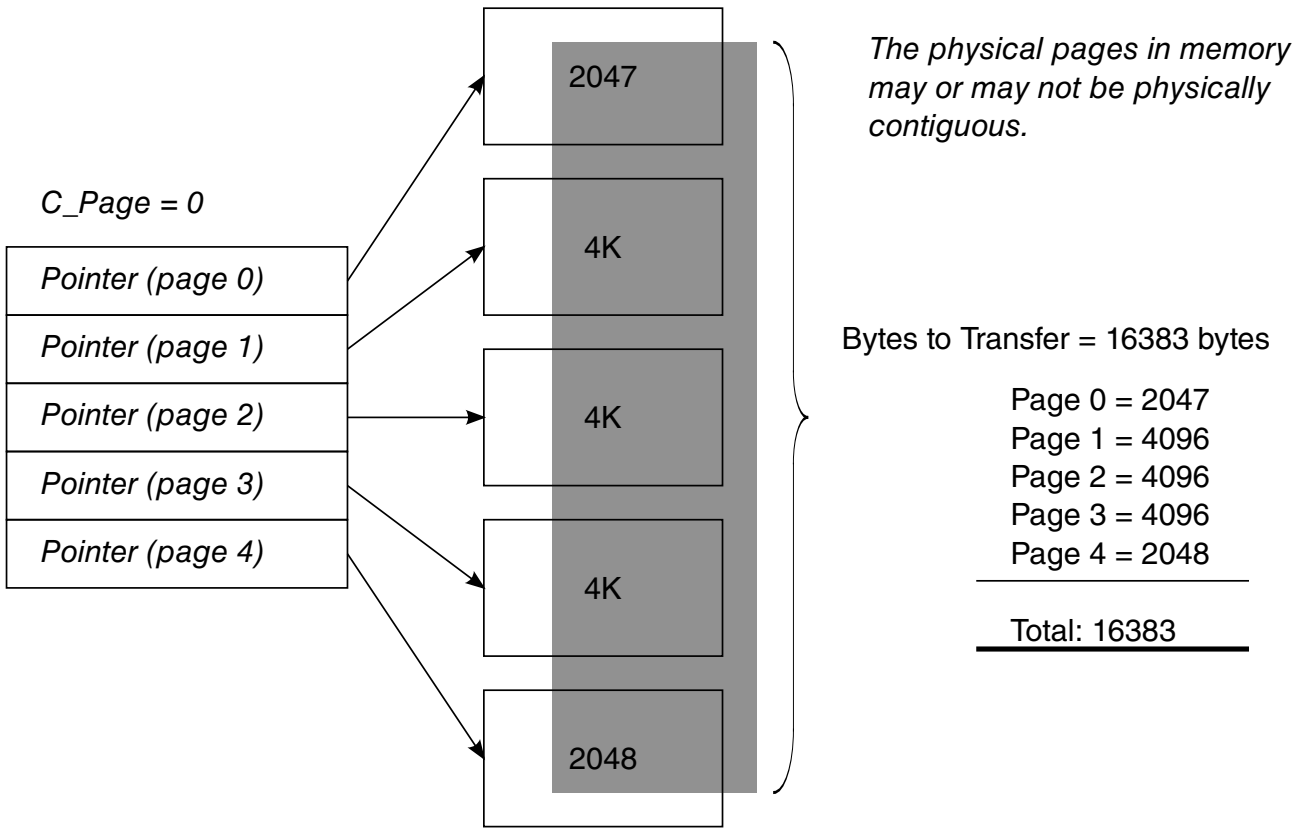

Figure 62-19. Example Mapping of qTD Buffer Pointers to Buffer Pages

For the first transaction on the qTD (assuming a 512-byte transaction), the host controller uses the first buffer pointer (page 0 because *C_Page* is set to zero) and concatenates the *Current Offset* field. The 512 bytes are moved during the transaction, the *Current Offset* and *Total Bytes to Transfer* are adjusted by 512 and written back to the queue head working area.

During the 4th transaction, the host controller needs 511 bytes in page 0 and one byte in page 1. The host controller increments *C_Page* (to 1) and use the page 1 pointer to move the final byte of the transaction. After the 4th transaction, the active page pointer is the page 1 pointer and *Current Offset* has rolled to one, and both are written back to the overlay area. The transactions continue for the rest of the buffer, with the host controller automatically moving to the next page pointer (that is *C_Page*) when necessary. The three conditions for how the host controller handles *C_Page*:

- The current transaction does not span a page boundary. The value of *C_Page* is not adjusted by the host controller.

- The current transaction does span a page boundary. The host controller must detect the page cross condition and advance to the next buffer while streaming data to/from the USB.
- The current transaction completes on a page boundary (that is the last byte moved for the current transaction is the last byte in the page for the current page pointer). The host controller must increment *C_Page* before writing back status for the transaction.

NOTE

The only valid adjustment the host controller may make to *C_Page* is to increment by one.

62.5.3.10.7 Adding Interrupt Queue Heads to the Periodic Schedule

The link path(s) from the periodic frame list to a queue head establishes in which frames a transaction can be executed for the queue head. Queue heads are linked into the periodic schedule so they are polled at the appropriate rate.

System software sets a bit in a queue head's *S-Mask* to indicate which micro-frame within 1 msec period a transaction should be executed for the queue head. Software must ensure that all queue heads in the periodic schedule have *S-Mask* set to a non-zero value. An *S-mask* with zero value in the context of the periodic schedule yields undefined results.

If the desired poll rate is greater than one frame, system software can use a combination of queue head linking and *S-Mask* values to spread interrupts of equal poll rates through the schedule so that the periodic bandwidth is allocated and managed in the most efficient manner possible. Some examples are illustrated in the following table.

Table 62-46. Example Periodic Reference Patterns for Interrupt Transfers with 2ms Poll Rate

Frame # Reference Sequence	Description
0, 2, 4, 6, 8, and so on *S-Mask* = 01h	A queue head for the *bInterval* of 2 msec (16 micro-frames) is linked into the periodic schedule so that it is reachable from the periodic frame list locations indicated in the previous column. In addition, the *S-Mask* field in the queue head is set to 01h, indicating that the transaction for the endpoint should be executed on the bus during micro-frame 0 of the frame.
0, 2, 4, 6, 8, and so on *S-Mask* = 02h	Another example of a queue head with a *bInterval* of 2 msec is linked into the periodic frame list at exactly the same interval as the previous example. However, the *S-Mask* is set to 02h indicating that the transaction for the endpoint should be executed on the bus during micro-frame 1 of the frame.

62.5.3.10.8 Managing Transfer Complete Interrupts from Queue Heads

The host controller sets an interrupt to be signaled at the next interrupt threshold when the completed transfer (qTD) has an *Interrupt on Complete* (*IOC*) bit set to one, or whenever a transfer (qTD) completes with a short packet.

If system software needs multiple qTDs to complete a client request (that is like a control transfer) the intermediate qTDs do not require interrupts. System software may only need a single interrupt to notify it that the complete buffer has been transferred. System software may set IOC's to occur more frequently. A motivation for this may be that it wants early notification so that interface data structures can be re-used in a timely manner.

62.5.3.11 Ping Control

USB 2.0 defines an addition to the protocol for high-speed devices called Ping. Ping is required for all USB 2.0 High-speed bulk and control endpoints.

Ping is not allowed for a split-transaction stream. This extension to the protocol eliminates the bad side-effects of Naking OUT endpoints. The *Status* field has a *Ping State* bit, which the host controller uses to determine the *next* actual PID it uses in the next transaction to the endpoint (see the table below).

The Ping State bit is only managed by the host controller for queue heads that meet the following criteria:

- Queue head is not an interrupt and
- *EPS* field equals High-Speed and
- *PIDCode* field equals OUT

The following table illustrates the state transition table for the host controller's responsibility for maintaining the PING protocol. Refer to Chapter 8 in the USB Specification Revision 2.0 for detailed description on the Ping protocol.

Table 62-47. Ping Control State Transition Table

Event			
Current	Host	Device	Next
Do Ping	PING	Nak	Do Ping
Do Ping	PING	Ack	Do OUT
Do Ping	PING	XactErr [1]	Do Ping
Do Ping	PING	Stall	N/C [2] Do
OUT	OUT	Nak	Do Ping
Do OUT	OUT	Nyet	Do Ping

Table continues on the next page...

Table 62-47. Ping Control State Transition Table (continued)

Do OUT	OUT	Ack	Do OUT
Do OUT	OUT	XactErr[1]	Do Ping
Do OUT	OUT	Stall	N/C [2]

1. Transaction Error (XactErr) is any time the host misses the handshake.
2. No transition change required for the Ping State bit. The Stall handshake results in the endpoint being halted (for example Active set to zero and Halt set to one). Software intervention is required to restart queue. 3 A Nyet response to an OUT means that the device has accepted the data, but cannot receive any more at this time. Host must advance the transfer state and additionally, transition the Ping State bit to Do Ping. The Ping State bit has the following encoding:

Table 62-48. Ping State bit Encoding

Value	Meaning
0B	Do OUT The host controller uses an OUT PID during the next bus transaction to this endpoint.
1B	Do Ping The host controller uses a PING PID during the next bus transaction to this endpoint.

The defined ping protocol (see USB 2.0 Specification, Chapter 8) allows the host to be *imprecise* on the initialization of the ping protocol (that is start in *Do OUT* when we don't know whether there is space on the device or not). The host controller manages the *Ping State* bit. System software sets the initial value in the queue head when it initializes a queue head. The host controller preserves the *Ping State* bit across all queue advancements. This means that when a new qTD is written into the queue head overlay area, the previous value of the *Ping State* bit is preserved.

62.5.3.12 Split Transactions

USB 2.0 defines extensions to the bus protocol for managing USB 1.x data streams through USB 2.0 Hubs.

This section describes how the host controller uses the interface data structures to manage data streams with full- and low-speed devices, connected below USB 2.0 hub, utilizing the split transaction protocol.

Refer to USB 2.0 Specification for the complete definition of the split transaction protocol. Full- and Low-speed devices are enumerated identically as high-speed devices, but the transactions to the Full- and Low-speed endpoints use the split-transaction protocol on the high-speed bus. The split transaction protocol is an encapsulation of (or wrapper around) the Full- or Low-speed transaction. The high-speed wrapper portion of the protocol is addressed to the USB 2.0 Hub and Transaction Translator below which the Full- or Low-speed device is attached.

The EHCI interface uses dedicated data structures for managing full-speed isochronous data streams (see Split Transaction Isochronous Transfer Descriptor (siTD)). Control, Bulk and Interrupt are managed using the queuing data structures (see Queue Head). The interface data structures need to be programmed with the device address and the Transaction Translator number of the USB 2.0 Hub operating as the Low-/Full-speed host controller for this link. The following sections describe the details of how the host controller must process and manage the split transaction protocol.

62.5.3.12.1 Split Transactions for Asynchronous Transfers

A queue head in the asynchronous schedule with an *EPS* field indicating a full-or low-speed device indicates to the host controller that it must use split transactions to stream data for this queue head.

All full-speed bulk and full-, low-speed control are managed through queue heads in the asynchronous schedule.

Software must initialize the queue head with the appropriate device address and port number for the transaction translator that is serving as the full/low-speed host controller for the links connecting the endpoint. Software must also initialize the split transaction state bit (*SplitXState*) to Do-Start-Split. Finally, if the endpoint is a control endpoint, then system software must set the *Control Transfer Type* (*C*) bit in the queue head to one. If this is not a control transfer type endpoint, the *C* bit must be initialized by software to be zero. This information is used by the host controller to properly set the Endpoint Type (ET) field in the split transaction bus token. When the *C* bit is zero, the split transaction token's ET field is set to indicate a bulk endpoint. When the *C* bit is one, the split transaction token's ET field is set to indicate a control endpoint. Refer to Chapter 8 of USB Specification Revision 2.0 for details.

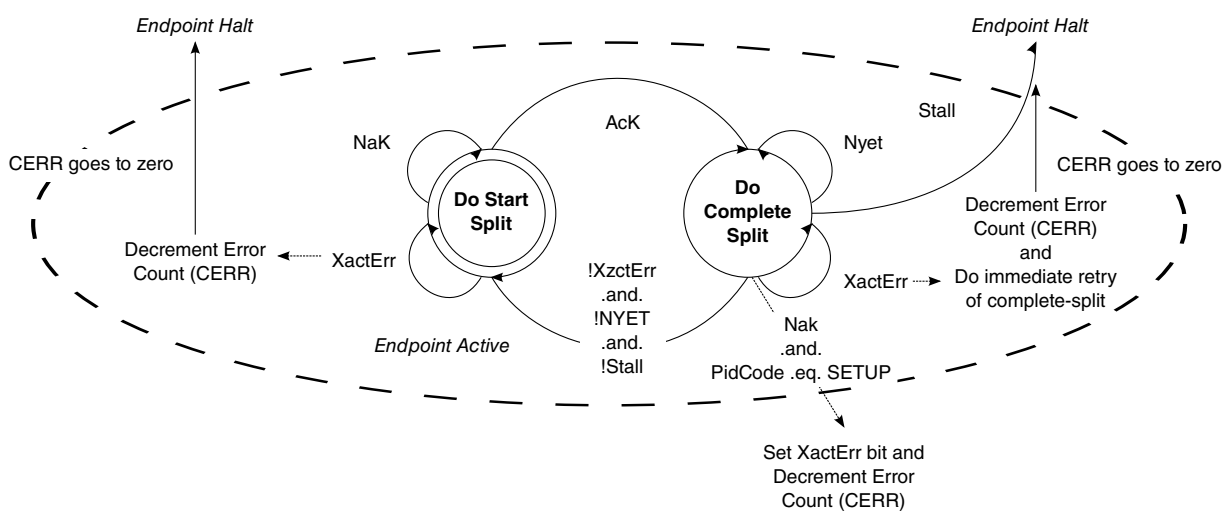

Figure 62-20. Host Controller Asynchronous Schedule Split-Transaction State Machine

62.5.3.12.1.1 Asynchronous - Do Start Split

This is the state which software must initialize a full- or low-speed asynchronous queue head. This state is entered from the Do Complete Split state only after a complete-split transaction receives a valid response from the transaction translator that is not a Nyet handshake.

For queue heads in this state, the host controller executes a start-split transaction to the appropriate transaction translator. If the bus transaction completes without an error and *PidCode* indicates an IN or OUT transaction, then the host controller reloads the error counter (*CErr*). If it is a successful bus transaction and the *PidCode* indicates a SETUP, the host controller does not reload the error counter. If the transaction translator responds with a Nak, the queue head is left in this state, and the host controller proceeds to the next queue head in the asynchronous schedule.

If the host controller times out the transaction (no response, or bad response) the host controller decrements *Cerr* and proceeds to the next queue head in the asynchronous schedule.

62.5.3.12.1.2 Asynchronous - Do Complete Split

This state is entered from the Do Start Split state only after a start-split transaction receives an Ack handshake from the transaction translator.

For queue heads in this state, the host controller executes a complete-split transaction to the appropriate transaction translator. If the transaction translator responds with a Nyet handshake, the queue head is left in this state, the error counter is reset and the host controller proceeds to the next queue head in the asynchronous schedule. When a Nyet handshake is received for a bus transaction where the queue head's *PidCode* indicates an IN or OUT, the host controller reloads the error counter (*CErr*). When a Nyet handshake is received for a complete-split bus transaction where the queue head's *PidCode* indicates a SETUP, the host controller must not adjust the value of *CErr*.

Independent of *PIDCode*, the following responses have the effects:

- Transaction Error (XactErr). Timeout or data CRC failure, and so on. The error counter (*Cerr*) is decremented by one and the complete split transaction is *immediately* retried (if possible). If there is not enough time in the micro-frame to execute the retry, the host controller MUST ensure that the next time the host controller begins executing from the Asynchronous schedule, it must begin executing from this queue head. If another start-split (for some other endpoint) is sent to the transaction translator before the complete-split is really completed, the transaction translator could dump the results (which were never delivered to the host). This is why the core specification states the retries must be immediate. A method to

accomplish this behavior is to not advance the asynchronous schedule. When the host controller returns to the asynchronous schedule in the next micro-frame, the first transaction from the schedule is the retry for this endpoint.

If *Cerr* went to zero, the host controller must halt the queue.

- NAK. The target endpoint Nak'd the full- or low-speed transaction. The state of the transfer is not advanced and the state is exited. If the *PidCode* is a SETUP, then the Nak response is a protocol error. The *XactErr* status bit is set to one and the *CErr* field is decremented.
- STALL. The target endpoint responded with a STALL handshake. The host controller sets the *halt* bit in the status byte, retires the qTD but does not attempt to advance the queue.

If the *PidCode* indicates an IN, then any of following responses are expected:

- DATA0/1. On reception of data, the host controller ensures the PID matches the expected data toggle and checks CRC. If the packet is *good*, the host controller advances the state of the transfer, for example move the data pointer by the number of bytes received, decrement *BytesToTransfer* field by the number of bytes received, and toggle the *dt* bit. The host controller then exit this state. The response and advancement of transfer may trigger other processing events, such as retirement of the qTD and advancement of the queue.

If the data sequence PID does not match the expected, the data is ignored, the transfer state is not advanced and this state is exited. If the *PidCode* indicates an OUT/SETUP, then any of following responses are expected:

- ACK. The target endpoint accepted the data, so the host controller must advance the state of the transfer. The *Current Offset* field is incremented by *Maximum Packet Length* or *Bytes to Transfer*, whichever is less. The field *Bytes To Transfer* is decremented by the same amount and the data toggle bit (*dt*) is toggled. The host controller then exit this state.
- Advancing the transfer state may cause other processing events such as retirement of the qTD and advancement of the queue (see Managing Control/Bulk/Interrupt Transfers through Queue Heads).

62.5.3.12.2 Split Transaction Interrupt

Split-transaction Interrupt-IN/OUT endpoints are managed through the same data structures used for high-speed interrupt endpoints. They both co-exist in the periodic schedule.

Queue heads/qTDs offer the set of features required for reliable data delivery, which is characteristic to interrupt transfer types. The split-transaction protocol is managed completely within this defined functional transfer framework. For example, for a high-speed endpoint, the host controller visits a queue head, execute a high-speed transaction (if criteria are met) and advance the transfer state (or not) depending on the results of the entire transaction. For low- and full-speed endpoints, the details of the *execution* phase are different (that is takes more than one bus transaction to complete), but the remainder of the operational framework is intact. This means that the transfer advancement, and so on, occurs as defined in Managing Control/Bulk/Interrupt Transfers through Queue Heads, but only occurs on the completion of a split transaction.

62.5.3.12.2.1 Split Transaction Scheduling Mechanisms for Interrupt

Full- and low-speed Interrupt queue heads have an *EPS* field indicating full- or low-speed and have a non-zero *S-mask* field.

The host controller can detect this combination of parameters and assume the endpoint is a periodic endpoint. Low- and full-speed interrupt queue heads require the use of the split transaction protocol. The host controller sets the Endpoint Type (ET) field in the split token to indicate the transaction is an interrupt. These transactions are managed through a transaction translator's periodic pipeline. Software should not set these fields to indicate the queue head is an interrupt unless the queue head is used in the periodic schedule.

System software manages the per/transaction translator periodic pipeline by budgeting and scheduling exactly during which micro-frames the start-splits and complete-splits for each endpoint occurs. The characteristics of the transaction translator are such that the high-speed transaction protocol must execute during explicit micro-frames, or the data or response information in the pipeline is lost.

The following figure illustrates the general scheduling boundary conditions that are supported by the EHCI periodic schedule and queue head data structure. The S and ^{C}X labels indicate micro-frames where software can schedule start-splits and complete splits (respectively).

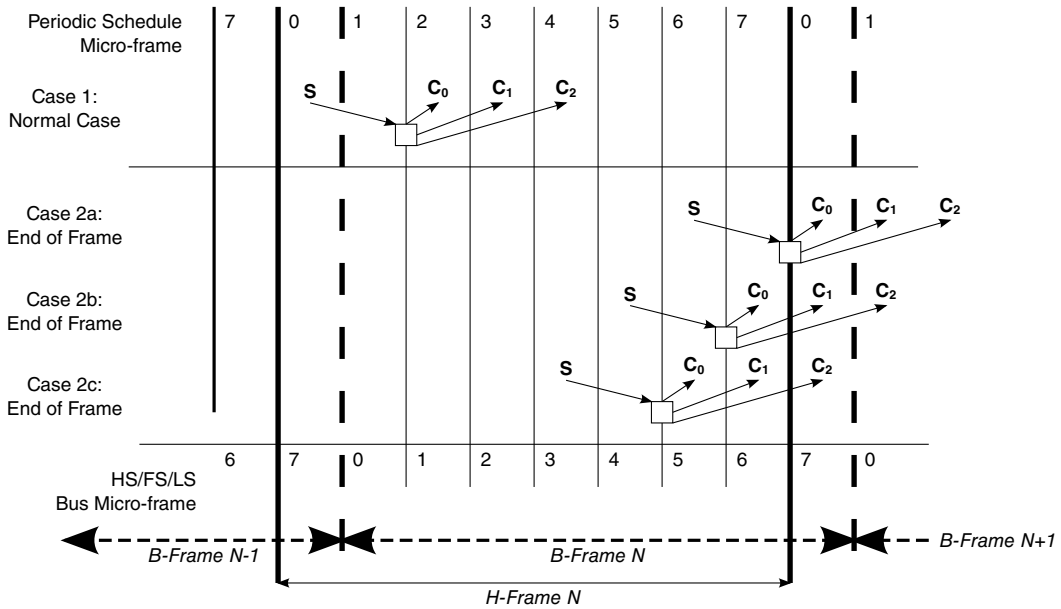

Figure 62-21. Split Transaction, Interrupt Scheduling Boundary Conditions

The scheduling cases are:

- Case 1: The normal scheduling case is where the entire split transaction is completely bounded by a frame (*H-Frame* in this case).
- Case 2a through Case 2c: The USB 2.0 Hub pipeline rules states clearly, when and how many complete-splits must be scheduled to account for earliest to latest execution on the full/low-speed link. The complete-splits may span the *H-Frame* boundary when the start-split is in micro-frame 4 or later. When this occurs, the *H-Frame* to *B-Frame* alignment requires that the queue head be reachable from consecutive periodic frame list locations. System software cannot build an efficient schedule that satisfies this requirement unless it uses FSTNs.

The figure below illustrates the general layout of the periodic schedule.

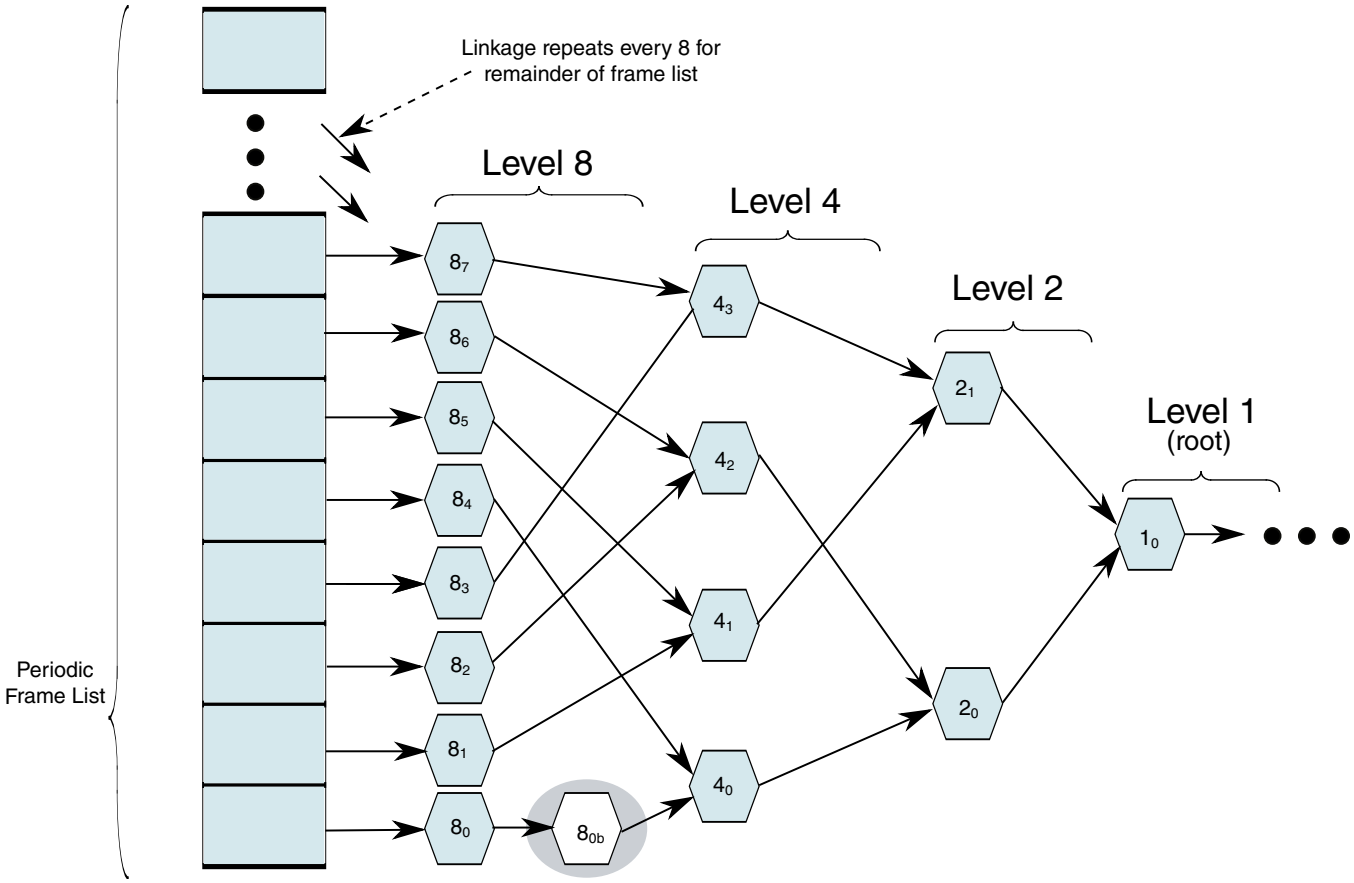

Figure 62-22. General Structure of EHCI Periodic Schedule Utilizing Interrupt Spreading

The periodic frame list is effectively the leaf level a binary tree, which is always traversed leaf to root. Each level in the tree corresponds to a 2^N poll rate. Software can efficiently manage periodic bandwidth on the USB by *spreading* interrupt queue heads that have the same poll rate requirement across all the available paths from the frame list. For example, system software can schedule eight poll rate 8 queue heads and account for them once in the high-speed bus bandwidth allocation.

When an endpoint is allocated an execution footprint that spans a frame boundary, the queue head for the endpoint must be reachable from consecutive locations in the frame list. An example would be if 8_{0b} where such an endpoint. Without additional support on the interface, to get 8_{0b} reachable at the correct time, software would have to link 8_1 to 8_{0b}. It would then have to move 4_1 and everything linked after into the same path as 4_0. This upsets the integrity of the binary tree and disallows the use of the spreading technique.

FSTN data structures are used to preserve the integrity of the binary-tree structure and enable the use of the spreading technique. Host Controller Operational Model for FSTNs defines the hardware and software operational model requirements for using FSTNs.

The following queue head fields are initialized by system software to instruct the host controller when to execute portions of the split-transaction protocol:

- *SplitXState*. This is single bit residing in the *Status* field of a queue head (see Table 62-25). This bit is used to track the current state of the split transaction.
- *Frame S-mask*. This is a bit-field where-in system software sets a bit corresponding to the micro-frame (within an *H-Frame*) that the host controller should execute a start-split transaction. This is always qualified by the value of the *SplitXState* bit in the *Status* field of the queue head. For example, referring to Figure 62-21, case one, the *S-mask* would have a value of 00000001b indicating that if the queue head is traversed by the host controller, and the *SplitXState* indicates Do_Start, and the current micro-frame as indicated by FRINDEX[2:0] is 0, then execute a start-split transaction.
- *Frame C-mask.* This is a bit-field where system software sets one or more bits corresponding to the micro-frames (within an *H-Frame*) that the host controller should execute complete-split transactions. The interpretation of this field is always qualified by the value of the *SplitXState* bit in the *Status* field of the queue head. For example, referring to Figure 62-21, case one, the *C-mask* would have a value of 00011100b indicating that if the queue head is traversed by the host controller, and the *SplitXState* indicates Do_Complete, and the current micro-frame as indicated by FRINDEX[2:0] is 2, 3, or 4, then execute a complete-split transaction. It is software's responsibility to ensure that the translation between *H-Frames* and *B-Frames* is correctly performed when setting bits in *S-mask* and *C-mask*

62.5.3.12.2.2 Host Controller Operational Model for FSTNs

The FSTN data structure is used to manage Low/Full-speed interrupt queue heads that need to be reached from consecutive frame list locations (that is boundary cases 2a through 2c).

An FSTN is essentially a *back pointer*, similar in intent to the back pointer field in the siTD data structure (see siTD Back Link Pointer).

This feature provides software a simple primitive to save a schedule position, redirect the host controller to traverse the necessary queue heads in the previous frame, then restore the original schedule position and complete normal traversal.

The four components to the use of FSTNs:

- FSTN data structure.
- A *Save Place* indicator. This is always an FSTN with its *Back Path Link Pointer.T-bit* set to zero.

- A *Restore* indicator. This is always an FSTN with its *Back Path Link Pointer.T-bit* set to one.
- Host controller FSTN traversal rules.

When the host controller encounters an FSTN during micro-frames 2 through 7 it simply follows the node's *Normal Path Link Pointer* to access the next schedule data structure.

NOTE

The FSTN's *Normal Path Link Pointer.T-bit* may set to one, which the host controller must interpret as the end of periodic list mark.

When the host controller encounters a *Save-Place* FSTN in micro-frames 0 or 1, it saves the value of the *Normal Path Link Pointer* and set an internal flag indicating that it is executing in *Recovery Path* mode. *Recovery Path* mode modifies the host controller's rules for how it traverses the schedule and limits which data structures is considered for execution of bus transactions. The host controller continues executing in *Recovery Path* mode until it encounters a *Restore* FSTN or it determines that it has reached the end of the micro-frame (see details in the list below).

The rules for schedule traversal and limited execution while in *Recovery Path* mode are:

- Always follow the *Normal Path Link Pointer* when it encounters an FSTN that is a *Save-Place* indicator. The host controller must not recursively follow *Save-Place* FSTNs. Therefore, while executing in *Recovery Path* mode, it must never follow an FSTN's *Back Path Link Pointer*.
- Do not process an siTD or, iTD data structure. Simply follow its *Next Link Pointer*.
- Do not process a QH (Queue Head) whose *EPS* field indicates a high-speed device. Simply follow its *Horizontal Link Pointer*.
- When a QH's *EPS* field indicates a Full/Low-speed device, the host controller considers only it for execution if its *SplitXState* is DoComplete (note: this applies whether the *PID Code* indicates an IN or an OUT). See Execute Transaction and Tracking Split Transaction Progress for Interrupt Transfers for a complete list of additional conditions that must be met in general for the host controller to issue a bus transaction.
  - The host controller must not execute a Start-split transaction while executing in *Recovery Path* mode. See Periodic Isochronous - Do Complete Split for special handling when in *Recovery Path* mode.
- Stop traversing the *recovery path* when it encounters an FSTN that is a *Restore* indicator. The host controller unconditionally uses the saved value of the *Save-Place* FSTN's *Normal Path Link Pointer* when returning to the normal path traversal. The

host controller must clear the context of executing a *Recovery Path* when it restores schedule traversal to the *Save-Place* FSTN's *Normal Path Link Pointer*.

- If the host controller determines that there is not enough time left in the micro-frame to complete processing of the periodic schedule, it abandons traversal of the recovery path, and clears the context of executing a recovery path. The result is that at the start of the next consecutive micro-frame, the host controller starts traversal at the frame list.

An example traversal of a periodic schedule that includes FSTNs is illustrated in the following figure.

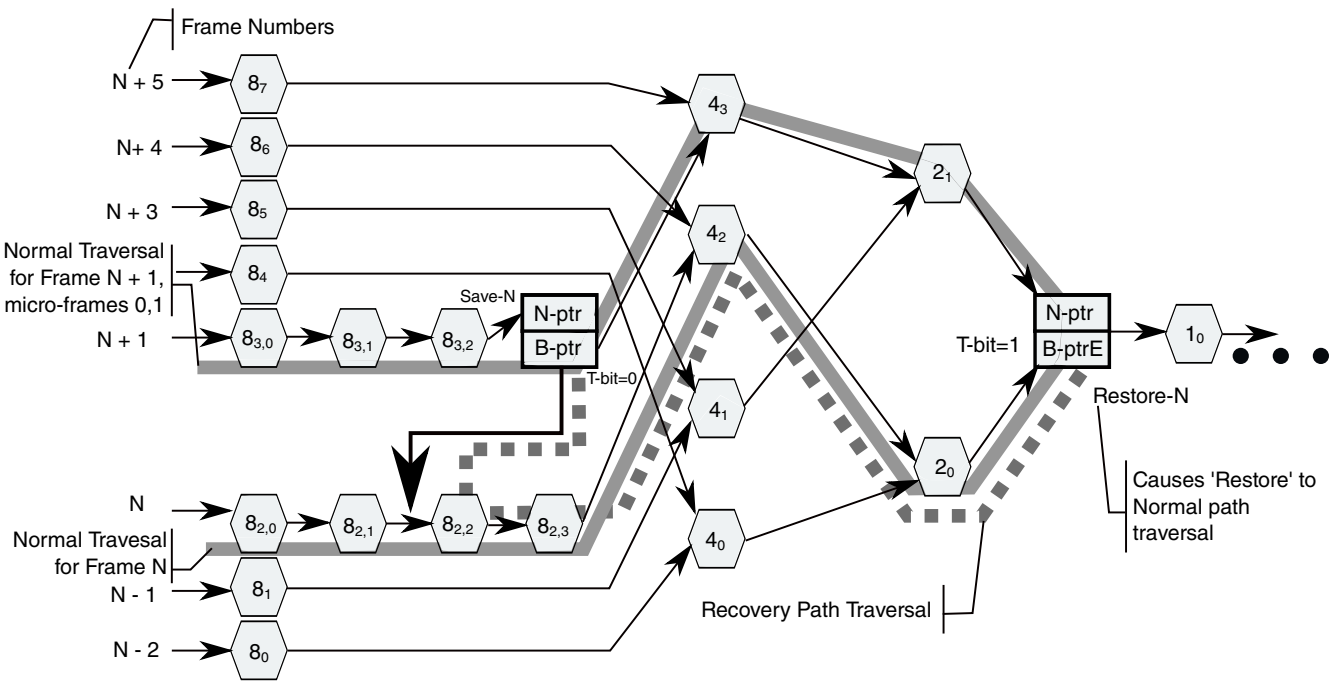

Figure 62-23. Example Host Controller Traversal of Recovery Path via FSTNs

In frame N+1 (micro-frames 0 and 1), when the host controller encounters Save-Path FSTN (Save-N), it observes that Save-N.Back Path Link Pointer.T-bit is zero (definition of a Save-Path indicator). The host controller saves the value of Save-N.Normal Path Link Pointer and follows Save-N.Back Path Link Pointer. At the same time, it sets an internal flag indicating that it is now in *Recovery Path* mode (the recovery path is annotated in the figure above with a large dashed line). The host controller continues traversing data structures on the recovery path and executing only those bus transactions as noted above, on the recovery path until it reaches Restore FSTN (Restore-N). Restore-N.Back Path Link Pointer.T-bit is set to one (definition of a Restore indicator), so the host controller exits *Recovery Path* mode by clearing the internal *Recovery Path* mode flag and commences (restores) schedule traversal using the saved value of the *Save-Place* FSTN's *Normal Path Link Pointer* (for example Save-N.Normal Path Link Pointer). The nodes traversed during these micro-frames include: {$8_{3.0}$, $8_{3.1}$, $8_{3.2}$, Save-A, $8_{2.2}$, $8_{2.3}$, 4_2,

2_0, Restore-N, 4_3, 2_1, Restore-N, 1_0 …}. The nodes on the recovery-path are in bold. In frame N (micro-frames 0-7), for this example, the host controller traverses all of the schedule data structures utilizing the *Normal Path Link Pointers* in any FSTNs it encounters. This is because the host controller has not yet encountered a *Save-Place* FSTN so it not executing in *Recovery Path* mode. When it encounters the *Restore* FSTN, (Restore-N), during micro-frames 0 and 1, it uses Restore-N.Normal Path Link Pointer to traverse to the next data structure (that is normal schedule traversal). This is because the host controller must use a Restore FSTN's *Normal Path Link Pointer* when not executing in a *Recovery-Path* mode. The nodes traversed during frame N include: {$8_{2.0}$, $8_{2.1}$, $8_{2.2}$, $8_{2.3}$, 4_2, 2_0, Restore-N, 1_0 …}.

In frame N+1 (micro-frames 2-7), when the host controller encounters Save-Path FSTN Save-N, it unconditionally follows Save-N.Normal Path Link Pointer. The nodes traversed during these micro-frames include: {$8_{3.0}$, $8_{3.1}$, $8_{3.2}$, Save-A, 4_3, 2_1, Restore-N, 1_0 …}.

62.5.3.12.2.3 Software Operational Model for FSTNs

Software must create a consistent, coherent schedule for the host controller to traverse.

When using FSTNs, system software must adhere to the following rules:

- Each *Save-Place* indicator requires a matching *Restore* indicator.
  - The *Save-Place* indicator is an FSTN with a valid *Back Path Link Pointer and T-bit* equal to zero.
    - *Back Path Link Pointer.Typ* field must be set to indicate the referenced data structure is a queue head. The *Restore* indicator is an FSTN with its *Back Path Link Pointer.T-bit* set to one.
  - A *Restore* FSTN may be matched to one or more *Save-Place* FSTNs. For example, if the schedule includes a poll-rate 1 level, then system software only needs to place a *Restore* FSTN at the beginning of this list in order to match all possible *Save-Place* FSTNs.
- If the schedule does not have elements linked at a poll-rate level of one, and one or more *Save-Place* FSTNs are used, then System Software must ensure the *Restore* FSTN's *Normal Path Link Pointer*'s *T-bit* is set to one, as this is used to mark the end of the periodic list.
- When the schedule does have elements linked at a poll rate level of one, a *Restore* FSTN must be the first data structure on the poll rate one list. All traversal paths from the frame list converge on the poll-rate one list. System software must ensure that *Recovery Path* mode is exited before the host controller is allowed to traverse the poll rate level one list.
- A *Save-Place* FSTN's *Back Path Link Pointer* must reference a queue head data structure. The referenced queue head must be reachable from the previous frame list

location. In other words, if the *Save-Place* FSTN is reachable from frame list offset N, then the FSTN's *Back Path Link Pointer* must reference a queue head that is reachable from frame list offset N-1.

Software should make the schedule as efficient as possible. What this means in this context is that software should have no more than one *Save-Place* FSTN reachable in any single frame. Note there is times when two (or more, depending on the implementation) could exist as full/low-speed footprints change with bandwidth adjustments. This could occur, for example when a bandwidth re-balance causes system software to move the *Save-Place* FSTN from one poll rate level to another. During the transition, software must preserve the integrity of the previous schedule until the new schedule is in place.

62.5.3.12.2.4 Tracking Split Transaction Progress for Interrupt Transfers

To correctly maintain the data stream, the host controller must be able to detect and report errors where data is lost.

For interrupt-IN transfers, data is lost when it makes it into the USB 2.0 hub, but the USB 2.0 host system is unable to get it from the USB 2.0 Hub and into the system before it expires from the transaction translator pipeline.

When a lost data condition is detected, the queue must be halted, thus signaling system software to recover from the error. A data-loss condition exists whenever a start-split is issued, accepted and successfully executed by the USB 2.0 Hub, but the complete-splits get unrecoverable errors on the high-speed link, or the complete-splits do not occur at the correct times. One reason complete-splits might not occur at the right time would be due to host-induced system hold-offs that cause the host controller to miss bus transactions because it cannot get timely access to the schedule in system memory.

The same condition can occur for an interrupt-OUT, but the result is not an endpoint halt condition, but rather effects only the progress of the transfer. The queue head has the following fields to track the progress of each split transaction. These fields are used to keep incremental state about which (and when) portions have been executed.

- *C-prog-mask*. This is an eight-bit bit-vector where the host controller keeps track of which complete-splits have been executed. Due to the nature of the Transaction Translator periodic pipeline, the complete-splits need to be executed in-order. The host controller needs to detect when the complete-splits have not been executed in order. This can only occur due to system hold-offs where the host controller cannot get to the memory-based schedule. *C-prog-mask* is a simple bit-vector that the host controller sets one of the *C-prog*-mask bits for each complete-split executed. The bit position is determined by the micro-frame number in which the complete-split was executed. The host controller always checks *C-prog-mask* before executing a

complete-split transaction. If the previous complete-splits have not been executed then it means one (or more) have been skipped and data has potentially been lost.
- *FrameTag*. This field is used by the host controller during the complete-split portion of the split transaction to tag the queue head with the frame number (*H-Frame* number) when the next complete split must be executed.
- *S-bytes*. This field can be used to store the number of data payload bytes sent during the start-split (if the transaction was an OUT). The *S-bytes* field must be used to accumulate the data payload bytes received during the complete-splits (for an IN).

62.5.3.12.2.5 Split Transaction Execution State Machine for Interrupt

In the following presentation, all references to micro-frame are in the context of a micro-frame within an *H-Frame.*

As with asynchronous Full- and Low-speed endpoints, a split-transaction state machine is used to manage the split transaction sequence.

Aside from the fields defined in the queue head for scheduling and tracking the split transaction, the host controller calculates one internal mechanism that is also used to manage the split transaction. The internal calculated mechanism is:

- *cMicroFrameBit* is a single-bit encoding of the current micro-frame number. It is an eight-bit value calculated by the host controller at the beginning of every micro-frame. It is calculated from the three least significant bits of the *FRINDEX* register (that is, *cMicroFrameBit* = (1 shifted-left(*FRINDEX*[2:0])). The *cMicroFrameBit* has at most one bit asserted, which always corresponds to the current micro-frame number. For example, if the current micro-frame is 0, then *cMicroFrameBit* will equal 00000001b. The variable *cMicroFrameBit* is used to compare against the *S-mask* and *C-mask* fields to determine whether the queue head is marked for a start- or complete-splt transaction for the current micro-frame.

The following figure illustrates the state machine for managing a complete interrupt split transaction. There are two phases to each split transaction. The first is a single start-split transaction, which occurs when the *SplitXState* is at Do_Start and the single bit in *cMicroFrameBit* has a corresponding bit active in *QH.S-mask*. The transaction translator does not acknowledge the receipt of the periodic start-split, so the host controller unconditionally transitions the state to Do_Complete. Due to the available jitter in the transaction translator pipeline, there will be more than one complete-split transaction scheduled by software for the Do_Complete state. This translates simply to the fact that there are multiple bits set to a one in the *QH.C-mask* field.

The host controller keeps the queue head in the Do_Complete state until the split transaction is complete (see definition below), or an error condition triggers the *three-strikes-rule* (for example, after the host tries the same transaction three times, and each

encounters an error, the host controller will stop retrying the bus transaction and halt the endpoint, thus requiring system software to detect the condition and perform system-dependent recovery).

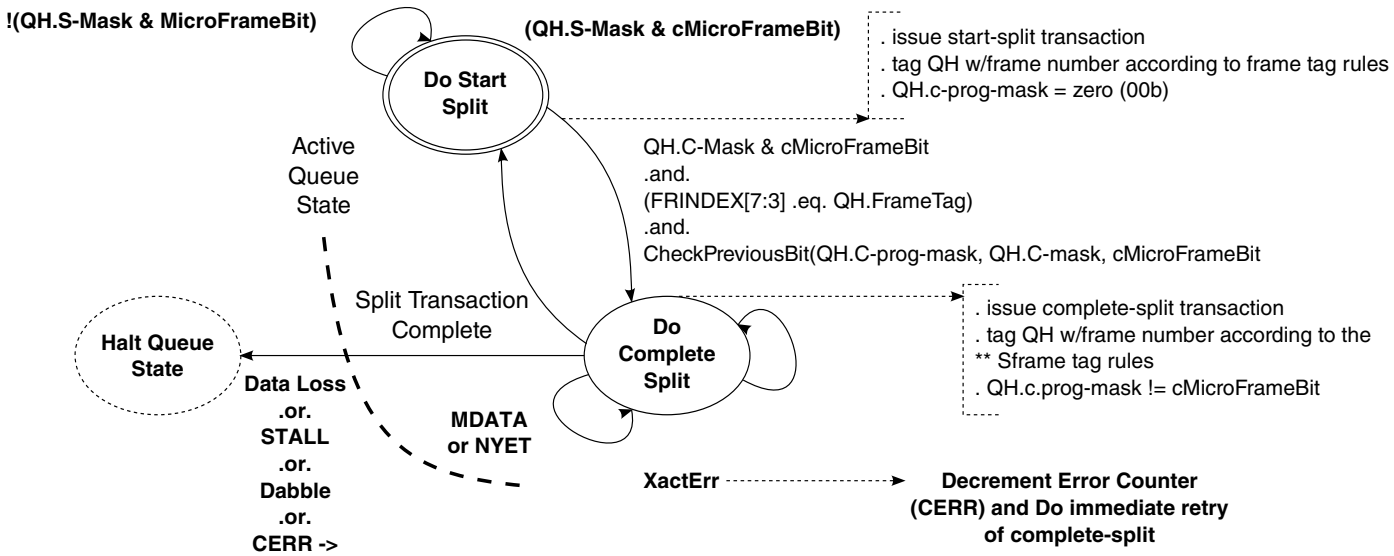

Figure 62-24. Split Transaction State Machine for Interrupt

See Previous Section for the frame tag management rules.

Periodic Interrupt - Do Start Split

This is the state software must initialize a full- or low-speed interrupt queue head *StartXState* bit. This state is entered from the Do_Complete Split state only after the split transaction is complete. This occurs when one of the following events occur: The transaction translator responds to a complete-split transaction with one of the following:

- NAK. A NAK response is a propagation of the full- or low-speed endpoint's NAK response.
- ACK. An ACK response is a propagation of the full- or low-speed endpoint's ACK response. Only occurs on an OUT endpoint.
- DATA 0/1. Only occurs for INs. Indicates that this is the last of the data from the endpoint for this split transaction.
- ERR. The transaction on the low-/full-speed link below the transaction translator had a failure (for example, timeout, bad CRC, etc.).
- NYET (and Last). The host controller issued the last complete-split and the transaction translator responded with a NYET handshake. This means that the start-split was not correctly received by the transaction translator, so it never executed a transaction to the full- or low-speed endpoint, see Section Periodic Isochronous - Do Complete Split for the definition of 'Last'.

Each time the host controller visits a queue head in this state (once within the Execute Transaction state), it performs the following test to determine whether to execute a start-split.

- *QH.S-mask* is bit-wise anded with *cMicroFrameBit*.

If the result is non-zero, then the host controller will issue a start-split transaction. If the *PIDCode* field indicates an IN transaction, the host controller must zero-out the *QH.S-bytes* field. After the split-transaction has been executed, the host controller sets up state in the queue head to track the progress of the complete-split phase of the split transaction. Specifically, it records the expected frame number into *QH.FrameTag* field (see Section), set *C-prog-mask* to zero (00h), and exits this state. Note that the host controller must not adjust the value of *CErr* as a result of completion of a start-split transaction.

Periodic Interrupt - Do Complete Split

This state is entered unconditionally from the Do Start Split state after a start-split transaction is executed on the bus. Each time the host controller visits a queue head in this state (once within the Execute Transaction state), it checks to determine whether a complete-split transaction should be executed now.

There are four tests to determine whether a complete-split transaction should be executed.

- Test A. *cMicroFrameBit* is bit-wise anded with *QH.C-mask* field. A non-zero result indicates that software scheduled a complete-split for this endpoint, during this micro-frame.
- Test B. *QH.FrameTag* is compared with the current contents of *FRINDEX*[7:3]. An equal indicates a match.
- Test C. The complete-split progress bit vector is checked to determine whether the previous bit is set, indicating that the previous complete-split was appropriately executed. An example algorithm for this test is provided below:

```
Algorithm Boolean CheckPreviousBit(QH.C-prog-mask, QH.C-mask, cMicroFrameBit)
Begin
-- Return values:
-- TRUE - no error
-- FALSE - error
--
Boolean rvalue = TRUE;
previousBit = cMicroframeBit logical-rotate-right(1)
-- Bit-wise anding previousBit with C-mask indicates
-- whether there was an intent
-- to send a complete split in the previous micro-frame. So,
-- if the
-- 'previous bit' is set in C-mask, check C-prog-mask to
-- make sure it
-- happened.
If (previousBit bitAND QH.C-mask)then
                                If not(previousBit bitAND QH.C-prog-mask) then
                      rvalue = FALSE;
          End if
End If
-- If the C-prog-mask already has a one in this bit position,
```

```
-- then an aliasing
-- error has occurred. It will probably get caught by the
-- FrameTag Test, but
-- at any rate it is an error condition that as detectable here
-- should not allow
-- a transaction to be executed.
If (cMicroFrameBit bitAND QH.C-prog-mask) then
 rvalue = FALSE;
End if
return (rvalue)
End Algorithm
```

- Test D. Check to see if a start-split should be executed in this micro-frame. Note this is the same test performed in the Do Start Split state (see Section Periodic Isochronous - Do Start Split). Whenever it evaluates to TRUE and the controller is NOT processing in the context of a *Recovery Path* mode, it means a start-split should occur in this micro-frame. Test D and Test A evaluating to TRUE at the same time is a system software error. Behavior is undefined.

If (A .and. B .and. C .and. not(D)) then the host controller will execute a complete-split transaction. When the host controller commits to executing the complete-split transaction, it updates *QH.C-prog-mask* by bit-ORing with *cMicroFrameBit*. On completion of the complete-split transaction, the host controller records the result of the transaction in the queue head and sets *QH.FrameTag* to the expected *H-Frame* number (see Section). The effect to the state of the queue head and thus the state of the transfer depends on the response by the transaction translator to the complete-split transaction. The following responses have the effects (note that any responses that result in decrementing of the *CErr* will result in the queue head being halted by the host controller if the result of the decrement is zero):

- NYET (and Last). On each NYET response, the host controller checks to determine whether this is the last complete-split for this split transaction. Last is defined in this context as the condition where all of the scheduled complete-splits have been executed. If it is the last complete-split (with a NYET response), then the transfer state of the queue head is not advanced (never received any data) and this state exited. The transaction translator must have responded to all the clompete-splits with NYETs, meaning that the start-split issued by the host controller was not received. The start-split should be retried at the next poll period.
- The test for whether this is the Last complete split can be performed by XOR *QH.C-mask* with *QH.C-prog-mask*. If the result is all zeros then all complete-splits have been executed. When this condition occurs, the *XactErr* status bit is set to a one and the *CErr* field is decremented.
- NYET (and not Last). See above description for testing for Last. The complete-split transaction received a NYET response from the transaction translator. Do not update any transfer state (except for *C-prog-mask* and *FrameTag*) and stay in this state. The host controller must not adjust *CErr* on this response.

- Transaction Error (XactErr). Timeout, data CRC failure, etc. The *CErr* field is decremented and the *XactErr* bit in the *Status* field is set to a one. The complete split transaction is *immediately* retried (if *Cerr* is non-zero).If there is not enough time in the micro-frame to complete the retry and the endpoint is an IN, or *CErr* is decremented to a zero from a one, the queue is halted. If there is not enough time in the micro-frame to complete the retry and the endpoint is an OUT and *CErr* is not zero, then this state is exited (that is, return to Do Start Split). This results in a retry of the entire OUT split transaction, at the next poll period. Refer to Chapter 11 Hubs (specifically the section full- and low-speed Interrupts) in the USB Specification Revision 2.0 for detailed requirements on why these errors must be immediately retried.
- ACK. This can only occur if the target endpoint is an OUT. The target endpoint ACK'd the data and this response is a propagation of the endpoint ACK up to the host controller. The host controller must advance the state of the transfer. The *Current Offset* field is incremented by *Maximum Packet Length* or *Bytes to Transfer*, whichever is less. The field *Bytes To Transfer* is decremented by the same amount. And the data toggle bit (*dt*) is toggled. The host controller will then exit this state for this queue head. The host controller must reload *CErr* with maximum value on this response. Advancing the transfer state may cause other process events such as retirement of the qTD and advancement of the queue (see Section Managing Control/Bulk/Interrupt Transfers through Queue Heads).
- MDATA. This response will only occur for an IN endpoint. The transaction translator responded with zero or more bytes of data and an MDATA PID. The incremental number of bytes received is accumulated in *QH.S-bytes*. The host controller must not adjust *CErr* on this response.
- DATA0/1. This response may only occur for an IN endpoint. The number of bytes received is added to the accumulated byte count in *QH.S-bytes*. The state of the transfer is advanced by the result and the host controller will exit this state for this queue head.
- Advancing the transfer state may cause other processing events such as retirement of the qTD and advancement of the queue (see Section Managing Control/Bulk/Interrupt Transfers through Queue Heads).
- If the data sequence PID does not match the expected, the entirety of the data received in this split transaction is ignored, the transfer state is not advanced and this state is exited.
- NAK. The target endpoint Nak'd the full- or low-speed transaction. The state of the transfer is not advanced, and this state is exited. The host controller must reload *CErr* with maximum value on this response.

- ERR. There was an error during the full- or low-speed transaction. The ERR status bit is set to a one, *Cerr* is decremented, the state of the transfer is not advanced, and this state is exited.
- STALL. The queue is halted (an exit condition of the Execute Transaction state). The status field bits: *Active* bit is set to zero and the *Halted* bit is set to a one and the qTD is retired. Responses which are not enumerated in the list or which are received out of sequence are illegal and may result in undefined host controller behavior. The other possible combinations of tests A, B, C, and D may indicate that data or response was lost. The table below lists the possible combinations and the appropriate action.

Table 62-49. Interrupt IN/OUT Do Complete Split State Execution Criteria

Condition	Action	Description
not(A) not(D)	Ignore QHD	Neither a start nor complete-split is scheduled for the current micro-frame.Host controller should continue walking the schedule.
A not(C)	If PIDCode = IN Halt QHD If PIDCode = OUT Retry start-split	Progress bit check failed. These means a complete-split has been missed. There is the possibility of lost data. If *PIDCode* is an IN, then the Queue head must be halted. If *PIDCode* is an OUT, then the transfer state is not advanced and the state exited (for example, start-split is retried). This is a host-induced error and does not effect *CER*R. In either case, set the *Missed Micro-frame* bit in the status field to a one.
A not(B) C	If PIDCode = IN Halt QHD If PIDCode = OUT Retry start-split	*QH.FrameTag* test failed. This means that exactly one or more *H-Frames* have been skipped. This means complete-splits and have missed. There is the possibility of lost data. If *PIDCode* is an IN, then the Queue head must be halted. If *PIDCode* is an OUT, then the transfer state is not advanced and the state exited (for example, start-split is retried). This is a host-induced error and does not effect *CER*R. In either case, set the *Missed Micro-frame* bit in the status field to a one.
A B C not(D)	Execute complete-split	This is the non-error case where the host controller executes a complete-split transaction.
D	If PIDCode = IN Halt QHD If PIDCode = OUT Retry start-split	This is a degenerate case where the start-split was issued, but all of the complete-splits were skipped and all possible intervening opportunities to detect the missed data failed to fire. If *PIDCode* is an IN, then the Queue head must be halted. If *PIDCode* is an OUT, then the transfer state is not advanced and the state exited (for example, start-split is retried). This is a host-induced error and does not effect *CER*R. In either case, set the *Missed Micro-frame* bit in the status field to a one. Note: When executing in the context of a *Recovery Path* mode, the host controller is allowed to process the queue head and take the actions indicated above, or it may wait until the queue head is visited in the

Table 62-49. Interrupt IN/OUT Do Complete Split State Execution Criteria

		normal processing mode. Regardless, the host controller must not execute a start-split in the context of a executing in a *Recovery Path* mode.

Managing QH.FrameTag Field

The *QH.FrameTag* field in a queue head is completely managed by the host controller. The rules for setting *QH.FrameTag* are simple:

- Rule 1: If transitioning from Do Start Split to Do Complete Split and the current value of *FRINDEX*[2:0] is 6 *QH.FrameTag* is set to *FRINDEX*[7:3] + 1. This accommodates split transactions whose start-split and complete-splits are in different *H-Frames* (case 2a, see Figure 62-21).
- Rule 2: If the current value of *FRINDEX*[2:0] is 7, *QH.FrameTag* is set to *FRINDEX*[7:3] + 1. This accommodates staying in Do Complete Split for cases 2a, 2b, and 2c (Figure 62-21).
- Rule 3: If transitioning from Do_Start Split to Do Complete Split and the current value of *FRINDEX*[2:0] is not 6, or currently in Do Complete Split and the current value of (*FRINDEX*[2:0]) is not 7, *FrameTag* is set to *FRINDEX*[7:3]. This accommodates all other cases (Figure 62-21).

62.5.3.12.2.6 Rebalancing the periodic schedule

System software must occasionally adjust a periodic queue head's S-mask and C-mask fields during operation.

This need occurs when adjustments to the periodic schedule create a new bandwidth budget and one or more queue head's are assigned new execution footprints (that is, new S-mask and C-mask values).

It is imperative that System software must not update these masks to new values in the midst of a split transaction. In order to avoid any race conditions with the update, the EHCI host controller provides a simple assist to system software. System software sets the *Inactivate-on-next-Transaction* (*I*) bit to a one to signal the host controller that it intends to update the S-mask and C-mask on this queue head. System software will then wait for the host controller to observe the *I-bit* is a one and transition the *Active* bit to a zero. The rules for how and when the host controller sets the *Active* bit to zero are enumerated below:

- If the *Active* bit is a zero, no action is taken. The host controller does not attempt to advance the queue when the *I-bit* is a one.
- If the *Active* bit is a one and the *SplitXState* is DoStart (regardless of the value of *S-mask*), the host controller will simply set *Active* bit to a zero. The host controller is

not required to write the transfer state back to the *current* qTD. Note that if the *S-mask* indicates that a start-split is scheduled for the current micro-frame, the host controller must not issue the start-split bus transaction. It must set the *Active* bit to zero.

System software must save transfer state before setting the *I-bit* to a one. This is required so that it can correctly determine what transfer progress (if any) occurred after the *I-bit* was set to a one and the host controller executed its final bus-transaction and set *Active* to a zero.

After system software has updated the S-mask and C-mask, it must then reactivate the queue head. Because the *Active* bit and the *I-bit* cannot be updated with the same write, system software needs to use the following algorithm to coherently re-activate a queue head that has been stopped via the *I-bit*.

1. Set the *Halted* bit to a one, then
2. Set the *I-bit* to a zero, then
3. Set the *Active* bit to a one and the *Halted* bit to a zero in the same write.

Setting the *Halted* bit to a one inhibits the host controller from attempting to advance the queue between the time the *I-bit* goes to a zero and the *Active* bit goes to a one.

62.5.3.12.3 Split Transaction Isochronous

Full-speed isochronous transfers are managed using the split-transaction protocol through a USB 2.0 transaction translator in a USB2.0 Hub. The EHCI controller utilizes siTD data structure to support the special requirements of isochronous split-transactions.

This data structure uses the scheduling model of isochronous TDs (iTD, Section Isochronous (High-Speed) Transfer Descriptor (iTD)) (see Section Managing Isochronous Transfers Using iTDs for the operational model of iTDs) with the contiguous data feature provided by queue heads. This simple arrangement allows a single isochronous scheduling model and adds the additional feature that all data received from the endpoint (per split transaction) must land into a contiguous buffer.

62.5.3.12.3.1 Split Transaction Scheduling Mechanisms for Isochronous

Full-speed isochronous transactions are managed through a transaction translator's periodic pipeline. As with full- and low-speed interrupt, system software manages each transaction translator's periodic pipeline by budgeting and scheduling exactly during which micro-frames the start-splits and complete-splits for each full-speed isochronous endpoint occur.

The requirements described in Section Split Transaction Scheduling Mechanisms for Interrupt apply. The following figure illustrates the general scheduling boundary conditions that are supported by the EHCI periodic schedule. The ^{S}X and ^{C}X labels indicate micro-frames where software can schedule start- and complete-splits (respectively). The *H-Frame* boundaries are marked with a large, solid bold vertical line. The *B-Frame* boundaries are marked with a large, bold, dashed line. The bottom of the figure illustrates the relationship of an siTD to the *H-Frame*.

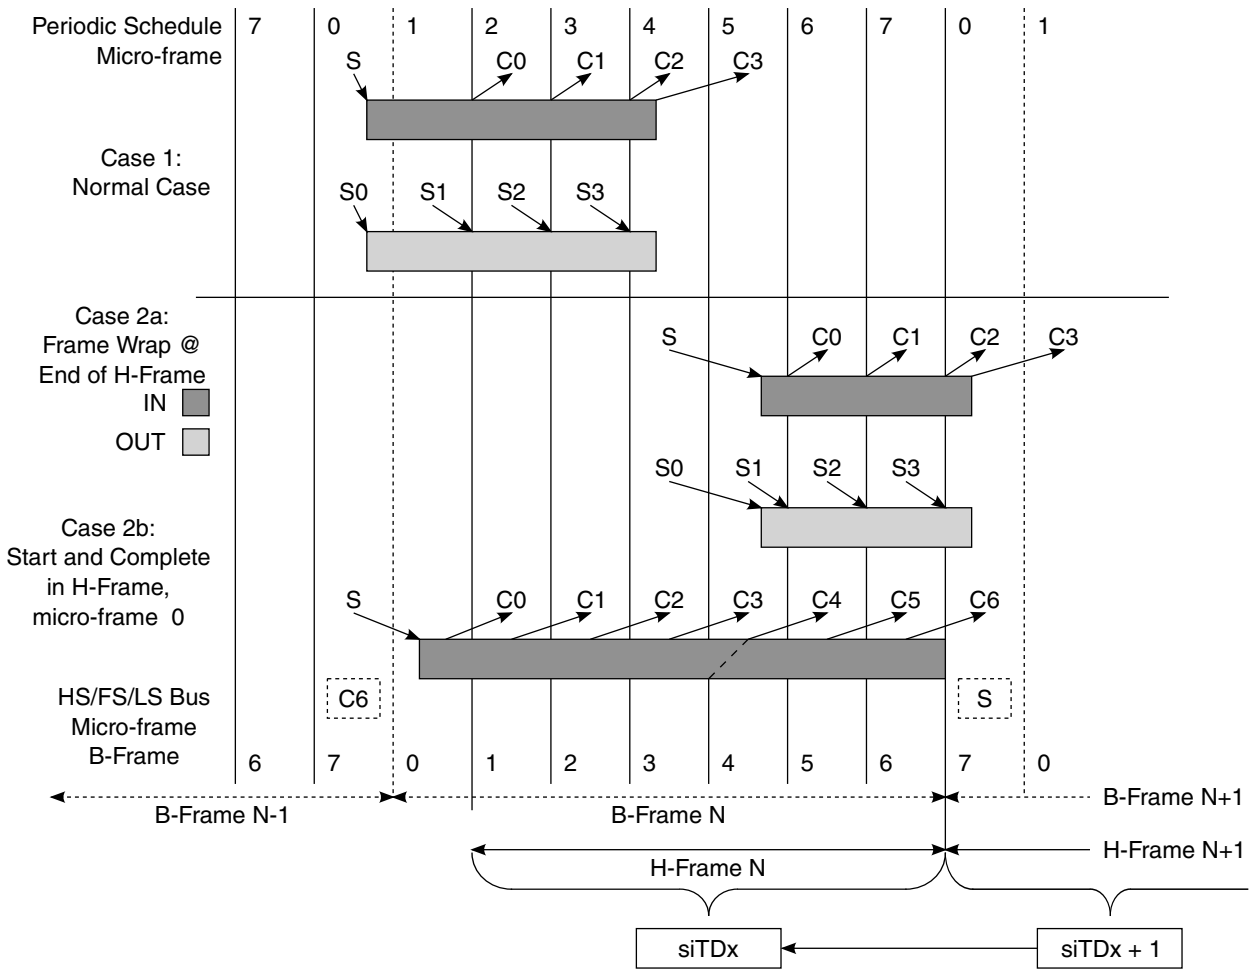

Figure 62-25. Split Transaction, Isochronous Scheduling Boundary Conditions

When the endpoint is an isochronous OUT, there are only start-splits, and no complete-splits. When the endpoint is an isochronous IN, there is at most one start-split and one to *N* complete-splits. The scheduling boundary cases are:

- *Case 1*: The entire split transaction is completely bounded by an *H-Frame*. For example: the start-splits and complete-splits are all scheduled to occur in the same *H-Frame*.

- *Case 2a*: This boundary case is where one or more (at most two) complete-splits of a split transaction IN are scheduled across an *H-Frame* boundary. This can only occur when the split transaction has the possibility of moving data in *B-Frame,* micro-frames 6 or 7 (*H-Frame* micro-frame 7 or 0). When an *H-Frame* boundary wrap condition occurs, the scheduling of the split transaction spans more than one location in the periodic list.(For example, it takes two siTDs in adjacent periodic frame list locations to fully describe the scheduling for the split transaction.)
- Although the scheduling of the split transaction may take two data structures, all of the complete-splits for each full-speed IN isochronous transaction must use only one data pointer. For this reason, siTDs contain a back pointer, the use of which is described below.
- Software must never schedule full-speed isochronous OUTs across an *H-Frame* boundary.
- *Case 2b*: This case can only occur for a very large isochronous IN. It is the only allowed scenario where a start-split and complete-split for the same endpoint can occur in the same micro-frame. Software must enforce this rule by scheduling the large transaction first. Large is defined to be anything larger than 579 byte maximum packet size.

A subset of the same mechanisms employed by full- and low-speed interrupt queue heads are employed in siTDs to schedule and track the portions of isochronous split transactions. The following fields are initialized by system software to instruct the host controller when to execute portions of the split transaction protocol.

- *SplitXState*. This is a single bit residing in the *Status* field of an siTD (see Figure 62-26). This bit is used to track the current state of the split transaction. The rules for managing this bit are described in Section Split Transaction Execution State Machine for Interrupt.
- *Frame S-mask*. This is a bit-field where-in system software sets a bit corresponding to the micro-frame (within an *H-Frame*) that the host controller should execute a start-split transaction. This is always qualified by the value of the *SplitXState* bit. For example, referring to the IN example in Figure 62-25, case one, the *S-mask* would have a value of 00000001b indicating that if the siTD is traversed by the host controller, and the *SplitXState* indicates Do Start Split, and the current micro-frame as indicated by USB_n_FRINDEX[2:0] is 0, then execute a start-split transaction.
- *Frame C-mask.* This is a bit-field where system software sets one or more bits corresponding to the micro-frames (within an *H-Frame*) that the host controller should execute complete-split transactions. The interpretation of this field is always qualified by the value of the *SplitXState* bit. For example, referring to the IN example in Figure 62-25, case one, the *C-mask* would have a value of 00111100b indicating that if the siTD is traversed by the host controller, and the *SplitXState* indicates Do

Complete Split, and the current micro-frame as indicated by *USB_n_FRINDEX*[2:0] is 2, 3, 4, or 5, then execute a complete-split transaction.

- *Back Pointer*. This field in a siTD is used to complete an IN split-transaction using the previous *H-Frame*'s siTD. This is only used when the scheduling of the complete-splits span an *H-Frame* boundary.

There exists a one-to-one relationship between a high-speed isochronous split transaction (including all start- and complete-splits) and one full-speed isochronous transaction. An siTD contains (amongst other things) buffer state and split transaction scheduling information. An siTD's buffer state always maps to one full-speed isochronous data payload. This means that for any full-speed transaction payload, a single siTD's data buffer must be used. This rule applies to both IN an OUTs. An siTD's scheduling information usually also maps to one high-speed isochronous split transaction. The exception to this rule is the *H-Frame* boundary wrap cases mentioned above.

The siTD data structure describes at most, one frame's worth of high-speed transactions and that description is strictly bounded within a frame boundary. The figure below illustrates some examples. On the top are examples of the full-speed transaction footprints for the boundary scheduling cases described above. In the middle are time-frame references for both the *B-Frames* (HS/FS/LS Bus) and the *H-Frames*. On the bottom is illustrated the relationship between the scope of an siTD description and the time references. Each *H-Frame* corresponds to a single location in the periodic frame list. The implication is that each siTD is reachable from a single periodic frame list location at a time.

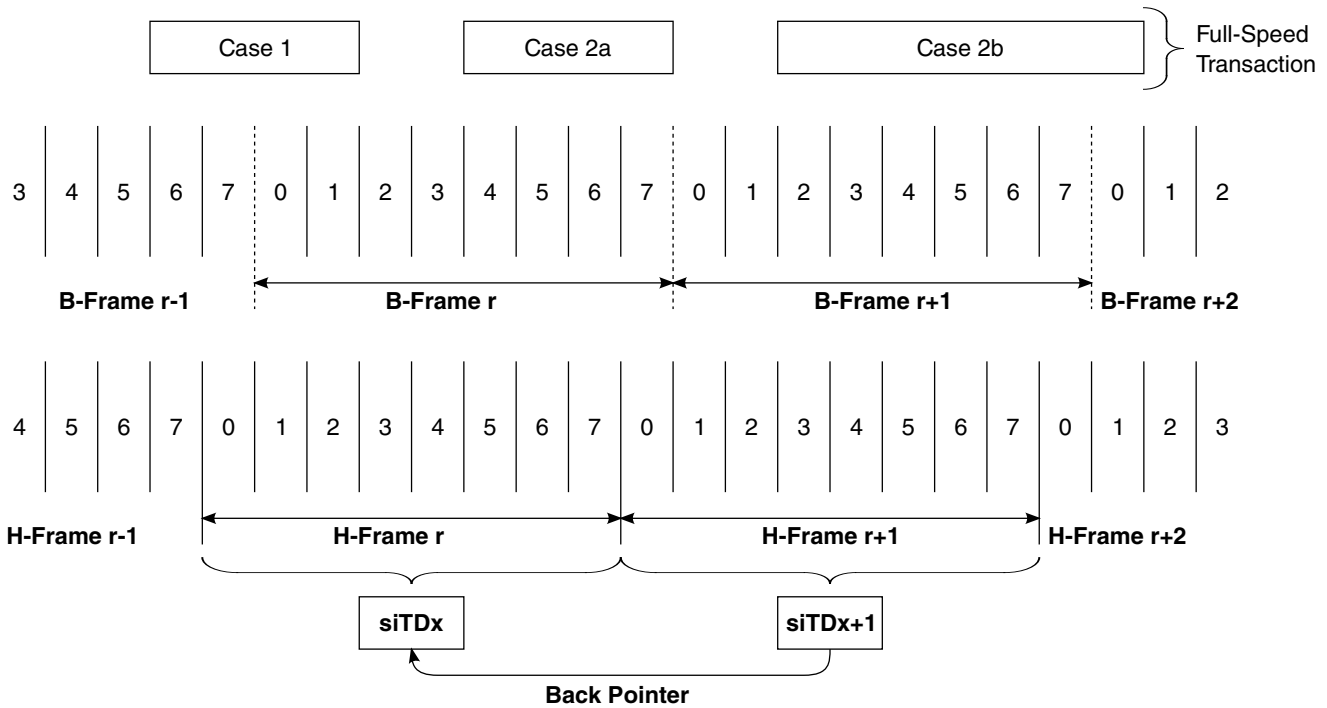

Figure 62-26. siTD Scheduling Boundary Examples

Each case is described below:

- *Case 1*: One siTD is sufficient to describe and complete the isochronous split transaction because the whole isochronous split transaction is tightly contained within a single *H-Frame*.
- *Case 2a, 2b*: Although both INs and OUTs can have these footprints, OUTs always take only one siTD to schedule. However, INs (for these boundary cases) require two siTDs to complete the scheduling of the isochronous split transaction $siTD_X$ is used to always issue the start-split and the first *N* complete-splits. The full-speed transaction (for these cases) can deliver data on the full-speed bus segment during micro-frame 7 of $H\text{-}Frame_{Y+1}$, or micro-frame 0 of $H\text{-}Frame_{Y+2}$. The complete splits are scheduled using $siTD_{X+2}$ (not shown). The complete-splits to extract this data must use the buffer pointer from $siTD_{X+1}$. The only way for the host controller to reach $siTD_{X+1}$ from $H\text{-}Frame_{Y+2}$is to use $siTD_{X+2}$'s back pointer. The host controller rules for when to use the back pointer are described is Section Periodic Isochronous - Do Complete Split .

Software must apply the following rules when calculating the schedule and linking the schedule data structures into the periodic schedule:

- Software must ensure that an isochronous split-transaction is started so that it will complete before the end of the *B-Frame*.
- Software must ensure that for a single full-speed isochronous endpoint, there is never a start-split and complete-split in *H-Frame, micro-frame 1*. This is mandated as a rule so that case 2a and case 2b can be discriminated. According to the core USB specification, the long isochronous transaction illustrated in Case 2b, could be scheduled so that the start-split was in micro-frame 1 of *H-Frame* N and the last complete-split would need to occur in micro-frame 1 of H-Frame N+1. However, it is impossible to discriminate between cases 2a and case 2b, which has significant impact on the complexity of the host controller.

62.5.3.12.3.2 Tracking Split Transaction Progress for Isochronous Transfers

To correctly maintain the data stream, the host controller must be able to detect and report errors where device to host data is lost. Isochronous endpoints do not employ the concept of a halt on error, however the host is required to identify and report per-packet errors observed in the data stream. This includes schedule traversal problems (skipped micro-frames), timeouts and corrupted data received.

In similar kind to interrupt split-transactions, the portions of the split transaction protocol must execute in the micro-frames they are scheduled. The queue head data structure used to manage full- and low-speed interrupt has several mechanisms for tracking when portions of a transaction have occurred. Isochronous transfers use siTDs, for their transfers, and the data structures are only reachable via the schedule in the exact micro-frame in which they are required (so all the mechanism employed for tracking in queue heads is not required for siTDs). Software has the option of reusing siTD several times in the complete periodic schedule. However, it must ensure that the results of split transaction N are consumed and the siTD reinitialized (activated) before the host controller gets back to the siTD (in a future micro-frame).

Split-transaction isochronous OUTs utilize a low-level protocol to indicate which portions of the split transaction data have arrived. Control over the low-level protocol is exposed in an siTD via the fields *Transaction Position* (*TP*) and *Transaction Count* (*T-count*). If the entire data payload for the OUT split transaction is larger than 188 bytes, there will be more than one start-split transaction, each of which require proper annotation. If host hold-offs occur, then the sequence of annotations received from the host will not be complete, which is detected and handled by the transaction translator. See Section Periodic Isochronous - Do Start Split for a description on how these fields are used during a sequence of start-split transactions.

The fields *siTD.T-Count* and *siTD.TP* are used by the host controller to drive and sequence the transaction position annotations. It is the responsibility of system software to properly initialize these fields in each siTD. Once the budget for a split-transaction

isochronous endpoint is established, *S-mask*, *T-Count*, and *TP* initialization values for all the siTD associated with the endpoint are constant. They remain constant until the budget for the endpoint is recalculated by software and the periodic schedule adjusted.

For IN-endpoints, the transaction translator simply annotates the response data packets with enough information to allow the host controller to identify the last data. As with split transaction Interrupt, it is the host controller's responsibility to detect when it has missed an opportunity to execute a complete-split. The following field in the siTD is used to track and detect errors in the execution of a split transaction for an IN isochronous endpoint.

- *C-prog-mask*. This is an eight-bit bit-vector where the host controller keeps track of which complete-splits have been executed. Due to the nature of the Transaction Translator periodic pipeline, the complete-splits need to be executed in-order. The host controller needs to detect when the complete-splits have not been executed in order. This can only occur due to system hold-offs where the host controller cannot get to the memory-based schedule. *C-prog-mask* is a simple bit-vector that the host controller sets a bit for each complete-split executed. The bit position is determined by the micro-frame (USB_n_FRINDEX[2:0]) number in which the complete-split was executed. The host controller always checks *C-prog-mask* before executing a complete-split transaction. If the previous complete-splits have not been executed, then it means one (or more) have been skipped and data has potentially been lost. System software is required to initialize this field to zero before setting an siTD's *Active* bit to a one.

If a transaction translator returns with the final data before all of the complete-splits have been executed, the state of the transfer is advanced so that the remaining complete-splits are not executed. Refer to Section Asynchronous - Do Complete Split for a description on how the state of the transfer is advanced. It is important to note that an IN siTD is retired based solely on the responses from the Transaction Translator to the complete-split transactions. This means, for example, that it is possible for a transaction translator to respond to a complete-split with an MDATA PID. The number of bytes in the MDATA's data payload could cause the siTD field *Total Bytes to Transfer* to decrement to zero. This response can occur, before all of the scheduled complete-splits have been executed. In other interface, data structures (for example, high-speed data streams through queue heads), the transition of *Total Bytes to Transfer* to zero signals the end of the transfer and results in setting of the *Active* bit to zero. However, in this case, the result has not been delivered by the Transaction Translator and the host must continue with the next complete-split transaction to extract the residual transaction state. This scenario occurs because of the pipeline rules for a Transaction Translator (see Chapter 11 of the Universal Serial Bus Revision 2.0). In summary the periodic pipeline rules require that on a micro-frame boundary, the Transaction Translator will hold the final two bytes received (if it has not seen an End Of Packet (EOP)) in the full-speed bus pipe stage and give the

remaining bytes to the high-speed pipeline stage. At the micro-frame boundary, the Transaction Translator could have received the entire packet (including both CRC bytes) but not received the packet EOP. In the next micro-frame, the Transaction Translator will respond with an MDATA and send all of the data bytes (with the two CRC bytes being held in the full-speed pipeline stage). This could cause the siTD to decrement its *Total Bytes to Transfer* field to zero, indicating it has received all expected data. The host must still execute one more (scheduled) complete-split transaction in order to extract the results of the full-speed transaction from the Transaction Translator (for example, the Transaction Translator may have detected a CRC failure, and this result must be forwarded to the host).

If the host experiences hold-offs that cause the host controller to skip one or more (but not all) scheduled split transactions for an isochronous OUT, then the protocol to the transaction translator will not be consistent and the transaction translator will detect and react to the problem. Likewise, for host hold-offs that cause the host controller to skip one or more (but not all) scheduled split transactions for an isochronous IN, the *C-prog-mask* is used by the host controller to detect errors. However, if the host experiences a hold-off that causes it to skip all of an siTD, or an siTD expires during a host hold off (for example, a hold-off occurs and the siTD is no longer reachable by the host controller in order for it to report the hold-off event), then system software must detect that the siTDs have not been processed by the host controller (that is, state not advanced) and report the appropriate error to the client driver.

62.5.3.12.3.3 Split Transaction Execution State Machine for Isochronous

In the following presentation, all references to micro-frame are in the context of a micro-frame within an *H-Frame.*

If the *Active* bit in the *Status* byte is a zero, the host controller will ignore the siTD and continue traversing the periodic schedule. Otherwise the host controller will process the siTD as specified below. A split transaction state machine is used to manage the split-transaction protocol sequence. The host controller uses the fields defined in Section Tracking Split Transaction Progress for Interrupt Transfers , plus the variable *cMicroFrameBit* defined in Section Split Transaction Execution State Machine for Interrupt to track the progress of an isochronous split transaction. The figure below illustrates the state machine for managing an siTD through an isochronous split transaction. Bold, dotted circles denote the state of the *Active* bit in the *Status* field of a siTD. The Bold, dotted arcs denote the transitions between these states. Solid circles denote the states of the split transaction state machine and the solid arcs denote the transitions between these states. Dotted arcs and boxes reference actions that take place either as a result of a transition or from being in a state.

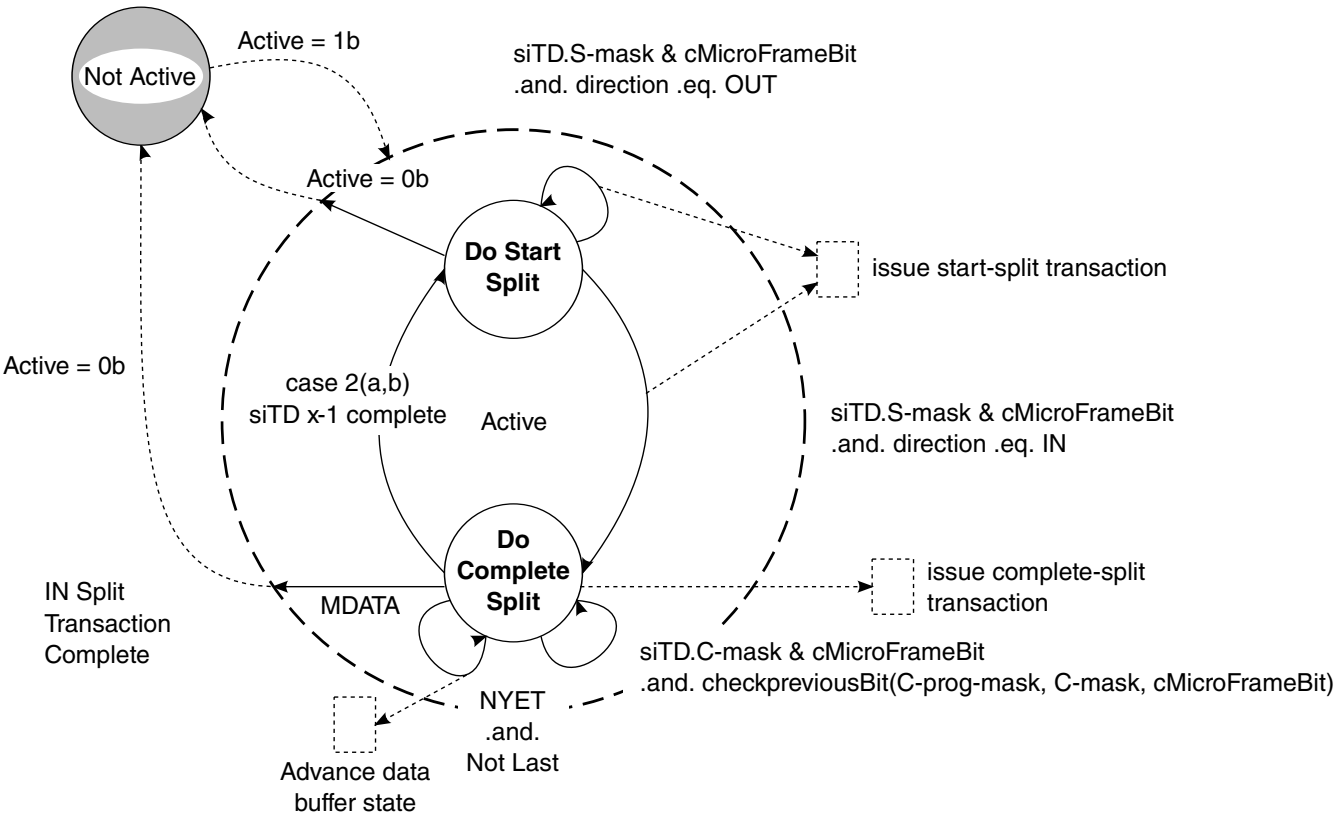

Figure 62-27. Split Transaction State Machine for Isochronous

62.5.3.12.3.4 Periodic Isochronous - Do Start Split

Isochronous split transaction OUTs use only this state.

An siTD for a split-transaction isochronous IN is either initialized to this state, or the siTD transitions to this state from Do Complete Split when a case 2a (IN) or 2b scheduling boundary isochronous split-transaction completes.

Each time the host controller reaches an active siTD in this state, it checks the *siTD.S-mask* against *cMicroFrameBit*. If there is a one in the appropriate position, the siTD will execute a start-split transaction. By definition, the host controller cannot *reach* an siTD at the wrong time. If the *I/O* field indicates an IN, then the start-split transaction includes only the extended token plus the full-speed token. Software must initialize the *siTD.Total Bytes To Transfer* field to the number of bytes expected. This is usually the maximum packet size for the full-speed endpoint. The host controller exits this state when the start-split transaction is complete.

The remainder of this section is specific to an isochronous OUT endpoint (that is, the *I/O* field indicates an OUT). When the host controller executes a start-split transaction for an isochronous OUT it includes a data payload in the start-split transaction. The memory

buffer address for the data payload is constructed by concatenating *siTD.Current Offset* with the page pointer indicated by the page selector field (*siTD.P*). A zero in this field selects Page 0 and a 1 selects Page 1. During the start-split for an OUT, if the data transfer crosses a page boundary during the transaction, the host controller must detect the page cross, update the *siTD.P*-bit from a zero to a one, and begin using the *siTD.Page 1* with *siTD.Current Offset* as the memory address pointer. The field *siTD.TP* is used to annotate each start-split transaction with the indication of which part of the split-transaction data the current payload represents (ALL, BEGIN, MID, END). In all cases the host controller simply uses the value in *siTD.TP* to mark the start-split with the correct transaction position code.

T-Count is always initialized to the number of start-splits for the current frame. *TP* is always initialized to the first required transaction position identifier. The scheduling boundary case (see Figure 62-26) is used to determine the initial value of *TP*. The initial cases are summarized in the following table.

Table 62-50. Initial Conditions for OUT siTD's TP and T-count Fields

Case	T-count	TP	Description
1, 2a	=1	ALL	When the OUT data payload is less than (or equal to) 188 bytes, only one start-split is required to move the data. The one start-split must be marked with an ALL.
1, 2a	!=1	BEGIN	When the OUT data payload is greater than 188 bytes more than one start-split must be used to move the data. The initial start-split must be marked with a BEGIN.

After each start-split transaction is complete, the host controller updates *T-Count* and *TP* appropriately so that the next start-split is correctly annotated.

The table below illustrates all of the *TP* and *T-count* transitions, which must be accomplished by the host controller.

.

Table 62-51. Transaction Position (TP)/Transaction Count (T-Count) Transition Table

TP	T-count next	TP next	Description
ALL	0	N/A	Transition from ALL, to done.
BEGIN	1	END	Transition from BEGIN to END. Occurs when *T-count* starts at 2.
BEGIN	!=1	MID	Transition from BEGIN to MID. Occurs when *T-count* starts at greater than 2.
MID	!=1	MID	*TP* stays at MID while *T-count* is not equal to 1 (that is, greater than 1). This case can occur for any of the scheduling boundary cases where the *T-count* starts greater than 3.
MID	1	END	Transition from MID to END. This case can occur for any of the scheduling boundary cases where the *T-count* starts greater than 2.

The start-split transactions do not receive a handshake from the transaction translator, so the host controller always advances the transfer state in the siTD after the bus transaction is complete. To advance the transfer state the following operations take place:

- The *siTD.Total Bytes To Transfer* and the *siTD.Current Offset* fields are adjusted to reflect the number of bytes transferred.
- The *siTD.P* (page selector) bit is updated appropriately.
- The *siTD.TP* and *siTD.T-count* fields are updated appropriately as defined in Table 62-51.

These fields are then written back to the memory based siTD. The *S-mask* is fixed for the life of the current budget. As mentioned above, *TP* and *T-count* are set specifically in each siTD to reflect the data to be sent from this siTD. Therefore, regardless of the value of *S-mask*, the actual number of start-split transactions depends on *T-count* (or equivalently, *Total Bytes to Transfer*). The host controller must set the *Active* bit to a zero when it detects that all of the schedule data has been sent to the bus. The preferred method is to detect when *T-Count* decrements to zero as a result of a start-split bus transaction. Equivalently, the host controller can detect when *Total Bytes to Transfer* decrements to zero. Either implementation must ensure that if the initial condition is *Total Bytes to Transfer* equal to zero and *T-count* is equal to a one, then the host controller will issue a single start-split, with a zero-length data payload. Software must ensure that *TP*, *T-count* and *Total Bytes to Transfer* are set to deliver the appropriate number of bus transactions from each siTD. An inconsistent combination will yield undefined behavior.

If the host experiences hold-offs that cause the host controller to skip start-split transactions for an OUT transfer, the state of the transfer will not progress appropriately. The transaction translator will observe protocol violations in the arrival of the start-splits for the OUT endpoint (that is, the transaction position annotation will be incorrect as received by the transaction translator).

Example scenarios are described in Section Split Transaction for Isochronous - Processing Examples.

A host controller implementation can optionally track the progress of an OUT split transaction by setting appropriate bits in the *siTD.C-prog-mask* as it executes each scheduled start-split. The *checkPreviousBit*() algorithm defined in Periodic Isochronous - Do Complete Split can be used prior to executing each start-split to determine whether start-splits were skipped. The host controller can use this mechanism to detect missed micro-frames. It can then set the siTD's *Active* bit to zero and stop execution of this siTD. This saves on both memory and high-speed bus bandwidth.

62.5.3.12.3.5 Periodic Isochronous - Do Complete Split

This state is only used by a split-transaction isochronous IN endpoint.

This state is entered unconditionally from the Do Start State after a start-split transaction is executed for an IN endpoint. Each time the host controller visits an siTD in this state, it conducts a number of tests to determine whether it should execute a complete-split transaction. The individual tests are listed below. The sequence they are applied depends on which micro-frame the host controller is currently executing which means that the tests might not be applied until after the siTD referenced from the back pointer has been fetched.

- Test A. *cMicroFrameBit* is bit-wise anded with *siTD.C-mask* field. A non-zero result indicates that software scheduled a complete-split for this endpoint, during this micro-frame. This test is always applied to a newly fetched siTD that is in this state.
- Test B. The *siTD.C-prog-mask* bit vector is checked to determine whether the previous complete splits have been executed. An example algorithm is below (this is slightly different than the algorithm used in Section Periodic Isochronous - Do Start Split). The sequence in which this test is applied depends on the current value of USB_n_FRINDEX[2:0]. If USB_n_FRINDEX[2:0] is 0 or 1, it is not applied until the back pointer has been used. Otherwise it is applied immediately.

```
Algorithm Boolean CheckPreviousBit(siTD.C-prog-mask, siTD.C-mask, cMicroFrameBit)
Begin
          Boolean rvalue = TRUE;
          previousBit = cMicroFrameBit rotate-right(1)
          -- Bit-wise anding previousBit with C-mask indicates whether there was an intent
          -- to send a complete split in the previous micro-frame. So, if the
          -- 'previous bit' is set in C-mask, check C-prog-mask to make sure it
          -- happened.
          if previousBit bitAND siTD.C-mask then
                    if not (previousBit bitAND siTD.C-prog-mask) then
                              rvalue = FALSE
                    End if
          End if
          Return rvalue
End Algorithm
```

If Test A is true and USB_n_FRINDEX[2:0] is zero or one, then this is a case 2a or 2b scheduling boundary (see Figure 62-25). See Section Periodic Isochronous - Do Start Split for details in handling this condition.

If Test A and Test B evaluate to true, then the host controller will execute a complete-split transaction using the transfer state of the current siTD. When the host controller commits to executing the complete-split transaction, it updates *QH.C-prog-mask* by bit-ORing with *cMicroFrameBit*. The transfer state is advanced based on the completion status of the complete-split transaction. To advance the transfer state of an IN siTD, the host controller must:

- Decrement the number of bytes received from *siTD.Total Bytes To Transfer,*
- Adjust *siTD.Current Offset* by the number of bytes received,

- Adjust *siTD.P* (page selector) field if the transfer caused the host controller to use the next page pointer, and
- Set any appropriate bits in the *siTD.Status* field, depending on the results of the transaction.

Note that if the host controller encounters a condition where *siTD.Total Bytes To Transfer* is zero, and it receives more data, the host controller must not write the additional data to memory. The *siTD.Status.Active* bit must be set to zero and the *siTD.Status.Babble Detected* bit must be set to a one. The fields *siTD.Total Bytes To Transfer*, *siTD.Current Offset*, and *siTD.P* (page selector) are not required to be updated as a result of this transaction attempt.

The host controller must accept (assuming good data packet CRC and sufficient room in the buffer as indicated by the value of *siTD.Total Bytes To Transfer*) MDATA and DATA0/1 data payloads up to and including 192 bytes. A host controller implementation may optionally set *siTD.Status Active* to a zero and *siTD.Status.Babble Detected* to a one when it receives and MDATA or DATA0/1 with a data payload of more than 192 bytes. The following responses have the noted effects:

- ERR. The full-speed transaction completed with a time-out or bad CRC and this is a reflection of that error to the host. The host controller sets the *ERR* bit in the *siTD.Status* field and sets the *Active* bit to a zero.
- Transaction Error (XactErr). The complete-split transaction encounters a Timeout, CRC16 failure, etc. The *siTD.Status* field *XactErr* field is set to a one and the complete-split transaction must be retried immediately. The host controller must use an internal error counter to count the number of retries as a counter field is not provided in the siTD data structure. The host controller will not retry more than two times. If the host controller exhausts the retries or the end of the micro-frame occurs, the *Active* bit is set to zero.
- DATAx (0 or 1). This response signals that the final data for the split transaction has arrived. The transfer state of the siTD is advanced and the *Active* bit is set to a zero. If the *Bytes To Transfer* field has not decremented to zero (including the reception of the data payload in the DATAx response), then less data than was expected, or allowed for was actually received. This *short packet* event does not set the USBINT status bit in the USBSTS register to a one. The host controller will not detect this condition.
- NYET (and Last). On each NYET response, the host controller also checks to determine whether this is the last complete-split for this split transaction. Last was defined in Section Periodic Isochronous - Do Complete Split . If it is the last complete-split (with a NYET response), then the transfer state of the siTD is not advanced (never received any data) and the *Active* bit is set to a zero. No bits are set in the *Status* field because this is essentially a skipped transaction. The transaction translator must have responded to all the scheduled clompete-splits with NYETs,

meaning that the start-split issued by the host controller was not received. This result should be interpreted by system software as if the transaction was completely skipped. The test for whether this is the last complete split can be performed by XORing C-mask with C-prog-mask. A zero result indicates that all complete-splits have been executed.

- MDATA (and Last). See above description for testing for Last. This can only occur when there is an error condition. Either there has been a babble condition on the full-speed link, which delayed the completion of the full-speed transaction, or software set up the *S-mask* and/or *C-mask*s incorrectly. The host controller must set *XactErr* bit to a one and the *Active* bit is set to a zero.
- NYET (and not Last). See above description for testing for Last. The complete-split transaction received a NYET response from the transaction translator. Do not update any transfer state (except for *C-prog-mask*) and stay in this state.
- MDATA (and not Last). The transaction translator responds with an MDATA when it has partial data for the split transaction. For example, the full-speed transaction data payload spans from micro-frame X to X+1 and during micro-frame X, the transaction translator will respond with an MDATA and the data accumulated up to the end of micro-frame X. The host controller advances the transfer state to reflect the number of bytes received.

If Test A succeeds, but Test B fails, it means that one or more of the complete-splits have been skipped. The host controller sets the *Missed Micro-Frame* status bit and sets the *Active* bit to a zero.

62.5.3.12.3.6 Complete-Split for Scheduling Boundary Cases 2a, 2b

Boundary cases 2a and 2b (INs only) (see Figure 62-25) require that the host controller use the transaction state context of the previous siTD to finish the split transaction. The table below enumerates the transaction state fields.

Table 62-52. Summary siTD Split Transaction State

Buffer State	Status	Execution Progress
Total Bytes To Transfer P (page select) Current Offset TP (transaction position) T-count (transaction count)	All bits in the status field	C-prog-mask

NOTE

TP and *T-count* are used only for Host to Device (OUT) endpoints.

If software has budgeted the schedule of this data stream with a frame wrap case, then it must initialize the *siTD.Back Pointer* field to reference a valid siTD and will have the *siTD.Back Pointer.T-bit* in the *siTD.Back Pointer*

field set to a zero. Otherwise, software must set the *siTD.Back Pointer.T-bit* in the *siTD.Back Pointer* field to a one. The host controller's rules for interpreting when to use the *siTD.Back Pointer* field are listed below. These rules apply only when the siTD's *Active* bit is a one and the *SplitXState* is Do Complete Split.

- When cMicroFrameBit is a 1h and the siTDX.Back Pointer.T-bit is a zero, or
- If cMicroFrameBit is a 2h and siTDX.S-mask[0] is a zero

When either of these conditions apply, then the host controller must use the transaction state from $siTD_{X-1}$.

In order to access $siTD_{X-1}$, the host controller reads on-chip the siTD referenced from $siTD_X$.*Back Pointer*.

The host controller must save the entire state from $siTD_X$ while processing $siTD_{X-1}$. This is to accommodate for case 2b processing. The host controller must not recursively walk the list of *siTD.Back Pointers*.

If $siTD_{X-1}$ is active (*Active* bit is a one and *SplitXStat* is Do Complete Split), then both Test A and Test B are applied as described above. If these criteria to execute a complete-split are met, the host controller executes the complete split and evaluates the results as described above. The transaction state (see Table 62-52) of $siTD_{X-1}$ is appropriately advanced based on the results and written back to memory. If the resultant state of $siTD_{X-1}$'s *Active* bit is a one, then the host controller returns to the context of $siTD_X$, and follows its next pointer to the next schedule item. No updates to $siTD_X$ are necessary.

If $siTD_{X-1}$ is active (*Active* bit is a one and *SplitXStat* is Do Start Split), then the host controller must set *Active* bit to a zero and *Missed Micro-Frame* status bit to a one and the resultant status written back to memory.

If $siTD_{X-1}$*'sActive* bit is a zero, (because it was zero when the host controller first visited $siTD_{X-1}$ via $siTD_X$*'s* back pointer, it transitioned to zero as a result of a detected error, or the results of $siTD_{X-1}$*'s* complete-split transaction transitioned it to zero), then the host controller returns to the context of $siTD_X$ and transitions its *SplitXState* to Do Start Split. The host controller then determines whether the case 2b start split boundary condition exists (that is, if *cMicroframeBit* is a 1b and $siTD_X$.*S-mask*[0] is a 1b). If this criterion is met the host controller immediately executes a start-split transaction and appropriately advances the transaction state of $siTD_X$, then follows $siTD_X$.*Next Pointer* to the next schedule item. If the criterion is not met, the host controller simply follows $siTD_X$.*Next Pointer* to the next schedule item. Note that in the case of a 2b boundary case, the split-transaction of $siTD_{X-1}$ will have its *Active* bit set to zero when the host controller returns

to the context of $siTD_X$. Also, note that software should not initialize an siTD with *C-mask* bits 0 and 1 set to a one and an *S-mask* with bit zero set to a one. This scheduling combination is not supported and the behavior of the host controller is undefined.

62.5.3.12.3.7 Split Transaction for Isochronous - Processing Examples

There is an important difference between how the hardware/software manages the isochronous split transaction state machine and how it manages the asynchronous and interrupt split transaction state machines.

The asynchronous and interrupt split transaction state machines are encapsulated within a single queue head. The progress of the data stream depends on the progress of each split transaction. In some respects, the split-transaction state machine is sequenced via the Execute Transaction queue head traversal state machine (see Figure 62-18).

Isochronous is a pure time-oriented transaction/data stream. The interface data structures are optimized to efficiently describe transactions that need to occur at specific times. The isochronous split-transaction state machine must be managed across these time-oriented data structures. This means that system software must correctly describe the scheduling of split-transactions across more than one data structure.

Then the host controller must make the appropriate state transitions at the appropriate times, in the correct data structures.

For example, the table below illustrates a couple of frames worth of scheduling required to schedule a case 2a full-speed isochronous data stream.

Table 62-53. Example Case 2a - Software Scheduling siTDs for an IN Endpoint

siTDX		Micro-Frames								Initial
#	Masks	0	1	2	3	4	5	6	7	SplitXState
X	S-Mask	-	-	-	-	1	-	-	-	Do Start Split
	C-Mask	1	1	-	-	-	-	1	1	
X+1	S-Mask	-	-	-	-	1	-	-	-	Do Complete Split
	C-Mask	1	1					1	1	
X+2	S-Mask	-	-	-	-	1	-	-	-	Do Complete Split
	C-Mask	1	1					1	1	
X+3	S-Mask	Repeats previous pattern								Do Complete Split
	C-Mask									

This example shows the first three siTDs for the transaction stream. Because this is the case-2a frame-wrap case, *S-masks* of all siTDs for this endpoint have a value of 10h (a one bit in micro-frame 4) and *C-mask* value of C3h (one-bits in micro-frames 0,1, 6 and 7). Additionally, sofware ensures that the *Back Pointer* field of each siTD references the appropriate siTD data structure (and the *Back PointerT-bits* are set to zero).

The initial *SplitXState* of the first siTD is Do Start Split. The host controller will visit the first siTD eight times during frame X. The C-mask bits in micro-frames 0 and 1 are ignored because the state is Do Start Split. During micro-frame 4, the host controller determines that it can run a start-split (and does) and changes *SplitXState* to Do Complete Split. During micro-frames 6 and 7, the host controller executes complete-splits. Notice the siTD for frame X+1 has its *SplitXState* initialized to Do Complete Split. As the host controller continues to traverse the schedule during *H-Frame* X+1, it will visit the second siTD eight times. During micro-frames 0 and 1 it will detect that it must execute complete-splits.

During *H-Frame* X+1, micro-frame 0, the host controller detects that $siTD_{X+1}$'s *Back Pointer.T-bit* is a zero, saves the state of $siTD_{X+1}$ and fetches $siTD_X$. It executes the complete split transaction using the transaction state of $siTD_X$. If the $siTD_X$ split transaction is complete, siTD's *Active* bit is set to zero and results written back to $siTD_X$. The host controller retains the fact that $siTD_X$ is retired and transitions the *SplitXState* in the $siTD_{X+1}$ to Do Start Split. At this point, the host controller is prepared to execute the start-split for $siTD_{X+1}$ when it reaches micro-frame 4. If the split-transaction completes early (transaction-complete is defined in Section Periodic Isochronous - Do Complete Split), that is, before all the scheduled complete-splits have been executed, the host controller will transition $siTD_X$.*SplitXState* to Do Start Split early and naturally skip the remaining scheduled complete-split transactions. For this example, $siTD_{X+1}$ does not receive a DATA0 response until *H-Frame* X+2, micro-frame 1.

During *H-Frame X+2,* micro-frame 0, the host controller detects that $siTD_{X+2}$'s *Back Pointer.T-bit* is a zero, saves the state of $siTD_{X+2}$ and fetches $siTD_{X+1}$. As described above, it executes another split transaction, receives an MDATA response, updates the transfer state, but does not modify the *Active* bit. The host controller returns to the context of $siTD_{X+2}$, and traverses its next pointer without any state change updates to $siTD_{X+2}$. S

During *H-Frame X+2*, micro-frame 1, the host controller detects $siTD_{X+2}$'s *S-mask[0]* is a zero, saves the state of $siTD_{X+2}$ and fetches $siTD_{X+1}$. It executes another complete-split transaction, receives a DATA0 response, updates the transfer state and sets the *Active* bit to a zero. It returns to the state of $siTD_{X+2}$ and changes its *SplitXState* to Do Start Split. At this point, the host controller is prepared to execute start-splits for $siTD_{X+2}$ when it reaches micro-frame 4.

62.5.3.13 Host Controller Pause

When the host controller's *HCHalted* bit in the USBSTS register is a zero, the host controller is sending SOF (Start OF Frame) packets down all enabled ports.

When the schedules are enabled, the EHCI host controller will access the schedules in main memory each micro-frame. This constant pinging of main memory is known to create Arm platform power management problems for mobile systems. Specifically, mobile systems aggressively manage the state of the Arm platform, based on recent history usage. In the more aggressive power saving modes, the Arm platform can disable its caches. Current PC architectures assume that bus-master accesses to main memory must be cache-coherent. So, when bus masters are busy touching memory, the Arm platform power management software can detect this activity over time and inhibit the transition of the Arm platform into its lowest power savings mode. USB controllers are bus-masters and the frequency at which they access their memory-based schedules keeps the Arm platform power management software from placing the Arm platform into its lowest power savings state.

USB Host controllers don't access main memory when they are suspended. However, there are a variety of reasons why placing the USB controllers into suspend won't work, but they are beyond the scope of this document. The base requirement is that the USB controller needs to be kept out of main memory, while at the same time, the USB bus is kept from going into suspend.

EHCI controllers provide a large-grained mechanism that can be manipulated by system software to change the memory access pattern of the host controller. System software can manipulate the schedule enable bits in the USBCMD register to turn on/off the scheduling traversal. A software heuristic can be applied to implement an on/off duty cycle that allows the USB to make reasonable progress and allow the Arm platform power management to get the Arm platform into its lowest power state. This method is not intended to be applied at all times to throttle USB, but should only be applied in very specific configurations and usage loads. For example, when only a keyboard or mouse is attached to the USB, the heuristic could detect times when the USB is attempting to move data only very infrequently and can adjust the duty cycle to allow the Arm platform to reach its low power state for longer periods of time. Similarly, it could detect increases in the USB load and adjust the duty cycle appropriately, even to the point where the schedules are never disabled. The assumption here is that the USB is moving data and the Arm platform will be required to process the data streams.

It is suggested that in order to provide a complete solution for the system, the companion host controllers should also provide a similar method to allow system software to inhibit the companion host controller from accessing its shared memory based data structures (schedule lists or otherwise).

62.5.3.14 Port Test Modes -Host Operational Model

EHCI host controllers must implement the port test modes Test J_State, Test K_State, Test_Packet, Test Force_Enable, and Test SE0_NAK as described in the USB Specification Revision 2.0.

The system is only allowed to test ports that are owned by the EHCI controller (for example, *CF-bit* is a one and *PortOwner* bit is a zero). System software is allowed to have at most one port in test mode at a time. Placing more than one port in test mode will yield undefined results. The required, per port test sequence is (assuming the *CF-bit* in the USB_n_CONFIGFLAG register is a one):

- Disable the periodic and asynchronous schedules by setting the *Asynchronous Schedule Enable* and *Periodic Schedule Enable* bits in the USBCMD register to a zero.
- Place all enabled root ports into the suspended state by setting the *Suspend* bit in each appropriate USB_n_PORTSC register to a one.
- Set the *Run/Stop* bit in the USBCMD register to a zero and wait for the *HCHalted* bit in the USBSTS register, to transition to a one. Note that an EHCI host controller implementation may optionally allow port testing with the *Run/Stop* bit set to a one. However, all host controllers must support port testing with *Run/Stop* set to a zero and *HCHalted* set to a one.
- Set the *Port Test Control* field in the port under test PORTSC register to the value corresponding to the desired test mode. If the selected test is Test_Force_Enable, then the *Run/Stop* bit in the USBCMD register must then be transitioned back to one, in order to enable transmission of SOFs out of the port under test.
- When the test is complete, system software must ensure the host controller is halted (*HCHalted* bit is a one) then it terminates and exits test mode by setting *HCReset* to a one.

62.5.3.15 Interrupts-Host Operational Model

The EHCI Host Controller hardware provides interrupt capability based on a number of sources.

There are several general groups of interrupt sources:

- Interrupts as a result of executing transactions from the schedule (success and error conditions),
- Host controller events (Port change events, etc.), and
- Host Controller error events

All transaction-based sources are maskable through the Host Controller's Interrupt Enable register (USBINTR). Additionally, individual transfer descriptors can be marked to generate an interrupt on completion. This section describes each interrupt source and the processing that occurs in response to the interrupt.

During normal operation, interrupts may be immediate or deferred until the next interrupt threshold occurs. The interrupt threshold is a tunable parameter via the *Interrupt Threshold Control* field in the USBCMD register. The value of this register controls when the host controller will generate an interrupt on behalf of normal transaction execution. When a transaction completes during an interrupt interval period, the interrupt signaling the completion of the transfer will not occur until the interrupt threshold occurs. For example, the default value is eight micro-frames. This means that the host controller will not generate interrupts any more frequently than once every eight micro-frames.

Section Host System Error details effects of a host system error.

If an interrupt has been scheduled to be generated for the current interrupt threshold interval, the interrupt is not signaled until after the status for the last complete transaction in the interval has been written back to host memory. This may sometimes result in the interrupt not being signaled until the next interrupt threshold.

Initial interrupt processing is the same, regardless of the reason for the interrupt. When an interrupt is signaled by the hardware, Arm platform control is transferred to host controller's USB interrupt handler. The precise mechanism to accomplish the transfer is OS specific. For this discussion it is just assumed that control is received. When the interrupt handler receives control, its first action is to reads the USBSTS (USB Status Register). It then acknowledges the interrupt by clearing all of the interrupt status bits by writing ones to these bit positions. The handler then determines whether the interrupt is due to schedule processing or some other event. After acknowledging the interrupt, the handler (via an OS-specific mechanism), schedules a deferred procedure call (DPC) which will execute later. The DPC routine processes the results of the schedule execution. The precise mechanisms used are beyond the scope of this document.

Note: the host controller is not required to de-assert a currently active interrupt condition when software sets the interrupt enables (in the USBINR register) to a zero. The only reliable method software should use for acknowledging an interrupt is by transitioning the appropriate status bits in the USBSTS register from a one to a zero.

62.5.3.15.1 Transfer/Transaction Based Interrupts

These interrupt sources are associated with transfer and transaction progress. They are all dependent on the next interrupt threshold.

62.5.3.15.1.1 Transaction Error

A transaction error is any error that caused the host controller to think that the transfer did not complete successfully.

The table below lists the events/responses that the host can observe as a result of a transaction. The effects of the error counter and interrupt status are summarized in the following paragraphs. Most of these errors set the *XactErr* status bit in the appropriate interface data structure.

There is a small set of protocol errors that relate only when executing a queue head and fit under the umbrella of a WRONG PID error that are significant to explicitly identify. When these errors occur, the *XactErr* status bit in the queue head is set and the *CErr* field is decremented. When the *PIDCode* indicates a SETUP, the following responses are protocol errors and result in *XactErr* bit being set to a one and the *CErr* field being decremented.

- *EPS* field indicates a high-speed device and it returns a Nak handshake to a SETUP.
- *EPS* field indicates a high-speed device and it returns a Nyet handshake to a SETUP.
- *EPS* field indicates a low- or full-speed device and the complete-split receives a Nak handshake.

Table 62-54. Summary of Transaction Errors

Event / Result	Queue Head/qTD/iTD/siTD Side-effects		USB Status Register (USBSTS)
	Cerr	Status Field	USBERRINT
CRC	-1	XactErr set to a one.	1[1]
Timeout	-1	XactErr set to a one.	1[1]
Bad PID[2]	-1	XactErr set to a one.	1[1]
Babble	N/A	Section Serial Bus Babble	1
Buffer Error	N/A	Section Data Buffer Error	

1. If occurs in a queue head, then *USBERRINT* is asserted only when *CErr* counts down from a one to a zero. In addition the queue is halted, see Halting a Queue Head.
2. The host controller received a response from the device, but it could not recognize the PID as a valid PID.

62.5.3.15.1.2 Serial Bus Babble

When a device transmits more data on the USB than the host controller is expecting for this transaction, it is defined to be babbling. In general, this is called a *Packet Babble*.

When a device sends more data than the *Maximum Length* number of bytes, the host controller sets the *Babble Detected* bit to a one and halts the endpoint if it is using a queue head (see Halting a Queue Head). *Maximum Length* is defined as the minimum of *Total Bytes to Transfer* and *Maximum Packet Size*. The *CErr* field is not decremented for a packet babble condition (only applies to queue heads). A babble condition also exists if IN transaction is in progress at High-speed EOF2 point. This is called a frame babble. A frame babble condition is recorded into the appropriate schedule data structure. In addition, the host controller must disable the port to which the frame babble is detected.

The *USBERRINT* bit in the USB_n_USBSTS register is set to a one and if the *USB Error Interrupt Enable* bit in the USB_n_USBINTR register is a one, then a hardware interrupt is signaled to the system at the next interrupt threshold. The host controller must never start an OUT transaction that will babble across a micro-frame EOF.

NOTE

When a host controller detects a data PID mismatch, it must either: disable the packet babble checking for the duration of the bus transaction or do packet babble checking based solely on *Maximum Packet Size*. The USB core specification defines the requirements on a data receiver when it receives a data PID mismatch (for example, expects a DATA0 and gets a DATA1 or visa-versa). In summary, it must ignore the received data and respond with an ACK handshake, in order to advance the transmitter's data sequence.

The EHCI interface allows System software to provide buffers for a Control, Bulk or Interrupt IN endpoint that are not an even multiple of the maximum packet size specified by the device. Whenever a device misses an ACK for an IN endpoint, the host and device are out of synchronization with respect to the progress of the data transfer. The host controller may have advanced the transfer to a buffer that is less than maximum packet size. The device will re-send its maximum packet size data packet, with the original data PID, in response to the next IN token. In order to properly manage the bus protocol, the host controller must disable the packet babble check when it observes the data PID mismatch.

62.5.3.15.1.3 Data Buffer Error

This event indicates that an overrun of incoming data or a underrun of outgoing data has occurred for this transaction.

This would generally be caused by the host controller not being able to access required data buffers in memory within necessary latency requirements. These conditions are not considered transaction errors, and do not effect the error count in the queue head. When these errors do occur, the host controller records the fact the error occurred by setting the *Data Buffer Error* bit in the queue head, iTD or siTD.

If the data buffer error occurs on a non-isochronous IN, the host controller will not issue a handshake to the endpoint. This will force the endpoint to resend the same data (and data toggle) in response to the next IN to the endpoint.

If the data buffer error occurs on an OUT, the host controller must corrupt the end of the packet so that it cannot be interpreted by the device as a good data packet. Simply truncating the packet is not considered acceptable. An acceptable implementation option is to 1's complement the CRC bytes and send them. There are other options suggested in the Transaction Translator section of the USB Specification Revision 2.0.

62.5.3.15.1.4 USB Interrupt (Interrupt on Completion (IOC))

Transfer Descriptors (iTDs, siTDs, and queue heads (qTDs)) contain a bit that can be set to cause an interrupt on their completion. The completion of the transfer associated with that schedule item causes the USB Interrupt (USBINT) bit in the USB_n_USBSTS register to be set to a one.

In addition, if a short packet is encountered on an IN transaction associated with a queue head, then this event also causes USBINT to be set to a one. If the USB Interrupt Enable bit in the USB_n_USBINTR register is set to a one, a hardware interrupt is signaled to the system at the next interrupt threshold. If the completion is because of errors, the *USBERRINT* bit in the USB_n_USBSTS register is also set to a one.

62.5.3.15.1.5 Short Packet

Reception of a data packet that is less than the endpoint's Max Packet size during Control, Bulk or Interrupt transfers signals the completion of the transfer. Whenever a short packet completion occurs during a queue head execution, the *USBINT* bit in the USB_n_USBSTS register is set to a one.

If the *USB Interrupt Enable* bit is set in the USB_n_USBINTR register, a hardware interrupt is signaled to the system at the next interrupt threshold.

62.5.3.15.2 Host Controller Event Interrupts

These interrupt sources are independent of the interrupt threshold (with the one exception being the Interrupt on Async Advance, see Section Interrupt on Async Advance).

62.5.3.15.2.1 Port Change Events

Port registers contain status and status change bits. When the status change bits are set to a one, the host controller sets the *Port Change Detect* bit in the USBSTS register to a one.

If the *Port Change Interrupt Enable* bit in the USB_n_USBINTR register is a one, then the host controller will issue a hardware interrupt. The port status change bits include:

- Connect Status Change
- Port Enable/Disable Change
- Over-current Change
- Force Port Resume

62.5.3.15.2.2 Frame List Rollover

This event indicates that the host controller has wrapped the frame list. The current programmed size of the frame list effects how often this interrupt occurs.

If the frame list size is 1024, then the interrupt will occur every 1024 milliseconds, if it is 512, then it will occur every 512 milliseconds, etc. When a frame list rollover is detected, the host controller sets the *Frame List Rollover* bit in the USB.USBSTS register to a one. If the *Frame List Rollover Enable* bit in the USB.USBINTR register is set to a one, the host controller issues a hardware interrupt. This interrupt is not delayed to the next interrupt threshold.

62.5.3.15.2.3 Interrupt on Async Advance

This event is used for deterministic removal of queue heads from the asynchronous schedule. Whenever the host controller advances the on-chip context of the asynchronous schedule, it evaluates the value of the *Interrupt on Async Advance Doorbell* bit in the USB.USBCMD register. If it is a one, it sets the *Interrupt on Async Advance* bit in the USB.USBSTS register to a one. If the *Interrupton Async Advance Enable* bit in the USB.USBINTR register is a one, the host controller issues a hardware interrupt at the next interrupt threshold. A detailed explanation of this feature is described in Section Removing Queue Heads from Asynchronous Schedule .

62.5.3.15.2.4 Host System Error

The host controller is a bus master and any interaction between the host controller and the system may experience errors.

The type of host error may be catastrophic to the host controller (such as a Master Abort) making it impossible for the host controller to continue in a coherent fashion.In the presence of non-catastrophic host errors, such as parity errors, the host controller could potentially continue operation. The recommended behavior for these types of errors is to escalate it to a catastrophic error and halt the host controller. Host-based error must result in the following actions:

- The *Run/Stop* bit in the USB.USBCMD register is set to a zero.
- The following bits in the USB.USBSTS register are set:
  - *Host System Error* bit is to a one.
  - *HCHalted* bit is set to a one.
- If the *Host System Error Enable* bit in the USB.USBINTR register is a one, then the host controller will issue a hardware interrupt. This interrupt is not delayed to the next interrupt threshold. The following table summarizes the required actions taken on the various host errors.

Table 62-55. Summary Behavior of EHCI Host Controller on Host System Errors

Cycle Type	Master Abort	Target Abort	Data Phase Parity
Frame list pointer fetch (read)	Fatal	Fatal	Fatal [o]
siTD fetch (read)	Fatal	Fatal	Fatal [o]
siTD status write-back (write)	Fatal [o]	Fatal [o]	Fatal [o]
iTD fetch (read)	Fatal	Fatal	Fatal [o]
iTD status write-back (write)	Fatal [o]	Fatal [o]	Fatal [o]
qTD fetch (read)	Fatal	Fatal	Fatal [o]
qHD status write-back (write)	Fatal [o]	Fatal [o]	Fatal [o]
Data write	Fatal [o]	Fatal [o]	Fatal [o]
Data read	Fatal	Fatal	Fatal [o]

Potentially, a host controller implementation could continue operation without a halt. However, the recommended behavior is to halt the host controller.

NOTE

After a *Host System Error*, Software must reset the host controller through *HCReset* in the USB.USBCMD register before re-initializing and restarting the host controller.

62.5.4 EHCI Deviation

For the purposes a dual-role Host/Device controller with support for On-The-Go applications, it is necessary to deviate from the EHCI specification. Enhanced Host Controller Interface Specification for Universal Serial Bus, Revision 0.95, November

2000, Intel Corporation. http://www.intel.com. Device operation & On-The-Go operation is not specified in the EHCI and thus the implementation supported in this core is proprietary.

The host mode operation of the core is near EHCI compatible with few minor differences documented in this section.

The particulars of the deviations occur in the areas summarized here:

- Embedded Transaction Translator - Allows direct attachment of FS and LS devices in host mode without the need for a companion controller.
- Device operation - In host mode the device operational registers are generally disabled and thus device mode is mostly transparent when in host mode. However, there are a couple exceptions documented in the following sections.
- Embedded design interface - This core does not have a PCI Interface and therefore the PCI configuration registers described in the EHCI specification are not applicable.
- On-The-Go Operation - This design includes an On-The-Go controller for Port #1.

62.5.4.1 Embedded Transaction Translator Function

The OTG controller supports directly connected full and low speed devices without requiring a companion controller by including the capabilities of a USB 2.0 high speed hub transaction translator.

Although there is no separate Transaction Translator block in the system, the transaction translator function normally associated with a high speed hub has been implemented within the DMA and Protocol engine blocks. The embedded transaction translator function is an extension to EHCI interface, but makes use of the standard data structures and operational models that exist in the EHCI specification to support full and low speed devices.

62.5.4.1.1 Capability Registers

The following additions have been added to the capability registers to support the embedded Transaction Translator Function:

- N_TT added to USB.HCSPARAMS - Host Control Structural Parameters
- N_PTT added to USB.HCSPARAMS - Host Control Structural Parameters

62.5.4.1.2 Operational Registers

The following additions have been added to the operational registers to support the embedded TT:

- Addition of two-bit Port Speed (PSPD) to the PORTSC1 register.

62.5.4.1.3 Discovery-EHCI Deviation

In a standard EHCI controller design, the EHCI host controller driver detects a Full speed (FS) or Low speed (LS) device by noting if the port enable bit is set after the port reset operation.

The port enable will only be set in a standard EHCI controller implementation after the port reset operation and when the host and device negotiate a High-Speed connection (that is, Chirp completes successfully).

Because this controller has an embedded Transaction Translator, the port enable will always be set after the port reset operation regardless of the result of the host device chirp result and the resulting port speed will be indicated by the PSPD field in USB.PORTSCx.

Therefore, the standard EHCI host controller driver requires an alteration to handle directly connected Full and Low speed devices or hubs.

The change is a fundamental one in that is summarized in the following table.

Table 62-56. Summary of EHCI

Standard EHCI	EHCI with embedded Transaction Translator
After port enable bit is set following a connection and reset sequence, the device/hub is assumed to be HS.	After port enable bit is set following a connection and reset sequence, the device/hub speed is noted from USB.PORTSCx.
FS and LS devices are assumed to be downstream from a HS hub thus, all port-level control is performed through the Hub Class to the nearest Hub.	FS and LS device can be either downstream from a HS hub or directly attached. When the FS/LS device is downstream from a HS hub, then port-level control is done using the Hub Class through the nearest Hub. When a FS/LS device is directly attached, then port-level control is accomplished using USB.PORTSCx.
FS and LS devices are assumed to be downstream from a HS hub with HubAddr=X. [where HubAddr > 0 and HubAddr is the address of the Hub where the bus transitions from HS to FS/LS (ie. Split target hub)]	FS and LS device can be either downstream from a HS hub with HubAddr = X [HubAddr > 0] or directly attached [where HubAddr = 0 and HubAddr is the address of the Root Hub where the bus transitions from HS to FS/LS (ie. Split target hub is the root hub)]

62.5.4.1.4 Data Structures

The same data structures used for FS/LS transactions though a HS hub are also used for transactions through the Root Hub with sm embedded Transaction Translator.

Here it is demonstrated how the Hub Address and Endpoint Speed fields should be set for directly attached FS/LS devices and hubs:

1. QH (for direct attach FS/LS) - Async. (Bulk/Control Endpoints) Periodic (Interrupt)
   - Hub Address = 0
   - Transactions to direct attached device/hub.
     - QH.EPS = Port Speed
   - Transactions to a device downstream from direct attached FS hub.
     - QH.EPS = Downstream Device Speed

NOTE

When QH.EPS = 01 (LS) and PORTSCx.PSPD = 00 (FS), a LS-pre-pid will be sent before the transmitting LS traffic.

Maximum Packet Size must be less than or equal 64 or undefined behaviour may result.

2. siTD (for direct attach FS) - Periodic (ISO Endpoint)
   - All FS ISO transactions:
     - Hub Address = 0
     - siTD.EPS = 00 (full speed)
       - Maximum Packet Size must less than or equal to 1023 or undefined behaviour may result.

62.5.4.1.5 Operational Model

The operational models are well defined for the behavior of the Transaction Translator (see USB 2.0 specification. Universal Serial Bus Specification, Revision 2.0, April 2000, Compaq, Hewlett-Packard, Intel, Lucent, Microsoft, NEC, Philips. http://www.usb.org) and for the EHCI controller moving packets between system memory and a USB-HS hub. Because the embedded Transaction Translator exists within the host controller there is no physical bus between EHCI host controller driver and the USB FS/LS bus. These sections will briefly discuss the operational model for how the EHCI and Transaction Translator operational models are combined without the physical bus between. The following sections assume the reader is familiar with both the EHCI and USB 2.0 Transaction Translator operational models.

62.5.4.1.5.1 Micro- frame Pipeline

The EHCI operational model uses the concept of H-frames and B-frames to describe the pipeline between the Host (H) and the Bus (B). The embedded Transaction Translator shall use the same pipeline algorithms specified in the USB 2.0 specification for a Hub-based Transaction Translator.

All periodic transfers always begin at B-frame 0 (after SOF) and continue until the stored periodic transfers are complete. As an example of the micro-frame pipeline implemented in the embedded Transaction Translator, all periodic transfers that are tagged in EHCI to execute in H-frame 0 will be ready to execute on the bus in B-frame 0.

It is important to note that when programming the S-mask and C-masks in the EHCI data structures to schedule periodic transfers for the embedded Transaction Translator, the EHCI host controller driver must follow the same rules specified in EHCI for programming the S-mask and C-mask for downstream Hub-based Transaction Translators.

Once periodic transfers are exhausted, any stored asynchronous transfer will be moved. Asynchronous transfers are opportunistic in that they shall execute whenever possible and their operation is not tied to H-frame and B-frame boundaries with the exception that an asynchronous transfer can not babble through the SOF (start of B-frame 0.)

62.5.4.1.5.2 Split State Machines

The start and complete split operational model differs from EHCI slightly because there is no bus medium between the EHCI controller and the embedded Transaction Translator.

Where a start or complete-split operation would occur by requesting the split to the HS hub, the start/complete split operation is simple an internal operation to the embedded Transaction Translator. The following table summarizes the conditions where handshakes are emulated from internal state instead of actual handshakes to HS split bus traffic.

Table 62-57. Summary of the Conditons of Handshakes[1]

Condition	Emulate TT Response
Start-Split: All asynchronous buffers full.	NAK
Start-Split: All periodic buffers full.	ERR
Start-Split: Success for start of Async. Transaction.	ACK
Start-Split: Start Periodic Transaction.	No Handshake (Ok)
Complete-Split: Failed to find transaction in queue.	Bus Time Out
Complete-Split: Transaction in Queue is Busy.	NYET
Complete-Split: Transaction in Queue is Complete.	[Actual Handshake from LS/FS device]

1. The un-shaded cells represent Start-Splits and the shaded cells represent Complete-Splits

62.5.4.1.5.3 Asynchronous Transaction Scheduling and Buffer Management

The following USB 2.0 specification items are implemented in the embedded Transaction Translator:

- Sequencing is provided & a packet length estimator ensures no full-speed/low-speed packet babbles into SOF time.
- Transaction tracking for 2 data pipes.

62.5.4.1.5.3.1 USB 2.0 - 11.17.3

- Sequencing is provided & a packet length estimator ensures no full-speed/low-speed packet babbles into SOF time.

62.5.4.1.5.3.2 USB 2.0 - 11.17.4

- Transaction tracking for 2 data pipes.

62.5.4.1.5.4 Periodic Transaction Scheduling and Buffer Management

The following USB 2.0 specification items are implemented in the embedded Transaction Translator:

- Abort of pending start-splits
  - EOF (and not started in micro-frames 6)
  - Idle for more than 4 micro-frames
- Abort of pending complete-splits
  - EOF
  - Idle for more than 4 micro-frames
- Transaction tracking for up to 16 data pipes.
- Complete-split transaction searching.

NOTE

There is no data schedule mechanism for these transactions other than the micro-frame pipeline. The embedded TT assumes the number of packets scheduled in a frame does not exceed the frame duration (1 ms) or else undefined behavior may result.

62.5.4.1.5.4.1 USB 2.0 - 11.18.6.[1-2]

- Abort of pending start-splits
  - EOF (and not started in micro-frames 6)
  - Idle for more than 4 micro-frames
- Abort of pending complete-splits
  - EOF
  - Idle for more than 4 micro-frames

62.5.4.1.5.4.2 USB 2.0 - 11.18.[7-8]

- Transaction tracking for up to 16 data pipes.
- Complete-split transaction searching.

NOTE

There is no data schedule mechanism for these transactions other than the micro-frame pipeline. The embedded TT assumes the number of packets scheduled in a frame does not exceed the frame duration (1 ms) or else undefined behavior may result.

62.5.4.1.5.5 Multiple Transaction Translators

The maximum number of embedded Transaction Translators that is currently supported is one as indicated by the N_TT field in the HCSPARAMS register.

62.5.4.2 Device Operation

The co-existence of a device operational controller within the host controller has little effect on EHCI compatibility for host operation except as noted in this section.

62.5.4.2.1 USB_USBMODE Register

Given that the dual-role controller is initialized in neither host nor device mode, the USB_nUSBMODE register must be programmed for host operation before the EHCI host controller driver can begin EHCI host operations.

62.5.4.2.2 Non-Zero Fields the Register File

Some of the reserved fields and reserved addresses in the capability registers and operational register have use in device mode, the following must be adhered to:

- Write operations to all EHCI reserved fields (some of which are device fields) with the operation registers should always be written to zero. This is an EHCI requirement of the device controller driver that must be adhered to.
- Read operations by the host controller must properly mask EHCI reserved fields (some of which are device fields) because fields that are used exclusive for device are undefined in host mode .

62.5.4.2.3 SOF Interrupt

This SOF Interrupt used for device mode is shared as a free running 125us interrupt for host mode.

EHCI does not specify this interrupt but it has been added for convenience and as a potential software time base. See USB_nUSBSTS and USB_nUSBINTR registers.

62.5.4.3 Embedded Design Interface

This is an Embedded USB Host Controller as defined by the EHCI specification and thus does not implement the PCI configuration registers.

62.5.4.3.1 Frame Adjust Register

Given that the optional PCI configuration registers are not included in this implementation, there is no corresponding bit level timing adjustments like is provided by the Frame Adjust register in the PCI configuration registers. Starts of micro-frames are timed precisely to 125 us using the transceiver clock as a reference clock. That is, a 60 Mhz transceiver clock for 8-bit physical interfaces & full-speed serial interfaces or 30 Mhz transceiver clock for 16-bit physical interfaces.

62.5.4.4 Miscellaneous variations from EHCI

62.5.4.4.1 Programmable Physical Interface Behaviour

This design supports multiple Physical interfaces which can operate in differing modes when the core is configured with software programmable Physical Interface Modes. Software programmability allows the selection of the Physical interface part during the board design phase instead of during the chip design phase. The control bits for selecting the Physical Interface operating mode have been added to the USB_nPORTSC1 register providing a capability that is not defined by EHCI.

62.5.4.4.2 Discovery

62.5.4.4.2.1 Port Reset

The port connect methods specified by EHCI require setting the port reset bit in the USB_nPORTSC1 register for a duration of 10ms. Due to the complexity required to support the attachment of devices that are not high speed there are counter already present in the design that can count the 10ms reset pulse to alleviate the requirement of the software to measure this duration. Therefore, the basic connection is then summarized as the following:

- [Port Change Interrupt] Port connect change occurs to notify the host controller driver that a device has attached.
- Software shall write a '1' to reset the device.

- Software shall write a '0' to reset the device after 10 ms.
  - This step, which is necessary in a standard EHCI design, may be omitted with this implementation. Should the EHCI host controller driver attempt to write a '0' to the reset bit while a reset is in progress, the write will simple be ignored and the reset will continue until completion.
- [Port Change Interrupt] Port enable change occurs to notify the host controller that the device in now operational and at this point the port speed has been determined.

62.5.4.4.2.2 Port Speed Detection

After the port change interrupt indicates that a port is enabled, the EHCI stack should determine the port speed. Unlike the EHCI implementation, which will re-assign the port owner for any device that does not connect at High-Speed, this host controller supports direct attach of non High-Speed devices.

Therefore, the following differences are important regarding port speed detection:

- Port Owner is read-only and always reads 0.
- A 2-bit Port Speed indicator has been added to PORTSC to provide the current operating speed of the port to the host controller driver.
- A 1-bit High Speed indicator has been added to PORTSC to signify that the port is in High-Speed vs. Full/Low Speed - *This information is redundant with the 2-bit Port Speed indicator above.*

62.5.4.4.3 Port Test Mode

Port Test Control mode behaves fully as described in EHCI. An alternate host controller driver procedure is not necessary or supported.

62.5.5 Device Data Structures

This section defines the interface data structures used to communicate control, status, and data between Device Controller Driver (DCD) Software and the Device Controller.

The data structure definitions in this chapter support a 32-bit memory buffer address space. The interface consists of device Queue Heads and Transfer Descriptors.

NOTE

Software must ensure that no interface data structure reachable by the Device Controller spans a 4K-page boundary.

The data structures defined in the chapter are (from the device controller's perspective) a mix of read-only and read/ writable fields. The device controller must preserve the read-only fields on all data structure writes.

The figure below shows the organization of the EndPoint Queue Head.

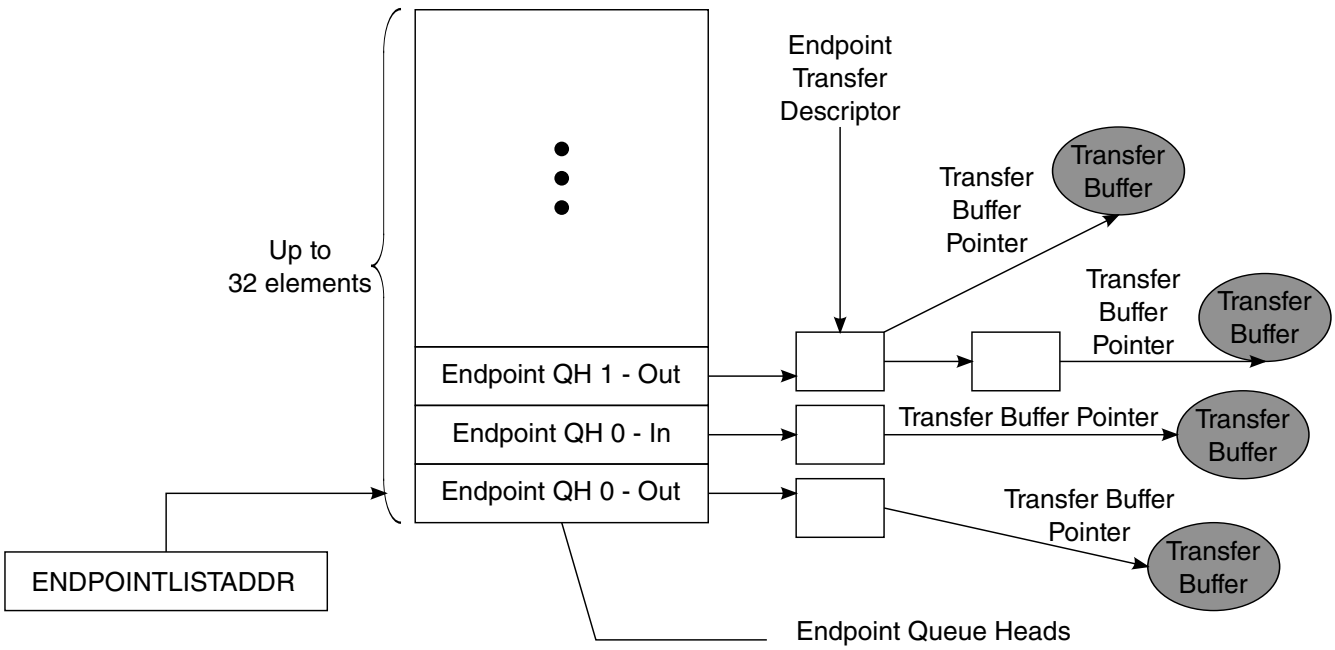

Figure 62-28. EndPoint Queue Head Organization

Endpoint queue heads are arranged in an array in a continuous area of memory pointed to by the USB.ENDPOINTLISTADDR pointer. The even-numbered device queue heads in the list support receive endpoints (OUT/SETUP) and the odd-numbered queue heads in the list are used for transmit endpoints (IN/INTERRUPT). That is, the device queue heads in the list with even offset support receiver endpoints (OUT) and the queue heads in the list with odd offset are used for transmit endpoint(IN). The device controller will index into this array based upon the endpoint number received from the USB bus. All information necessary to respond to transactions for all primed transfers is contained in this list so the Device Controller can readily respond to incoming requests without having to traverse a linked list.

NOTE

The Endpoint Queue Head List must be aligned to a 2k boundary.

62.5.5.1 Endpoint Queue Head (dQH)

The device Endpoint Queue Head (dQH) is where all transfers for a given endpoint are managed. The dQH is a 48-byte data structure, but must be aligned on 64-byte boundaries.

During priming of an endpoint, the dTD (device transfer descriptor) is copied into the overlay area of the dQH, which starts at the nextTD pointer DWord and continues through the end of the buffer pointers DWords. After a transfer is complete, the dTD status DWord is updated in the dTD pointed to by the currentTD pointer. While a packet is in progress, the overlay area of the dQH is used as a staging area for the dTD so that the Device Controller can access needed information with little minimal latency.

Table 62-58. Endpoint Queue Head (dQH)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Host Controller Read/Write

Host Controller Read Only

62.5.5.1.1 Endpoint Capabilities/Characteristics

This DWord specifies static information about the endpoint, in other words, this information does not change over the lifetime of the endpoint. Device Controller software should not attempt to modify this information while the corresponding endpoint is enabled.

Table 62-59 describes the endpoint capabilities.

Table 62-59. Endpoint Capabilities/Characteristics

Bit	Description
31-30	Mult. This field is used to indicate the number of packets executed per transaction description as given by the following: 00 - Execute N Transactions as demonstrated by the USB variable length packet protocol where N is computed using the Maximum Packet Length (dQH) and the Total Bytes field (dTD) 01 Execute 1 Transaction. 10 Execute 2 Transactions. 11 Execute 3 Transactions. **NOTE:** Non-ISO endpoints must set Mult="00". ISO endpoints must set Mult="01", "10", or "11" as needed.
29	Zero Length Termination Select. This bit is used to indicate when a zero length packet is used to terminate transfers where to total transfer length is a multiple . This bit is not relevant for Isochronous 0 - Enable zero length packet to terminate transfers equal to a multiple of the Maximum Packet Length. (default). 1 - Disable the zero length packet on transfers that are equal in length to a multiple Maximum Packet Length.
28-27	Reserved. These bit reserved for future use and should be set to zero.
26-16	Maximum Packet Length. This directly corresponds to the maximum packet size of the associated endpoint (wMaxPacketSize). The maximum value this field may contain is 0x400 (1024).
15	Interrupt On Setup (IOS). This bit is used on control type endpoints to indicate if USBINT is set in response to a setup being received.
14-0	Reserved. Bits reserved for future use and should be set to zero.

62.5.5.1.2 Transfer Overlay-Endpoint Queue Head

The seven DWords in the overlay area represent a transaction working space for the device controller.

The general operational model is that the device controller can detect whether the overlay area contains a description of an active transfer. If it does not contain an active transfer, then it will not read the associated endpoint.

After an endpoint is readied, the dTD will be copied into this queue head overlay area by the device controller. Until a transfer is expired, software must not write the queue head overlay area or the associated transfer descriptor. When the transfer is complete, the device controller will write the results back to the original transfer descriptor and advance the queue.

See dTD for a description of the overlay fields.

62.5.5.1.3 Current dTD Pointer

The current dTD pointer is used by the device controller to locate the transfer in progress. This word is for Device Controller (hardware) use only and should not be modified by DCD software.

The following table describes the dTD Pointer.

Table 62-60. Next dTD Pointer

Bit	Description
31-5	Current dTD. This field is a pointer to the dTD that is represented in the transfer overlay area. This field will be modified by the Device Controller to next dTD pointer during endpoint priming or queue advance.
4-0	Reserved. Bit reserved for future use and should be set to zero.

62.5.5.1.4 Set-up Buffer

The set-up buffer is dedicated storage for the 8-byte data that follows a set-up PID.

NOTE

Each endpoint has a TX and an RX dQH associated with it, and only the RX queue head is used for receiving setup data packets.

The following table describes the Multiple Mode Control.

Table 62-61. Multiple Mode Control (HCCPARAMS)

DWord	Bits	Description
1	31-0	Setup Buffer 0. This buffer contains bytes 3 to 0 of an incoming setup buffer packet and is written by the device controller to be read by software.
2	31-0	Setup Buffer 1. This buffer contains bytes 7 to 4 of an incoming setup buffer packet and is written by the device controller to be read by software.

62.5.5.2 Endpoint Transfer Descriptor (dTD)

The dTD describes to the device controller the location and quantity of data to be sent/ received for a given transfer.

The DCD should not attempt to modify any field in an active dTD except the Next Like Pointer, which should only be modified as described in section Managing Transfers with Transfer Descriptors.

Table below shows the Endpoint Transfer Descriptor (dTD).

Table 62-62. Endpoint Transfer Descriptor (dTD)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Buffer Pointer (Page 2)																				Reserved											
Buffer Pointer (Page 3)																				Reserved											
Buffer Pointer (Page 4)																				Reserved											

Host Controller Read/Write

Host Controller Read Only

The following table describes the dTD Pointer.

Table 62-63. Next dTD Pointer

Bit	Description
31-5	Next Transfer Element Pointer. This field contains the physical memory address of the next dTD to be processed. The field corresponds to memory address signals [31:5], respectively.
4-1	Reserved. Bits reserved for future use and should be set to zero.
0	Terminate (T). 1=pointer is invalid. 0=Pointer is valid (points to a valid Transfer Element Descriptor). This bit indicates to the Device Controller that there are no more valid entries in the queue.

The following table describes the dTD Token.

Table 62-64. dTD Token

Bit	Description
31	Reserved. Bit reserved for future use and should be set to zero.
30-16	Total Bytes. This field specifies the total number of bytes to be moved with this transfer descriptor. This field is decremented by the number of bytes actually moved during the transaction and only on the successful completion of the transaction. The maximum value software may store in the field is 5*4K (5000H). This is the maximum number of bytes 5 page pointers can access. Although it is possible to create a transfer up to 20K this assumes the 1st offset into the first page is 0. When the offset cannot be predetermined, crossing past the 5th page can be guaranteed by limiting the total bytes to 16K**. Therefore, the maximum recommended transfer is 16K (4000H). If the value of the field is zero when the host controller fetches this transfer descriptor (and the active bit is set), the device controller executes a zero-length transaction and retires the transfer descriptor.

Table continues on the next page...

Table 62-64. dTD Token (continued)

	It is not a requirement for IN transfers that Total Bytes To Transfer be an even multiple of *Maximum Packet Length*. If software builds such a transfer descriptor for an IN transfer, the last transaction will always be less that *Maximum Packet Length*.
15	Interrupt On Complete (IOC). This bit is used to indicate if USBINT is to be set in response to device controller being finished with this dTD.
14-12	Reserved. Bits reserved for future use and should be set to zero.
11-10	Multiplier Override (MultO). This field can be used for transmit ISO's (ie. ISO-IN) to override the multiplier in the QH. This field must be zero for all packet types that are not transmit-ISO. Example: if QH.multiplier = 3; Maximum packet size = 8; Total Bytes = 15; MultiO = 0 [default] Three packets are sent: {Data2(8); Data1(7); Data0(0)} if QH.multiplier = 3; Maximum packet size = 8; Total Bytes = 15; MultiO = 2 Two packets are sent: {Data1(8); Data0(7)} For maximal efficiency, software should compute MultO = greatest integer of (Total Bytes / Max. Packet Size) except for the case when Total Bytes = 0; then MultO should be 1. Note: Non-ISO and Non-TX endpoints must set MultO = "00".
9-8	Reserved. Bits reserved for future use and should be set to zero.
7-0	Status. This field is used by the Device Controller to communicate individual command execution states back to the Device Controller software. This field contains the status of the last transaction performed on this qTD. The bit encodings are: Bit Status Field Description 7 Active. 6 Halted. 5 Data Buffer Error. 3 Transaction Error. 4, 2, 0 Reserved.

The table below describes the dTD Buffer Page Pointer List.

Table 62-65. dTD Buffer Page Pointer List

Bit	Description
31-12	Buffer Pointer. Selects the page offset in memory for the packet buffer. Non virtual memory systems will typically set the buffer pointers to a series of incrementing integers.
0,11-0	Current Offset. Offset into the 4kb buffer where the packet is to begin.
1,10-0	Frame Number. Written by the device controller to indicate the frame number in which a packet finishes. This is typically be used to correlate relative completion times of packets on an ISO endpoint.

62.5.6 Device Operational Model

The function of the device operation is to transfer a request in the memory image to and from the Universal Serial Bus.

Using a set of linked list transfer descriptors, pointed to by a queue head, the device controller will perform the data transfers. The following sections explain the use of the device controller from the device controller driver (DCD) point-of-view and further describe how specific USB bus events relate to status changes in the device controller programmer's interface.

62.5.6.1 Device Controller Initialization

After hardware reset, the device is disabled until the Run/Stop bit is set to a '1'. In the disabled state, the pull-up on the USB D+ is not active which prevents an attach event from occurring. At a minimum, it is necessary to have the queue heads setup for endpoint zero before the device attach occurs.

Shortly after the device is enabled, a USB reset will occur followed by setup packet arriving at endpoint 0. A Queue head must be prepared so that the device controller can store the incoming setup packet.

In order to initialize a device, the software should perform the following steps:

- Set Controller Mode in the USB.USBMODE register to device mode.

NOTE

Transitioning from host mode to device mode requires a device controller reset before modifying USB.USBMODE.

- Allocate and Initialize device queue heads in system memory.
  - Minimum: Initialize device queue heads 0 Tx & 0 Rx.

NOTE

All device queue heads for control endpoints must be initialized before the endpoint is enabled. Non-Control device queue heads before the endpoint can be used.

  - For information on device queue heads, refer to section Device Data Structures.
- Configure USB.ENDPOINTLISTADDR Pointer.
  - For additional information on USB.ENDPOINTLISTADDR, refer to the register table.
- Enable the microprocessor interrupt associated with the USB core.
  - Recommended: enable all device interrupts including: USBINT, USBERRINT, Port Change Detect, USB Reset Received, DCSuspend.
  - For a list of available interrupts refer to the USB_nUSBINTR and the USB_nUSBSTS register tables.
- Set Run/Stop bit to Run Mode.

- After the Run bit is set and the device is connected to a host, a Bus Reset will be issued by host downstream port. The DCD must monitor the reset event and adjust the software state as described in the Bus Reset section of the Port State and Control section below.

NOTE

Endpoint 0 is designed as a control endpoint only and does not need to be configured using ENDPTCTRL0 register.

It is also not necessary to prime Endpoint 0 initially because the first packet received will always be a setup packet. The contents of the first setup packet will require a response in accordance with USB device framework (Chapter 9) command set.

62.5.6.2 Port State and Control

From a chip or system reset, the device controller enters the *powered* state. A transition from the *powered* state to the *attach* state occurs when the Run/Stop bit is set to a '1'.

After receiving a reset on the bus, the port will enter the *defaultFS or defaultHS* state in accordance with the reset protocol described in Appendix C.2 of the USB Specification Rev. 2.0.

The following state diagram depicts the state of a USB 2.0 device.

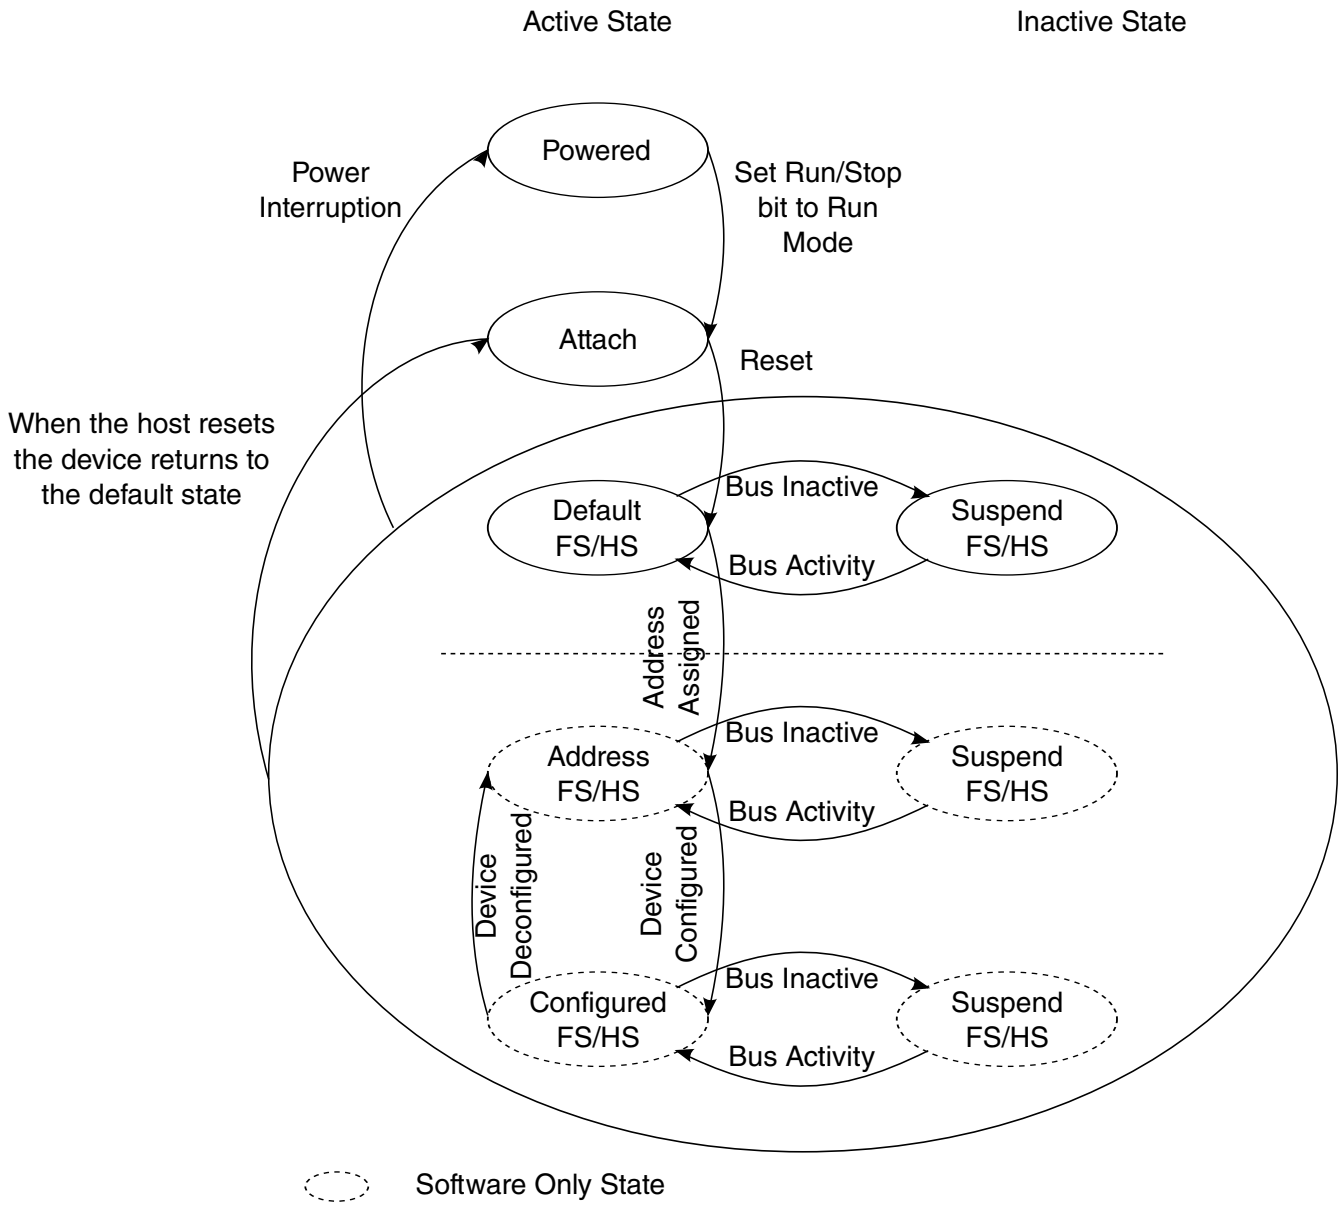

Figure 62-29. Device State Diagram

States *powered, attach, defaultFS/HS, suspendFS/HS* are implemented in the device controller and are communicated to the DCD using the following status bits:

The following table describes the Device Controller State Information Bits.

Table 62-66. Device Controller State Information Bits

Bit	Register
DCSuspend	USBSTS
USB Reset Received	USBSTS
Port Change Detect	USBSTS
High-Speed Port	PORTSC1

It is the responsibility of the DCD to maintain a state variable to differentiate between the *DefaultFS/HS* state and the *Address/Configured* states. Change of state from *Default* to *Address* and the *Configured* states is part of the enumeration process described in the device framework section of the USB 2.0 Specification.

As a result of entering the *Address* state, the device address register (DEVICEADDR) must be programmed by the DCD.

Entry into the *Configured* indicates that all endpoints to be used in the operation of the device have been properly initialized by programming the USB_UOG_ENDPTCTRLx registers and initializing the associated queue heads.

62.5.6.2.1 Bus Reset

A bus reset is used by the host to initialize downstream devices.

When a bus reset is detected, the device controller will renegotiate its attachment speed, reset the device address to 0, and notify the DCD by interrupt (assuming the USB Reset Interrupt Enable is set). After a reset is received, all endpoints (except endpoint 0) are disabled and any primed transactions will be cancelled by the device controller. The concept of priming will be clarified below, but the DCD must perform the following tasks when a reset is received:

Clear all setup token semaphores by reading the USB_nENDPTSTAT register and writing the same value back to the USB_nENDPTSTAT register.

Clear all the endpoint complete status bits by reading the USB_nPTCOMPLETE register and writing the same value back to the USB_nENDPTCOMPLETE register.

Cancel all primed status by waiting until all bits in the USB_nENDPTPRIME are 0 and then writing 0xFFFFFFFF to USB_nENDPTFLUSH.

Read the reset bit in the USB_nPORTSC1 register and make sure that it is still active. A USB reset will occur for a minimum of 3 ms and the DCD must reach this point in the reset cleanup before end of the reset occurs, otherwise a hardware reset of the device controller is recommended (rare.)

- A hardware reset can be performed by writing a one to the device controller reset bit in the USBCMD reset. Note: a hardware reset will cause the device to detach from the bus by clearing the Run/Stop bit. Thus, the DCD must completely re-initialize the device controller after a hardware reset.

Free all allocated dTDs because they will no longer be executed by the device controller. If this is the first time the DCD is processing a USB reset event, then it is likely that no dTDs have been allocated.

At this time, the DCD may release control back to the OS because no further changes to the device controller are permitted until a Port Change Detect is indicated.

After a Port Change Detect, the device has reached the default state and the DCD can read the USB_nPORTSC1 to determine if the device is operating in FS or HS mode. At this time, the device controller has reached normal operating mode and DCD can begin enumeration according to the USB Chapter 9 - Device Framework.

NOTE

The device DCD may use the FS/HS mode information to determine the bandwidth mode of the device

In some applications, it may not be possible to enable one or more pipes while in FS mode. *Beyond the data rate issue, there is no difference in DCD operation between FS and HS modes.*

62.5.6.2.2 Suspend/Resume

The detials of suspend and resume are explained in these sections.

62.5.6.2.2.1 Suspend

Suspend Description

In order to conserve power, USB devices automatically enter the suspended state when the device has observed no bus traffic for a specified period. When suspended, the USB device maintains any internal status, including its address and configuration. Attached devices must be prepared to suspend at any time they are powered, regardless of if they have been assigned a non-default address, are configured, or neither. Bus activity may cease due to the host entering a suspend mode of its own. In addition, a USB device shall also enter the suspended state when the hub port it is attached to is disabled.

A USB device exits suspend mode when there is bus activity. A USB device may also request the host to exit suspend mode or selective suspend by using electrical signaling to indicate remote wakeup. The ability of a device to signal remote wakeup is optional. If the USB device is capable of remote wakeup signaling, the device must support the ability of the host to enable and disable this capability. When the device is reset, remote wakeup signaling must be disabled.

Suspend Operational Model

The device controller moves into the suspend state when suspend signaling is detected or activity is missing on the upstream port for more than a specific period. After the device controller enters the suspend state, the DCD is notified by an interrupt (assuming *DC Suspend Interrupt* is enabled). When the *DCSuspend* bit in the USB_nPORTSC1 is set to a '1', the device controller is suspended.

DCD response when the device controller is suspended is application specific and may involve switching to low power operation.

Information on the bus power limits in suspend state can be found in USB 2.0 specification.

NOTE

Review system level clocking issues defined in section (Ref: Signals-Clocking) for the clocking requirements of a suspended device controller.

62.5.6.2.2.2 Resume

If the device controller is suspended, its operation is resumed when any non-idle signaling is received on its upstream facing port. In addition, the device can signal the system to resume operation by forcing resume signaling to the upstream port.

Resume signaling is sent upstream by writing a '1' to the Resume bit in the in the USB_nPORTSC1 while the device is in suspend state. Sending resume signal to an upstream port should cause the host to issue resume signaling and bring the suspended bus segment (one more devices) back to the active condition.

NOTE

Before resume signaling can be used, the host must enable it by using the Set Feature command defined in device framework (chapter 9) of the USB 2.0 Specification.

62.5.6.3 Managing Endpoints

The USB 2.0 specification defines an endpoint, also called a device endpoint or an address endpoint as a uniquely addressable portion of a USB device that can source or sink data in a communications channel between the host and the device.

The endpoint address is specified by the combination of the endpoint number and the endpoint direction.

The channel between the host and an endpoint at a specific device represents a data pipe. Endpoint 0 for a device is always a *control* type data channel used for device discovery and enumeration. Other types of endpoints support by USB include *bulk, interrupt*, and *isochronous*. Each endpoint type has specific behavior related to packet response and error handling. More detail on endpoint operation can be found in the USB 2.0 specification.

The USB OTG device controller hardware supports up to 8 endpoint numbers.

Each endpoint direction is essentially independent and can be configured with differing behavior in each direction. For example, the DCD can configure endpoint 1-IN to be a bulk endpoint and endpoint 1-OUT to be an isochronous endpoint. This helps to conserve the total number of endpoints required for device operation. The only exception is that control endpoints must use both directions on a single endpoint number to function as a control endpoint. Endpoint 0 is, for example, is always a control endpoint and uses the pair of directions.

Each endpoint direction requires a *queue head* allocated in memory. To support the 8 endpoint numbers, 16 *queue heads* are required. The operation of an endpoint and use of *queue heads* are described later in this document.

62.5.6.3.1 Endpoint Initialization

After hardware reset, all endpoints except endpoint zero are uninitialized and disabled. The DCD must configure and enable each endpoint by writing to configuration bit in the USB_UOG_ENDPTCTRLx register.

Each 32-bit USB_UOG_ENDPTCTRLx is split into an upper and lower half. The lower half of USB_UOG_ENDPTCTRLx is used to configure the receive or OUT endpoint and the upper half is likewise used to configure the corresponding transmit or IN endpoint. Control endpoints must be configured the same in both the upper and lower half of the USB_UOG_ENDPTCTRLx register otherwise the behavior is undefined. The following table shows how to construct a configuration word for endpoint initialization. The following table shows the fields and values for the Device Controller Endpoint initialization.

Table 62-67. Device Controller Endpoint Initialization

Field	Value
Data Toggle Reset	1
Data Toggle Inhibit	0
Endpoint Type	00 Control 01 Isochronous 10 Bulk

Table continues on the next page...

Table 62-67. Device Controller Endpoint Initialization (continued)

	11 Interrupt
Endpoint Stall	0

62.5.6.3.2 Stalling

There are two occasions where the device controller may need to return to the host a STALL.

The first occasion is the functional stall, which is a condition set by the DCD as described in the USB 2.0 device framework. A functional stall is only used on non-control endpoints and can be enabled in the device controller by setting the endpoint stall bit in the USB_UOG_ENDPTCTRLx register associated with the given endpoint and the given direction. In a functional stall condition, the device controller will continue to return STALL responses to all transactions occurring on the respective endpoint and direction until the endpoint stall bit is cleared by the DCD.

A protocol stall, unlike a function stall, is used on control endpoints is automatically cleared by the device controller at the start of a new control transaction (setup phase). When enabling a protocol stall, the DCD should enable the stall bits (both directions) as a pair. A single write to the USB_UOG_ENDPTCTRLx register can ensure that both stall bits are set at the same instant.

NOTE

Any write to the USB_UOG_ENDPTCTRLx register during operational mode must preserve the endpoint type field (that is, perform a read-modify-write).

The following table shows the response matrix for the Device Controller Stall.

Table 62-68. Device Controller Stall Response Matrix

USB Packet	Endpoint Stall Bit.	Effect on STALL bit.	USB Response
SETUP packet received by a non-control endpoint.	N/A	None.	STALL
IN/OUT/PING packet received by a non-control endpoint.	'1'	None.	STALL
IN/OUT/PING packet received by a non-control endpoint.	'0'	None.	ACK/ NAK/ NYET
SETUP packet received by a control endpoint.	N/A	Cleared	ACK
IN/OUT/PING packet received by a control endpoint	'1'	None	STALL

Table continues on the next page...

Table 62-68. Device Controller Stall Response Matrix (continued)

IN/OUT/PING packet received by a control endpoint.	'0'	None.	ACK/ NAK/ NYET

62.5.6.3.3 Data Toggle

Data toggle is a mechanism to maintain data coherency between host and device for any given data pipe.

For more information on data toggle, refer to the USB 2.0 specification.

62.5.6.3.3.1 Data Toggle Reset

The DCD may reset the data toggle state bit and cause the data toggle sequence to reset in the device controller by writing a '1' to the data toggle reset bit in the USB_UOG_ENDPTCTRLx register.

This should only be necessary when configuring/initializing an endpoint or returning from a STALL condition.

62.5.6.3.3.2 Data Toggle Inhibit

NOTE

This feature is for test purposes only and should never be used during normal device controller operation.

Setting the *data toggle Inhibit bit* active ('1') causes the device controller to ignore the data toggle pattern that is normally sent and accept all incoming data packets regardless of the data toggle state.

In normal operation, the device controller checks the DATA0/DATA1 bit against the data toggle to determine if the packet is valid. If Data PID does not match the data toggle state bit maintained by the device controller for that endpoint, the Data toggle is considered not valid. If the data toggle is not valid, the device controller assumes the packet was already received and discards the packet (not reporting it to the DCD). To prevent the host controller from re-sending the same packet, the device controller will respond to the error packet by acknowledging it with either an ACK or NYET response.

62.5.6.3.3.3 Priming Transmit Endpoints

Priming a transmit endpoint will cause the device controller to fetch the device transfer descriptor (dTD) for the transaction pointed to by the device queue head (dQH).

After the dTD is fetched, it will be stored in the dQH until the device controller completes the transfer described by the dTD. Storing the dTD in the dQH allows the device controller to fetch the operating context needed to handle a request from the host without the need to follow the linked list, starting at the dQH when the host request is received.

After the device has loaded the dTD, the leading data in the packet is stored in a FIFO in the device controller. This FIFO is split into virtual channels so that the leading data can be stored for any endpoint up to the maximum number of endpoints configured at device synthesis time.

After a priming request is complete, an endpoint state of primed is indicated in the USB_UOG_ENDPTSTATUS register. For a primed transmit endpoint, the device controller can respond to an IN request from the host and meet the stringent bus turnaround time of High Speed USB.

Because only the leading data is stored in the device controller FIFO, it is necessary for the device controller to begin filling in behind leading data after the transaction starts. The FIFO must be sized to account for the maximum latency that can be incurred by the system memory bus. More information about FIFO sizing is presented in section .

62.5.6.3.3.4 Priming Receive Endpoints

Priming receive endpoints is identical to priming of transmit endpoints from the point of view of the DCD. At the device controller the major difference in the operational model is that there is no data movement of the leading packet data simply because the data is to be received from the host.

Note as part of the architecture, the FIFO for the receive endpoints is not partitioned into multiple channels like the transmit FIFO. Thus, the size of the RX FIFO does not scale with the number of endpoints.

62.5.6.4 Operational Model For Packet Transfers

All transactions on the USB bus are initiated by the host and in turn, the device must respond to any request from the host within the turnaround time stated in the USB 2.0 Specification.

At USB 1.1 Full or Low Speed rates, this turnaround time was significant and the USB 1.1 device controllers were architected so that the device controller could access main memory or interrupt a host protocol processor in order to respond to the USB 1.1

transaction. The architecture of the USB 2.0 device controller must be different because same methods will not meet USB 2.0 High-speed turnaround time requirements by simply increasing clock rate.

A USB host will send requests to the device controller in an order that can not be precisely predicted as a single pipeline, so it is not possible to prepare a single packet for the device controller to execute. However, the order of packet requests is predictable when the endpoint number and direction is considered. For example, if endpoint 3 (transmit direction) is configured as a bulk pipe, then we can expect the host will send IN requests to that endpoint. This device controller is architected in such a way that it can prepare packets for each endpoint/direction in anticipation of the host request. The process of preparing the device controller to send or receive data in response to host initiated transaction on the bus is referred to as "priming" the endpoint. This term will be used throughout the following documentation to describe the device controller operation so the DCD can be architected properly use priming. Further, note that the term "flushing" is used to describe the action of clearing a packet that was queued for execution.

62.5.6.4.1 Interrupt/Bulk Endpoint Operational Model

The behaviors of the device controller for interrupt and bulk endpoints are identical.

All valid IN and OUT transactions to bulk pipes will handshake with a NAK unless the endpoint had been primed. Once the endpoint has been primed, data delivery will commence.

A dTD will be retired by the device controller when the packets described in the transfer descriptor have been completed. Each dTD describes N packets to be transferred according to the USB Variable Length transfer protocol. The formula and table on the following page describe how the device controller computes the number and length of the packets to be sent/received by the USB vary according to the total number of bytes and maximum packet length.

With Zero Length Termination (ZLT) = 0

N = INT(Number Of Bytes/Max. Packet Length) + 1

With Zero Length Termination (ZLT) = 1

N = MAXINT(Number Of Bytes/Max. Packet Length)

Table 62-69. Variable Length Transfer Protocol Example (ZLT = 0)

Bytes (dTD)	Max. Packet Length (dQH)	N	P1	P2	P3
511	256	2	256	255	

Table continues on the next page...

Table 62-69. Variable Length Transfer Protocol Example (ZLT = 0) (continued)

512	256	3	256	256	0
512	512	2	512	0	

Table 62-70. Variable Length Transfer Protocol Example (ZLT = 1)

Bytes (dTD)	Max. Packet Length (dQH)	N	P1	P2	P3
511	256	2	256	255	
512	256	2	256	256	
512	512	1	512		

NOTE

The MULT field in the dQH must be set to "00" for bulk, interrupt, and control endpoints.

TX-dTD is complete when:

- All packets described dTD were successfully transmitted. *** Total bytes in dTD will equal zero when this occurs.

RX-dTD is complete when:

- All packets described in dTD were successfully received. *** Total bytes in dTD will equal zero when this occurs.
- A short packet (number of bytes < maximum packet length) was received. *** This is a successful transfer completion; DCD must check Total Bytes in dTD to determine the number of bytes that are remaining. From the total bytes remaining in the dTD, the DCD can compute the actual bytes received.
- A long packet was received (number of bytes > maximum packet size) OR (total bytes received > total bytes specified). *** This is an error condition. The device controller will discard the remaining packet, and set the Buffer Error bit in the dTD. In addition, the endpoint will be flushed and the USBERR interrupt will become active.

On the successful completion of the packet(s) described by the dTD, the active bit in the dTD will be cleared and the next pointer will be followed when the Terminate bit is clear. When the Terminate bit is set, the device controller will flush the endpoint/direction and cease operations for that endpoint/direction.

On the unsuccessful completion of a packet (see long packet above), the dQH will be left pointing to the dTD that was in error. In order to recover from this error condition, the DCD must properly reinitialize the dQH by clearing the active bit and update the nextTD pointer before attempting to re-prime the endpoint.

NOTE

All packet level errors such as a missing handshake or CRC error will be retried automatically by the device controller.

There is no required interaction with the DCD for handling such errors.

62.5.6.4.1.1 Interrupt/Bulk Endpoint Bus Response Matrix

The table below shows the response matrix for Interrput/Bulk Endpoint Bus.

Table 62-71. Interrupt/Bulk Endpoint Bus Response Matrix

	Stall	Not Primed	Primed	Underflow	Overflow
Setup	Ignore	Ignore	Ignore	N/A	N/A
In	STALL	NAK	Transmit	BS Error	N/A
Out	STALL	NAK	Receive + NYET/ACK	N/A	NAK
Ping	STALL	NAK	ACK	N/A	N/A
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore

NOTE

BS Error = Force Bit Stuff Error

NYET/ACK - NYET unless the Transfer Descriptor has packets remaining according to the USB variable length protocol then ACK.

SYSERR - System error should never occur when the latency FIFOs are correctly sized and the DCD is responsive.

62.5.6.4.2 Control Endpoint Operation Model

This section details the setup phase, data phase, status phase, and the control endpoint bus response matrix.

62.5.6.4.2.1 Setup Phase

All requests to a control endpoint begin with a setup phase followed by an optional data phase and a required status phase. The device controller will always accept the setup phase unless the setup lockout is engaged.

The setup lockout will engage so that future setup packets are ignored. Lockout of setup packets ensures that while software is reading the setup packet stored in the queue head, that data is not written as it is being read potentially causing an invalid setup packet.

The setup lockout mechanism can be disabled and a new tripwire type semaphore will ensure that the setup packet payload is extracted from the queue head without being corrupted be an incoming setup packet. This is the preferred behavior because ignoring repeated setup packets due to long software interrupt latency would be a compliance issue.

- Disable Setup Lockout by writing 1 to Setup Lockout Mode (SLOM) in USB_nUSBMODE. (once at initialization). Setup lockout is not necessary when using the tripwire as described below.

NOTE

Leaving the Setup Lockout Mode As 0 will result in pre-2.3 hardware behavior.

- After receiving an interrupt and inspecting UBS_nENDSETUPSTAT to determine that a setup packet was received on a particular pipe:
  a. Write 1 to clear corresponding bit UBS_nENDSETUPSTAT.
  b. Write 1 to Setup Tripwire (SUTW) in USB_nUSBCMD register.
  c. Duplicate contents of dQH.SetupBuffer into local software byte array.
  d. Read Setup TripWire (SUTW) in USB_nUSBCMD register. (if set - continue; if cleared - goto 2)
  e. Write 0 to clear Setup Tripwire (SUTW) in USB nUSBCMD register.
  f. Process setup packet using local software byte array copy and execute status/ handshake phases.

NOTE

After receiving a new setup packet the status and/or handshake phases may still be pending from a previous control sequence. These should be flushed & deallocated before linking a new status and/or handshake dTD for the most recent setup packet.

62.5.6.4.2.2 Data Phase

Following the setup phase, the DCD must create a device transfer descriptor for the data phase and prime the transfer.

After priming the packet, the DCD must verify a new setup packet has not been received by reading the USB.ENDPTSETUPSTAT register immediately verifying that the prime had completed. A prime will complete when the associated bit in the USB_nENDPTPRIME register is zero and the associated bit in the USB_nENDPTSTAT register is a one. If a prime fails, ie. The USB_nENDPTPRIME bit goes to zero and the USB_nENDPTSTAT bit is not set, then the prime has failed. This can only be due to

improper setup of the dQH, dTD or a setup arriving during the prime operation. If a new setup packet is indicated after the ENDPTPRIME bit is cleared, then the transfer descriptor can be freed and the DCD must reinterpret the setup packet.

Should a setup arrive after the data stage is primed, the device controller will automatically clear the prime status (USB_nENDPTSTAT) to enforce data coherency with the setup packet.

NOTE

- The MULT field in the dQH must be set to "00" for bulk, interrupt, and control endpoints.
- Error handling of data phase packets is the same as bulk packets described previously.

62.5.6.4.2.3 Status Phase

Similar to the data phase, the DCD must create a transfer descriptor (with byte length equal zero) and prime the endpoint for the status phase.

The DCD must also perform the same checks of the USB.ENDPTSETUPSTAT as described above in the data phase.

NOTE

- The MULT field in the dQH must be set to 00 for bulk, interrupt, and control endpoints.
- Error handling of data phase packets is the same as bulk packets described previously.

62.5.6.4.2.4 Control Endpoint Bus Response Matrix

Shown in the following table is the device controller response to packets on a control endpoint according to the device controller state.

The table below shows the response matrix for the Control Endpoint Bus.

Table 62-72. Control Endpoint Bus Response Matrix

Token Type	Endpoint State					Setup Lockout
	Stall	Not Primed	Primed	Underflow	Overflow	
Setup	ACK	ACK	ACK	N/A	SYSERR	
In	STALL	NAK	Transmit	BS Error	N/A	N/A
Out	STALL	NAK	Receive + NYET/ACK	N/A	NAK	N/A
Ping	STALL	NAK	ACK	N/A	N/A	N/A
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore	Ignore

BS Error = Force Bit Stuff Error

NYET/ACK - NYET unless the Transfer Descriptor has packets remaining according to the USB variable length protocol then ACK.

SYSERR - System error should never occur when the latency FIFOs are correctly sized and the DCD is responsive.

62.5.6.4.3 Isochronous Endpoint Operational Model

Isochronous endpoints are used for real-time scheduled delivery of data and their operational model is significantly different than the host throttled Bulk, Interrupt, and Control data pipes.

Real time delivery by the device controller will be accomplished by the following:

- Exactly MULT Packets per (micro) Frame are transmitted/received. Note: MULT is a two-bit field in the device Queue Head. The variable length packet protocol is not used on isochronous endpoints.
- NAK responses are not used. Instead, zero length packets are sent in response to an IN request to an unprimed endpoints. For unprimed RX endpoints, the response to an OUT transaction is to ignore the packet within the device controller.
- Prime requests always schedule the transfer described in the dTD for the next (micro) frame. If the ISO-dTD is still active after that frame, then the ISO-dTD will be held ready until executed or canceled by the DCD.

An EHCI compatible host controller uses the periodic frame list to schedule data exchanges to Isochronous endpoints. The operational model for device mode does not use such a data structure. Instead, the same dTD used for Control/Bulk/Interrupt endpoints is also used for isochronous endpoints. The difference is in the handling of the dTD.

The first difference between bulk and ISO-endpoints is that priming an ISO-endpoint is a delayed operation such that an endpoint will become primed only after a SOF is received. After the DCD writes the prime bit, the prime bit will be cleared as usual to indicate to software that the device controller completed a priming the dTD for transfer. Internal to the design, the device controller hardware masks that prime start until the next frame boundary. This behavior is hidden from the DCD but occurs so that the device controller can match the dTD to a specific (micro)frame.

Another difference with isochronous endpoints is that the transaction must wholly complete in a (micro)frame. Once an ISO transaction is started in a (micro)frame it will retire the corresponding dTD when MULT transactions occur or the device controller finds a fulfillment condition.

The transaction error bit set in the status field indicates a fulfillment error condition. When a fulfillment error occurs, the frame after the transfer failed to complete wholly, the device controller will force retire the ISO-dTD and move to the next ISO-dTD.

It is important to note that fulfillment errors are only caused due to partially completed packets. If no activity occurs to a primed ISO-dTD, the transaction will stay primed indefinitely. This means it is up to software discard transmit ISO-dTDs that pile up from a failure of the host to move the data.

Finally, the last difference with ISO packets is in the data level error handling. When a CRC error occurs on a received packet, the packet is not retried similar to bulk and control endpoints. Instead, the CRC is noted by setting the *Transaction Error* bit and the data is stored as usual for the application software to sort out.

- TX Packet Retired
  - MULT counter reaches zero.
  - Fulfillment Error [*Transaction Error* bit is set]
    - # Packets Occurred > 0 AND # Packets Occurred < MULT

NOTE

For TX-ISO, MULT Counter can be loaded with a lesser value in the dTD Multiplier Override field in hardware versions 2.3 and later. If the Multiplier Override is zero, the MULT Counter is initialized to the Multiplier in the QH.

- RX Packet Retired:
  - MULT counter reaches zero.
  - Non-MDATA Data PID is received**
    - ** Exit criteria only valid in hardware version 2.3 or later. Previous to hardware version 2.3, any PID sequence that did not match the MULT field exactly would be flagged as a transaction error due to PID mismatch or fulfillment error.
  - Overflow Error:
    - Packet received is > maximum packet length. [*Buffer Error* bit is set]
    - Packet received exceeds total bytes allocated in dTD. [*Buffer Error* bit is set]
  - Fulfillment Error [*Transaction Error* bit is set]
    - # Packets Occurred > 0 AND # Packets Occurred < MULT
  - CRC Error [*Transaction Error* bit is set]

NOTE

For ISO, when a dTD is retired, the next dTD is primed for the next frame. For continuous (micro)frame to (micro)frame

operation the DCD should ensure that the dTD linked-list is out ahead of the device controller by at least two (micro)frames.

62.5.6.4.3.1 Isochronous Pipe Synchronization

When it is necessary to synchronize an isochronous data pipe to the host, the (micro) frame number (USB_UOG_FRINDEX register) can be used as a marker.

To cause a packet transfer to occur at a specific (micro) frame number [N], the DCD should interrupt on SOF during frame N-1. When the USB_UOG_FRINDEX=N-1, the DCD must write the prime bit. The device controller will prime the isochronous endpoint in (micro) frame N-1 so that the device controller will execute delivery during (micro) frame N.

NOTE

Priming an endpoint towards the end of (micro) frame N-1 will not guarantee delivery in (micro) frame N. The delivery may actually occur in (micro) frame N+1 if device controller does not have enough time to complete the prime before the SOF for packet N is received.

62.5.6.4.3.2 Isochronous Endpoint Bus Response Matrix

The following table shows the response matrix for the Isochronous Endpoint Bus.

Table 62-73. Isochronous Endpoint Bus Response Matrix

	Stall	Not Primed	Primed	Underflow	Overflow
Setup	STALL	STALL	STALL	N/A	N/A
In	NULL Packet	NULL Packet	Transmit	BS Error	N/A
Out	Ignore	Ignore	Receive	N/A	Drop Packet
Ping	Ignore	Ignore	Ignore	Ignore	Ignore
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore

1. BS Error = Force Bit Stuff Error

   NULL Packet = Zero Length Packet

62.5.6.5 Managing Queue Heads

The following figure shows the End Point Queue Head.

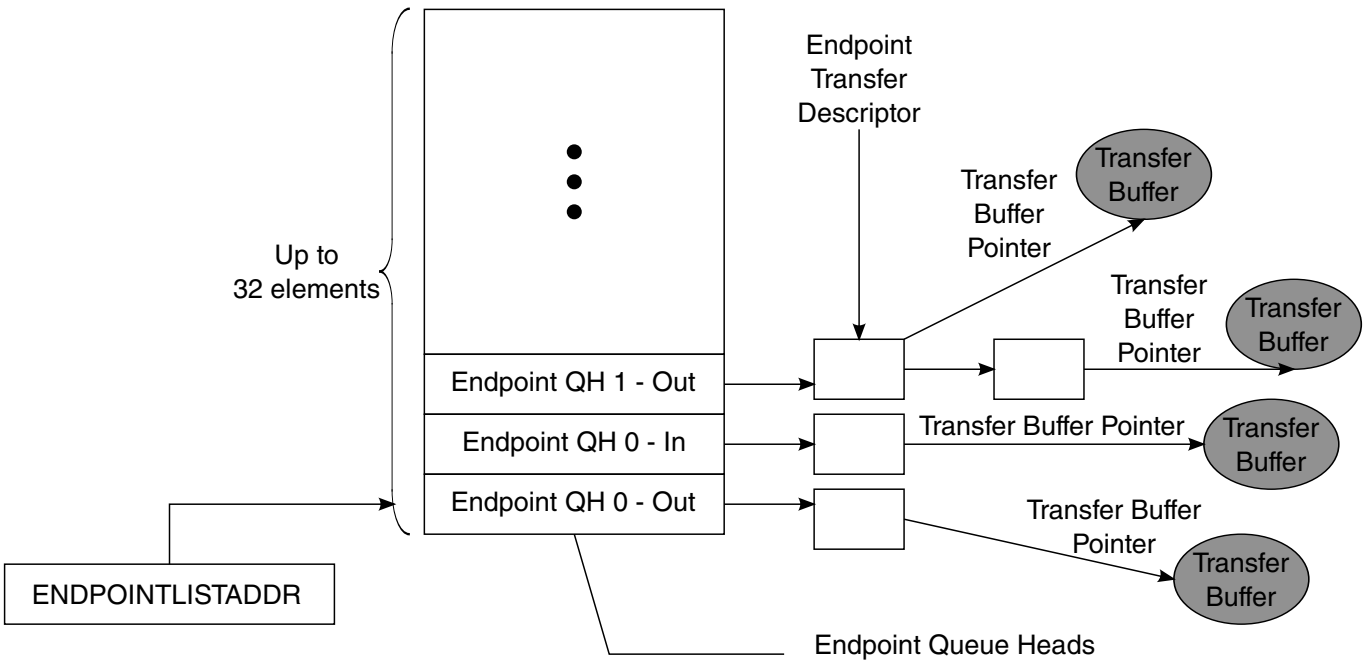

Figure 62-30. End Point Queue Head Diagram

The device queue head (dQH) points to the linked list of transfer tasks, each depicted by the device Transfer Descriptor (dTD). An area of memory pointed to by USB.ENDPOINTLISTADDR contains a group of all dQH's in a sequential list as shown in Figure 62-30. The even elements in the list of dQH's are used for receive endpoints (OUT/SETUP) and the odd elements are used for transmit endpoints (IN/INTERRUPT). Device transfer descriptors are linked head to tail starting at the queue head and ending at a terminate bit. Once the dTD has been retired, it will no longer be part of the linked list from the queue head. Therefore, software is required to track all transfer descriptors because pointers will no longer exist within the queue head once the dTD is retired (see section Software Link Pointers).

In addition to the current and next pointers and the dTD overlay examined in section Operational Model For Packet Transfers, the dQH also contains the following parameters for the associated endpoint: Multipler, Maximum Packet Length, Interrupt On Setup. The complete initialization of the dQH including these fields is demonstrated in the next section.

62.5.6.5.1 Queue Head Initialization

One device queue head must be initialized for each active endpoint.

To initialize a device queue head:

- Write the wMaxPacketSize field as required by the USB Chapter 9 or application specific protocol.
- Write the multiplier field to 0 for control, bulk, and interrupt endpoints. For ISO endpoints, set the multiplier to 1,2, or 3 as required bandwidth and in conjunction with the USB Chapter 9 protocol.

NOTE

In FS mode, the multiplier field can only be 1 for ISO endpoints.

- Write the next dTD Terminate bit field to 1.
- Write the Active bit in the status field to 0.
- Write the Halt bit in the status field to 0.

NOTE

The DCD must only modify dQH if the associated endpoint is not primed and there are no outstanding dTD's.

62.5.6.5.2 Operational Model For Setup Transfers

As discussed in section Control Endpoint Operation Model, setup transfer requires special treatment by the DCD. A setup transfer does not use a dTD but instead stores the incoming data from a setup packet in an 8-byte buffer within the dQH.

Upon receiving notification of the setup packet, the DCD should handle the setup transfer as demonstrated here:

1. Copy setup buffer contents from dQH - RX to software buffer.
2. Acknowledge setup backup by writing a "1" to the corresponding bit in ENDPTSETUPSTAT.

NOTE

- The acknowledge must occur before continuing to process the setup packet.
- After the acknowledge has occurred, the DCD must not attempt to access the setup buffer in the dQH - RX. Only the local software copy should be examined.

3. Check for pending data or status dTD's from previous control transfers and flush if any exist as discussed in section Flushing/De-priming an Endpoint.
4. Decode setup packet and prepare data phase [optional] and status phase transfer as required by the USB Chapter 9 or application specific protocol.

NOTE

It is possible for the device controller to receive setup packets before previous control transfers complete. Existing control packets in progress must be flushed and the new control packet completed.

62.5.6.6 Managing Transfers with Transfer Descriptors

These sections detail how to build, execute, and complete transfers with transfer descriptors.

62.5.6.6.1 Software Link Pointers

It is necessary for the DCD software to maintain head and tail pointers to the for the linked list of dTDs for each respective queue head.

This is necessary because the dQH only maintains pointers to the current working dTD and the next dTD to be executed. The operations described in next section for managing dTD will assume the DCD can use reference the head and tail of the dTD linked list. The following figure shows the Software Link Pointers.

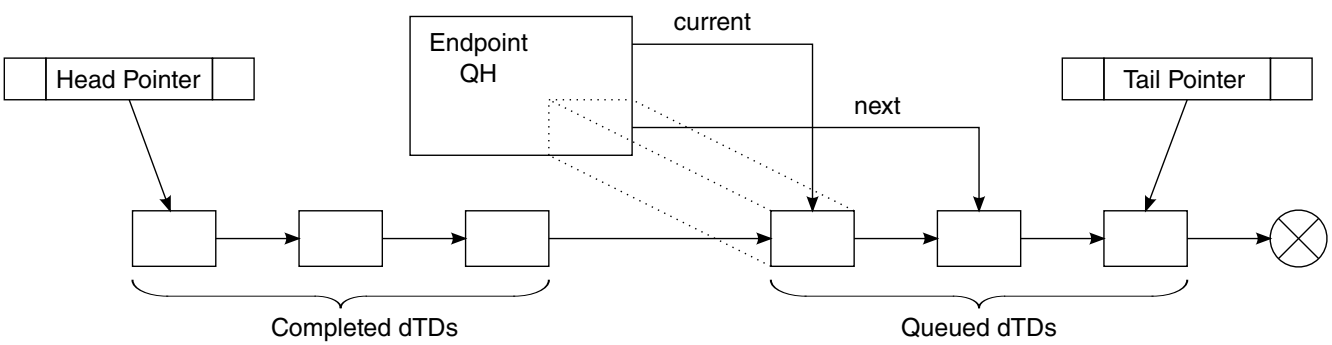

Figure 62-31. Software Link Pointers

NOTE

To conserve memory, the reserved fields at the end of the dQH can be used to store the Head & Tail pointers, but it still remains the responsibility of the DCD to maintain the pointers.

62.5.6.6.2 Building a Transfer Descriptor

Before a transfer can be executed from the linked list, a dTD must be built to describe the transfer.

Use the following procedure for building dTDs.

Allocate 8-DWord dTD block of memory aligned to 8-DWord boundaries. Example: bit address 4:0 would be equal to "00000"

Write the following fields:

1. Initialize first 7 DWords to 0.
2. Set the terminate bit to 1.
3. Fill in total bytes with transfer size.
4. Set the interrupt on complete if desired.
5. Initialize the status field with the active bit set to 1 and all remaining status bits set to 0.
6. Fill in buffer pointer page 0 and the current offset to point to the start of the data buffer.
7. Initialize buffer pointer page 1 through page 4 to be one greater than each of the previous buffer pointer.

62.5.6.6.3 Executing A Transfer Descriptor

To safely add a dTD, the DCD must be follow this procedure which will handle the event where the device controller reaches the end of the dTD list at the same time a new dTD is being added to the end of the list.

Determine whether the link list is empty: Check DCD driver to see if pipe is empty (internal representation of linked-list should indicate if any packets are outstanding).

- Case 1: Link list is empty
  a. Write dQH next pointer AND dQH terminate bit to 0 as a single DWord operation.
  b. Clear active & halt bit in dQH (in case set from a previous error).
  c. Prime endpoint by writing 1 to correct bit position in ENDPTPRIME. Software should check that the dTD/dQH content in external memory is updated before setting the bit in ENDPTPRIME register.
- Case 2: Link list is not empty
  a. Add dTD to end of linked list.
  b. Read correct prime bit in ENDPTPRIME - if 1 DONE.
  c. Set ATDTW bit in USBCMD register to 1.
  d. Read correct status bit in ENDPTSTAT. (store in tmp. variable for later)
  e. Read ATDTW bit in USBCMD register.

- If 0 goto 3.
- If 1 continue to 6.

f. Write ATDTW bit in USBCMD register to 0.
g. If status bit read in (3) is 1 DONE.
h. If status bit read in (3) is 0 then Goto Case 1: Step 1.

62.5.6.6.4 Transfer Completion

After a dTD has been initialized and the associated endpoint primed the device controller will execute the transfer upon the host-initiated request. The DCD will be notified with a USB interrupt if the Interrupt On Complete bit was set or alternately, the DCD can poll the endpoint complete register to find when the dTD had been executed. After a dTD has been executed, DCD can check the status bits to determine success or failure.

NOTE

Multiple dTD can be completed in a single endpoint complete notification. After clearing the notification, DCD must search the dTD linked list and retire all dTDs that have finished (Active bit cleared).

By reading the status fields of the completed dTDs, the DCD can determine if the transfers completed successfully. Success is determined with the following combination of status bits:

- Active = 0
- Halted = 0
- Transaction Error = 0
- Data Buffer Error = 0

Should any combination other than the one shown above exist, the DCD must take proper action. Transfer failure mechanisms are indicated in the Device Error Matrix.

In addition to checking the status bit the DCD must read the Transfer Bytes field to determine the actual bytes transferred. When a transfer is complete, the Total Bytes transferred is by decremented by the actual bytes transferred. For Transmit packets, a packet is only complete after the actual bytes reaches zero, but for receive packets, the host may send fewer bytes in the transfer according the USB variable length packet protocol.

62.5.6.6.5 Flushing/De-priming an Endpoint

It is necessary for the DCD to flush to de-prime one more endpoints on a USB device reset or during a broken control transfer.

There may also be application specific requirements to stop transfers in progress. The following procedure can be used by the DCD to stop a transfer in progress:

1. Write a '1' to the corresponding bit(s) in ENDPTFLUSH.
2. Wait until all bits in ENDPTFLUSH are '0'.
   - Software note: this operation may take a large amount of time depending on the USB bus activity. It is not desirable to have this wait loop within an interrupt service routine.
3. Read ENDPTSTAT register to ensure that for all endpoints commanded to be flushed, that the corresponding bits are now '0'. If the corresponding bits are '1' after step #2 has finished, then the flush failed as described in the following:
   - Explanation: In very rare cases, a packet is in progress to the particular endpoint when commanded flush using ENDPTFLUSH register. A safeguard is in place to refuse the flush to ensure that the packet in progress completes successfully. The DCD may need to repeatedly flush any endpoints that fail to flush be repeating steps 1-3 until each endpoint is successfully flushed.

62.5.6.6.6 Device Error Matrix

The following table summarizes packet errors that are not automatically handled by the Device Controller.

Table 62-74. Device Error Matrix

Error	Direction	Packet Type	Data Buffer Error Bit	Transaction Error Bit
Overflow **	RX	Any	1	0
ISO Packet Error	RX	ISO	0	1
ISO Fulfillment Error	Both	ISO	0	1

Notice that the device controller handles all errors on Bulk/Control/Interrupt Endpoints except for a data buffer overflow. However, for ISO endpoints, errors packets are not retried and errors are tagged as indicated. The table below describes the errors.

Table 62-75. Error Descriptions

Error	Description
Overflow	Number of bytes received exceeded max. packet size or total buffer length. ** This error will also set the Halt bit in the dQH and if there are dTDs remaining in the linked list for the endpoint, then those will not be executed.
ISO Packet Error	CRC Error on received ISO packet. Contents not guaranteed to be correct.
ISO Fulfillment Error	Host failed to complete the number of packets defined in the dQH mult field within the given (micro)frame. For scheduled data delivery the DCD may need to readjust the data queue because a fulfillment error will cause Device Controller to cease data transfers on the pipe for one (micro)frame. During the "dead" (micro)frame, the Device Controller reports error on the pipe and primes for the following frame.

62.5.6.7 Servicing Interrupts

The interrupt service routine must consider that there are high-frequency, low-frequency operations, and error operations and order accordingly.

62.5.6.7.1 High-Frequency Interrupts

High frequency interrupts in particular should be handled in the order below. The most important of these is listed first because the DCD must acknowledge a setup buffer in the timeliest manner possible.

The table below describes the High frequency interrupt events.

Table 62-76. High Frequency Interrupt Events

Execution Order	Interrupt	Action
1a	USB Interrupt - USB.ENDPTSETUPSTATUS	Copy contents of setup buffer and acknowledge setup packet (as indicated in Figure 62-30 shows the End Point Queue Head). Process setup packet according to USB 2.0 Chapter 9 or application specific protocol.
1b	USB Interrupt[1] - USB.ENDPTCOMPLETE	Handle completion of dTD as indicated in Figure 62-30 shows the End Point Queue Head.
2	SOF Interrupt	Action as deemed necessary by application. This interrupt may not have a use in all applications.

1. It is likely that multiple interrupts to stack up on any call to the Interrupt Service Routine AND during the Interrupt Service Routine.

62.5.6.7.2 Low-Frequency Interrupts

The low frequency interrupts can be handled in any order because they do not occur often in comparison to the high-frequency interrupts.

The table below shows the Low frequency interrupt events.

Table 62-77. Low Frequency Interrupt Events

Interrupt	Action
Port Change	Change software state information.
Sleep Enable (Suspend)	Change software state information. Low power handling as necessary.
Reset Received	Change software state information. Abort pending transfers.

62.5.6.7.3 Error Interrupts

Error interrupts will be least frequent and should be placed last in the interrupt service routine.

The following table shows the error interrput events.

Table 62-78. Error Interrupt Events

Interrupt	Action
USB Error Interrupt	This error is redundant because it combines USB Interrupt and an error status in the dTD. The DCD will more aptly handle packet-level errors by checking dTD status field upon receipt of USB Interrupt (w/ USB.ENDPTCOMPLETE).
System Error	Unrecoverable error. Immediate Reset of core; free transfers buffers in progress and restart the DCD.

62.6 USB Non-Core Memory Map/Register Definition

62.6.1 USBNC register descriptions

There are two kinds of registers in the USB module: USB core registers and USB non-core registers. USB core registers are used to control USB core functions, and more independent of USB features. Each USB controller core has its own core registers. USB non-core registers are additional to USB core registers, and more dependent on USB features. i.MX series products vary in non-core registers.

This section describes only the USB non-core registers. For detailed descriptions of USB core registers, please refer to Register Interface .

NOTE

- For reserved bits, please preserve the value when writing (read its reset value, then write this value back)

62.6.1.1 USBNC memory map

USBNC_OTG1 base address: 4043_0200h

USBNC_OTG2 base address: 4042_C200h

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)
0	USB OTG Control 1 Register (CTRL1)	32	RW	3000_1000
4	USB OTG Control 2 Register (CTRL2)	32	RW	5F00_0000
10	USB Host HSIC Control Register (HSIC_CTRL)	32	RW	1000_4084

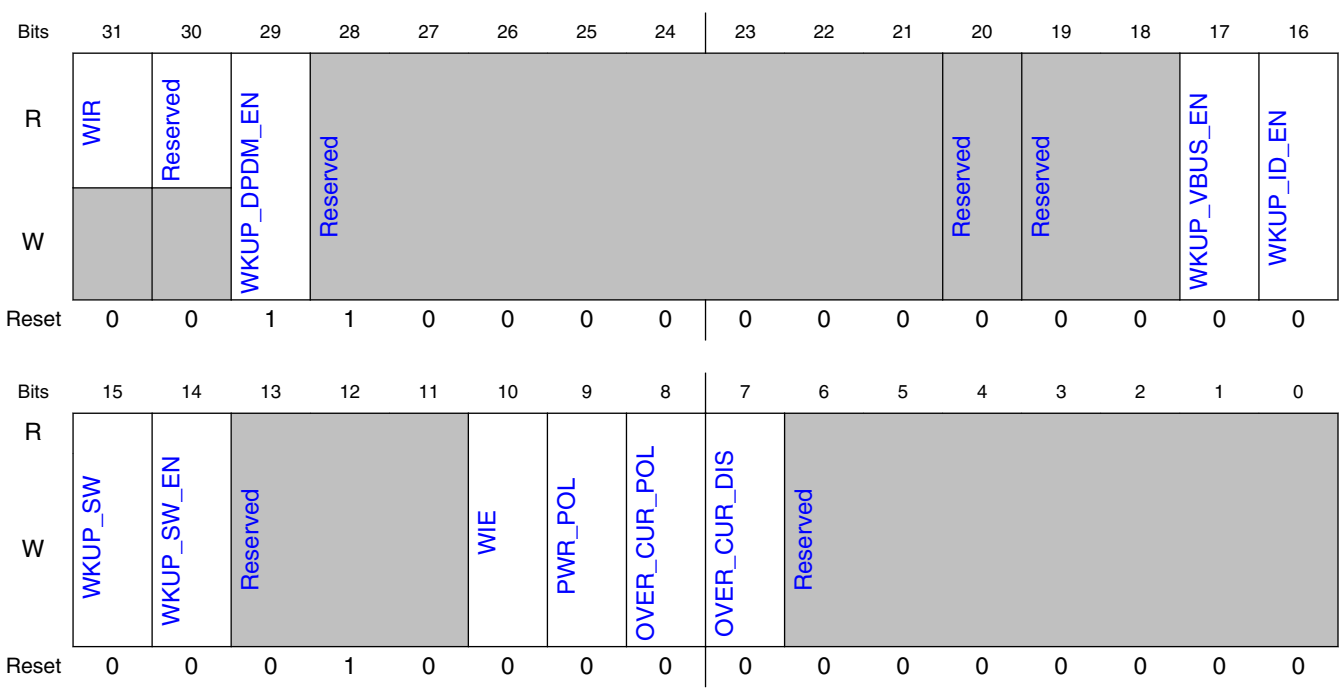
62.6.1.2 USB OTG Control 1 Register (CTRL1)

The USB Control 1 register controls the integration specific features of the USB OTG1 and OTG2 module. These features are not directly related to the USB functionality, but control special features, interfacing on the USB ports, as well as power control and wake-up functionality.

62.6.1.2.1 Offset

Register	Offset
CTRL1	0h

62.6.1.2.2 Diagram



62.6.1.2.3 Fields

Field	Description
31 WIR	WIR Wake-up Interrupt Request This bit indicates that a wake-up interrupt request is received on the OTG1 port. This bit is cleared by disabling the wake-up interrupt (clearing bit "OWIE"). 0 - No wake-up interrupt request received 1 - Wake-up Interrupt Request received
30 —	Reserved
29 WKUP_DPDM_EN	Wake-up on DPDM change enable 0 - DPDM changes wake-up to be disabled only when VBUS is 0. 1 - (Default) DPDM changes wake-up to be enabled, it is for device only.
28-21 —	Reserved
20 —	- Reserved
19-18 —	- Reserved
17 WKUP_VBUS_EN	WKUP_VBUS_EN Wake-up on VBUS change enable 0 - Disable 1 - Enable
16 WKUP_ID_EN	WKUP_ID_EN Wake-up on ID change enable 0 - Disable 1 - Enable
15 WKUP_SW	WKUP_SW Software Wake-up 0 - Inactive 1 - Force wake-up
14 WKUP_SW_EN	WKUP_SW_EN Software Wake-up Enable 0 - Disable 1 - Enable
13-11 —	- Reserved
10 WIE	WIE Wake-up Interrupt Enable

Table continues on the next page...

Field	Description
	This bit enables or disables the OTG1 wake-up interrupt. Disabling the interrupt also clears the Interrupt request bit. Wake-up interrupt enable should be turned off after receiving a wake-up interrupt and turned on again prior to going in suspend mode 0 - Interrupt Disabled 1 - Interrupt Enabled
9 PWR_POL	PWR_POL Power Polarity This bit should be set according to PMIC Power Pin polarity. 0 - PMIC Power Pin is Low active. 1 - PMIC Power Pin is High active.
8 OVER_CUR_POL	OVER_CUR_POL Polarity of Overcurrent The polarity of OTG1/OTG2 port overcurrent event 0 - High active (high on this signal represents an overcurrent condition) 1 - Low active (low on this signal represents an overcurrent condition)
7 OVER_CUR_DIS	OVER_CUR_DIS Disable Overcurrent Detection 0 - Enables overcurrent detection 1 - Disables overcurrent detection
6-0 —	- Reserved

62.6.1.3 USB OTG Control 2 Register (CTRL2)

The USB Control 2 register controls the integration specific features of the USB module. These features are not directly related to the USB functionality, but control special features, interfacing on the USB ports, as well as power control and wakeup functionality.

62.6.1.3.1 Offset

62.7.1.6.3 Fields

Field	Description
31-24 —	- Reserved
23-16 TXCHANADD	TXCHANADD TX FIFO Buffer size is: (2^TXCHANADD) * 4 Bytes. These bits are set to '08h', so buffer size is 256*4 Bytes. For the OTG controller operating in device mode, this is the FIFO buffer size per endpoint. As the OTG controller has 8 TX endpoint, there are 8 of these buffers. For the OTG controller operating in host mode, or for Host-only controller, the entire buffer memory is used as a single TX buffer. Therefore, there is only 1 of this buffer
15-8 —	- Reserved
7-0 TXBURST	TXBURST Default burst size for memory to TX buffer transfer. This is reset value of TXPBURST bits in USB core register USB_n_BURSTSIZE. Please see BURSTSIZE .

62.7.1.7 RX Buffer Hardware Parameters (HWRXBUF)

62.7.1.7.1 Offset

62.7.1.8.3 Fields

Field	Description
31-24 —	- Reserved
23-0 GPTLD	GPTLD General Purpose Timer Load Value These bit fields are loaded to GPTCNT bits when GPTRST bit is set '1b'. This value represents the time in microseconds minus 1 for the timer duration. Example: for a one millisecond timer, load 1000-1=999 or 0x0003E7. **NOTE:** Max value is 0xFFFFFF or 16.777215 seconds.

62.7.1.9 General Purpose Timer #0 Controller (GPTIMER0CTRL)

This register contains the control for this countdown timer and a data field can be queried to determine the running count value. This timer has granularity on 1 us and can be programmed to a little over 16 seconds. There are two counter modes which are described in the register table below. When the timer counter value transitions to zero, an interrupt could be generated if enable.

Interrupt status bit is TI0 bit in n_USBSTS register (See USBSTS), interrupt enable bit is TIE0 bit in n_USBINTR register. (See USBINTR .)

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	N_CC				N_PCC				Reserved			PPC	N_PORTS			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	1

62.7.1.15.3 Fields

Field	Description
31-28	-
—	Reserved
27-24	N_TT
N_TT	Number of Transaction Translators (N_TT). Default value '0000b'
	This field indicates the number of embedded transaction translators associated with the USB2.0 host controller.
	These bits would be set to '0001b' for Multi-Port Host, and '0000b' for Single-Port Host.
23-20	N_PTT
N_PTT	Number of Ports per Transaction Translator (N_PTT). Default value '0000b'
	This field indicates the number of ports assigned to each transaction translator within the USB2.0 host controller.
	These bits would be set to equal N_PORTS for Multi-Port Host, and '0000b' for Single-Port Host.
19-17	-
—	Reserved
16	PI
PI	Port Indicators (P INDICATOR)
	This bit indicates whether the ports support port indicator control. When set to one, the port status and control registers include a read/writeable field for controlling the state of the port indicator
	This bit is "1b" in all controller core.
15-12	N_CC
N_CC	Number of Companion Controller (N_CC).
	This field indicates the number of companion controllers associated with this USB2.0 host controller.
	These bits are '0000b' in all controller core.
	0000 - There is no internal Companion Controller and port-ownership hand-off is not supported.
	0001 - There are internal companion controller(s) and port-ownership hand-offs is supported.
11-8	N_PCC
N_PCC	Number of Ports per Companion Controller
	This field indicates the number of ports supported per internal Companion Controller. It is used to indicate the port routing configuration to the system software.
	For example, if N_PORTS has a value of 6 and N_CC has a value of 2 then N_PCC could have a value of 3. The convention is that the first N_PCC ports are assumed to be routed to companion controller 1, the next N_PCC ports to companion controller 2, etc. In the previous example, the N_PCC could have been 4, where the first 4 are routed to companion controller 1 and the last two are routed to companion controller 2. The number in this field must be consistent with N_PORTS and N_CC.
	These bits are '0000b' in all controller core.
7-5	-
—	Reserved
4	PPC
PPC	Port Power Control

Table continues on the next page...

Field	Description
	This field indicates whether the host controller implementation includes port power control. A one indicates the ports have port power switches. A zero indicates the ports do not have port power switches. The value of this field affects the functionality of the Port Power field in each port status and control register
3-0 N_PORTS	N_PORTS Number of downstream ports. This field specifies the number of physical downstream ports implemented on this host controller. The value of this field determines how many port registers are addressable in the Operational Register. Valid values are in the range of 1h to Fh. A zero in this field is undefined. These bits are always set to '0001b' because all controller cores are Single-Port Host.

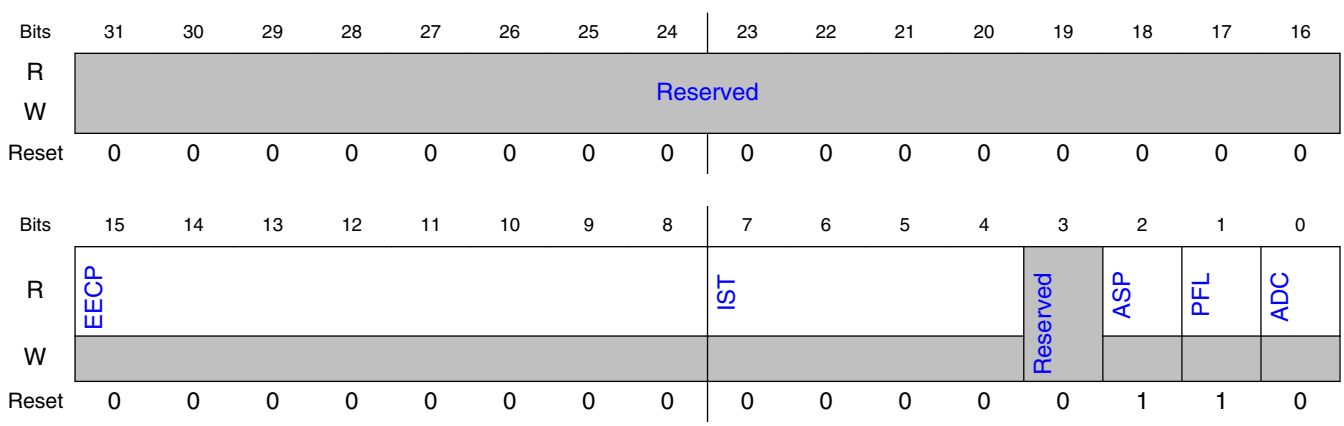
62.7.1.16 Host Controller Capability Parameters (HCCPARAMS)

This register identifies multiple mode control (time-base bit functionality), addressing capability.

62.7.1.16.1 Offset

Register	Offset
HCCPARAMS	108h

62.7.1.16.2 Diagram



62.7.1.16.3 Fields

Field	Description
31-16 —	- Reserved
15-8 EECP	EECP EHCI Extended Capabilities Pointer. This field indicates the existence of a capabilities list. A value of 00h indicates no extended capabilities are implemented. A non-zero value in this register indicates the offset in PCI configuration space of the first EHCI extended capability. The pointer value must be 40h or greater if implemented to maintain the consistency of the PCI header defined for this class of device. **NOTE:** These bits are set '00h' in all controller core.
7-4 IST	IST Isochronous Scheduling Threshold. This field indicates, relative to the current position of the executing host controller, where software can reliably update the isochronous schedule. When bit [7] is zero, the value of the least significant 3 bits indicates the number of micro-frames a host controller can hold a set of isochronous data structures (one or more) before flushing the state. When bit [7] is a one, then host software assumes the host controller may cache an isochronous data structure for an entire frame. These bits are set '00h' in all controller core.
3 —	- Reserved
2 ASP	ASP Asynchronous Schedule Park Capability If this bit is set to a one, then the host controller supports the park feature for high-speed queue heads in the Asynchronous Schedule. The feature can be disabled or enabled and set to a specific level by using the *Asynchronous Schedule Park Mode Enable* and *Asynchronous Schedule Park Mode Count* fields in the USBCMD register. **NOTE:** ASP bit reset value: '00b' for OTG controller core, '11b' for Host-only controller core.
1 PFL	PFL Programmable Frame List Flag If this bit is set to zero, then the system software must use a frame list length of 1024 elements with this host controller. The USBCMD register Frame List Size field is a read-only register and must be set to zero. If set to a one, then the system software can specify and use a smaller frame list and configure the host controller via the USBCMD register Frame List Size field. The frame list must always be aligned on a 4K-page boundary. This requirement ensures that the frame list is always physically contiguous. This bit is set '1b' in all controller core.
0 ADC	ADC 64-bit Addressing Capability This bit is set '0b' in all controller core, no 64-bit addressing capability is supported.

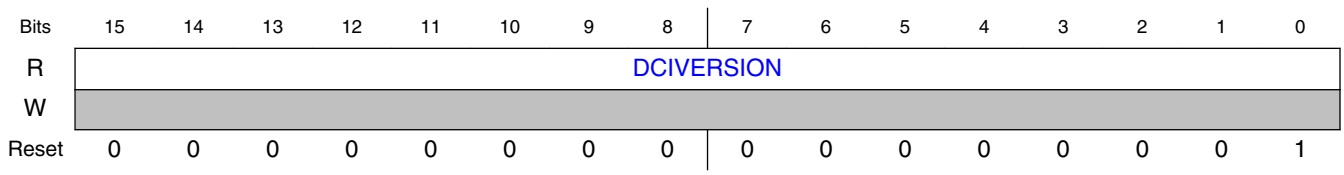
62.7.1.17 Device Controller Interface Version (DCIVERSION)

This register indicates the two-byte BCD encoding of the device controller interface version number.

62.7.1.17.1 Offset

Register	Offset
DCIVERSION	120h

62.7.1.17.2 Diagram



62.7.1.17.3 Fields

Field	Description
15-0 DCIVERSION	DCIVERSION Device Controller Interface Version Number Default value is '01h', which means rev0.1.

62.7.1.18 Device Controller Capability Parameters (DCCPARAMS)

These fields describe the overall device capability of the controller.

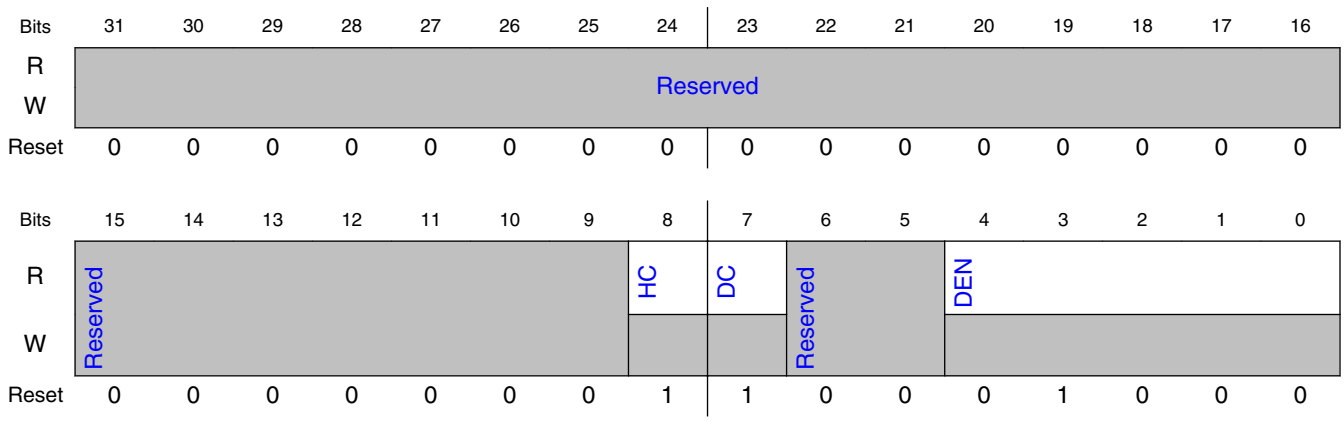
NOTE

This register is only available in OTG controller core.

62.7.1.18.1 Offset

Register	Offset
DCCPARAMS	124h

62.7.1.18.2 Diagram



62.7.1.18.3 Fields

Field	Description
31-9 —	- Reserved
8 HC	HC Host Capable When this bit is 1, this controller is capable of operating as an EHCI compatible USB 2.0 host controller.
7 DC	DC Device Capable When this bit is 1, this controller is capable of operating as a USB 2.0 device.
6-5 —	- Reserved
4-0 DEN	DEN Device Endpoint Number This field indicates the number of endpoints built into the device controller. If this controller is not device capable, then this field will be zero. Valid values are 0 - 15.

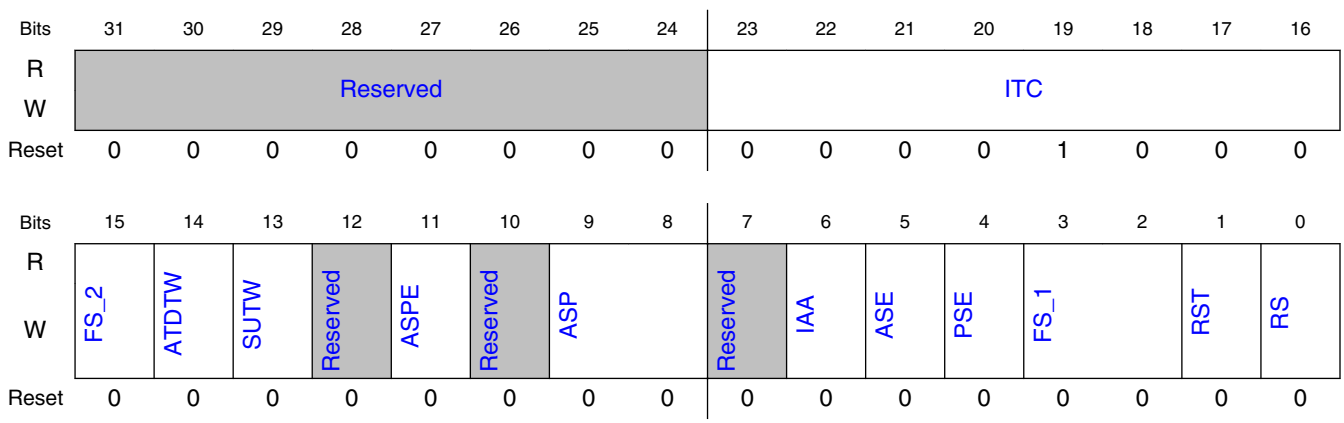
62.7.1.19 USB Command Register (USBCMD)

The Command Register indicates the command to be executed by the serial bus host/device controller. Writing to the register causes a command to be executed.

62.7.1.19.1 Offset

Register	Offset
USBCMD	140h

62.7.1.19.2 Diagram



62.7.1.19.3 Fields

Field	Description
31-24 —	- Reserved
23-16 ITC	ITC Interrupt Threshold Control -Read/Write. The system software uses this field to set the maximum rate at which the host/device controller will issue interrupts. ITC contains the maximum interrupt interval measured in micro-frames. Valid values are shown below. Value Maximum Interrupt Interval 00000000 - Immediate (no threshold) 00000001 - 1 micro-frame 00000010 - 2 micro-frames 00000100 - 4 micro-frames

Table continues on the next page...

Field	Description
	00001000 - 8 micro-frames 00010000 - 16 micro-frames 00100000 - 32 micro-frames 01000000 - 64 micro-frames
15 FS_2	FS_2 Frame List Size - (Read/Write or Read Only). [host mode only] This field is Read/Write only if Programmable Frame List Flag in the HCCPARAMS registers is set to one. This field specifies the size of the frame list that controls which bits in the Frame Index Register should be used for the Frame List Current index. **NOTE:** This field is made up from USBCMD bits 15, 3 and 2. Value Meaning 0b000 - 1024 elements (4096 bytes) Default value 0b001 - 512 elements (2048 bytes) 0b010 - 256 elements (1024 bytes) 0b011 - 128 elements (512 bytes) 0b100 - 64 elements (256 bytes) 0b101 - 32 elements (128 bytes) 0b110 - 16 elements (64 bytes) 0b111 - 8 elements (32 bytes)
14 ATDTW	ATDTW Add dTD TripWire - Read/Write. [device mode only] This bit is used as a semaphore to ensure proper addition of a new dTD to an active (primed) endpoint's linked list. This bit is set and cleared by software. This bit would also be cleared by hardware when state machine is hazard region for which adding a dTD to a primed endpoint may go unrecognized.
13 SUTW	SUTW Setup TripWire - Read/Write. [device mode only] This bit is used as a semaphore to ensure that the setup data payload of 8 bytes is extracted from a QH by the DCD without being corrupted. If the setup lockout mode is off (SLOM bit in USB core register n_USBMODE, see USBMODE) then there is a hazard when new setup data arrives while the DCD is copying the setup data payload from the QH for a previous setup packet. This bit is set and cleared by software. This bit would also be cleared by hardware when a hazard detected.
12 —	- Reserved
11 ASPE	ASPE Asynchronous Schedule Park Mode Enable - Read/Write. If the *Asynchronous Park Capability* bit in the HCCPARAMS register is a one, then this bit defaults to a 1h and is R/W. Otherwise the bit must be a zero and is RO. Software uses this bit to enable or disable Park mode. When this bit is one, Park mode is enabled. When this bit is a zero, Park mode is disabled. **NOTE:** ASPE bit reset value: '0b' for OTG controller .

Table continues on the next page...

Field	Description
10 —	- Reserved
9-8 ASP	ASP Asynchronous Schedule Park Mode Count - Read/Write. If the *Asynchronous Park Capability* bit in the HCCPARAMS register is a one, then this field defaults to 3h and is R/W. Otherwise it defaults to zero and is Read-Only. It contains a count of the number of successive transactions the host controller is allowed to execute from a high-speed queue head on the Asynchronous schedule before continuing traversal of the Asynchronous schedule. Valid values are 1h to 3h. Software must not write a zero to this bit when *Park Mode Enable* is a one as this will result in undefined behavior. This field is set to 3h in all controller core.
7 —	- Reserved
6 IAA	IAA Interrupt on Async Advance Doorbell - Read/Write. This bit is used as a doorbell by software to tell the host controller to issue an interrupt the next time it advances asynchronous schedule. Software must write a 1 to this bit to ring the doorbell. When the host controller has evicted all appropriate cached schedule states, it sets the Interrupt on Async Advance status bit in the USBSTS register. If the Interrupt on Sync Advance Enable bit in the USBINTR register is one, then the host controller will assert an interrupt at the next interrupt threshold. The host controller sets this bit to zero after it has set the Interrupt on Sync Advance status bit in the USBSTS register to one. Software should not write a one to this bit when the asynchronous schedule is inactive. Doing so will yield undefined results. This bit is only used in host mode. Writing a one to this bit when device mode is selected will have undefined results.
5 ASE	ASE Asynchronous Schedule Enable - Read/Write. Default 0b. This bit controls whether the host controller skips processing the Asynchronous Schedule. Only the host controller uses this bit. Values Meaning 0 - Do not process the Asynchronous Schedule. 1 - Use the ASYNCLISTADDR register to access the Asynchronous Schedule.
4 PSE	PSE Periodic Schedule Enable- Read/Write. Default 0b. This bit controls whether the host controller skips processing the Periodic Schedule. Only the host controller uses this bit. Values Meaning 0 - Do not process the Periodic Schedule 1 - Use the PERIODICLISTBASE register to access the Periodic Schedule.
3-2 FS_1	FS_1 See description at bit 15
1	RST

Table continues on the next page...

Field	Description
RST	Controller Reset (RESET) - Read/Write. Software uses this bit to reset the controller. This bit is set to zero by the Host/Device Controller when the reset process is complete. Software cannot terminate the reset process early by writing a zero to this register. Host operation mode: When software writes a one to this bit, the Controller resets its internal pipelines, timers, counters, state machines etc. to their initial value. Any transaction currently in progress on USB is immediately terminated. A USB reset is not driven on downstream ports. Software should not set this bit to a one when the HCHalted bit in the USBSTS register is a zero. Attempting to reset an actively running host controller will result in undefined behavior. Device operation mode: When software writes a one to this bit, the Controller resets its internal pipelines, timers, counters, state machines etc. to their initial value. Writing a one to this bit when the device is in the attached state is not recommended, because the effect on an attached host is undefined. In order to ensure that the device is not in an attached state before initiating a device controller reset, all primed endpoints should be flushed and the USBCMD Run/Stop bit should be set to 0.
0 RS	RS Run/Stop (RS) - Read/Write. Default 0b. 1=Run. 0=Stop. Host operation mode: When set to '1b', the Controller proceeds with the execution of the schedule. The Controller continues execution as long as this bit is set to a one. When this bit is set to 0, the Host Controller completes the current transaction on the USB and then halts. The HC Halted bit in the status register indicates when the Controller has finished the transaction and has entered the stopped state. Software should not write a one to this field unless the controller is in the Halted state (that is, HCHalted in the USBSTS register is a one). Device operation mode: Writing a one to this bit will cause the controller to enable a pull-up on D+ and initiate an attach event. This control bit is not directly connected to the pull-up enable, as the pull-up will become disabled upon transitioning into high-speed mode. Software should use this bit to prevent an attach event before the controller has been properly initialized. Writing a 0 to this will cause a detach event.

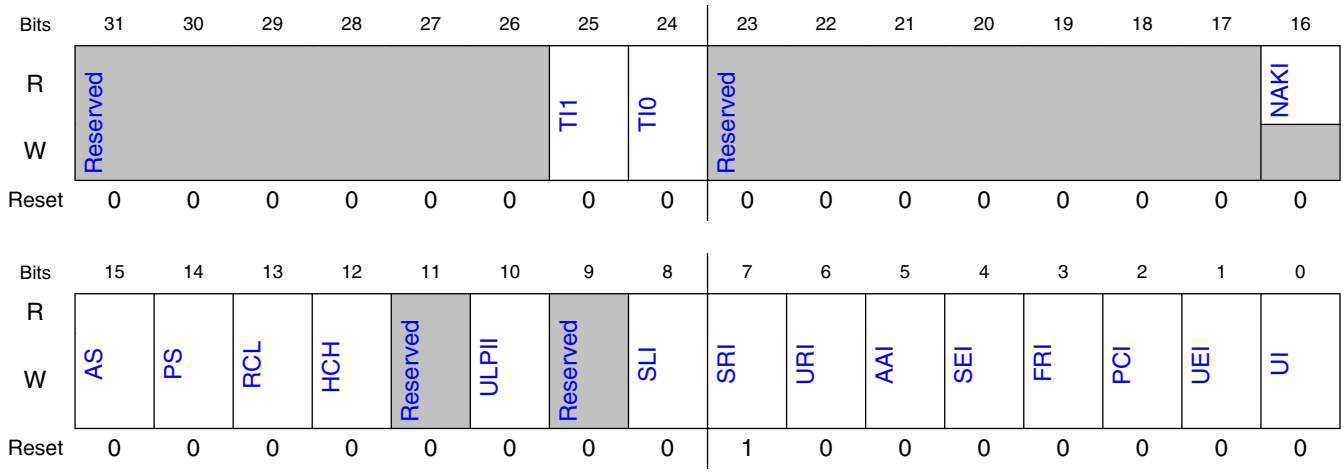
62.7.1.20 USB Status Register (USBSTS)

This register indicates various states of the Host/Device Controller and any pending interrupts. This register does not indicate status resulting from a transaction on the serial bus.

62.7.1.20.1 Offset

Register	Offset
USBSTS	144h

62.7.1.20.2 Diagram



62.7.1.20.3 Fields

Field	Description
31-26 —	- Reserved
25 TI1	TI1 General Purpose Timer Interrupt 1(GPTINT1)--R/WC. This bit is set when the counter in the GPTIMER1CTRL register transitions to zero, writing a one to this bit will clear it.
24 TI0	TI0 General Purpose Timer Interrupt 0(GPTINT0)--R/WC. This bit is set when the counter in the GPTIMER0CTRL register transitions to zero, writing a one to this bit clears it.
23-17 —	- Reserved
16 NAKI	NAKI NAK Interrupt Bit--RO. This bit is set by hardware when for a particular endpoint both the TX/RX Endpoint NAK bit and corresponding TX/RX Endpoint NAK Enable bit are set. This bit is automatically cleared by hardware when all Enabled TX/RX Endpoint NAK bits are cleared.
15 AS	AS Asynchronous Schedule Status - Read Only. This bit reports the current real status of the Asynchronous Schedule. When set to zero the asynchronous schedule status is disabled and if set to one the status is enabled. The Host Controller is not required to immediately disable or enable the Asynchronous Schedule when software transitions the Asynchronous Schedule Enable bit in the USBCMD register. When this bit and the Asynchronous Schedule Enable bit are the same value, the Asynchronous Schedule is either enabled (1) or disabled (0). Only used in the host operation mode.

Table continues on the next page...

Field	Description
14 PS	PS Periodic Schedule Status - Read Only. This bit reports the current real status of the Periodic Schedule. When set to zero the periodic schedule is disabled, and if set to one the status is enabled. The Host Controller is not required to immediately disable or enable the Periodic Schedule when software transitions the Periodic Schedule Enable bit in the USBCMD register. When this bit and the Periodic Schedule Enable bit are the same value, the Periodic Schedule is either enabled (1) or disabled (0). Only used in the host operation mode.
13 RCL	RCL Reclamation - Read Only. This is a read-only status bit used to detect an empty asynchronous schedule. Only used in the host operation mode.
12 HCH	HCH HCHalted - Read Only. This bit is a zero whenever the Run/Stop bit is a one. The Controller sets this bit to one after it has stopped executing because of the Run/Stop bit being set to 0, either by software or by the Controller hardware (for example, an internal error). Only used in the host operation mode. Default value is '0b' for OTG core . This is because OTG core is not operating as host in default. Please see CM bit in USB_n_USBMODE register. **NOTE:** HCH bit reset value: '0b' for OTG controller core .
11 —	- Reserved
10 ULPII	ULPII ULPI Interrupt - R/WC. This bit will be set '1b' by hardware when there is an event completion in ULPI viewport. This bit is usable only if the controller support UPLI interface mode.
9 —	- Reserved
8 SLI	SLI DCSuspend - R/WC. When a controller enters a suspend state from an active state, this bit will be set to a one. The device controller clears the bit upon exiting from a suspend state. Only used in device operation mode.
7 SRI	SRI SOF Received - R/WC. When the device controller detects a Start Of (micro) Frame, this bit will be set to a one. When a SOF is extremely late, the device controller will automatically set this bit to indicate that an SOF was expected. Therefore, this bit will be set roughly every 1ms in device FS mode and every 125ms in HS mode and will be synchronized to the actual SOF that is received. Because the device controller is initialized to FS before connect, this bit will be set at an interval of 1ms during the prelude to connect and chirp.

Table continues on the next page...

Field	Description
	In host mode, this bit will be set every 125us and can be used by host controller driver as a time base. Software writes a 1 to this bit to clear it.
6 URI	URI USB Reset Received - R/WC. When the device controller detects a USB Reset and enters the default state, this bit will be set to a one. Software can write a 1 to this bit to clear the USB Reset Received status bit. Only used in device operation mode.
5 AAI	AAI Interrupt on Async Advance - R/WC. System software can force the host controller to issue an interrupt the next time the host controller advances the asynchronous schedule by writing a one to the Interrupt on Async Advance Doorbell bit in the n_USBCMD register. This status bit indicates the assertion of that interrupt source. Only used in host operation mode.
4 SEI	SEI System Error- R/WC. This bit is will be set to '1b' when an Error response is seen to a read on the system interface.
3 FRI	FRI Frame List Rollover - R/WC. The Host Controller sets this bit to a one when the Frame List Index rolls over from its maximum value to zero. The exact value at which the rollover occurs depends on the frame list size. For example. If the frame list size (as programmed in the Frame List Size field of the USB_n_USBCMD register) is 1024, the Frame Index Register rolls over every time FRINDEX [13] toggles. Similarly, if the size is 512, the Host Controller sets this bit to a one every time FHINDEX [12] toggles. Only used in host operation mode.
2 PCI	PCI Port Change Detect - R/WC. The Host Controller sets this bit to a one when on any port a Connect Status occurs, a Port Enable/ Disable Change occurs, or the Force Port Resume bit is set as the result of a J-K transition on the suspended port. The Device Controller sets this bit to a one when the port controller enters the full or high-speed operational state. When the port controller exits the full or high-speed operation states due to Reset or Suspend events, the notification mechanisms are the USB Reset Received bit and the DCSuspend bits respectively.
1 UEI	UEI USB Error Interrupt (USBERRINT) - R/WC. When completion of a USB transaction results in an error condition, this bit is set by the Host/Device Controller. This bit is set along with the USBINT bit, if the TD on which the error interrupt occurred also had its interrupt on complete (IOC) bit set. The device controller detects resume signaling only.
0 UI	UI USB Interrupt (USBINT) - R/WC. This bit is set by the Host/Device Controller when the cause of an interrupt is a completion of a USB transaction where the Transfer Descriptor (TD) has an interrupt on complete (IOC) bit set.

Field	Description
	This bit is also set by the Host/Device Controller when a short packet is detected. A short packet is when the actual number of bytes received was less than the expected number of bytes.

62.7.1.21 Interrupt Enable Register (USBINTR)

The interrupts to software are enabled with this register. An interrupt is generated when a bit is set and the corresponding interrupt source is active. The USB Status register (n_USBSTS) still shows interrupt sources even if they are disabled by the n_USBINTR register, allowing polling of interrupt events by the software.

17 —	- Reserved
16 NAKE	NAKE NAK Interrupt Enable When this bit is one and the NAKI bit in n_USBSTS register is a one the controller will issue an interrupt.
15-11 —	- These bits are reserved and should be set to zero.
10 ULPIE	ULPIE ULPI Interrupt Enable When this bit is one and the UPLII bit in n_USBSTS register is a one the controller will issue an interrupt. This bit is usable only if the controller support UPLI interface mode.
9 —	- Reserved
8 SLE	SLE Sleep Interrupt Enable When this bit is one and the SLI bit in n_n_USBSTS register is a one the controller will issue an interrupt. Only used in device operation mode.
7 SRE	SRE SOF Received Interrupt Enable When this bit is one and the SRI bit in n_USBSTS register is a one the controller will issue an interrupt.
6 URE	URE USB Reset Interrupt Enable When this bit is one and the URI bit in n_USBSTS register is a one the controller will issue an interrupt. Only used in device operation mode.

Table continues on the next page...

Field	Description
5 AAE	AAE Async Advance Interrupt Enable When this bit is one and the AAI bit in n_USBSTS register is a one the controller will issue an interrupt. Only used in host operation mode.
4 SEE	SEE System Error Interrupt Enable When this bit is one and the SEI bit in n_USBSTS register is a one the controller will issue an interrupt. Only used in host operation mode.
3 FRE	FRE Frame List Rollover Interrupt Enable When this bit is one and the FRI bit in n_USBSTS register is a one the controller will issue an interrupt. Only used in host operation mode.
2 PCE	PCE Port Change Detect Interrupt Enable When this bit is one and the PCI bit in n_USBSTS register is a one the controller will issue an interrupt.
1 UEE	UEE USB Error Interrupt Enable When this bit is one and the UEI bit in n_USBSTS register is a one the controller will issue an interrupt.
0 UE	UE USB Interrupt Enable When this bit is one and the UI bit in n_USBSTS register is a one the controller will issue an interrupt.

62.7.1.22 USB Frame Index (FRINDEX)

This register is used by the host controller to index the periodic frame list. The register updates every 125 microseconds (once each micro-frame). Bits [N: 3] are used to select a particular entry in the Periodic Frame List during periodic schedule execution. The number of bits used for the index depends on the size of the frame list as set by system software in the Frame List Size field in the n_USBCMD register.

This register must be written as a DWord. Byte writes produce undefined results. This register cannot be written unless the Host Controller is in the 'Halted' state as indicated by the HCHalted bit. A write to this register while the Run/Stop hit is set to a one produces undefined results. Writes to this register also affect the SOF value.

In device mode this register is read only and, the device controller updates the FRINDEX [13:3] register from the frame number indicated by the SOF marker. Whenever a SOF is received by the USB bus, FRINDEX [13:3] will be checked against the SOF marker. If

FRINDEX [13:3] is different from the SOF marker, FRINDEX [13:3] will be set to the SOF value and FRINDEX [2:0] will be set to zero (that is, SOF for 1 ms frame). If FRINDEX [13:3] is equal to the SOF value, FRINDEX [2:0] will be increment (that is, SOF for 125 us micro-frame.).

62.7.1.22.1 Offset

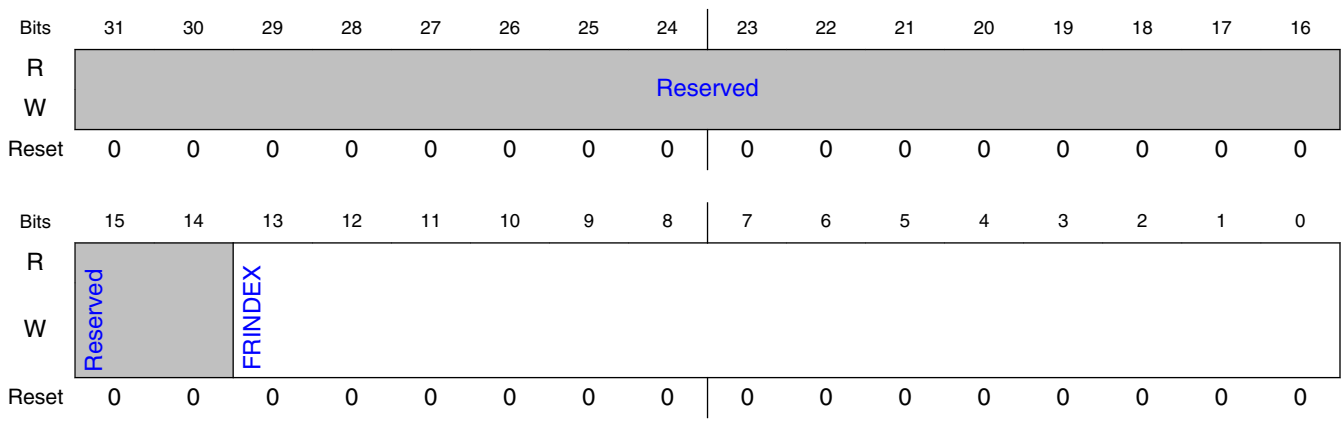
FRINDEX	14Ch

62.7.1.22.2 Diagram



62.7.1.22.3 Fields

Field	Description
31-14 —	- Reserved
13-0 FRINDEX	FRINDEX Frame Index. The value, in this register, increments at the end of each time frame (micro-frame). Bits [N: 3] are used for the Frame List current index. This means that each location of the frame list is accessed 8 times (frames or micro-frames) before moving to the next index. The following illustrates values of N based on the value of the Frame List Size field in the USBCMD register, when used in host mode. USBCMD [Frame List Size] Number Elements N In device mode the value is the current frame number of the last frame transmitted. It is not used as an index. In either mode bits 2:0 indicate the current microframe.

Field	Description
	The bit field values description below is represented as (Frame List Size) Number Elements N. 00000000000000 - (1024) 12 00000000000001 - (512) 11 00000000000010 - (256) 10 00000000000011 - (128) 9 00000000000100 - (64) 8 00000000000101 - (32) 7 00000000000110 - (16) 6 00000000000111 - (8) 5

62.7.1.23 Device Address (DEVICEADDR)

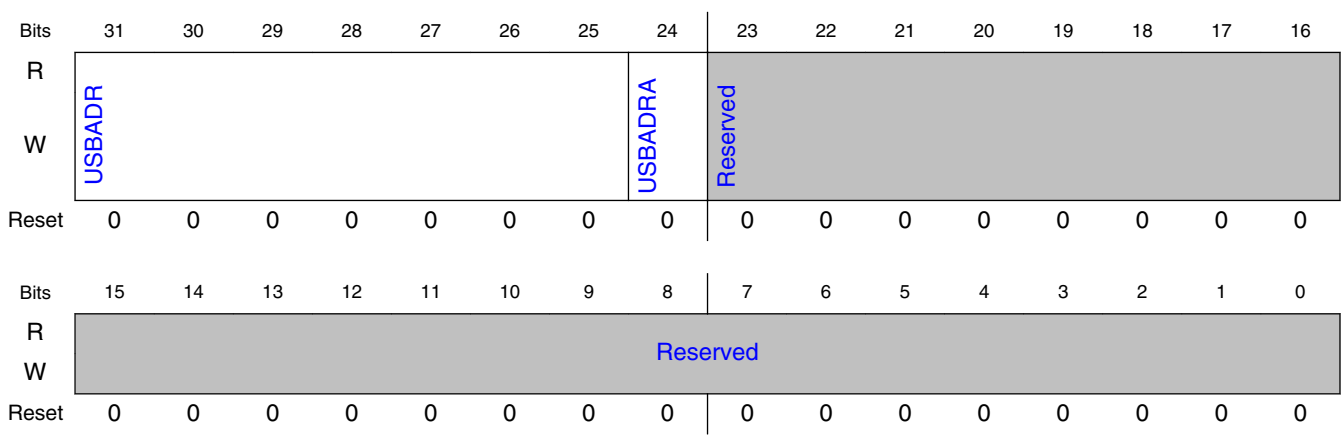
Device Controller only

The upper seven bits of this register represent the device address. After any controller reset or a USB reset, the device address is set to the default address (0). The default address will match all incoming addresses. Software shall reprogram the address after receiving a SET_ADDRESS descriptor.

62.7.1.23.1 Offset

Register	Offset
DEVICEADDR	154h

62.7.1.23.2 Diagram



62.7.1.23.3 Fields

Field	Description
31-25 USBADR	USBADR Device Address. These bits correspond to the USB device address
24 USBADRA	USBADRA Device Address Advance. Default=0. When this bit is '0', any writes to USBADR are instantaneous. When this bit is written to a '1' at the same time or before USBADR is written, the write to the USBADR field is staged and held in a hidden register. After an IN occurs on endpoint 0 and is ACKed, USBADR will be loaded from the holding register. Hardware will automatically clear this bit on the following conditions: 1) IN is ACKed to endpoint 0. (USBADR is updated from staging register). 2) OUT/SETUP occur to endpoint 0. (USBADR is not updated). 3) Device Reset occurs (USBADR is reset to 0). **NOTE:** After the status phase of the SET_ADDRESS descriptor, the DCD has 2 ms to program the USBADR field. This mechanism will ensure this specification is met when the DCD can not write of the device address within 2ms from the SET_ADDRESS status phase. If the DCD writes the USBADR with USBADRA=1 after the SET_ADDRESS data phase (before the prime of the status phase), the USBADR will be programmed instantly at the correct time and meet the 2ms USB requirement.
23-0 —	- Reserved

62.7.1.24 Frame List Base Address (PERIODICLISTBASE)

Host Controller only

This 32-bit register contains the beginning address of the Periodic Frame List in the system memory. HCD loads this register prior to starting the schedule execution by the Host Controller. The memory structure referenced by this physical memory pointer is assumed to be 4-Kbyte aligned. The contents of this register are combined with the Frame Index Register (USB_n_FRINDEX) to enable the Host Controller to step through the Periodic Frame List in sequence.

31-17 —	- Reserved
16-8 TXPBURST	TXPBURST Programmable TX Burst Size. Default value is determined by TXBURST bits in n_HWTXBUF. This register represents the maximum length of a the burst in 32-bit words while moving data from system memory to the USB bus.
7-0 RXPBURST	RXPBURST Programmable RX Burst Size. Default value is determined by TXBURST bits in n_HWRXBUF. This register represents the maximum length of a the burst in 32-bit words while moving data from the USB bus to system memory.

62.7.1.28 TX FIFO Fill Tuning (TXFILLTUNING)

The fields in this register control performance tuning associated with how the host controller posts data to the TX latency FIFO before moving the data onto the USB bus. The specific areas of performance include the how much data to post into the FIFO and an estimate for how long that operation should take in the target system.

Definitions:

T_0 = Standard packet overhead

T_1 = Time to send data payload

T_{ff} = Time to fetch packet into TX FIFO up to specified level.

T_s = Total Packet Flight Time (send-only) packet

$T_s = T_0 + T_1$

T_p = Total Packet Time (fetch and send) packet

$T_p = T_{ff} + T_0 + T_1$

Upon discovery of a transmit (OUT/SETUP) packet in the data structures, host controller checks to ensure T_p remains before the end of the [micro]frame. If so it proceeds to pre-fill the TX FIFO. If at anytime during the pre-fill operation the time remaining the [micro]frame is < T_s then the packet attempt ceases and the packet is tried at a later time. Although this is not an error condition and the host controller will eventually recover, a mark will be made the scheduler health counter to note the occurrence of a "back-off" event. When a back-off event is detected, the partial packet fetched may need to be discarded from the latency buffer to make room for periodic traffic that will begin after the next SOF. Too many back-off events can waste bandwidth and power on the system bus and thus should be minimized (not necessarily eliminated). Back-offs can be minimized with use of the n_TSCHHEALTH (T_{ff}) described below.

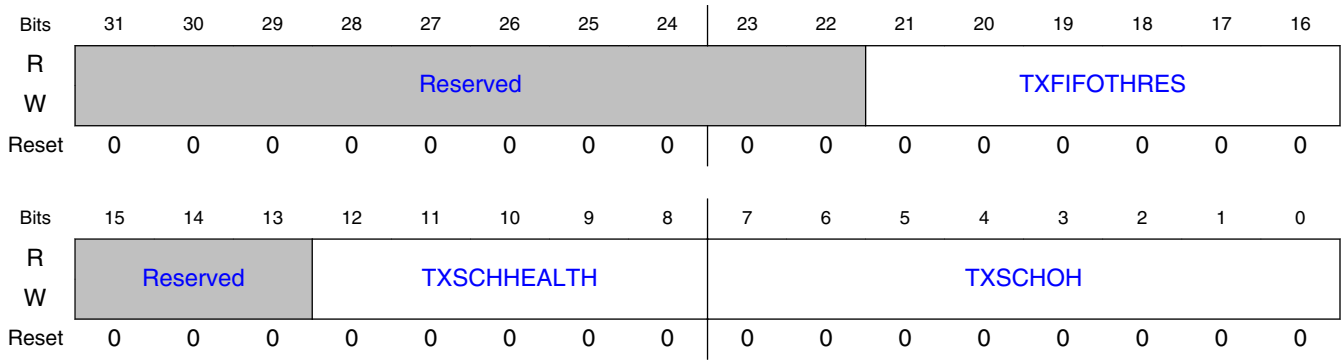
NOTE

The reset value could vary from instance to instance. Please see the detail in bit field description and ignore reset value in summary table in this case!

62.7.1.28.1 Offset

Register	Offset
TXFILLTUNING	164h

62.7.1.28.2 Diagram



62.7.1.28.3 Fields

Field	Description
31-22 —	- Reserved
21-16 TXFIFOTHRES	TXFIFOTHRES FIFO Burst Threshold. (Read/Write) This register controls the number of data bursts that are posted to the TX latency FIFO in host mode before the packet begins on to the bus. The minimum value is 2 and this value should be a low as possible to maximize USB performance. A higher value can be used in systems with unpredictable latency and/or insufficient bandwidth where the FIFO may underrun because the data transferred from the latency FIFO to USB occurs before it can be replenished from system memory. This value is ignored if the Stream Disable bit in USB_n_USBMODE register is set.
15-13 —	- Reserved
12-8 TXSCHHEALTH	TXSCHHEALTH Scheduler Health Counter. (Read/Write To Clear) This register increments when the host controller fails to fill the TX latency FIFO to the level programmed by TXFIFOTHRES before running out of time to send the packet before the next Start-Of-Frame. This health counter measures the number of times this occurs to provide feedback to selecting a proper TXSCHOH. Writing to this register will clear the counter and this counter will max. at 31.
7-0 TXSCHOH	TXSCHOH Scheduler Overhead. (Read/Write) [Default = 0] This register adds an additional fixed offset to the schedule time estimator described above as Tff. As an approximation, the value chosen for this register should limit the number of back-off events captured in the TXSCHHEALTH to less than 10 per second in a highly utilized bus. Choosing a value that is too high for this register is not desired as it can needlessly reduce USB utilization. The time unit represented in this register is 1.267us when a device is connected in High-Speed Mode. The time unit represented in this register is 6.333us when a device is connected in Low/Full Speed Mode. Default value is '08h' for OTG controller core .

0 CF	CF Configure Flag Host software sets this bit as the last action in its process of configuring the Host Controller. This bit controls the default port-routing control logic. 0 - Port routing control logic default-routes each port to an implementation dependent classic host controller. 1 - Port routing control logic default-routes all ports to this host controller.

62.7.1.32 Port Status & Control (PORTSC1)

Host Controller

A host controller could implement one to eight port status and control registers. The number is determined by N_PORTs bits in HWSPARAMs register (please see HCSPARAMS). Software could read this parameter register to determine how many ports need service.

All controller cores on this product are Single-Port, so there is only one port status and control register for each controller core.

This register is only reset by power on reset or controller core reset. The initial conditions of a port are:

- No device connected
- Port disabled

If the port supports power control, this state remains until port power is supplied (by software).

Device Controller

A controller operating in device mode has only port register one (PORTSC1) and it does not support power control in that mode. Port control in device mode is only used for status port reset, suspend, and current connect status. It is also used to initiate test mode or force signaling and allows software to put the PHY into low power suspend mode and disable the PHY clock.

For OTG core, it's Read-Only. For Host1/Host2/Host3 core, it's Read/Write. **NOTE:** All USB port interface modes are listed in this field description, but not all are supported. For detail feature of each controller core, please see Features . The behaviour is unknown when unsupported interface mode is selected.
29 STS	STS Serial Transceiver Select 1 Serial Interface Engine is selected 0 Parallel Interface signals is selected Serial Interface Engine can be used in combination with UTMI+/ULPI physical interface to provide FS/LS signaling instead of the parallel interface signals. When this bit is set '1b', serial interface engine will be used instead of parallel interface signals. This bit has no effect unless PTS bits is set to select UTMI+/ULPI interface. The Serial/USB1.1 PHY/IC-USB will use the serial interface engine for FS/LS signaling regardless of this bit value.
28 PTW	PTW Parallel Transceiver Width

Table continues on the next page...

Field	Description
	This bit has no effect if serial interface engine is used. 0 - Select the 8-bit UTMI interface [60MHz] 1 - Select the 16-bit UTMI interface [30MHz]
27-26 PSPD	PSPD Port Speed - Read Only. This register field indicates the speed at which the port is operating. 00 - Full Speed 01 - Low Speed 10 - High Speed 11 - Undefined
25 PTS_2	PTS_2 See description at bits 31-30
24 PFSC	PFSC Port Force Full Speed Connect - Read/Write. Default = 0b. When this bit is set to '1b', the port will be forced to only connect at Full Speed, It disables the chirp sequence that allows the port to identify itself as High Speed. 0 - Normal operation 1 - Forced to full speed
23 PHCD	PHCD PHY Low Power Suspend - Clock Disable (PLPSCD) - Read/Write. Default = 0b. When this bit is set to '1b', the PHY clock is disabled. Reading this bit will indicate the status of the PHY clock. **NOTE:** The PHY clock cannot be disabled if it is being used as the system clock. In device mode, The PHY can be put into Low Power Suspend when the device is not running (USBCMD Run/Stop=0b) or the host has signalled suspend (PORTSC1 SUSPEND=1b). PHY Low power suspend will be cleared automatically when the host initials resume. Before forcing a resume from the device, the device controller driver must clear this bit. In host mode, the PHY can be put into Low Power Suspend when the downstream device has been put into suspend mode or when no downstream device is connected. Low power suspend is completely under the control of software. 0 - Enable PHY clock 1 - Disable PHY clock
22 WKOC	WKOC Wake on Over-current Enable (WKOC_E) - Read/Write. Default = 0b. Writing this bit to a one enables the port to be sensitive to over-current conditions as wake-up events. This field is zero if *Port Power(*PORTSC1*)* is zero.
21 WKDC	WKDC Wake on Disconnect Enable (WKDSCNNT_E) - Read/Write. Default=0b. Writing this bit to a one enables the port to be sensitive to device disconnects as wake-up events. This field is zero if *Port Power(*PORTSC1*)* is zero or in device mode.
20 WKCN	WKCN Wake on Connect Enable (WKCNNT_E) - Read/Write. Default=0b.

Table continues on the next page...

Field	Description
	Writing this bit to a one enables the port to be sensitive to device connects as wake-up events. This field is zero if *Port Power(*PORTSC1*)* is zero or in device mode.
19-16 PTC	PTC Port Test Control - Read/Write. Default = 0000b. Refer to Port Test Mode for the operational model for using these test modes and the USB Specification Revision 2.0, Chapter 7 for details on each test mode. The FORCE_ENABLE_FS and FORCE ENABLE_LS are extensions to the test mode support specified in the EHCI specification. Writing the PTC field to any of the FORCE_ENABLE_{HS/FS/LS} values will force the port into the connected and enabled state at the selected speed. Writing the PTC field back to TEST_MODE_DISABLE will allow the port state machines to progress normally from that point. **NOTE:** *Low speed operations are not supported as a peripheral device.* Any other value than zero indicates that the port is operating in test mode. Value Specific Test 0000 - TEST_MODE_DISABLE 0001 - J_STATE 0010 - K_STATE 0011 - SE0 (host) / NAK (device) 0100 - Packet 0101 - FORCE_ENABLE_HS 0110 - FORCE_ENABLE_FS 0111 - FORCE_ENABLE_LS 1000-1111 - Reserved
15-14 PIC	PIC Port Indicator Control - Read/Write. Default = Ob. Writing to this field has no effect if the P_INDICATOR bit in the HCSPARAMS register is a zero. Refer to the USB Specification Revision 2.0 for a description on how these bits are to be used. This field is zero if *Port Power* is zero. Bit Value Meaning 00 - Port indicators are off 01 - Amber 10 - Green 11 - Undefined
13 PO	PO Port Owner-Read/Write. Default = 0. This bit unconditionally goes to a 0 when the configured bit in the CONFIGFLAG register makes a 0 to 1 transition. This bit unconditionally goes to 1 whenever the Configured bit is zero System software uses this field to release ownership of the port to a selected host controller (in the event that the attached device is not a high-speed device). Software writes a one to this bit when the attached device is not a high-speed device. A one in this bit means that an internal companion controller owns and controls the port. Port owner handoff is not supported in all controller cores, therefore this bit will always be 0.
12	PP

Table continues on the next page...

Field	Description
PP	Port Power (PP)-Read/Write or Read Only. The function of this bit depends on the value of the Port Power Switching (PPC) field in the HCSPARAMS register. The behavior is as follows: PPC PP Operation 0 1b *Read Only - Host controller does not have port power control switches. Each port is hard-wired to power.* 1 1b/0b - *Read/Write. OTG controller requires port power control switches. This bit represents the current setting of the switch (0=off, 1=on). When power is not available on a port (that is, PP equals a 0), the port is non-functional and will not report attaches, detaches, etc.* When an over-current condition is detected on a powered port and PPC is a one, the PP bit in each affected port may be transitional by the host controller driver from a one to a zero (removing power from the port). This feature is implemented in all controller cores (PPC = 1).
11-10 LS	LS Line Status-Read Only. These bits reflect the current logical levels of the D+ (bit 11) and D- (bit 10) signal lines. In host mode, the use of linestate by the host controller driver is not necessary (unlike EHCI), because the port controller state machine and the port routing manage the connection of LS and FS. In device mode, the use of linestate by the device controller driver is not necessary. The encoding of the bits are: Bits [11:10] Meaning 00 - SE0 01 - K-state 10 - J-state 11 - Undefined
9 HSP	HSP High-Speed Port - Read Only. Default = 0b. When the bit is one, the host/device connected to the port is in high-speed mode and if set to zero, the host/device connected to the port is not in a high-speed mode. **NOTE:** HSP is redundant with PSPD(bit 27, 26) but remained for compatibility.
8 PR	PR Port Reset - Read/Write or Read Only. Default = 0b. In Host Mode: Read/Write. 1=Port is in Reset. 0=Port is not in Reset. Default 0. When software writes a one to this bit the bus-reset sequence as defined in the USB Specification Revision 2.0 is started. *This bit will automatically change to zero after the reset sequence is complete. This behavior is different from EHCI where the host controller driver is required to set this bit to a zero after the reset duration is timed in the driver.* In Device Mode: This bit is a read only status bit. Device reset from the USB bus is also indicated in the USBSTS register. This field is zero if *Port Power(*PORTSC1*)* is zero.

Table continues on the next page...

Field	Description
7 SUSP	SUSP Suspend - Read/Write or Read Only. Default = 0b. 1=Port in suspend state. 0=Port not in suspend state. In Host Mode: Read/Write. Port Enabled Bit and Suspend bit of this register define the port states as follows: Bits [Port Enabled, Suspend] Port State 0x Disable 10 Enable 11 Suspend When in suspend state, downstream propagation of data is blocked on this port, except for port reset. The blocking occurs at the end of the current transaction if a transaction was in progress when this bit was written to 1. In the suspend state, the port is sensitive to resume detection. Note that the bit status does not change until the port is suspended and that there may be a delay in suspending a port if there is a transaction currently in progress on the USB. The host controller will unconditionally set this bit to zero when software sets the *Force Port Resume* bit to zero. The host controller ignores a write of zero to this bit. If host software sets this bit to a one when the port is not enabled (that is, *Port enabled* bit is a zero) the results are undefined. This field is zero if *Port Power(*PORTSC1*)* is zero in host mode. In Device Mode: Read Only. In device mode this bit is a read only status bit.
6 FPR	FPR Force Port Resume -Read/Write. 1= Resume detected/driven on port. 0=No resume (K-state) detected/driven on port. Default = 0. In Host Mode: Software sets this bit to one to drive resume signaling. The Host Controller sets this bit to one if a J-to-K transition is detected while the port is in the Suspend state. When this bit transitions to a one because a J-to-K transition is detected, the *Port Change Detect* bit in the USBSTS register is also set to one. *This bit will automatically change to zero after the resume sequence is complete. This behavior is different from EHCI where the host controller driver is required to set this bit to a zero after the resume duration is timed in the driver.* Note that when the Host controller owns the port, the resume sequence follows the defined sequence documented in the USB Specification Revision 2.0. The resume signaling (Full-speed 'K') is driven on the port as long as this bit remains a one. This bit will remain a one until the port has switched to the high-speed idle. Writing a zero has no effect because the port controller will time the resume operation, clear the bit the port control state switches to HS or FS idle. This field is zero if *Port Power(*PORTSC1*)* is zero in host mode. This bit is not-EHCI compatible. In Device mode: After the device has been in Suspend State for 5ms or more, software must set this bit to one to drive resume signaling before clearing. The Device Controller will set this bit to one if a J-to-K transition is detected while the port is in the Suspend state. The bit will be cleared when the device returns to normal operation. Also, when this bit wil be cleared because a K-to-J transition detected, the *Port Change Detect* bit in the USBSTS register is also set to one.
5	OCC

Table continues on the next page...

Field	Description
OCC	Over-current Change-R/WC. Default=0. This bit is set '1b' by hardware when there is a change to Over-current Active. Software can clear this bit by writing a one to this bit position.
4 OCA	OCA Over-current Active-Read Only. Default 0. This bit will automatically transition from one to zero when the over current condition is removed. 0 - This port does not have an over-current condition. 1 - This port currently has an over-current condition
3 PEC	PEC Port Enable/Disable Change-R/WC. 1=Port enabled/disabled status has changed. 0=No change. Default = 0. In Host Mode: For the root hub, this bit is set to a one only when a port is disabled due to disconnect on the port or due to the appropriate conditions existing at the EOF2 point (See Chapter 11 of the USB Specification). Software clears this by writing a one to it. This field is zero if *Port Power(*PORTSC1*)* is zero. In Device mode: The device port is always enabled, so this bit is always '0b'.
2 PE	PE Port Enabled/Disabled-Read/Write. 1=Enable. 0=Disable. Default 0. In Host Mode: Ports can only be enabled by the host controller as a part of the reset and enable. Software cannot enable a port by writing a one to this field. Ports can be disabled by either a fault condition (disconnect event or other fault condition) or by the host software. Note that the bit status does not change until the port state actually changes. There may be a delay in disabling or enabling a port due to other host controller and bus events. When the port is disabled, (0b) downstream propagation of data is blocked except for reset. This field is zero if *Port Power(*PORTSC1*)* is zero in host mode. In Device Mode: The device port is always enabled, so this bit is always '1b'.
1 CSC	CSC Connect Status Change-R/WC. 1 =Change in Current Connect Status. 0=No change. Default 0. In Host Mode: Indicates a change has occurred in the port's Current Connect Status. The host/device controller sets this bit for all changes to the port device connect status, even if system software has not cleared an existing connect status change. For example, the insertion status changes twice before system software has cleared the changed condition, hub hardware will be 'setting' an already-set bit (that is, the bit will remain set). Software clears this bit by writing a one to it. This field is zero if *Port Power(*PORTSC1*)* is zero in host mode. In Device Mode: This bit is undefined in device controller mode.
0	CCS

Field	Description
CCS	Current Connect Status-Read Only. In Host Mode: 1=Device is present on port. 0=No device is present. Default = 0. This value reflects the current state of the port, and may not correspond directly to the event that caused the *Connect Status Change* bit (Bit 1) to be set. This field is zero if *Port Power(*PORTSC1*)* is zero in host mode. In Device Mode: 1=Attached. 0=Not Attached. Default=0. A one indicates that the device successfully attached and is operating in either high speed or full speed as indicated by the High Speed Port bit in this register. A zero indicates that the device did not attach successfully or was forcibly disconnected by the software writing a zero to the Run bit in the USBCMD register. It does not state the device being disconnected or suspended.

62.7.1.33 On-The-Go Status & control (OTGSC)

This register is availabe only in OTG controller core. It has four sections:

- OTG Interrupt enables (Read/Write)
- OTG Interrupt status (Read/Write to Clear)
- OTG Status inputs (Read Only)
- OTG Controls (Read/Write)

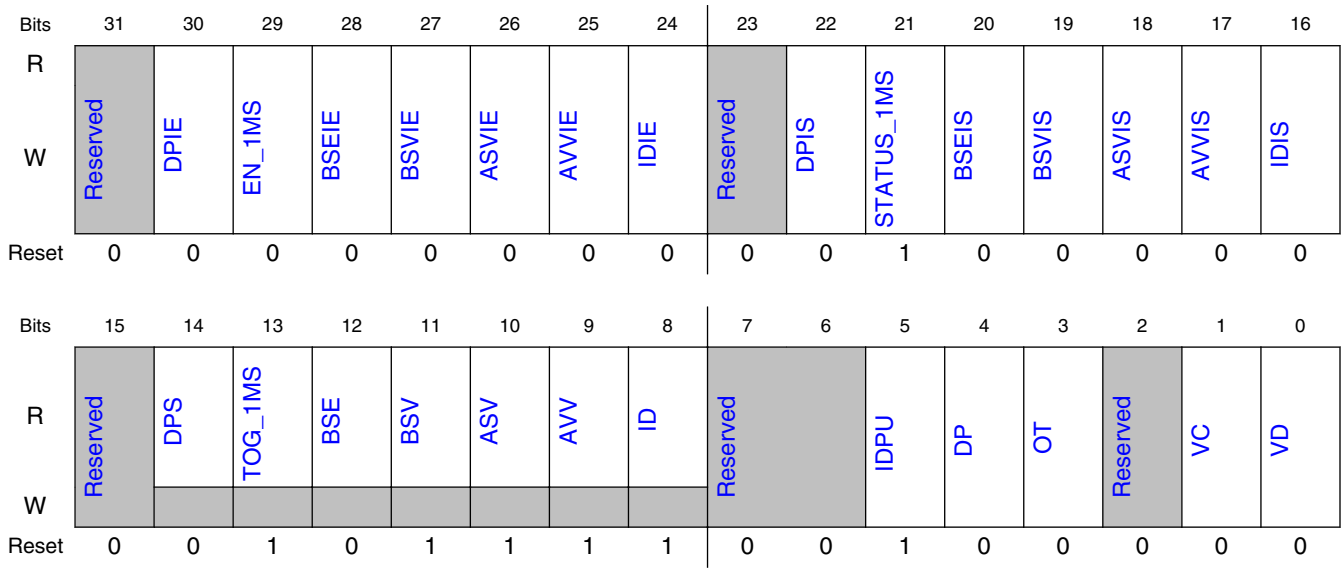
The status inputs are debounced using a 1 ms time constant. Values on the status inputs that do not persist for more than 1 ms does not cause an update of the status input register, or cause an OTG interrupt.

See also USBMODE register.

62.7.1.33.1 Offset

Register	Offset
OTGSC	1A4h

62.7.1.33.2 Diagram



62.7.1.33.3 Fields

Field	Description
31 —	- Reserved
30 DPIE	DPIE Data Pulse Interrupt Enable
29 EN_1MS	EN_1MS 1 millisecond timer Interrupt Enable - Read/Write
28 BSEIE	BSEIE B Session End Interrupt Enable - Read/Write. Setting this bit enables the B session end interrupt.
27 BSVIE	BSVIE B Session Valid Interrupt Enable - Read/Write. Setting this bit enables the B session valid interrupt.
26 ASVIE	ASVIE A Session Valid Interrupt Enable - Read/Write. Setting this bit enables the A session valid interrupt.
25 AVVIE	AVVIE A VBus Valid Interrupt Enable - Read/Write. Setting this bit enables the A VBus valid interrupt.
24 IDIE	IDIE USB ID Interrupt Enable - Read/Write.

Table continues on the next page...

Field	Description
	Setting this bit enables the USB ID interrupt.
23 —	- Reserved
22 DPIS	DPIS Data Pulse Interrupt Status - Read/Write to Clear. This bit is set when data bus pulsing occurs on DP or DM. Data bus pulsing is only detected when USBMODE.CM = Host (11) and PORTSC1(0)[PP] = 0. Software must write a one to clear this bit.
21 STATUS_1MS	STATUS_1MS 1 millisecond timer Interrupt Status - Read/Write to Clear. This bit is set once every millisecond. Software must write a one to clear this bit.
20 BSEIS	BSEIS B Session End Interrupt Status - Read/Write to Clear. This bit is set when VBus has fallen below the B session end threshold. Software must write a one to clear this bit.
19 BSVIS	BSVIS B Session Valid Interrupt Status - Read/Write to Clear. This bit is set when VBus has either risen above or fallen below the B session valid threshold. Software must write a one to clear this bit.
18 ASVIS	ASVIS A Session Valid Interrupt Status - Read/Write to Clear. This bit is set when VBus has either risen above or fallen below the A session valid threshold. Software must write a one to clear this bit.
17 AVVIS	AVVIS A VBus Valid Interrupt Status - Read/Write to Clear. This bit is set when VBus has either risen above or fallen below the VBus valid threshold on an A device. Software must write a one to clear this bit.
16 IDIS	IDIS USB ID Interrupt Status - Read/Write. This bit is set when a change on the ID input has been detected. Software must write a one to clear this bit.
15 —	- Reserved
14 DPS	DPS Data Bus Pulsing Status - Read Only. A '1' indicates data bus pulsing is being detected on the port.
13 TOG_1MS	TOG_1MS 1 millisecond timer toggle - Read Only. This bit toggles once per millisecond.

Table continues on the next page...

Field	Description
12 BSE	BSE B Session End - Read Only. Indicates VBus is below the B session end threshold.
11 BSV	BSV B Session Valid - Read Only. Indicates VBus is above the B session valid threshold.
10 ASV	ASV A Session Valid - Read Only. Indicates VBus is above the A session valid threshold.
9 AVV	AVV A VBus Valid - Read Only. Indicates VBus is above the A VBus valid threshold.
8 ID	ID USB ID - Read Only. 0 = A device, 1 = B device
7-6 —	- Reserved
5 IDPU	IDPU ID Pullup - Read/Write This bit provide control over the ID pull-up resistor; 0 = off, 1 = on [default]. When this bit is 0, the ID input will not be sampled.
4 DP	DP Data Pulsing - Read/Write. Setting this bit causes the pullup on DP to be asserted for data pulsing during SRP.
3 OT	OT OTG Termination - Read/Write. This bit must be set when the OTG device is in device mode, this controls the pulldown on DM.
2 —	- Reserved
1 VC	VC VBUS Charge - Read/Write. Setting this bit causes the VBus line to be charged. This is used for VBus pulsing during SRP.
0 VD	VD VBUS_Discharge - Read/Write. Setting this bit causes VBus to discharge through a resistor.

62.7.1.34.3 Fields

Field	Description
31-16 —	- Reserved
15 —	- Reserved
14-5 —	- Reserved
4 SDIS	SDIS Stream Disable Mode. (0 - Inactive [default]; 1 - Active) Device Mode: Setting to a '1' disables double priming on both RX and TX for low bandwidth systems. This mode ensures that when the RX and TX buffers are sufficient to contain an entire packet that the standard double buffering scheme is disabled to prevent overruns/underruns in bandwidth limited systems. Note: In High Speed Mode, all packets received are responded to with a NYET handshake when stream disable is active.

Table continues on the next page...

Field	Description
	Host Mode: Setting to a '1' ensures that overruns/underruns of the latency FIFO are eliminated for low bandwidth systems where the RX and TX buffers are sufficient to contain the entire packet. Enabling stream disable also has the effect of ensuring the TX latency is filled to capacity before the packet is launched onto the USB. **NOTE:** Time duration to pre-fill the FIFO becomes significant when stream disable is active. See TXFILLTUNING and TXTTFILLTUNING [MPH Only] to characterize the adjustments needed for the scheduler when using this feature. **NOTE:** The use of this feature substantially limits of the overall USB performance that can be achieved.
3 SLOM	SLOM Setup Lockout Mode. In device mode, this bit controls behavior of the setup lock mechanism. See Control Endpoint Operation Model . 0 - Setup Lockouts On (default); 1 - Setup Lockouts Off. DCD requires use of Setup Data Buffer Tripwire in USBCMD.
2 ES	ES Endian Select - Read/Write. This bit can change the byte alignment of the transfer buffers to match the host microprocessor. The bit fields in the microprocessor interface and the data structures are unaffected by the value of this bit because they are based upon the 32-bit word. Bit Meaning 0 - Little Endian [Default] 1 - Big Endian
1-0 CM	CM Controller Mode - R/WO. Controller mode is defaulted to the proper mode for host only and device only implementations. For those designs that contain both host & device capability, the controller defaults to an idle state and needs to be initialized to the desired operating mode after reset. For combination host/device controllers, this register can only be written once after reset. If it is necessary to switch modes, software must reset the controller by writing to the *RESET* bit in the USBCMD register before reprogramming this register. For OTG controller core, reset value is '00b'. 00 - Idle [Default for combination host/device] 01 - Reserved 10 - Device Controller [Default for device only controller] 11 - Host Controller [Default for host only controller]

62.7.1.35.3 Fields

Field	Description
31-16 —	- Reserved
15-0 ENDPTSETUPSTAT	ENDPTSETUPSTAT Setup Endpoint Status. For every setup transaction that is received, a corresponding bit in this register is set to one. Software must clear or acknowledge the setup transfer by writing a one to a respective bit after it has read the setup data from Queue head. The response to a setup packet as in the order of operations and total response time is crucial to limit bus time outs while the setup lock our mechanism is engaged. See Managing Endpoints in the Device Operational Model. This register is only used in device mode.

62.7.1.36 Endpoint Prime (ENDPTPRIME)

This register is only used in device mode.

When software sets the prime bit for a given endpoint, the device controller loads the transfer descriptor, pointed to by the queue head, such that the endpoint is ready to transmit or receive when the host sends a request (IN/OUT token). The endpoint will NAK all requests from the host until the endpoint is primed. The controller will automatically re-prime the endpoint with a new transfer descriptor when one is found via the next_dtd pointer of the current transfer descriptor. Hence, the prime bit must only be set by software when a descriptor is added to the queue head.

23-16 PETB	PETB Prime Endpoint Transmit Buffer - R/WS. For each endpoint a corresponding bit is used to request that a buffer is prepared for a transmit operation in order to respond to a USB IN/INTERRUPT transaction. Software should write a one to the corresponding bit when posting a new transfer descriptor to an endpoint queue head. Hardware automatically uses this bit to begin parsing for a new transfer descriptor from the queue head and prepare a transmit buffer. Hardware clears this bit when the associated endpoint(s) is (are) successfully primed. **NOTE:** These bits are momentarily set by hardware during hardware re-priming operations when a dTD is retired, and the dQH is updated. PETB[N] - Endpoint #N, N is in 0..7
15-8 —	- Reserved
7-0 PERB	PERB Prime Endpoint Receive Buffer - R/WS. For each endpoint, a corresponding bit is used to request a buffer prepare for a receive operation for when a USB host initiates a USB OUT transaction. Software should write a one to the corresponding bit whenever posting a new transfer descriptor to an endpoint queue head. Hardware automatically uses this bit to begin parsing for a new transfer descriptor from the queue head and prepare a receive buffer. Hardware clears this bit when the associated endpoint(s) is (are) successfully primed. **NOTE:** These bits are momentarily set by hardware during hardware re-priming operations when a dTD is retired, and the dQH is updated.

23-16 ETCE	ETCE Endpoint Transmit Complete Event - R/WC. Each bit indicates a transmit event (IN/INTERRUPT) occurred and software should read the corresponding endpoint queue to determine the endpoint status. If the corresponding IOC bit is set in the Transfer Descriptor, then this bit is set simultaneously with the *USBINT* . Writing one clears the corresponding bit in this register. ETCE[N] - Endpoint #N, N is in 0..7
15-8 —	- Reserved
7-0 ERCE	ERCE Endpoint Receive Complete Event - RW/C. Each bit indicates a received event (OUT/SETUP) occurred and software should read the corresponding endpoint queue to determine the transfer status. If the corresponding IOC bit is set in the Transfer Descriptor, then this bit is set simultaneously with the *USBINT* . Writing one clears the corresponding bit in this register. ERCE[N] - Endpoint #N, N is in 0..7

62.7.1.40 Endpoint Control0 (ENDPTCTRL0)

Every Device implements Endpoint 0 as a control endpoint.

Field	Description
31-24 —	- Reserved
23 TXE	TXE TX Endpoint Enable 1 Enabled Endpoint0 is always enabled.
22-20 —	- Reserved
19-18 TXT	TXT TX Endpoint Type - Read/Write 00 - Control Endpoint0 is fixed as a Control End Point.
17 —	- Reserved
16 TXS	TXS TX Endpoint Stall - Read/Write

Table continues on the next page...

Field	Description
	0 End Point OK [Default] 1 End Point Stalled Software can write a one to this bit to force the endpoint to return a STALL handshake to the Host. It continues returning STALL until the bit is cleared by software or it is automatically cleared upon receipt of a new SETUP request. After receiving a SETUP request, this bit will continue to be cleared by hardware until the associated ENDPTSETUPSTAT bit is cleared. **NOTE:** There is a slight delay (50 clocks max.) between the endptsetupstat being cleared and hardware continuing to clear this bit. In most systems it is unlikely the DCD software will observe this delay. However, should the dcd observe that the stall bit is not set after writing a one to it then follow this procedure: continually write this stall bit until it is set or until a newsetup has been received by checking the associated endptsetupstat bit.
15-8 —	- Reserved
7 RXE	RXE RX Endpoint Enable 1 Enabled Endpoint0 is always enabled.
6-4 —	- Reserved

However, should the dcd observe that the stall bit is not set after writing a one to it then follow this procedure: continually write this stall bit until it is set or until a newsetup has been received by checking the associated endptsetupstat bit.

62.7.1.41 Endpoint Control 1 (ENDPTCTRL1)

This is endpoint control register for endpoint 1 in device operation mode.

NOTE

If one endpoint direction is enabled and the paired endpoint of opposite direction is disabled then the unused direction type must be changed from the default control-type to any other type (that is Bulk-type). leaving an unconfigured endpoint control causes undefined behavior for the data pid tracking on the active endpoint/direction.

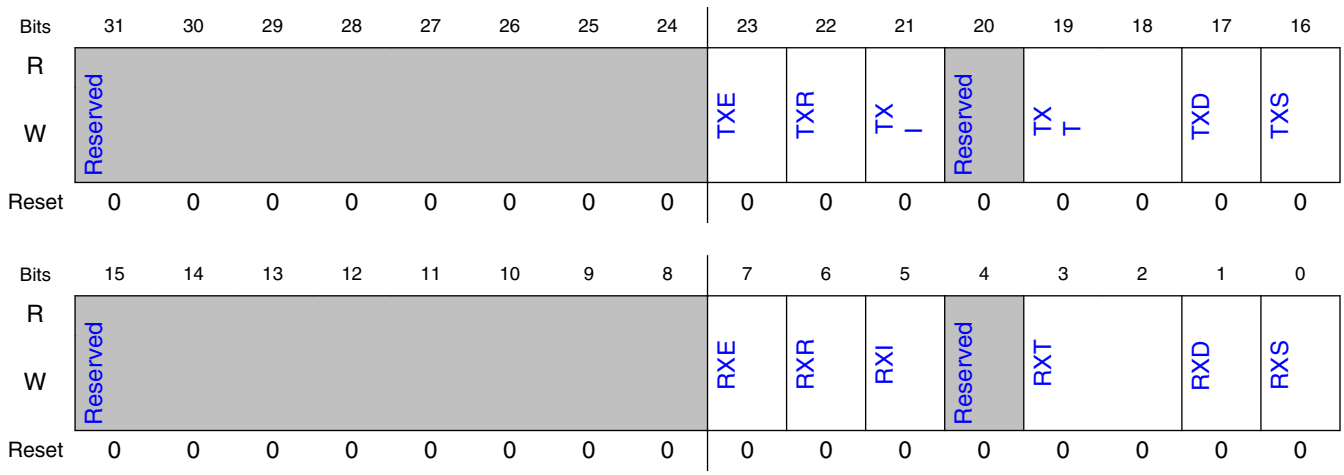
62.7.1.47.2 Diagram



62.7.1.47.3 Fields

Field	Description
31-24 —	- Reserved
23 TXE	TXE TX Endpoint Enable 0 Disabled [Default] 1 Enabled An Endpoint should be enabled only after it has been configured.
22 TXR	TXR TX Data Toggle Reset (WS) Write 1 - Reset PID Sequence Whenever a configuration event is received for this Endpoint, software must write a one to this bit in order to synchronize the data PID's between the Host and device.
21 TXI	TXI TX Data Toggle Inhibit 0 PID Sequencing Enabled. [Default] 1 PID Sequencing Disabled.

Table continues on the next page...

Field	Description
	This bit is only used for test and should always be written as zero. Writing a one to this bit causes this endpoint to ignore the data toggle sequence and always transmit DATA0 for a data packet.
20 —	- Reserved
19-18 TXT	TXT TX Endpoint Type - Read/Write 00 Control 01 Isochronous 10 Bulk 11 Interrupt
17 TXD	TXD TX Endpoint Data Source - Read/Write 0 Dual Port Memory Buffer/DMA Engine [DEFAULT] Should always be written as 0.
16 TXS	TXS TX Endpoint Stall - Read/Write 0 End Point OK 1 End Point Stalled This bit will be cleared automatically upon receipt of a SETUP request if this Endpoint is configured as a Control Endpoint and this bit will continue to be cleared by hardware until the associated ENDPTSETUPSTAT bit is cleared. Software can write a one to this bit to force the endpoint to return a STALL handshake to the Host. This control will continue to STALL until this bit is either cleared by software or automatically cleared as above for control endpoints. **NOTE:** [CONTROL ENDPOINT TYPES ONLY]: there is a slight delay (50 clocks max) between the ENDPTSETUPSTAT begin cleared and hardware continuing to clear this bit. In most systems, it is unlikely the DCD software will observe this delay. However, should the DCD observe that the stall bit is not set after writing a one to it then follow this procedure: continually write this stall bit until it is set or until a new setup has been received by checking the associated endptsetupstat bit.
15-8 —	- Reserved
7 RXE	RXE RX Endpoint Enable 0 Disabled [Default] 1 Enabled An Endpoint should be enabled only after it has been configured.
6 RXR	RXR RX Data Toggle Reset (WS) Write 1 - Reset PID Sequence Whenever a configuration event is received for this Endpoint, software must write a one to this bit in order to synchronize the data PID's between the host and device.
5	RXI

Table continues on the next page...

Field	Description
RXI	RX Data Toggle Inhibit 0 Disabled [Default] 1 Enabled This bit is only used for test and should always be written as zero. Writing a one to this bit causes this endpoint to ignore the data toggle sequence and always accept data packet regardless of their data PID.
4 —	- Reserved.
3-2 RXT	RXT RX Endpoint Type - Read/Write 00 Control 01 Isochronous 10 Bulk 11 Interrupt
1 RXD	RXD RX Endpoint Data Sink - Read/Write 0 Dual Port Memory Buffer/DMA Engine [Default] Should always be written as zero.
0 RXS	RXS RX Endpoint Stall - Read/Write 0 End Point OK. [Default] 1 End Point Stalled This bit is set automatically upon receipt of a SETUP request if this Endpoint is configured as a Control Endpoint and this bit will continue to be cleared by hardware until the associated ENDPTSETUPSTAT bit is cleared. Software can write a one to this bit to force the endpoint to return a STALL handshake to the Host. This control will continue to STALL until this bit is either cleared by software or automatically cleared as above for control endpoints. **NOTE:** [CONTROL ENDPOINT TYPES ONLY]: there is a slight delay (50 clocks max) between the ENDPTSETUPSTAT begin cleared and hardware continuing to clear this bit. In most systems, it is unlikely the DCD software will observe this delay. However, should the DCD observe that the stall bit is not set after writing a one to it then follow this procedure: continually write this stall bit until it is set or until a new setup has been received by checking the associated endptsetupstat bit.

63.2 Overview

The integrated USB 2.0 PHY interfaces to USB host/device systems at the USB low-speed (LS) rate of 1.5 Mbits/s, full-speed (FS) rate of 12 Mbits/s, or at the USB 2.0 high-speed (HS) rate of 480 Mbits/s. The following subsections describe the external interfaces, internal interfaces, major blocks, and programmable registers that comprise the integrated USB 2.0 PHY

63.2.1 Block Diagram

The block diagram of the USB PHY. The integrated PHY provides a standard UTM interface. The DP and DN pins connect directly to a USB connector.

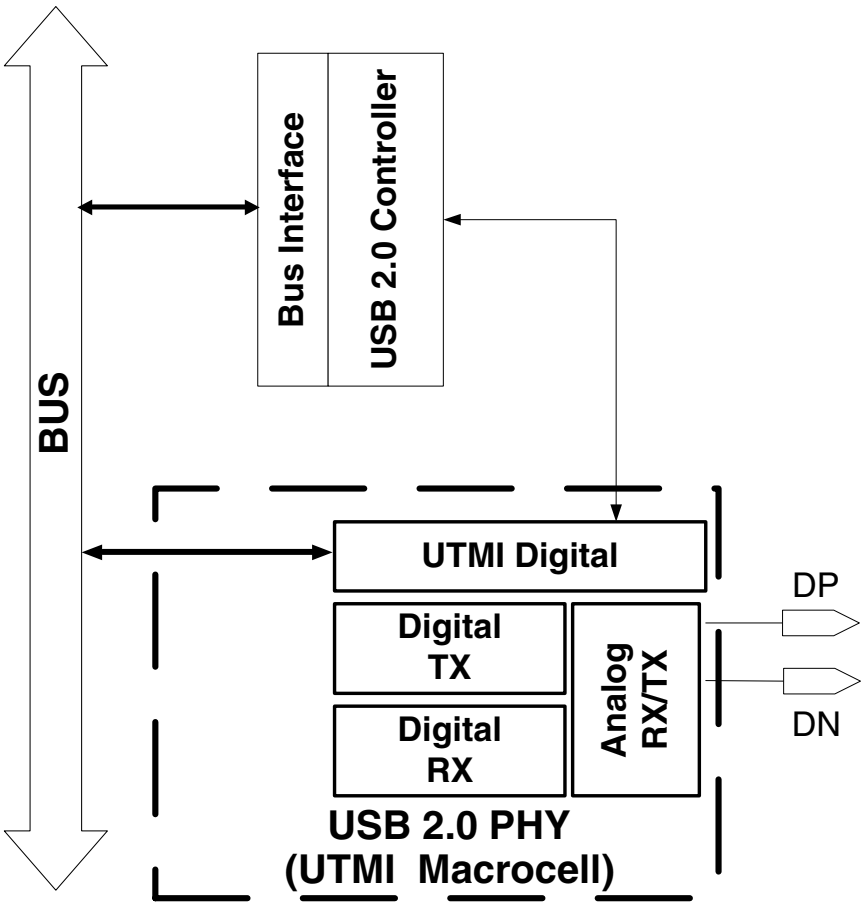

Figure 63-1. USB 2.0 PHY Block Diagram

63.3 Functional Description

This section covers the core components of the USB PHY.

- The digital portions of the USBPHY block include the UTMI, digital transmitter, digital receiver, and the programmable registers.
- The analog transceiver section comprises an analog receiver and an analog transmitter, as shown in Figure 63-2.

63.3.1 UTMI

The UTMI block handles the line_state bits, reset buffering, suspend distribution, transceiver speed selection, transceiver termination selection, and clock generation logic for the clocks derived from the PHY's USB PLL.

The PLL in the USB PHY supplies a 480MHz clock to UTMI digital. The UTMI block will divide the clock to generate the 30MHz clock used in the interface.

63.3.2 Digital Transmitter

The digital transmitter receives the 16-bit transmit data from the USB controller and handles the tx_valid, tx_validh and tx_ready handshake. In addition, it contains the transmit serializer that converts the 16-bit parallel words at 30 MHz to a single bitstream at 480 Mbit for high-speed or 12 Mbit for full-speed or 1.5 Mbit for low-speed. It does this while implementing the bit-stuffing algorithm and the NRZI encoder that are used to remove the DC component from the serial bitstream. The output of this encoder is sent to the low-speed (LS), full-speed (FS) or high-speed (HS) drivers in the analog transceiver section's transmitter block.

63.3.3 Digital Receiver

The digital receiver receives the raw serial bitstream from the low speed (LS) differential transceiver, full speed (FS) differential transceiver, and 480 MHz sampled data from the high speed (HS) differential transceiver. As the phase of the USB host transmitter shifts relative to the local PLL, the receiver section's HS DLL tracks these changes to give a reliable sample of the incoming 480 Mbit/s bitstream. Since this sample point shifts relative to the PLL phase used by the digital logic, a rate-matching elastic buffer is provided to cross this clock domain boundary.

Once the bitstream is in the local clock domain, an NRZI decoder and bit unstuffer restore the original payload data bitstream and pass it to a deserializer and holding register. The receive state machine handles the rx_valid, rx_validh, and handshake with the USB controller. The handshake is not interlocked, in that there is no rx_ready signal coming from the controller. The controller must take each 16-bit value as presented by the PHY. The receive state machine provides an rx_active signal to the controller that indicates when it is inside a valid packet (SYNC detected, and so on).

63.3.4 Analog Receiver

The analog receiver is comprised of five differential receivers, two single-ended receivers, a 9X, and a 480 MHz HS data sampling module that are illustrated in the figure below and described further in this section.

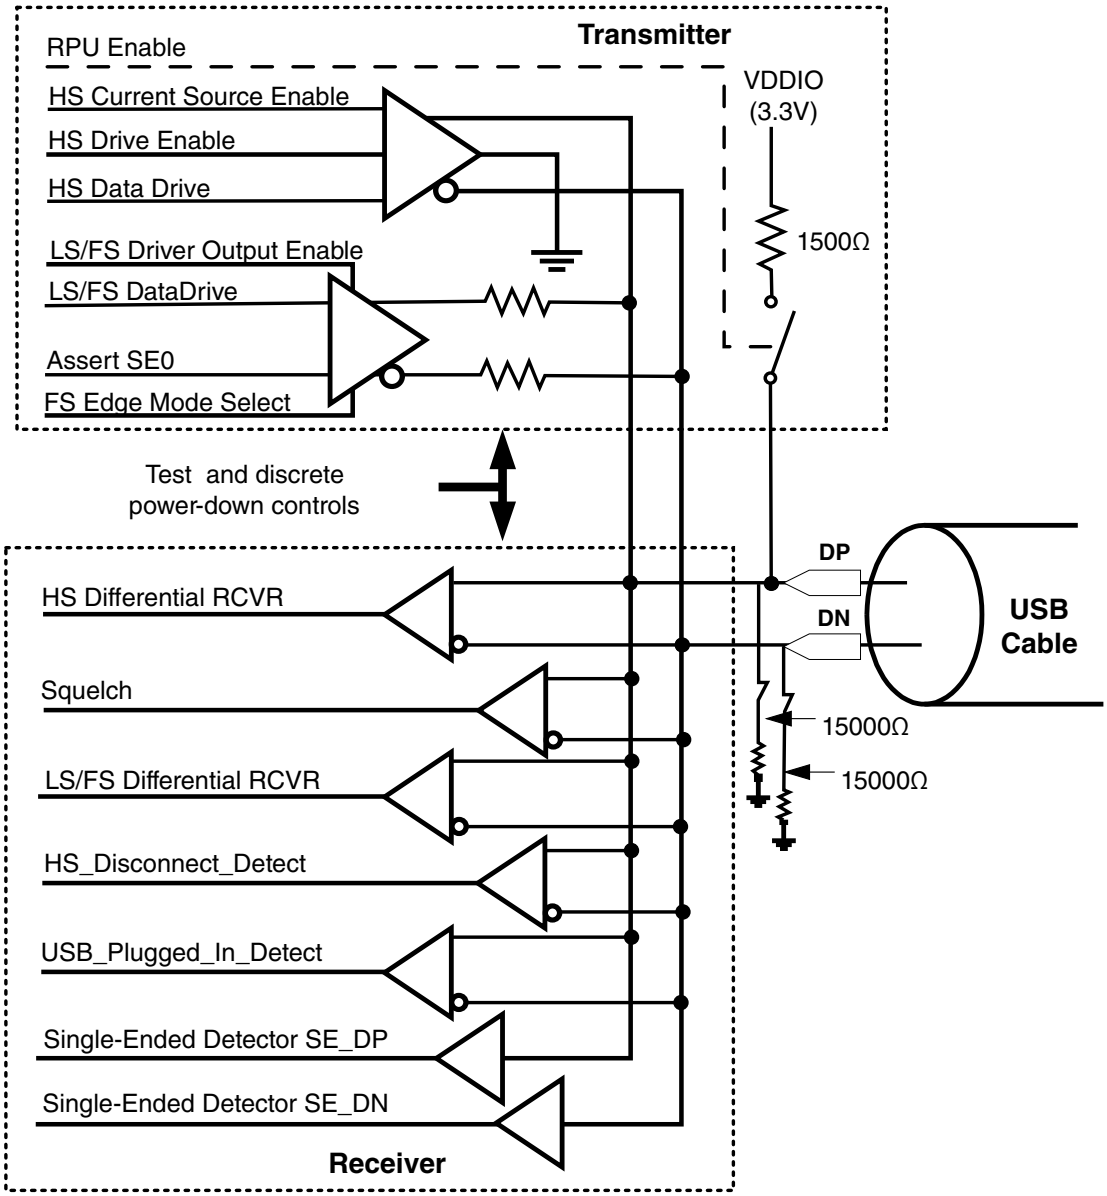

Figure 63-2. USB 2.0 PHY Analog Transceiver Block Diagram

63.3.4.1 HS Differential Receiver

The high-speed differential receiver is both a differential analog receiver and threshold comparator. Its output is high (1'b1) if the differential signal is greater than a 0-V threshold. Otherwise, its output is low (1'b0). Its purpose is to discriminate the ± 400-mV differential voltage resulting from the high-speed drivers current flow into the dual 45Ω terminations found on each pin of the differential pair. The envelope or squelch detector, described below, ensures that the differential signal has sufficient magnitude to be valid. The HS differential receiver tolerates up to 500 mV of common mode offset.

63.3.4.2 Squelch Detector

The squelch detector is a differential analog receiver and threshold comparator. Its output is high (1'b1) if the differential magnitude is less than a nominal 100 mV threshold. Otherwise, its output is low (1'b0). Its purpose is to invalidate the HS differential receiver when the incoming signal is too low to receive reliably.

63.3.4.3 LS/FS Differential Receiver

The low-speed/full-speed differential receiver is both a differential analog receiver and threshold comparator. The crossover voltage falls between 1.3 V and 2.0 V. Its output is 1, when the DP line is above the crossover point and the DN line is below the crossover point. The digital receiver section decodes the receiver data into J or K state according to the speed.

63.3.4.4 HS Disconnect Detector

It is a differential analog receiver and threshold comparator. It outputs high when differential magnitude is greater than a nominal 575-mV threshold. Otherwise, it outputs low.

63.3.4.5 USB Plugged-In Detector

When operating in device mode, USB PHY provides the following methods for the local USB device to detect the attachment of a cable to a remote USB host or hub. Only one method should be enabled at a time when waiting to identify the cable attachment event, and all of methods must be disabled during USB data communication.

- USB plugged-in detector method looks for both DP and DN to be high. There is a pair of large on-chip pullup resistors (200 KΩ) that hold both DP and DN high when the USB cable is not attached. The USB plugged-in detector signals a 0 in this case.When operating in device mode, the upstream port in host/hub interface contains a 15 KΩ pulldown resistor which could easily override the 200 KΩ pullup resistor. When plugged in, at least one signal in the pair will be low, which will force the plugged-in detector's output high. The USB plugged-in detector is controlled through the CTRL[ENDEVPLUGINDET] bit field and results are observable through the STATUS[DEVPLUGIN_STATUS] bit field.

- The Data Contact Detect method functions per the *USB Battery Charging Specification, Revision 1.2*. The use of this method is described in the USB Device Charger Detection (USBDCD) Chapter.
- Resistive detection method described in the *USB Battery Charging Specification, Revision 1.0*. This method enables a 125 KΩ pullup resistor on the DP pin and a 375 KΩ pulldown resistor on the DN pin. When no cable is plugged in, the DP pin will be high and the DN pin will be low. If the local device has a cable attached to a remote host or hub, due to the host 15 KΩ pulldowns both the DP and DN pins will be low. If the local device has a cable attached to a dedicated charger with no pullup/ pulldown resistors, both the DP and DN pins will be high. This method is enabled through the VBUS_DETECT[EN_CHARGER_RESISTOR] bit field. Results can be observed using the single ended receiver status in the CHRG_DET_STAT[DP_STATE, DM_STATE] bit fields.

63.3.4.6 Single-Ended DP Receiver

The single-ended DP receiver output is high whenever the DP input is above its nominal 1.8 V threshold.

63.3.4.7 Single-Ended DN Receiver

The single-ended DN receiver output is high whenever the DN input is above its nominal 1.8 V threshold.

63.3.5 Analog Transmitter

The analog transmitter comprises two differential drivers: one for high-speed signaling and one for full-speed signaling. It also contains the switchable 1.5 KΩ pullup resistor. See Figure 63-3.

63.3.5.1 Switchable High-Speed 45Ω Termination Resistors

High-speed current mode differential signaling requires good 90Ω differential termination at each end of the USB cable. This results from switching in 45Ω terminating resistors from each signal line to ground at each end of the cable.

Because each signal is parallel terminated with 45Ω at each end, each driver sees a 22.5Ω load. This load impedance is much too low for full-speed signaling levels, hence the need for switchable high-speed terminating resistors. Switchable trimming resistors are provided to tune the actual termination resistance of each device, as shown in USB 2.0 PHY Transmitter Block Diagram. The TX[TXCAL45DP] bit field, for example, allows one of 16 trimming resistor values to be placed in parallel with the 45Ω terminator on the DP signal.

63.3.5.2 Low-Speed/Full-Speed Differential Driver

The low-speed/full-speed differential drivers are essentially a pair of low-impedance pullup/pulldown devices that are switched in a differential mode for most low-speed or full-speed signaling. One output is driven high while the other output is driven low to signal the "J" state or the "K" state. Both outputs are driven low for the low-speed/full-speed "SE0" state.

63.3.5.3 High-Speed Differential Driver

The high-speed differential driver receives a 17.78 mA current from the constant current source (Iref) and essentially steers it down either the DP signal or the DN signal or alternatively to ground. This current will produce approximately a 400 mV drop across the 22.5 Ω termination seen by the driver when it is steered onto one of the signal lines. The approximately 17.78 mA current source is referenced back to the integrated voltage-band-gap (Vbg) circuit.

63.3.5.4 Switchable 1.5KΩ DP Pullup Resistor

This product contains a switchable 1.5 KΩ pullup resistor on the DP signal. This resistor is switched on to indicate to the host/hub controller that a full-speed-capable device is on the USB cable, powered on, and ready. This resistor is switched off at power-on reset so the host does not recognize a USB device until the processor software enables the announcement of a full-speed device.

63.3.5.5 Switchable 15KΩ DP and DN Pulldown Resistors

The chip contains switchable 15 KΩ pulldown resistors on both DP and DN signals. They are enabled in host mode to indicate to the device controller that a host is present.

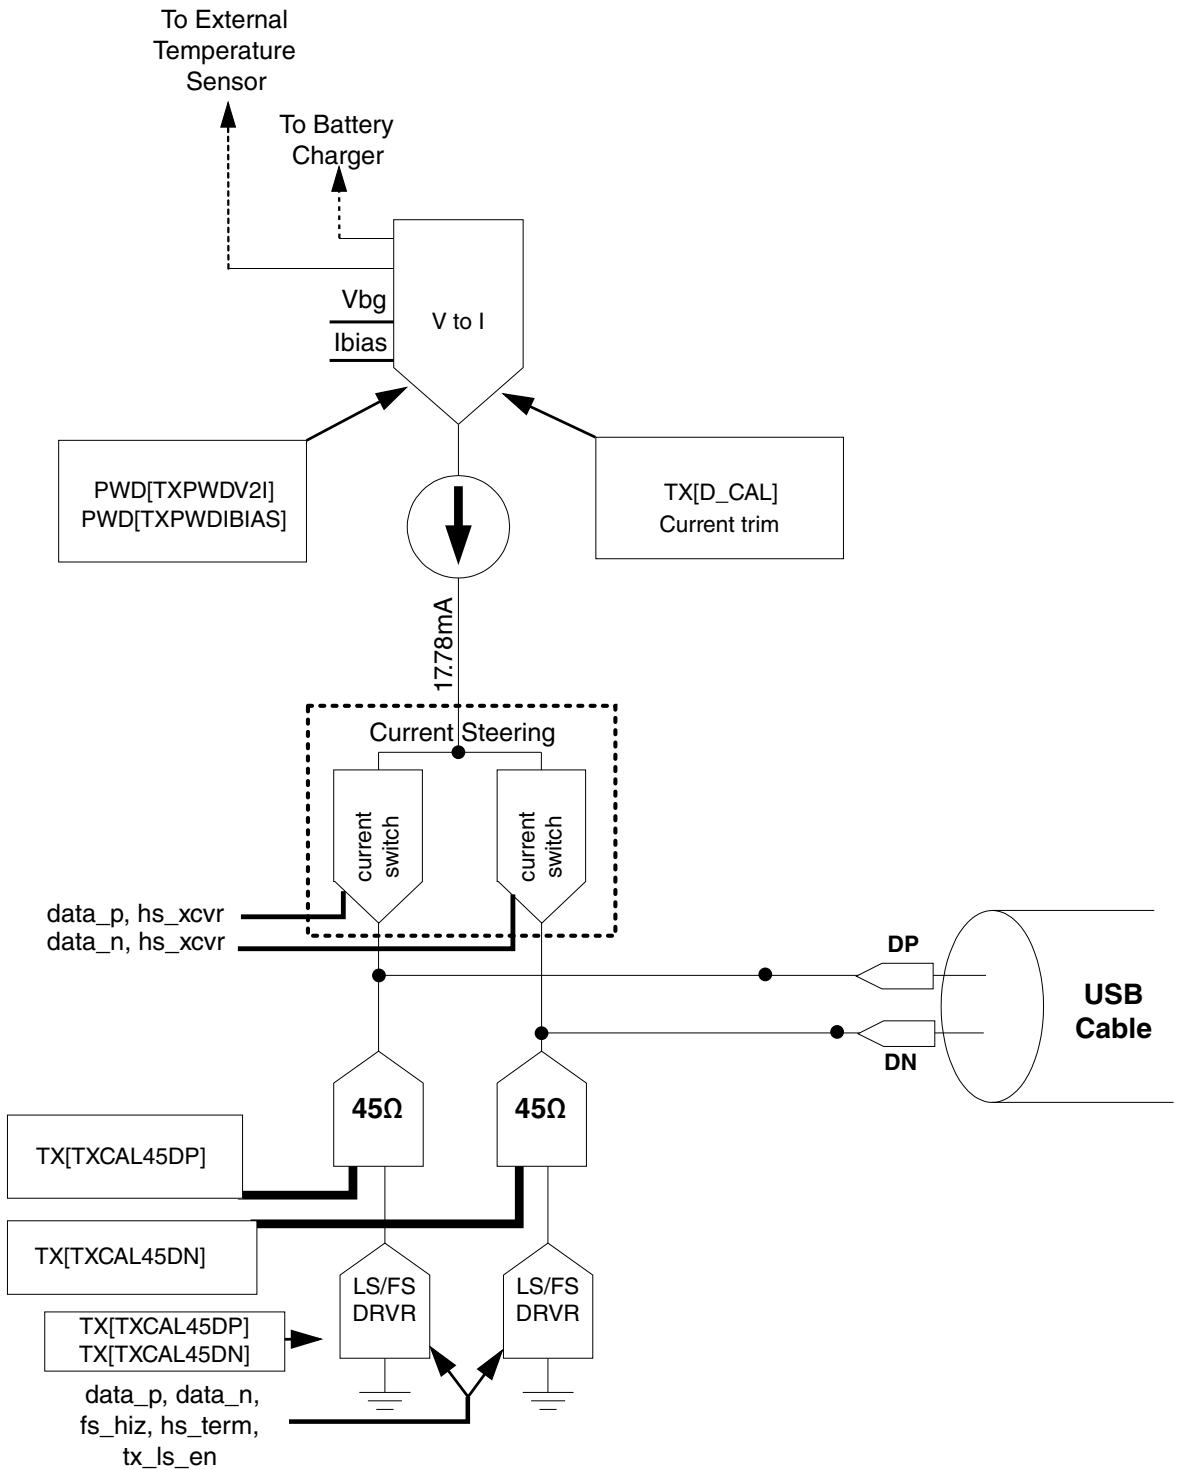

Figure 63-3. USB 2.0 PHY Transmitter Block Diagram

63.3.6 Clocks

The following table describes the clock sources for the USB PHY module. Please see Clock Controller Module (CCM) for clock setting, configuration and gating information.

Table 63-2. USB PHY Clocks

Clock name	Description
ipg_clk	Peripheral clock
ipg_clk_s	Peripheral access clock

63.4 External Signals

There are no external signals pinned out for the USB PHY.

63.5 Initialization and Application Information

In order to bring up the internal 480MHz USB PLL clock, several conditions should be met, as noted below:

1. The reference clock for USB PLL must be enabled.
2. Enable the USB PHY PLL Regulator
3. Release the PHY from Reset
4. Power up the PLL
5. The system oscillator ranges from 16 MHz to 32 MHz. PLL_SIC[PLL_DIV_SEL] should be programmed properly as per the external reference selected.

63.6 Recommended Register Configuration for USB Certification

The USB HS PHY has programmability to adjust several transceiver parameters.

- The TX HS driver termination impedance, FS driver output impedance, and HS driver output currents can be adjusted through bit fields of the TX Register.
  - The ability to override the default parametric trim bit fields using the TX Register has to be enabled by setting bit fields in the TRIM_OVERRIDE_EN Register.

- The TX HS driver pre-emphasis feature can be enabled and configured through bitfields of the ANACTRL Register.
- The HS RX thresholds for the Envelope Detector/Squelch comparator and the Host Disconnect comparator can be adjusted through bit fields of the RX Register.

The default values of the bit fields for the transceiver parametric trims are centered with no changes needed for USB Certification testing when the chip is used with boards optimized for signal integrity on the HS USB Port.

In cases where external components are inserted between the USB DP/DN pins, or compromises are made on USB DP/DN signal routing, changes to the parametric trim bit fields may be useful.

Depending on the board layout, to pass the certification, trim the register repeatedly until the eye diagram meets the requirements of the template.

63.7 Register Macro Usage

A common operation is to update one field without disturbing the contents of the remaining fields in the register. Normally, this requires a read-modify-write (RMW) operation, where the CPU reads the register, modifies the target field, then writes the results back to the register. This is an expensive operation in terms of CPU cycles, because of the initial register read.

To address this issue, some hardware registers are implemented as a group, including registers that can be used to either set, clear, or toggle (SCT) individual bits of the primary register. When writing to an SCT register, all bits set to 1 perform the associated operation on the primary register, while all bits set to 0 are not affected. The SCT registers always read back 0, and should be considered write-only. The SCT registers are not implemented if the primary register is read-only.

With this architecture, it is possible to update one or more fields using only register writes. First, all bits of the target fields are cleared by a write to the associated clear register, then the desired value of the target fields is written to the set register. This sequence of two writes is referred to as a clear-set (CS) operation.

A CS operation does have one potential drawback. Whenever a field is modified, the hardware sees a value of 0 before the final value is written. For most fields, passing through the 0 state is not a problem. Nonetheless, this behavior is something to consider when using a CS operation.

Also, a CS operation is not required for fields that are one bit wide. While the CS operation works in this case, it is more efficient to simply set or clear the target bit (that is, one write instead of two). A simple set or clear operation is also atomic, while a CS operation is not.

Note that not all macros for set, clear, or toggle (SCT) are atomic. For registers that do not provide hardware support for this functionality, these macros are implemented as a sequence of read/modify/write operations. When atomic operation is required, the developer should pay attention to this detail, because unexpected behavior might result if an interrupt occurs in the middle of the critical section comprising the update sequence.

63.8 USB PHY Memory Map/Register Definition

The USB PHY Memory Map/Register Definition can be found here.

63.8.1 USBPHY register descriptions

USBPHY Hardware Register Format Summary

Information for using the Set, Clear, Toggle register features is located in the **Register Macro Usage** section.

63.8.1.2 USB PHY Power-Down Register (PWD)

The USB PHY Power-Down Register provides overall control of the PHY power state. Before programming this register, the PHY clocks must be enabled.

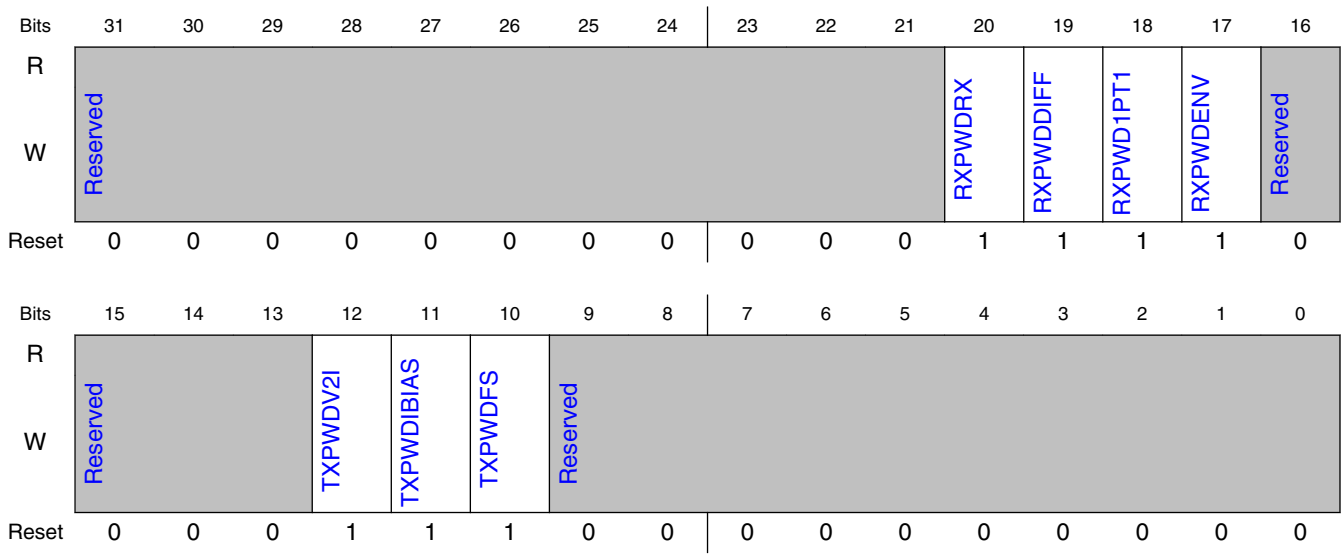
63.8.1.2.1 Offset

Register	Offset	Description
PWD	0h	USB PHY Power-Down Register
PWD_SET	4h	Writing a 1 to a bit in this register sets the corresponding bit in PWD
PWD_CLR	8h	Writing a 1 to a bit in this register clears the corresponding bit in PWD

Table continues on the next page...

Register	Offset	Description
PWD_TOG	Ch	Writing a 1 to a bit in this register toggles the corresponding bit in PWD

63.8.1.2.2 Diagram



63.8.1.2.3 Fields

Field	Description
31-21 —	- Reserved.
20 RXPWDRX	RXPWDRX **NOTE:** This bit will be auto cleared if there is USB wakeup event while ENAUTOCLR_PHY_PWD bit of CTRL is enabled. 0 - Normal operation 1 - Power-down the entire USB PHY receiver block except for the full-speed differential receiver
19 RXPWDDIFF	RXPWDDIFF **NOTE:** This bit will be auto cleared if there is USB wakeup event while ENAUTOCLR_PHY_PWD bit of CTRL is enabled. 0 - Normal operation. 1 - Power-down the USB high-speed differential receiver
18 RXPWD1PT1	RXPWD1PT1 **NOTE:** This bit will be auto cleared if there is USB wakeup event while ENAUTOCLR_PHY_PWD bit of CTRL is enabled. 0 - Normal operation

Table continues on the next page...

Field	Description
	1 - Power-down the USB full-speed differential receiver.
17 RXPWDENV	RXPWDENV **NOTE:** This bit will be auto cleared if there is USB wakeup event while ENAUTOCLR_PHY_PWD bit of CTRL is enabled. 0 - Normal operation. 1 - Power-down the USB high-speed receiver envelope detector (squelch signal)
16-13 —	- Reserved.
12 TXPWDV2I	TXPWDV2I **NOTE:** This bit will be auto cleared if there is USB wakeup event while ENAUTOCLR_PHY_PWD bit of CTRL is enabled. **NOTE:** These circuits are shared with the battery charge circuit. Setting this to 1 does not power-down these circuits, unless the corresponding bit in the battery charger is also set for power-down. 0 - Normal operation. 1 - Power-down the USB PHY transmit V-to-I converter and the current mirror
11 TXPWDIBIAS	TXPWDIBIAS **NOTE:** This bit will be auto cleared if there is USB wakeup event while ENAUTOCLR_PHY_PWD bit of CTRL is enabled. **NOTE:** These circuits are shared with the battery charge circuit. Setting this bit to 1 does not power-down these circuits, unless the corresponding bit in the battery charger is also set for power-down. 0 - Normal operation 1 - Power-down the USB PHY current bias block for the transmitter. This bit should be set only when the USB is in suspend mode. This effectively powers down the entire USB transmit path
10 TXPWDFS	TXPWDFS **NOTE:** This bit will be auto cleared if there is USB wakeup event while ENAUTOCLR_PHY_PWD bit of CTRL is enabled. 0 - Normal operation. 1 - Power-down the USB full-speed drivers. This turns off the current starvation sources and puts the drivers into high-impedance output
9-0 —	- Reserved.

63.8.1.3 USB PHY Transmitter Control Register (TX)

The USB PHY Transmitter Control Register allows adjustment of transmit parametric values.

63.8.1.3.1 Offset

Register	Offset	Description
TX	10h	USB PHY Transmitter Control Register
TX_SET	14h	Writing a 1 to a bit in this register sets the corresponding bit in TX
TX_CLR	18h	Writing a 1 to a bit in this register clears the corresponding bit in TX
TX_TOG	1Ch	Writing a 1 to a bit in this register toggles the corresponding bit in TX

13 —	- Reserved. This bit field must remain at value 1'b0.
12 —	- Reserved.
11-8 TXCAL45DN	TXCAL45DN Decode to trim the nominal 45Ω series termination resistance to the DN output pin. Maximum resistance = 0000. Resistance is centered by design at 0110.
7-4 —	- Reserved. **Note:** This bit should remain clear.
3-0 D_CAL	D_CAL Decode to trim the nominal 17.78mA current source for the High Speed TX drivers on DP and DN. This current is directly proportional to the amplitude of the High Speed TX eye diagram. 0000 - Maximum current, approximately 19% above nominal. 0111 - Nominal 1111 - Minimum current, approximately 19% below nominal.

63.8.1.4 USB PHY Receiver Control Register (RX)

The USB PHY Receiver Control Register allows adjustment of receive parametric values.

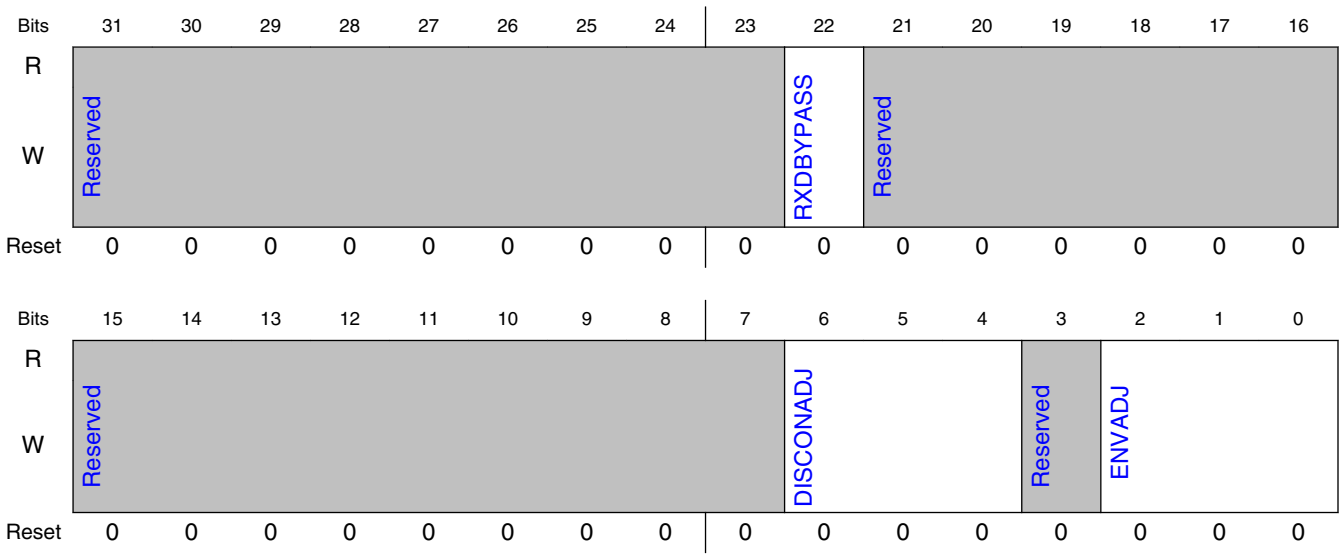
63.8.1.4.1 Offset

Register	Offset	Description
RX	20h	USB PHY Receiver Control Register
RX_SET	24h	Writing a 1 to a bit in this register sets the corresponding bit in RX
RX_CLR	28h	Writing a 1 to a bit in this register clears the corresponding bit in RX

Table continues on the next page...

Register	Offset	Description
RX_TOG	2Ch	Writing a 1 to a bit in this register toggles the corresponding bit in RX

63.8.1.4.2 Diagram



63.8.1.4.3 Fields

Field	Description
31-23 —	- Reserved.
22 RXDBYPASS	RXDBYPASS This test mode is intended for lab use only, replace FS differential receiver with DP single ended receiver. 0 - Normal operation. 1 - Use the output of the USB_DP single-ended receiver in place of the full-speed differential receiver
21-7 —	- Reserved.
6-4 DISCONADJ	DISCONADJ The DISCONADJ field adjusts the trip point for the disconnect detector. 000 - Trip-Level Voltage is 0.56875 V 001 - Trip-Level Voltage is 0.55000 V 010 - Trip-Level Voltage is 0.58125 V 011 - Trip-Level Voltage is 0.60000 V 1xx - Reserved

Table continues on the next page...

Field	Description
3 —	- Reserved.
2-0 ENVADJ	ENVADJ The ENVADJ field adjusts the trip point for the envelope detector. Values shown below are nominal DC settings to indicate effect of changing these bits. AC values measured during compliance testing will be somewhat higher. 000 - Trip-Level Voltage is 0.1000 V 001 - Trip-Level Voltage is 0.1125 V 010 - Trip-Level Voltage is 0.1250 V 011 - Trip-Level Voltage is 0.0875 V 1xx - Reserved

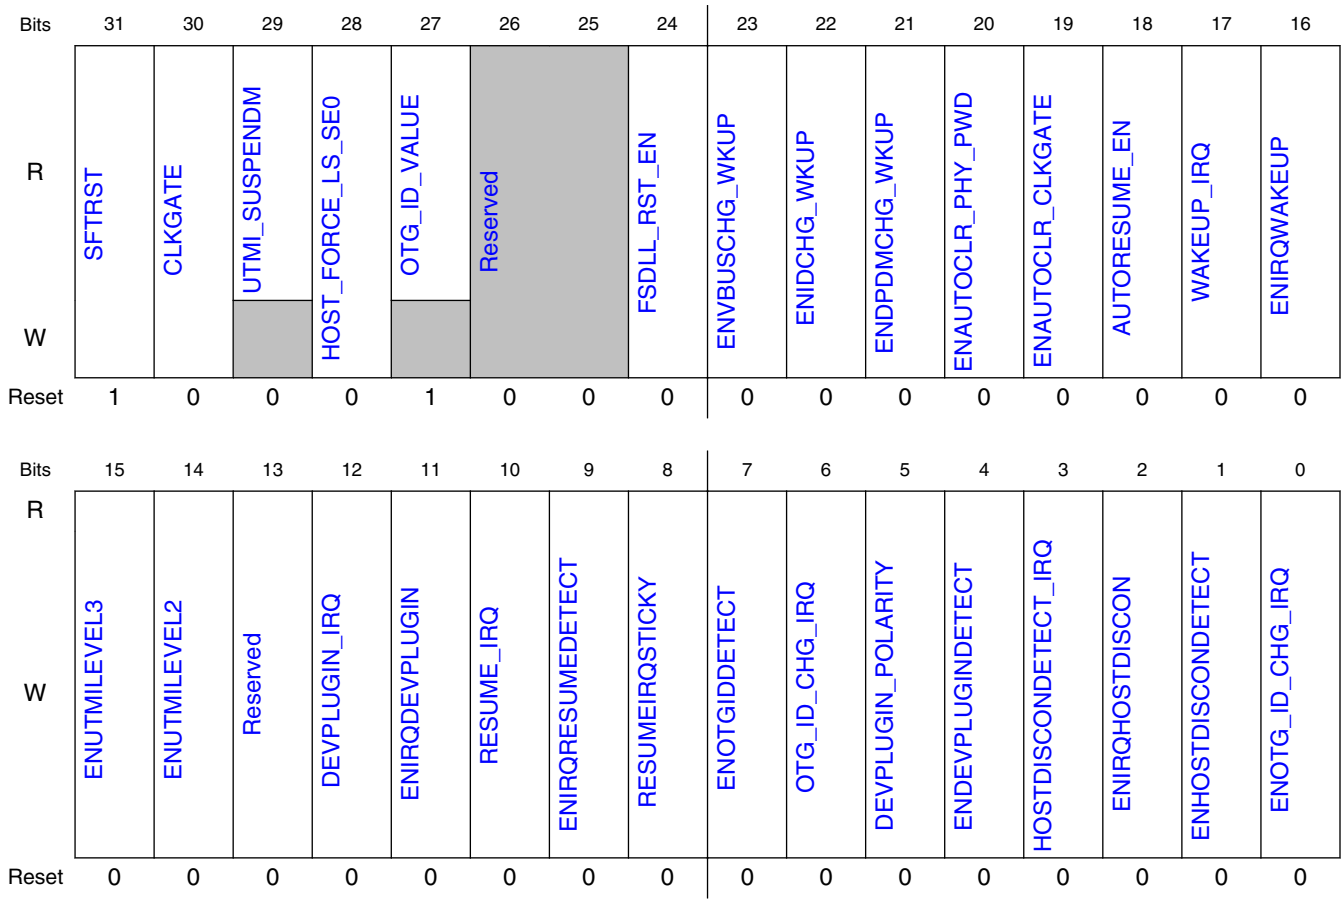
63.8.1.5 USB PHY General Control Register (CTRL)

The USB PHY General Control Register handles OTG and Host controls. This register also includes interrupt enables and connectivity detect enables and results.

63.8.1.5.1 Offset

Register	Offset	Description
CTRL	30h	USB PHY General Control Register
CTRL_SET	34h	Writing a 1 to a bit in this register sets the corresponding bit in CTRL
CTRL_CLR	38h	Writing a 1 to a bit in this register clears the corresponding bit in CTRL
CTRL_TOG	3Ch	Writing a 1 to a bit in this register toggles the corresponding bit in CTRL

63.8.1.5.2 Diagram



63.8.1.5.3 Fields

Field	Description
31 SFTRST	SFTRST Writing a 1 to this bit will soft-reset the PWD, TX, RX, and CTRL Registers. Set to 0 to release the PHY from reset.
30 CLKGATE	CLKGATE Gate UTMI Clocks. Clear to 0 to run clocks. Set to 1 to gate clocks. Set this to save power while the USB is not actively being used. Configuration state is kept while the clock is gated. **NOTE:** This bit can be auto-cleared if there is any wakeup event when USB is suspended while CTRL[ENAUTOCLR_CLKGATE] bit is enabled.
29 UTMI_SUSPENDM	UTMI_SUSPENDM Used by the PHY to indicate a powered-down state. If all the power-down bits in the PWD are enabled, UTMI_SUSPENDM will be 0, otherwise 1 when USB controller entering into Suspend mode. UTMI_SUSPENDM is negative logic, as required by the UTMI specification.
28 HOST_FORCE_LS_SE0	HOST_FORCE_LS_SE0

Table continues on the next page...

Field	Description
	Forces the next FS packet that is transmitted to have a EOP with low-speed timing. This bit is used in host mode for the resume sequence. After the packet is transferred, this bit is cleared. The design can use this function to force the LS SE0 or use the CTRL_UTMI_SUSPENDM to trigger this event when leaving suspend. This bit is used in conjunction with DEBUG_HOST_RESUME_DEBUG.
27 OTG_ID_VALUE	OTG_ID_VALUE Indicates the results of USB_ID pin while monitoring the cable plugged into the Micro- or Mini-AB receptacle. False (0) is when ID resistance is less than Ra_Plug_ID, indicating host (A) side. True (1) is when ID resistance is greater than Rb_Plug_ID, indicating device (B) side. Similar to the function of the OTGID_STATUS bit in the STATUS Register, but OTG_ID_VALUE has debounce and system clock synchronization logic to filter the glitches on the USB ID pad.
26-25 —	- Reserved.
24 FSDLL_RST_EN	FSDLL_RST_EN Enables the feature to reset the FSDLL lock detection logic at the end of each TX packet.
23 ENVBUSCHG_WKUP	ENVBUSCHG_WKUP Enables the feature to wakeup USB if VBUS is toggled when USB is suspended.
22 ENIDCHG_WKUP	ENIDCHG_WKUP Enables the feature to wakeup USB if ID is toggled when USB is suspended.
21 ENDPDMCHG_WKUP	ENDPDMCHG_WKUP Enables the feature to wakeup USB if DP/DN is toggled when USB is suspended.
20 ENAUTOCLR_PHY_PWD	ENAUTOCLR_PHY_PWD Enables the feature to auto-clear the PWD register bits in PWD if there is wakeup event while USB is suspended. This should be enabled if needed to support auto wakeup without software interaction.
19 ENAUTOCLR_CLKGATE	ENAUTOCLR_CLKGATE Enables the feature to auto-clear the CLKGATE bit if there is wakeup event while USB is suspended. This should be enabled if needed to support auto wakeup without software interaction.
18 AUTORESUME_EN	AUTORESUME_EN Enable the auto resume feature, when set, HW will use 32KHz clock to send Resume to respond to the device remote wakeup(for host mode only). It's useful when PLL is off and reference clock is also powered down.
17 WAKEUP_IRQ	WAKEUP_IRQ Indicates that there is a wakeup event. Reset this bit by writing a 1 to the clear address space and not by a general write.
16 ENIRQWAKEUP	ENIRQWAKEUP Enables interrupt for the wakeup events.
15 ENUTMILEVEL3	ENUTMILEVEL3 Enables UTMI+ Level 3 operation for the USB HS PHY. This should be enabled if an Embedded Host use case needs to support an external FS Hub with a LS device connected.
14	ENUTMILEVEL2

Table continues on the next page...

Field	Description
ENUTMILEVEL2	Enables UTMI+ Level 2 operation for the USB HS PHY. This should be enabled if an Embedded Host use case needs to support a LS device.
13 — 	- Reserved This bit field must remain at value 1'b0.
12 DEVPLUGIN_IRQ	DEVPLUGIN_IRQ Indicates that the device is connected. Reset this bit by writing a 1 to the SCT clear address space and not by a general write.
11 ENIRQDEVPLUGIN	ENIRQDEVPLUGIN Enables interrupt for the detection of connectivity to the USB line.
10 RESUME_IRQ	RESUME_IRQ Indicates that the host is sending a wake-up after suspend. This bit is also set on a reset during suspend. Use this bit to wake up from suspend for either the resume or the reset case. Reset this bit by writing a 1 to the clear address space and not by a general write.
9 ENIRQRESUMEDETECT	ENIRQRESUMEDETECT Enables interrupt for detection of a non-J state on the USB line. This should only be enabled after the device has entered suspend mode.
8 RESUMEIRQSTICKY	RESUMEIRQSTICKY Set to 1 will make RESUME_IRQ bit a sticky bit until software clear it. Set to 0, RESUME_IRQ only set during the wake-up period.
7 ENOTGIDDETECT	ENOTGIDDETECT Enables circuit to detect resistance of MiniAB ID pin.
6 OTG_ID_CHG_IRQ	OTG_ID_CHG_IRQ OTG ID change interrupt. Indicates the value of ID pin changed.
5 DEVPLUGIN_POLARITY	DEVPLUGIN_POLARITY For device mode, if this bit is cleared to 0, then it trips the interrupt if the device is plugged in. If set to 1, then it trips the interrupt if the device is unplugged.
4 ENDEVPLUGINDETECT	Enables non-standard resistive plugged-in detection This bit field controls connection of nominal 200kΩ resistors to both the DP and DN pins as one method of detecting when a USB cable is attached in device mode. This bit field must remain at a value of 1'b0 for normal USB data communication, or when using the USBHSDCD module for battery charger detection per the *USB Battery Charger Specification Revision 1.2* or any other detection mechanism for USB cable plugin. The results of this detection method are reported in STATUS[DEVPLUGIN_STATUS]. 0 - Disables 200kΩ pullup resistors on DP and DN pins 1 - Enables 200kΩ pullup resistors on DP and DN pins
3 HOSTDISCONDETECT_IRQ	HOSTDISCONDETECT_IRQ Indicates that the device has disconnected in High-Speed mode. Reset this bit by writing a 1 to the SCT clear address space and not by a general write.
2	ENIRQHOSTDISCON

Table continues on the next page...

Field	Description
ENIRQHOSTDISCON	Enables interrupt for detection of disconnection to Device when in high-speed host mode. This should be enabled after ENDEVPLUGINDETECT is enabled.
1 ENHOSTDISCONDETECT	ENHOSTDISCONDETECT For host mode, enables high-speed disconnect detector. This signal allows the override of enabling the detection that is normally done in the UTMI controller. The UTMI controller enables this circuit whenever the host sends a start-of-frame packet. Software shall set this bit when a high-speed device is connected, which is suggested during bus reset. Software shall ensure this bit is not set at the end of Resume, otherwise a wrong disconnect status may be detected.
0 ENOTG_ID_CHG_IRQ	ENOTG_ID_CHG_IRQ Enables the interrupt for ID change.

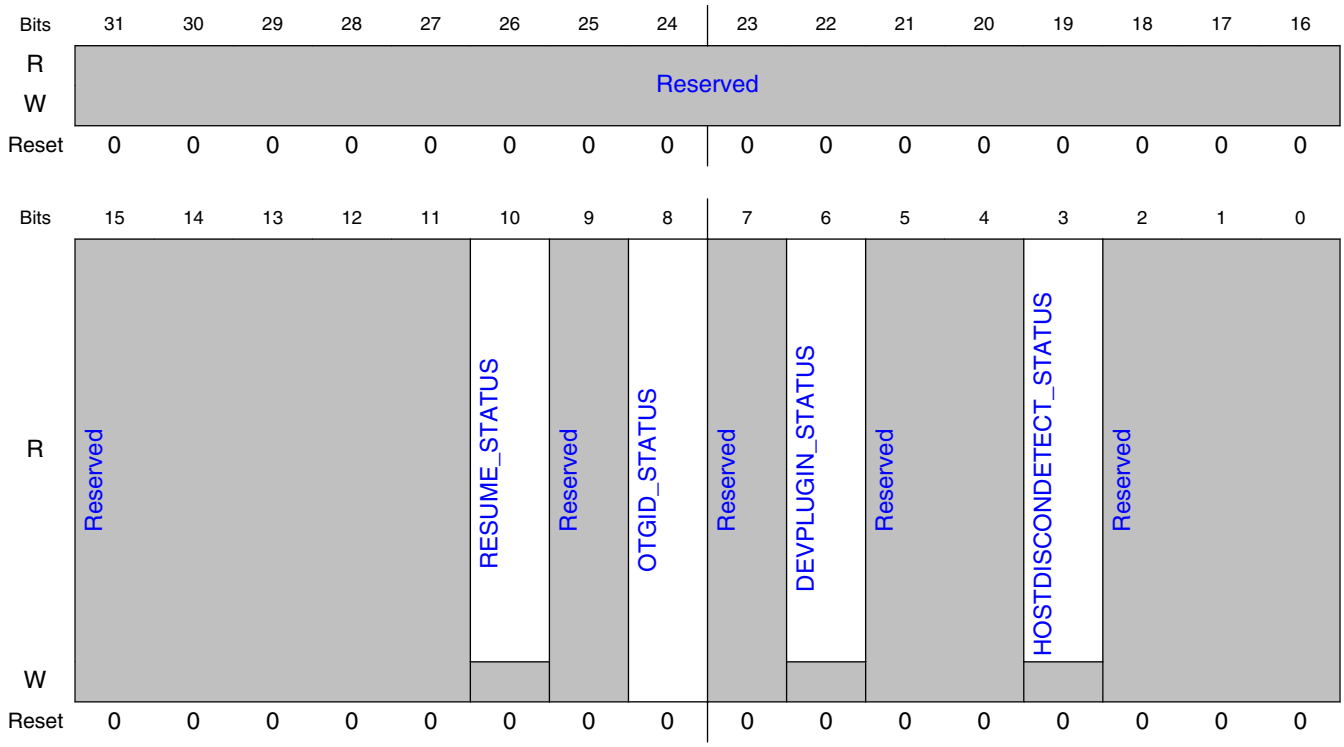
63.8.1.6 USB PHY Status Register (STATUS)

The USB PHY Status Register holds results of IRQ and other detects.

63.8.1.6.1 Offset

Register	Offset
STATUS	40h

63.8.1.6.2 Diagram



63.8.1.6.3 Fields

Field	Description
31-11 —	- Reserved.
10 RESUME_STATUS	RESUME_STATUS Indicates that the host is sending a wake-up after Suspend and has triggered an interrupt.
9 —	- Reserved.
8 OTGID_STATUS	OTGID_STATUS Indicates the results of USB_ID pin on the USB cable plugged into the local Micro- or Mini-AB receptacle. False (0) is when ID resistance to ground is less than Ra_Plug_ID, indicating host (A) side. True (1) is when ID resistance is greater than Rb_Plug_ID, indicating device (B) side.
7 —	- Reserved.
6 DEVPLUGIN_STATUS	Status indicator for non-standard resistive plugged-in detection Indicates that the device has been connected on the DP and DN lines using the non-standard resistive plugged-in detection method controlled by CTRL[ENDEVPLUGINDETECT].

Table continues on the next page...

Field	Description
	When a USB cable attached to a remote host is attached to the local device, the 15kΩ host pulldowns will override the high value resistors used in this detection method. 0 - No attachment to a USB host is detected 1 - Cable attachment to a USB host is detected
5-4 —	- Reserved.
3 HOSTDISCONDETECT_STATUS	HOSTDISCONDETECT_STATUS Indicates at the local host (downstream) port that the remote device has disconnected while in High-Speed mode. 0 - USB cable disconnect has not been detected at the local host 1 - USB cable disconnect has been detected at the local host
2-0 —	- Reserved.

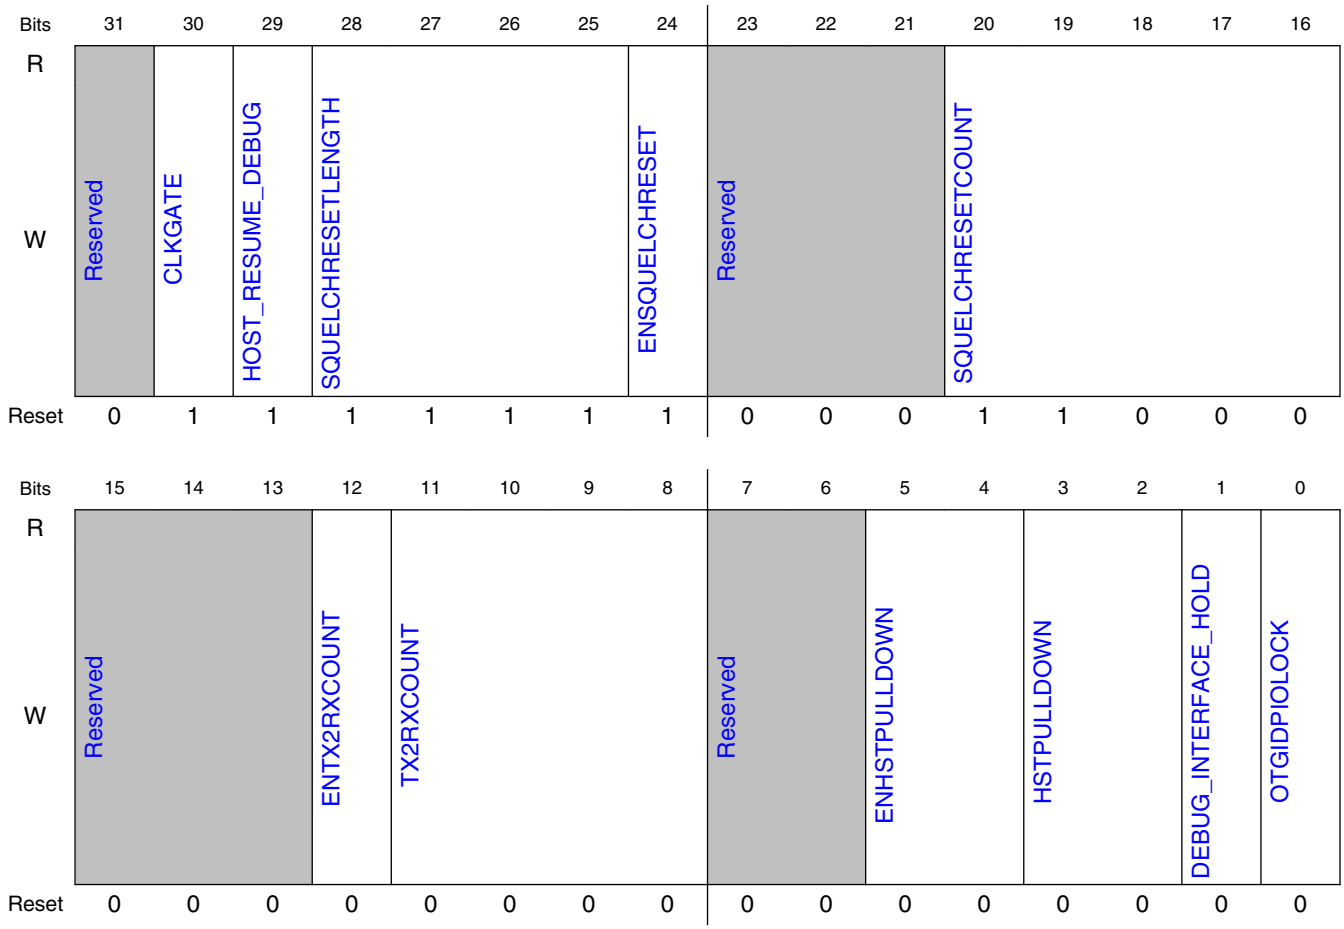
63.8.1.7 USB PHY Debug Register (DEBUG)

This register is used to debug the USB PHY.

63.8.1.7.1 Offset

Register	Offset	Description
DEBUG	50h	USB PHY Debug Register
DEBUG_SET	54h	Writing a 1 to a bit in this register sets the corresponding bit in DEBUG
DEBUG_CLR	58h	Writing a 1 to a bit in this register clears the corresponding bit in DEBUG
DEBUG_TOG	5Ch	Writing a 1 to a bit in this register toggles the corresponding bit in DEBUG

63.8.1.7.2 Diagram



63.8.1.7.3 Fields

Field	Description
31 —	- Reserved.
30 CLKGATE	CLKGATE Gate Test Clocks. Clear to 0 for running clocks. Set to 1 to gate clocks. Set this to save power while the USB is not actively being used. Configuration state is kept while the clock is gated.
29 HOST_RESUME_DEBUG	HOST_RESUME_DEBUG Choose to trigger the host resume SE0 with HOST_FORCE_LS_SE0 = 0 or UTMI_SUSPEND = 1.
28-25 SQUELCHRESETLENGTH	SQUELCHRESETLENGTH Duration of RESET in terms of the number of 480-MHz cycles.

Table continues on the next page...

Field	Description
24 ENSQUELCHRESET	ENSQUELCHRESET Set bit to allow squelch to reset high-speed receive.
23-21 —	- Reserved.
20-16 SQUELCHRESETCOUNT	SQUELCHRESETCOUNT Delay in between the detection of squelch to the reset of high-speed RX.
15-13 —	- Reserved.
12 ENTX2RXCOUNT	ENTX2RXCOUNT Set this bit to allow a countdown to transition in between TX and RX.
11-8 TX2RXCOUNT	TX2RXCOUNT Delay in between the end of transmit to the beginning of receive. This is a Johnson count value and thus will count to 8.
7-6 —	- Reserved.
5-4 ENHSTPULLDOWN	ENHSTPULLDOWN This bit field selects host pulldown overdrive mode. Set bit 5 to value 1'b1 to override the control of the DP 15kΩ pulldown. Set bit 4 to value 1'b1 to override the control of the DN 15Ω pulldown. Clear both bits to value 2'b00 to disable the host pulldown overdrive mode. When in host pulldown overdrive mode, the connection of the individual pulldown resistors is further controlled by the DEBUG[HSTPULLDOWN] bit field.
3-2 HSTPULLDOWN	HSTPULLDOWN This bit field selects whether to connect pulldown resistors on the DP/DN pins if the corresponding pulldown overdrive mode is enabled through DEBUG[ENHSTPULLDOWN} Set bit 3 to value 1'b1 to connect the 15Ω pulldown on DP line. Set bit 2 to value 1'b1 to connect the 15Ω pulldown on the DN line. Clear both bits to value 2'b00 to disconnect the pulldowns in override mode.
1 DEBUG_INTERFACE_HOLD	DEBUG_INTERFACE_HOLD Use holding registers to assist in timing for external UTMI interface.
0 OTGIDPIOLOCK	OTGIDPIOLOCK Once OTG ID from STATUS_OTGID_STATUS, use this to hold the value. This is to save power for the comparators that are used to determine the ID status.

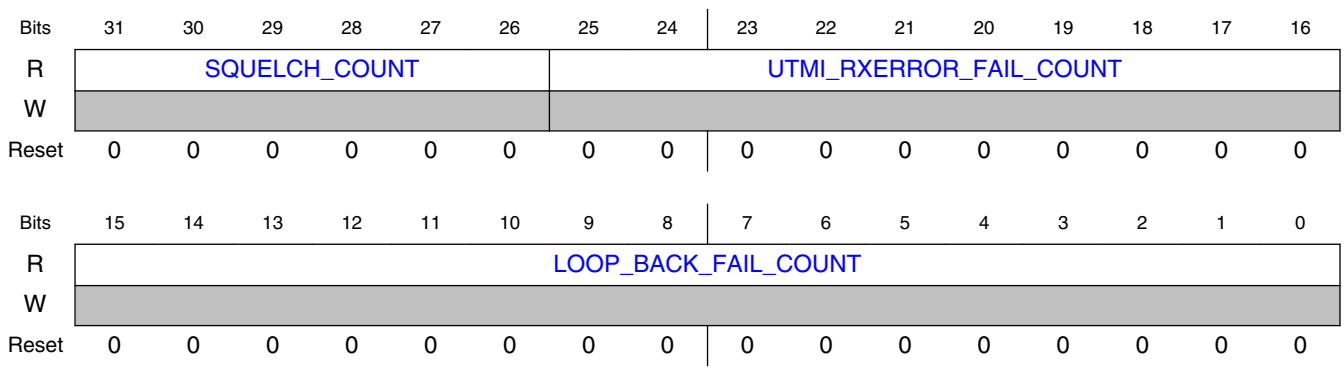
63.8.1.8 UTMI Debug Status Register 0 (DEBUG0_STATUS)

The UTMI Debug Status Register 0 holds multiple views for counters and status of state machines. This is used in conjunction with the DEBUG1[DBG_ADDRESS] field to choose which function to view. The default is described in the bit fields below and is used to count errors.

63.8.1.8.1 Offset

Register	Offset
DEBUG0_STATUS	60h

63.8.1.8.2 Diagram



63.8.1.8.3 Fields

Field	Description
31-26 SQUELCH_COUNT	SQUELCH_COUNT Running count of the squelch reset instead of normal end for HS RX.
25-16 UTMI_RXERROR_FAIL_COUNT	UTMI_RXERROR_FAIL_COUNT Running count of the UTMI_RXERROR.
15-0 LOOP_BACK_FAIL_COUNT	LOOP_BACK_FAIL_COUNT Running count of the failed pseudo-random generator loopback. Each time entering testmode, counter goes to 900D and will count up for every detected packet failure in digital/analog loopback tests.

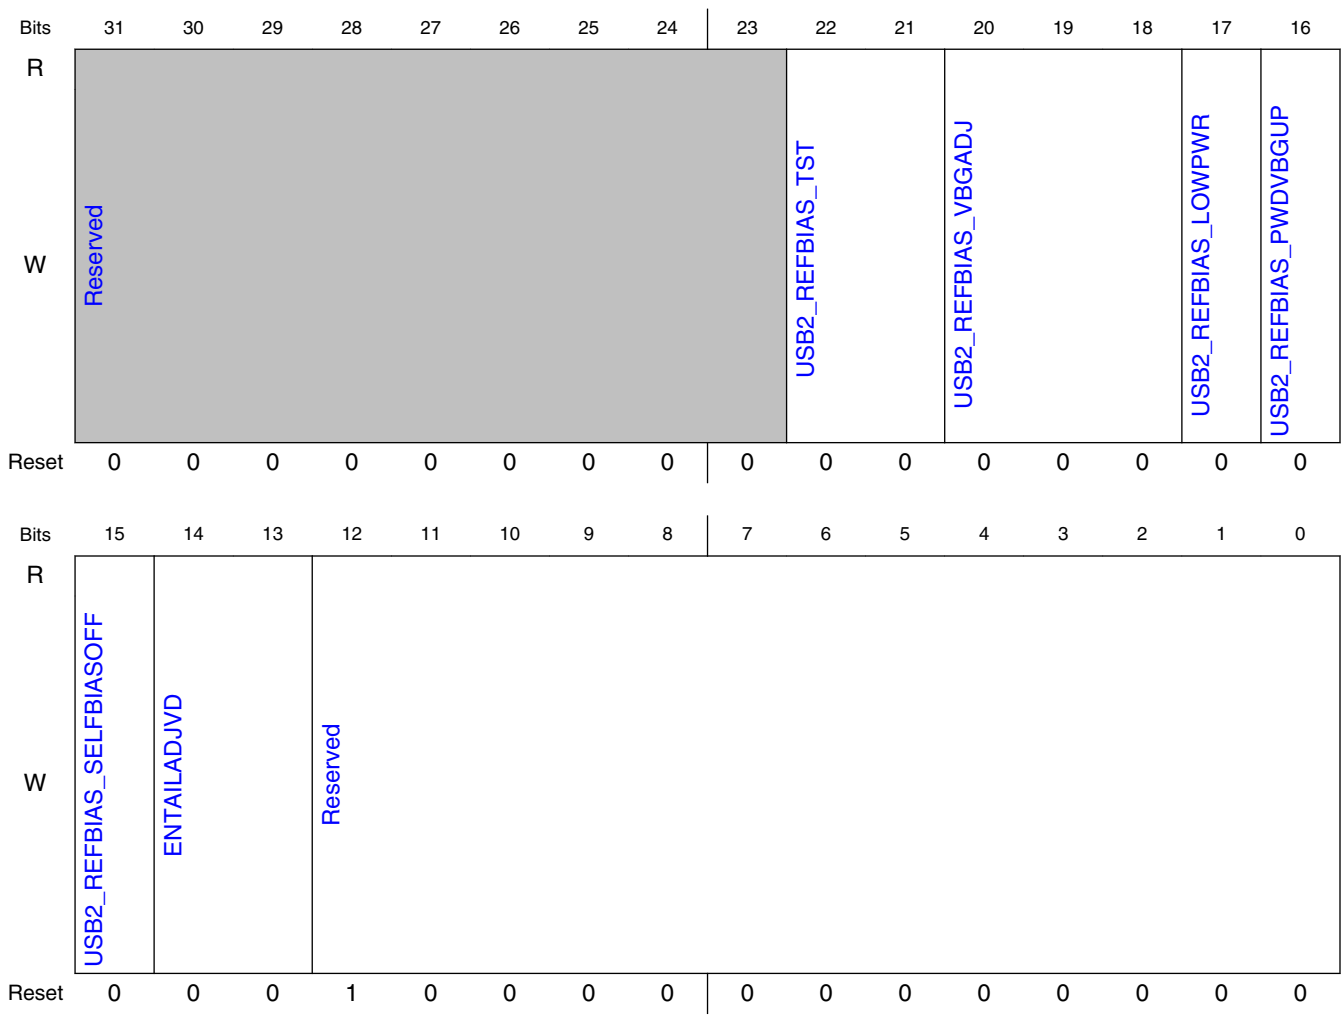
63.8.1.9 UTMI Debug Status Register 1 (DEBUG1)

Chooses the muxing of the debug register to be shown in USBPHYx_DEBUG0_STATUS.

63.8.1.9.1 Offset

Register	Offset	Description
DEBUG1	70h	UTMI Debug Status Register 1
DEBUG1_SET	74h	Writing a 1 to a bit in this register sets the corresponding bit in DEBUG1
DEBUG1_CLR	78h	Writing a 1 to a bit in this register clears the corresponding bit in DEBUG1
DEBUG1_TOG	7Ch	Writing a 1 to a bit in this register toggles the corresponding bit in DEBUG1

63.8.1.9.2 Diagram



63.8.1.9.3 Fields

Field	Description
31-23 —	- Reserved.
22-21 USB2_REFBIAS_TST	Bias current control for usb2_phy
20-18 USB2_REFBIAS_VBGADJ	Adjustment bits on bandgap
17 USB2_REFBIAS_LOWPWR	to be added
16 USB2_REFBIAS_PWDVBGUP	Powers down the bandgap detect logic, will affect vbgup on misc1 register.
15 USB2_REFBIAS_SELFBIASOFF	Set to 1 to disable self bias, 100 us after power up refbias(usb2_refbias_pwd).This can reduce noise on power. It has to be cleared before clear refbias_pwd, that is, must use self bias before power up refbias, otherwise no bias.
14-13 ENTAILADJVD	ENTAILADJVD Delay increment of the rise of squelch. This bit field only has effect if it is enabled by the TRIM_OVERRIDE_EN[TRIM_ENV_TAIL_ADJ_VD_OVERRIDE] bit. 00 - Delay is nominal 01 - Delay is +20% 10 - Delay is -20% 11 - Delay is -40%
12-0 —	- Reserved. **Note:** This bit should remain clear.

63.8.1.10 UTMI RTL Version (VERSION)

Fields for RTL Version.

63.8.1.10.1 Offset

Register	Offset
VERSION	80h

63.8.1.10.2 Diagram

63.8.1.10.3 Fields

Field	Description
31-24	MAJOR
MAJOR	Fixed read-only value reflecting the MAJOR field of the RTL version.
23-16	MINOR
MINOR	Fixed read-only value reflecting the MINOR field of the RTL version.
15-0	STEP
STEP	Fixed read-only value reflecting the stepping of the RTL version.

63.8.1.11 USB PHY PLL Control/Status Register (PLL_SIC)

This register configures the 480MHz USB PHY PLL.

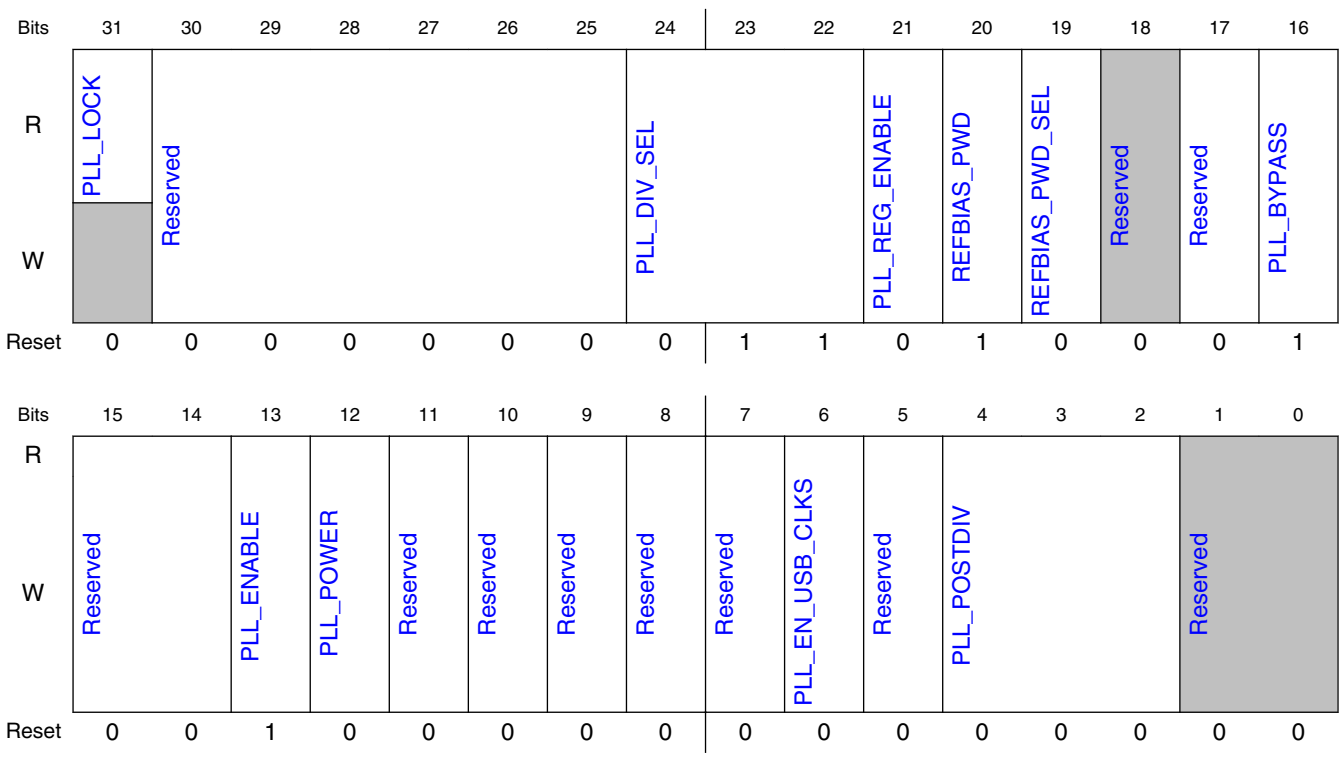
63.8.1.11.1 Offset

Register	Offset	Description
PLL_SIC	A0h	USB PHY PLL Control/Status Register

Table continues on the next page...

Register	Offset	Description
PLL_SIC_SET	A4h	Writing a 1 to a bit in this register sets the corresponding bit in PLL_SIC
PLL_SIC_CLR	A8h	Writing a 1 to a bit in this register clears the corresponding bit in PLL_SIC
PLL_SIC_TOG	ACh	Writing a 1 to a bit in this register toggles the corresponding bit in PLL_SIC

63.8.1.11.2 Diagram



63.8.1.11.3 Fields

Field	Description
31 PLL_LOCK	PLL_LOCK USB PLL lock status indicator 0 - PLL is not currently locked 1 - PLL is currently locked
30-25 —	Reserved
24-22	PLL_DIV_SEL

Table continues on the next page...

Field	Description
PLL_DIV_SEL	This field controls the USB PLL feedback loop divider. Valid range for divider values: 13-240. Fout = Fin * div_select. The USB PLL is designed to produce a 480 MHz output clock. This bit field allows use of different frequency signals for the PLL reference clock input connected to the OSCCLK signal from the system oscillator. When override is enabled through TRIM_OVERRIDE_EN[0], the USB PLL will use this register value. 000 - Divide by 13 001 - Divide by 15 010 - Divide by 16 011 - Divide by 20 100 - Divide by 22 101 - Divide by 25 110 - Divide by 30 111 - Divide by 240
21 PLL_REG_ENABLE	PLL_REG_ENABLE This field controls the USB PLL regulator, set to enable the regulator. SW must set this bit 15 us before settiing PLL_POWER to avoid glitches on PLL output clock.
20 REFBIAS_PWD	Power down the reference bias This bit is only used when REFBIAS_PWD_SEL is set to 1.
19 REFBIAS_PWD_SEL	REFBIAS_PWD_SEL Reference bias power down select. 0 - Selects PLL_POWER to control the reference bias 1 - Selects REFBIAS_PWD to control the reference bias.
18 —	- Reserved
17 —	- Reserved. This bit field must remain at value 1'b0.
16 PLL_BYPASS	PLL_BYPASS Bypass the USB PLL.
15-14 —	Reserved This bit field has no effect for this module.
13 PLL_ENABLE	PLL_ENABLE Enable the clock output from the USB PLL. PLL output enable signal is also controlled by PLL power up control. Hardware will disable the PLL output before PLL power down, and enable the PLL output after PLL power up. The software only needs to set it when initializing the PLL.
12 PLL_POWER	PLL_POWER Power up the USB PLL. PLL power up is also controlled by hardware. Hardware will power down PLL when USB is suspended and not in use.
11 —	- Reserved. This bit field must remain at value 1'b0 for normal operation.
10	Reserved

Table continues on the next page...

Field	Description
—	Not for customer use. This bit field must remain at value 1'b0.
9 —	Reserved Not for customer use. This bit field must remain at value 1'b0.
8 —	Reserved Not for customer use. This bit field must remain at value 1'b0.
7 —	Reserved Not for customer use. This bit field must remain at value 1'b0.
6 PLL_EN_USB_CLKS	PLL_EN_USB_CLKS Enable the USB clock output from the USB PHY PLL.
5 —	Reserved Not for customer use. This bit field must remain at value 1'b0.
4-2 PLL_POSTDIV	PLL_POSTDIV pll_postdiv to analog.
1-0 —	- Reserved

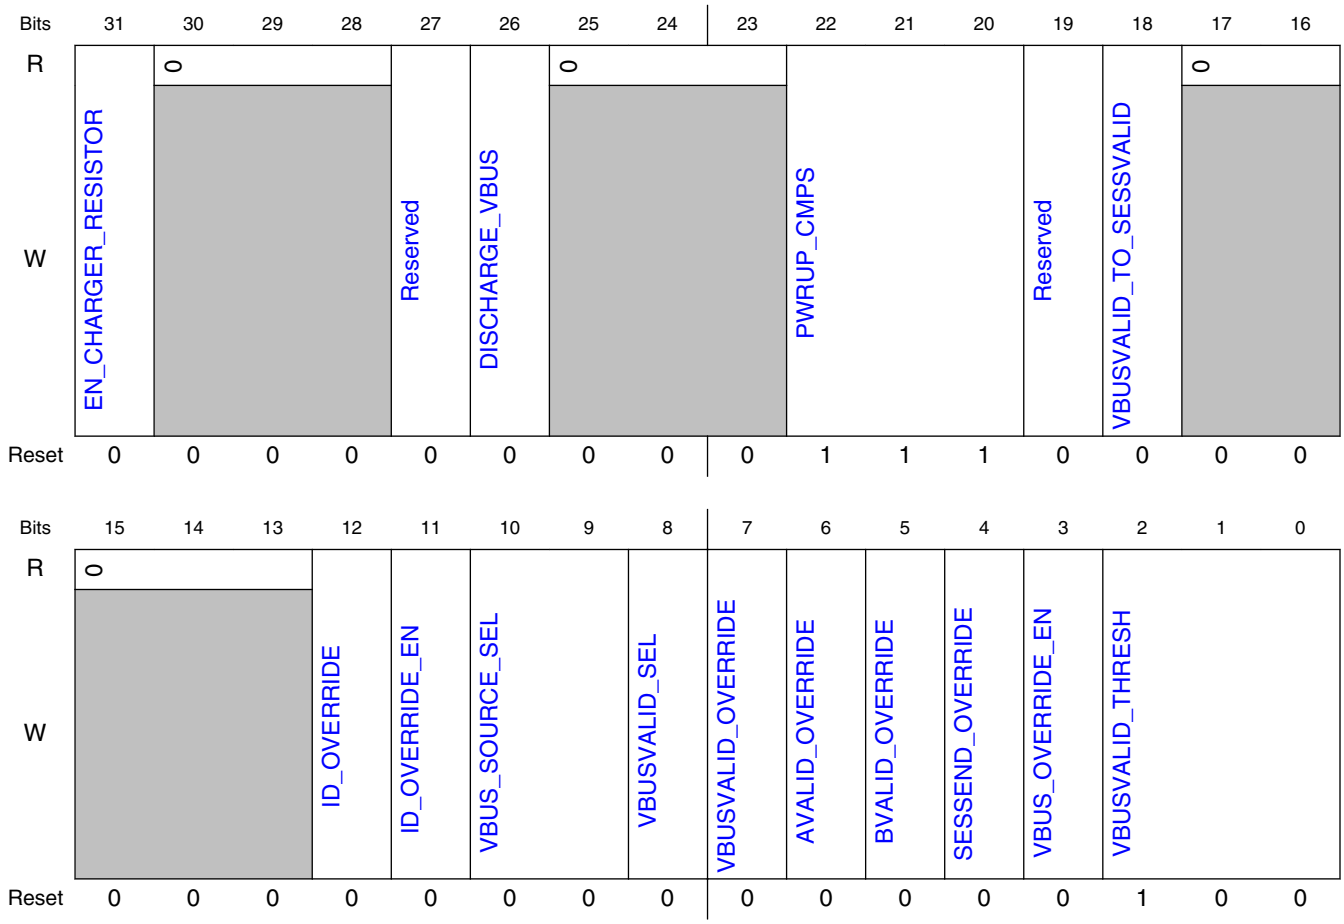
63.8.1.12 USB PHY VBUS Detect Control Register (USB1_VBUS_DETECT)

This register defines controls for USB VBUS detect and some additional out of band signaling functions.

63.8.1.12.1 Offset

Register	Offset	Description
USB1_VBUS_DETECT	C0h	USB PHY VBUS Detect Control Register
USB1_VBUS_DETECT_SET	C4h	Writing a 1 to a bit in this register sets the corresponding bit in USB1_VBUS_DETECT
USB1_VBUS_DETECT_CLR	C8h	Writing a 1 to a bit in this register clears the corresponding bit in USB1_VBUS_DETECT
USB1_VBUS_DETECT_TOG	CCh	Writing a 1 to a bit in this register toggles the corresponding bit in USB1_VBUS_DETECT

63.8.1.12.2 Diagram



63.8.1.12.3 Fields

Field	Description
31 EN_CHARGER_RESISTOR	Enables resistors used for an older method of resistive battery charger detection This bit field enables a nominal 125kΩ pullup on DP and a nominal 375kΩ pulldown on DN. This allows resistive battery charger detection per the *USB Battery Charging Specification Revision 1.0* which is now obsolete. Detection of DP and DN pin states using this method is done with the CHRG_DET_STAT[3:2] bit fields. This bit field must remain at a value of 1'b0 for normal USB data communication, or when using the USBHSDCD module for battery charger detection per the *USB Battery Charger Specification Revision 1.2* or any other detection mechanism for USB cable plugin. 0 - Disable resistive charger detection resistors on DP and DP 1 - Enable resistive charger detection resistors on DP and DP
30-28 —	Reserved

Table continues on the next page...

Field	Description
27 —	Reserved This bit field has no effect for this module.
26 DISCHARGE_VBUS	Controls VBUS discharge resistor This bit field controls a nominal 22kΩ resistor between the USB1_VBUS pin and ground. It can be used to accelerate the fall of the VBUS signal at the end of a session. 0 - VBUS discharge resistor is disabled (Default) 1 - VBUS discharge resistor is enabled
25-23 —	Reserved
22-20 PWRUP_CMPS	Enables the VBUS_VALID comparator Powers up the comparator used for the VBUS_VALID detector. This bit field can be reset to value 1'b0 to save power if the internal VBUS_VALID comparator is not used. Default value is 3'h7 000 - Powers down the VBUS_VALID comparator 001 - Enables the SESS_VALID comparator (default) 010 - Enables the 3Vdetect (default)
19 —	Reserved This bit field has no effect for this module.
18 VBUSVALID_TO_SESSVALID	Selects the comparator used for VBUS_VALID This bit field controls the comparator used to report the VBUS_VALID results in USB1_VBUS_DETECT[3] between the VBUS_VALID comparator and the Session Valid comparator. The VBUS_VALID comparator is the most accurate and has a programmable threshold set by USB_VBUS_DETECT[2:0]. The Session Valid comparator may be useful in systems using non-standard VBUS voltages. The mux selection in this bit field happens before any VBUS_VALID selection controlled by the USB1_VBUS_DETECT[10:8] bits. 0 - Use the VBUS_VALID comparator for VBUS_VALID results 1 - Use the Session End comparator for VBUS_VALID results. The Session End threshold is >0.8V and <4.0V.
17-13 —	Reserved
12 ID_OVERRIDE	TBA
11 ID_OVERRIDE_EN	TBA
10-9 VBUS_SOURCE_SEL	Selects the source of the VBUS_VALID signal reported to the USB controller This is one of the bit fields that selects the source of the VBUS_VALID signal reported to the USB controller. The VBUS_VALID source selections in this bit field only take effect if both USB1_VBUS_DETECT[8] and USB1_VBUS_DETECT[3] each have the value 1'b0. This bit field does not impact the VBUS_VALID value reported in USB1_VBUS_DET_STAT[3].

Table continues on the next page...

Field	Description
	00 - Use the VBUS_VALID comparator results for signal reported to the USB controller (Default) 01 - Use the Session Valid comparator results for signal reported to the USB controller 10 - Use the Session Valid comparator results for signal reported to the USB controller 11 - Reserved, do not use
8 VBUSVALID_SEL	Selects the source of the VBUS_VALID signal reported to the USB controller This is one of the bit fields that selects the source of the VBUS_VALID signal reported to the USB controller. The VBUS_VALID source selection in this bit field only takes effect if USB1_VBUS_DETECT[3] has the value 1'b0. This bit field does not impact the VBUS_VALID value reported in USB1_VBUS_DET_STAT[3]. 0 - Use the VBUS_VALID comparator results for signal reported to the USB controller (Default) 1 - Use the VBUS_VALID_3V detector results for signal reported to the USB controller
7 VBUSVALID_OVERRIDE	Override value for VBUS_VALID signal sent to USB controller The bit field provides the value for VBUS_VALID reported to the USB controller if the value of USB1_VBUS_DETECT[3] is set to 1'b1. The value of this bit field does not affect the value of USB1_VBUS_DET_STAT[3].
6 AVALID_OVERRIDE	Override value for A-Device Session Valid The bit field provides the value for USB1_VBUS_DET_STAT[2] if USB_VBUS_DETECT[3] is set to value 1'b1.
5 BVALID_OVERRIDE	Override value for B-Device Session Valid The bit field provides the value for USB1_VBUS_DET_STAT[1] if USB_VBUS_DETECT[3] is set to value 1'b1.
4 SESSEND_OVERRIDE	Override value for SESSEND The bit field provides the value for USB1_VBUS_DET_STAT[0] if USB_VBUS_DETECT[3] is set to value 1'b1.
3 VBUS_OVERRIDE_EN	VBUS detect signal override enable This bit field allows SW to override the results from the VBUS_VALID and Session Valid comparators using the values in USB1_VBUS_DETECT[7:4]. The VBUS_VALID, AVALID, BVALID, and SESSEND signals sent to the USB controller are each affected by these bit selections. The values reported for AVALID, BVALID, and SESSEND in USB1_VBUS_DET_STAT[2:0] are also affected but the value reported for VBUS_VALID in USB1_VBUS_DET_STAT[3] is not affected. This override method may be useful if VBUS detection is not done with the internal VBUS_VALID or Session End comparators. 0 - Use the results of the internal VBUS_VALID and Session Valid comparators for VBUS_VALID, AVALID, BVALID, and SESSEND (Default) 1 - Use the override values for VBUS_VALID, AVALID, BVALID, and SESSEND
2-0 VBUSVALID_THRESH	VBUSVALID_THRESH Sets the threshold for the VBUSVALID comparator. This comparator is the most accurate method to determine the presence of 5v, and includes hystersis to minimize the need for software debounce of the detection. This comparator has ~50mV of hystersis to prevent chattering at the comparator trip point. 000 - 4.0 V 001 - 4.1 V

Field	Description
	010 - 4.2 V 011 - 4.3 V 100 - 4.4 V (Default) 101 - 4.5 V 110 - 4.6 V 111 - 4.7 V

63.8.1.13 USB PHY VBUS Detector Status Register (USB1_VBUS_DET_STAT)

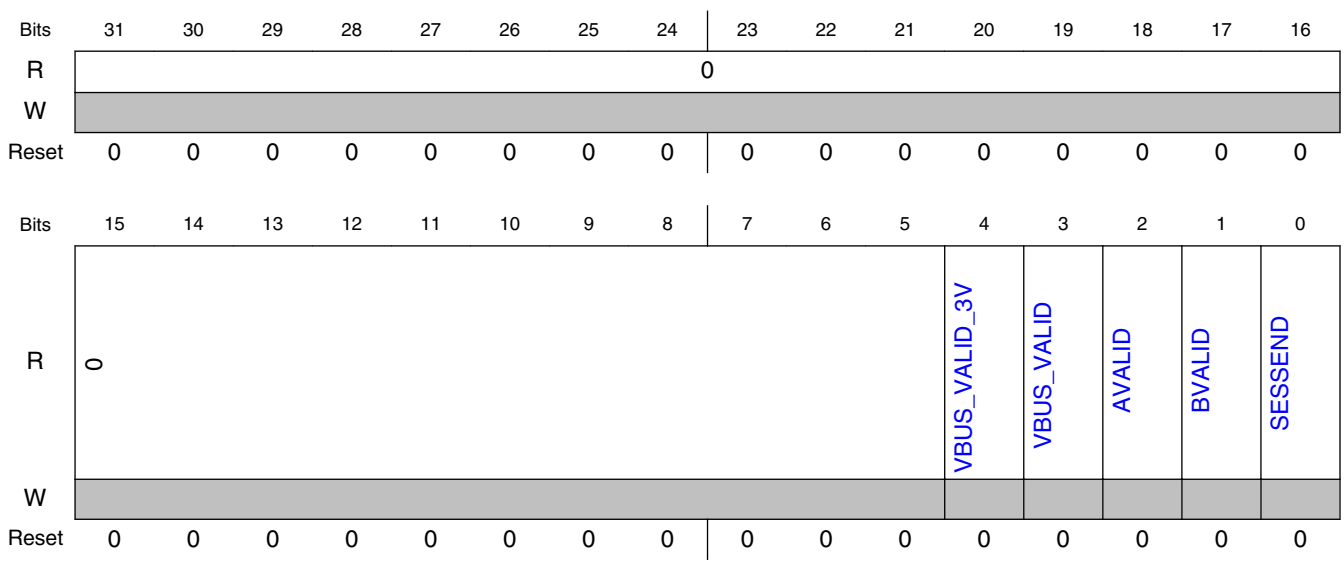
This register allows observation of status for USB VBUS detect functions.

The values reported in this register are synchronized by the apb_clk.

63.8.1.13.1 Offset

Register	Offset
USB1_VBUS_DET_STAT	D0h

63.8.1.13.2 Diagram



63.8.1.13.3 Fields

Field	Description
31-5 —	Reserved
4 VBUS_VALID_3V	VBUS_VALID_3V detector status The VBUS_VALID_3V detector has a lower threshold for the voltage on the USB1_VBUS pin than either the Session Valid or VBUS_VALID comparators. This signal may be useful for applications using a non-standard VBUS voltage. 0 - VBUS voltage is below VBUS_VALID_3V threshold 1 - VBUS voltage is above VBUS_VALID_3V threshold
3 VBUS_VALID	VBUS voltage status This bit field shows the result of VBUS_VALID detection for the USB1_VBUS pin. The VBUS_VALID comparator used is selected by USB1_VBUS_DETECT[18]. The VBUS_VALID source is not affected by the values of USB1_VBUS_DETECT[7, 3] and cannot be overwritten by SW. 0 - VBUS is below the comparator threshold 1 - VBUS is above the comparator threshold
2 AVALID	A-Device Session Valid status A-Device Session Valid status, determined by the Session Valid comparator. The default value of this bit is determined by the voltage on the USB1_VBUS pin. This bit can be overwritten by SW using the VBUS_DETECT[6, 3] bit fields. 0 - The VBUS voltage is below the Session Valid threshold 1 - The VBUS voltage is above the Session Valid threshold
1 BVALID	B-Device Session Valid status B-Device Session Valid status, determined by the Session Valid comparator. The default value of this bit is determined by the voltage on the USB1_VBUS pin. This bit can be overwritten by SW using the VBUS_DETECT[5, 3] bit fields. 0 - The VBUS voltage is below the Session Valid threshold 1 - The VBUS voltage is above the Session Valid threshold
0 SESSEND	Session End indicator Session End status, value inverted from Session Valid comparator. The default value of this bit is determined by the voltage on the USB1_VBUS pin. This bit can be overwritten by SW using the VBUS_DETECT[4, 3] bit fields. 0 - The VBUS voltage is above the Session Valid threshold 1 - The VBUS voltage is below the Session Valid threshold

63.8.1.14 USB PHY Charger Detect Control Register (USB1_CHRG_DETECT)

This register defines controls for USB Battery Charging detection functions.

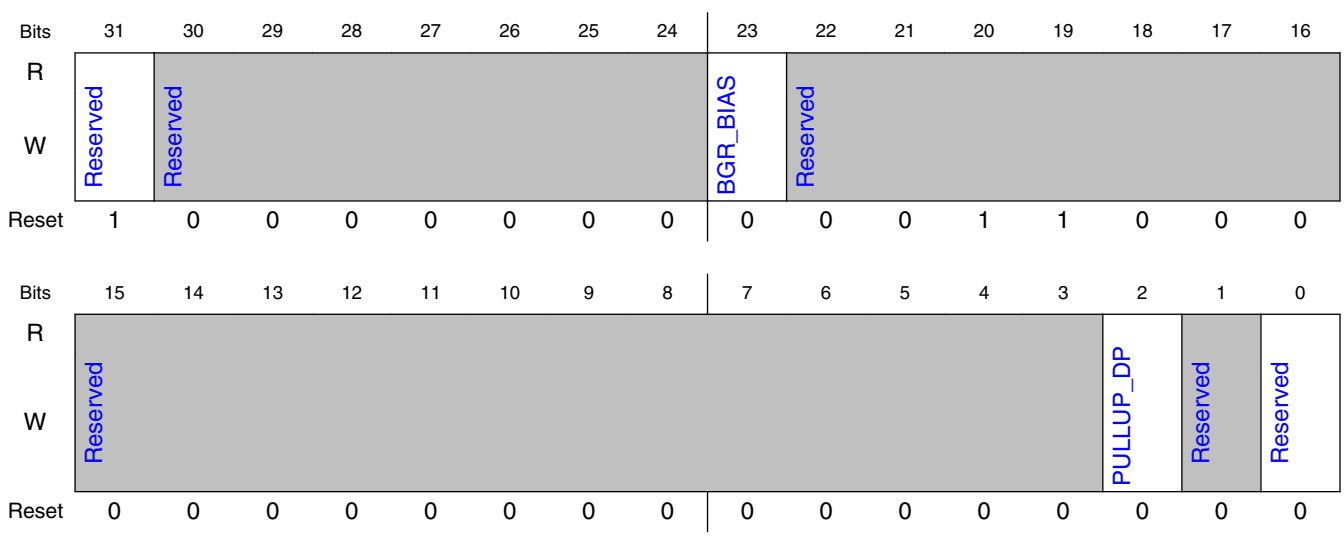
The control of the USB Battery Charging detection functions has been moved to the USBDCD module.

Bit fields are still implemented, but their values should not be changed except for characterization tasks.

63.8.1.14.1 Offset

Register	Offset	Description
USB1_CHRG_DETECT	E0h	USB PHY Charger Detect Control Register
USB1_CHRG_DETECT_SET	E4h	Writing a 1 to a bit in this register sets the corresponding bit in USB1_CHRG_DETECT
USB1_CHRG_DETECT_CLR	E8h	Writing a 1 to a bit in this register clears the corresponding bit in USB1_CHRG_DETECT
USB1_CHRG_DETECT_TOG	ECh	Writing a 1 to a bit in this register toggles the corresponding bit in USB1_CHRG_DETECT

63.8.1.14.2 Diagram



63.8.1.14.3 Fields

Field	Description
31 — 	- Reserved The bit field must remain unchanged
30-24 —	- Reserved
23 BGR_BIAS	BGR_BIAS selects the bias method used for the voltage and current sources used for the analog circuits associated with USB Battery Charging detection in the USBHSDCD instantiation of the USBDCD module. The V_{DP_SRC} and V_{DN_SRC} bias is generated from the USB1_VBUS voltage independelt of the value of this bit field. 0 - Use local bias powered from USB1_VBUS for 10uA reference (Default) 1 - Use bandgap bias powered from VREGIN0/VREGIN1 for 10uA reference
22-3 —	- Reserved
2 PULLUP_DP	PULLUP_DP This bit is used to pull up DP, for digital charge detect.
1 —	- Reserved
0 —	- The bit field must remain at value 1'b0 to avoid interfering with USB Battery Charging Detection.

63.8.1.15 USB PHY Charger Detect Status Register (USB1_CHRG_DET_STAT)

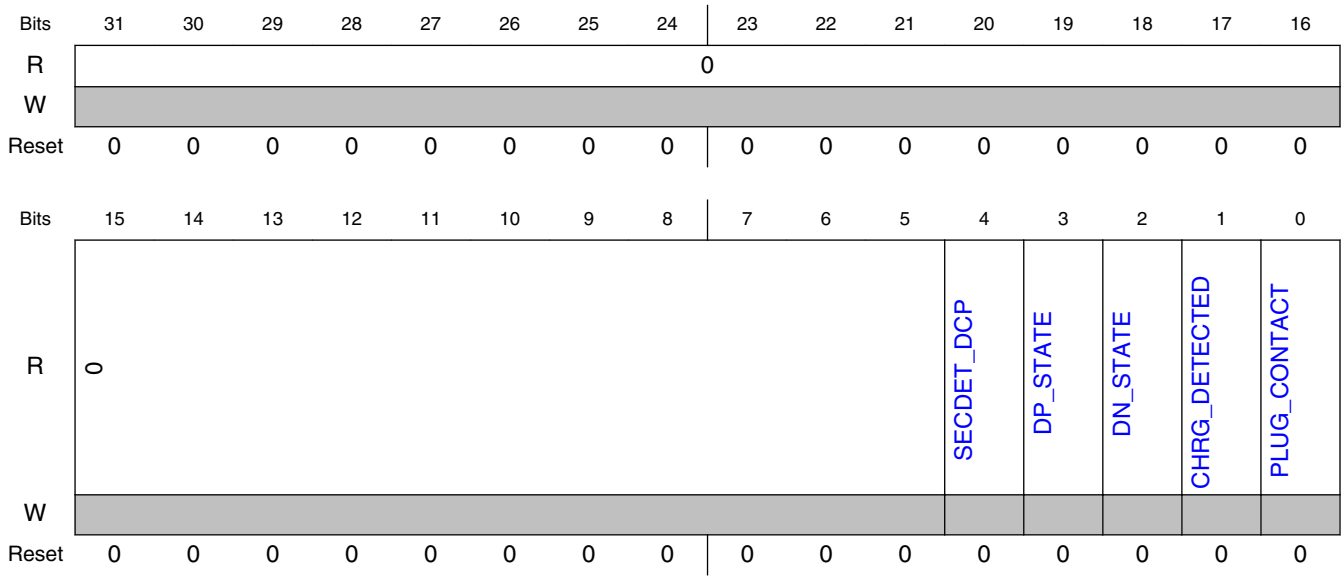
The control of the USB Battery Charging detection functions has been moved to the USBHSDCD instantiation of the USBDCD module for this product.

For standards-based charger detection purposes, the USBHSDCD registers should be used rather than this register. However, the status values in this register may be useful for debugging or in case other detection methods are used.

63.8.1.15.1 Offset

Register	Offset
USB1_CHRG_DET_STAT	F0h

63.8.1.15.2 Diagram



63.8.1.15.3 Fields

Field	Description
31-5 —	Reserved
4 SECDET_DCP	Battery Charging Secondary Detection phase output During the USB Battery Charging Secondary Detection phase using the USBHSDCD module, this bit field indicates which kind of Charging Port was detected. 0 - Charging Downstream Port (CDP) has been detected 1 - Downstream Charging Port (DCP) has been detected
3 DP_STATE	DP_STATE Single ended receiver output for the DP pin, from charger detection circuits. 0 - DP pin voltage is < 0.8V 1 - DP pin voltage is > 2.0V
2 DN_STATE	DN_STATE Single ended receiver output for the DN pin, from charger detection circuits. 0 - DN pin voltage is < 0.8V 1 - DN pin voltage is > 2.0V
1 CHRG_DETECTED	Battery Charging Primary Detection phase output During the USB Battery Charging Primary Detection phase using the USBHSDCD module, this bit field indicates whether a Standard Downstream Port or Charging Port was detected. 0 - Standard Downstream Port (SDP) has been detected

Table continues on the next page...

Field	Description
	1 - Charging Port has been detected
0 PLUG_CONTACT	Battery Charging Data Contact Detection phase output During the Data Contact Detection phase per the *USB Battery Charging Specification Revision 1.2* using the USBHSDCD module, this bit field indicates whether a USB cable has been attached between the remote host and the local device. 0 - No USB cable attachment has been detected 1 - A USB cable attachment between the device and host has been detected

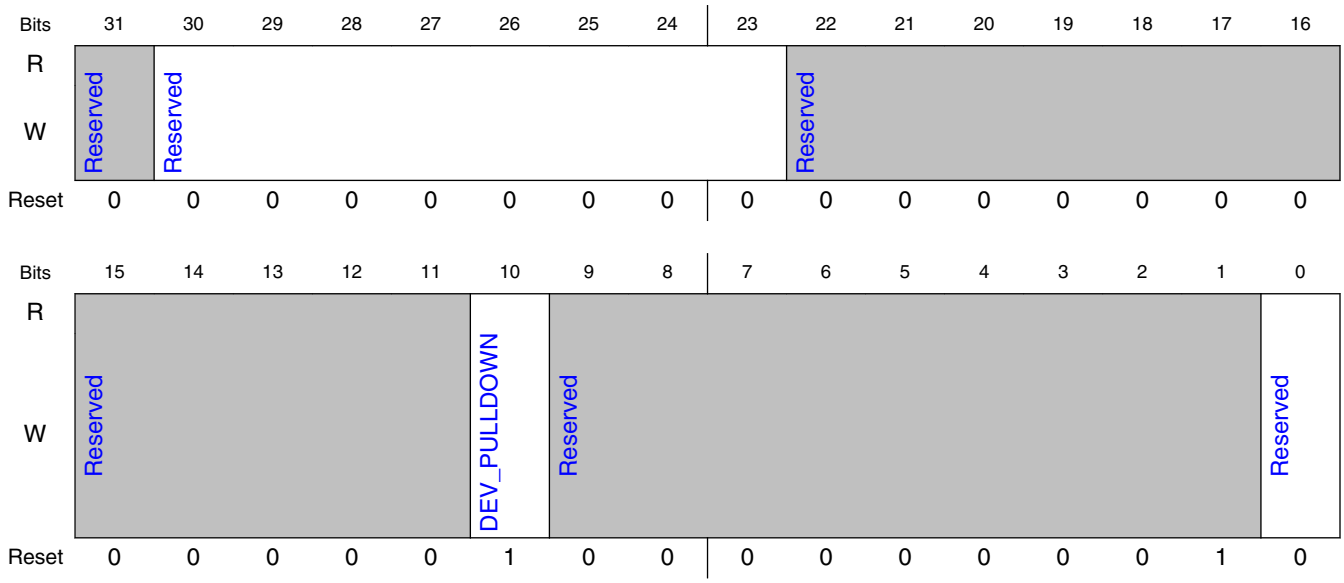
63.8.1.16 USB PHY Analog Control Register (ANACTRL)

The ANACTRL register has bit fields for adding pre-emphasis to the USB High-Speed TX output drivers.

63.8.1.16.1 Offset

Register	Offset	Description
ANACTRL	100h	USB PHY Analog Control Register
ANACTRL_SET	104h	Writing a 1 to a bit in this register sets the corresponding bit in ANACTRL
ANACTRL_CLR	108h	Writing a 1 to a bit in this register clears the corresponding bit in ANACTRL
ANACTRL_TOG	10Ch	Writing a 1 to a bit in this register toggles the corresponding bit in ANACTRL

63.8.1.16.2 Diagram



63.8.1.16.3 Fields

Field	Description
31 —	- Reserved
30-23 —	Reserved Not for customer use. For normal USB operation this bit field must remain cleared at value 8'h00.
22-11 —	- Reserved
10 DEV_PULLDOWN	DEV_PULLDOWN Setting this field to 1'b1 will enable the 15kΩ pulldown resistors on both DP and DN pins. This feature can be used in device mode while the USB cable is disconnected to keep the data pins at known values, avoiding unnecessary interrupts from the single ended receivers. This bit must be reset to 1'b0 during normal USB data communication in device mode, or while battery charger detection using the USBHSDCD module is used. 0 - The 15kΩ nominal pulldowns on the DP and DN pinsare disabled in device mode. 1 - The 15kΩ nominal pulldowns on the DP and DN pinsare enabled in device mode.
9-1 —	- Reserved
0 —	- Reserved The value of this bit field must remain at 1'b0 for normal operation.

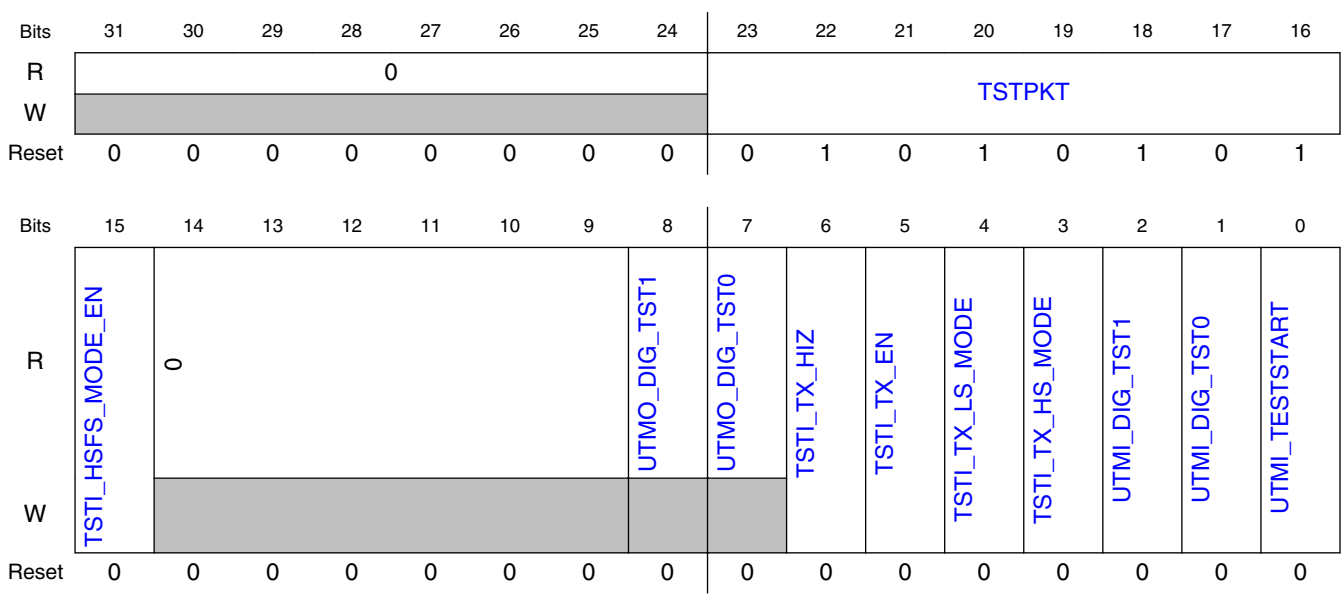
63.8.1.17 USB PHY Loopback Control/Status Register (USB1_LOOPBACK)

This register controls loopback testing of the USB PHY. Loopback mode is for test purposes only; it cannot be used during normal USB data communication.

63.8.1.17.1 Offset

Register	Offset	Description
USB1_LOOPBACK	110h	USB PHY Loopback Control/Status Register
USB1_LOOPBACK_SET	114h	Writing a 1 to a bit in this register sets the corresponding bit in USB1_LOOPBACK
USB1_LOOPBACK_CLR	118h	Writing a 1 to a bit in this register clears the corresponding bit in USB1_LOOPBACK
USB1_LOOPBACK_TOG	11Ch	Writing a 1 to a bit in this register toggles the corresponding bit in USB1_LOOPBACK

63.8.1.17.2 Diagram



63.8.1.17.3 Fields

Field	Description
31-24 —	Reserved
23-16 TSTPKT	TSTPKT Selects the packet data byte used for USB loopback testing in Pulse mode. Pulse mode is selected by setting USB1_LOOPBACK[2:1] to a value of 2'b01. Default value produces a data inversion at each unit interval.
15 TSTI_HSFS_MODE_EN	TSTI_HSFS_MODE_EN Setting this bit field to value 1'b1 will enable the loopback test to dynamically change the packet speed. It will send a number of High Speed packets determined by USB1_LOOPBACK_HSFSCNT[TSTI_HS_NUMBER], followed by a number of Full Speed packets determined by USB1_LOOPBACK_HSFSCNT[TSTI_FS_NUMBER].
14-9 —	Reserved
8 UTMO_DIG_TST1	UTMO_DIG_TST1 This read-only bit is a status bit for USB loopback test. Value = 1'b1 indicates a passing result. Test results are only valid while UTMI_TESTSTART is set to value 1'b1.
7 UTMO_DIG_TST0	UTMO_DIG_TST0 This read-only bit is a status bit for USB loopback test results. Value = 1'b0 indicates a passing result. Test results are only valid while UTMI_TESTSTART is set to value 1'b1.
6 TSTI_TX_HIZ	TSTI_TX_HIZ Sets TX Hi-Z for USB loopback test.
5 TSTI_TX_EN	TSTI_TX_EN Enable TX for USB loopback test.
4 TSTI_TX_LS_MODE	TSTI_TX_LS_MODE Set to value 1'b1 to choose LS for USB loopback testing, set to value 1'b0 to choose HS or FS mode which is defined by TSTI1_TX_HS.
3 TSTI_TX_HS_MODE	TSTI_TX_HS_MODE Select HS or FS mode for USB loopback testing. Set to value 1'b1 to choose HS for USB loopback testing, set to value 1'b0 to choose FS mode.
2 UTMI_DIG_TST1	UTMI_DIG_TST1 Mode control for USB loopback test. Setting this bit to a value of 1'b1 while UTMI_DIG_TST0 remains at a value of 1'b0 selects Psuedorandom modes for the loopback test.
1 UTMI_DIG_TST0	UTMI_DIG_TST0 Mode control for USB loopback test. Setting this bit to a value of 1'b1 while UTMI_DIG_TST1 remains at a value of 1'b0 selects Pulse mode for the loopback test.
0	UTMI_TESTSTART

Field	Description
UTMI_TESTSTART	This bit enables the USB loopback test.

63.8.1.18 USB PHY Loopback Packet Number Select Register (USB1_LOOPBACK_HSFSCNT)

63.8.1.18.1 Offset

Register	Offset	Description
USB1_LOOPBACK_HSFSCNT	120h	USB PHY Loopback Packet Number Select Register
USB1_LOOPBACK_HSFSCNT_SET	124h	Writing a 1 to a bit in this register sets the corresponding bit in USB1_LOOPBACK_HSFSCNT
USB1_LOOPBACK_HSFSCNT_CLR	128h	Writing a 1 to a bit in this register clears the corresponding bit in USB1_LOOPBACK_HSFSCNT
USB1_LOOPBACK_HSFSCNT_TOG	12Ch	Writing a 1 to a bit in this register toggles the corresponding bit in USB1_LOOPBACK_HSFSCNT

63.8.1.18.2 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

63.8.1.18.3 Fields

Field	Description
31-16	TSTI_FS_NUMBER Full speed packet number, used when USB1_LOOPBACK[TSTI_HSFS_MODE_EN] is set to value 1'b1.

Table continues on the next page...

Field	Description
TSTI_FS_NUMBER	
15-0 TSTI_HS_NUMBER	TSTI_HS_NUMBER High speed packet number, used when USB1_LOOPBACK[TSTI_HSFS_MODE_EN] is set to value 1'b1.

63.8.1.19 USB PHY Trim Override Enable Register (TRIM_OVERRIDE_EN)

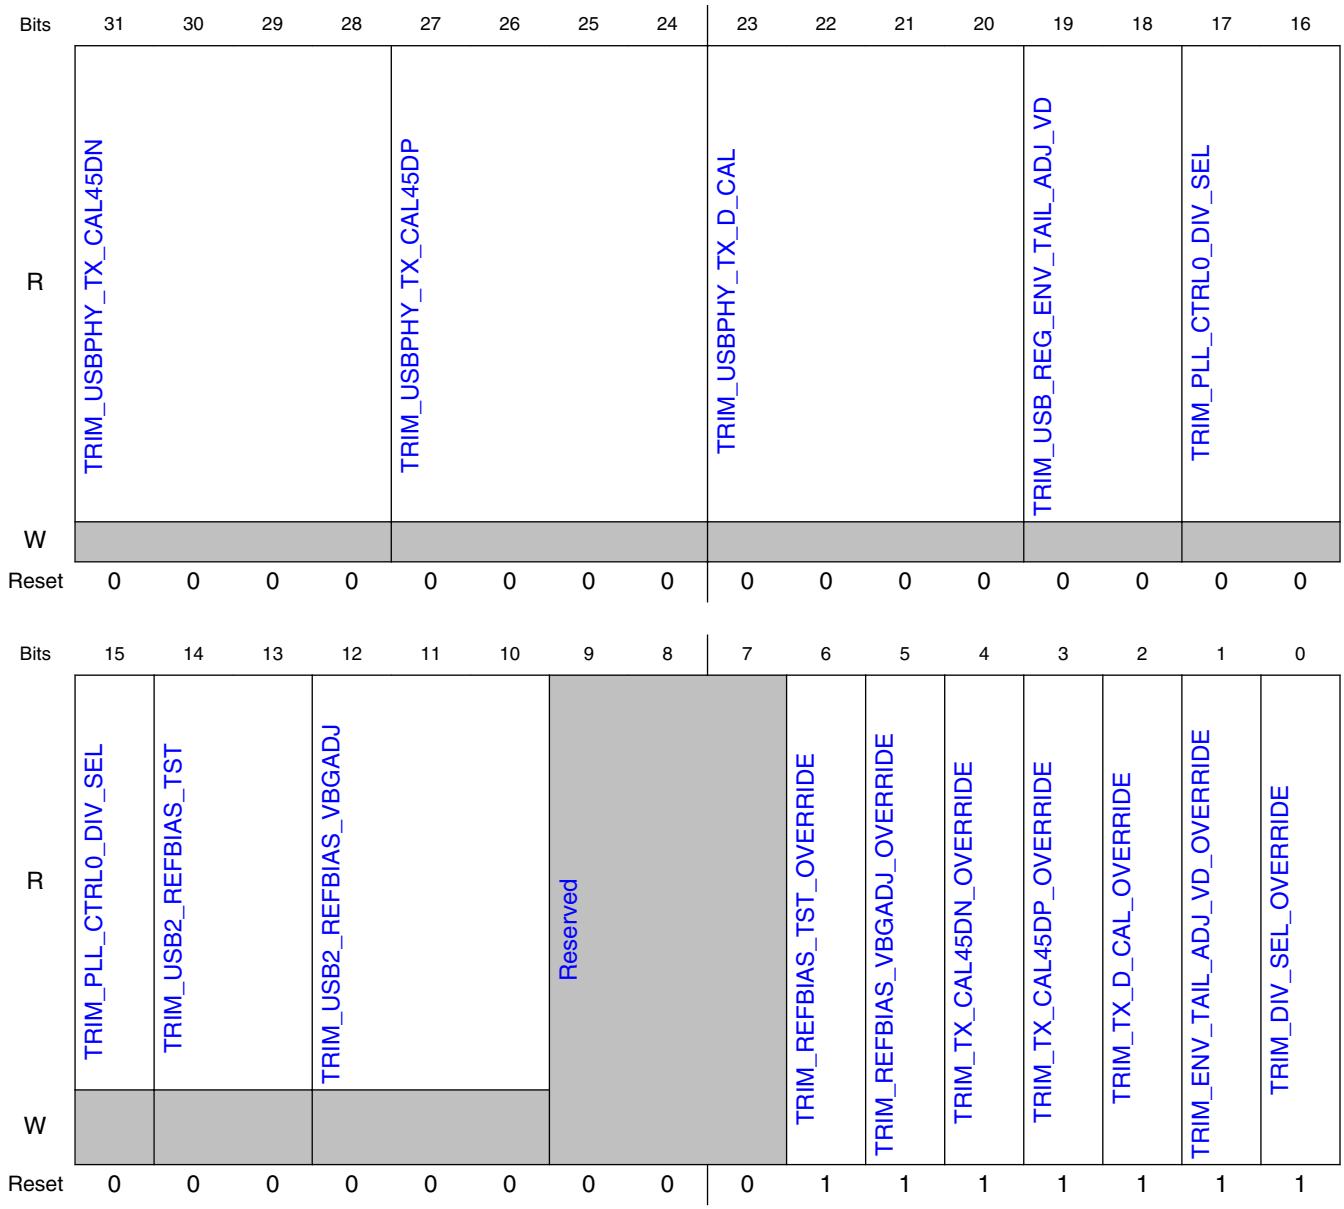
The bit fields in this register allow observation of the default IFR settings of Phy parameters for TX_CAL45DN, TX_CAL45DP, TX_D_CAL, ENV_TAIL_ADJ, and PLL_DIV_SEL.

Additional bit fields also determine whether those values can be overridden by settings in the TX, DEBUG1, and PLL_SIC registers.

63.8.1.19.1 Offset

Register	Offset	Description
TRIM_OVERRIDE_EN	130h	USB PHY Trim Override Enable Register
TRIM_OVERRIDE_EN_SET	134h	Writing a 1 to a bit in this register sets the corresponding bit in TRIM_OVERRIDE_EN
TRIM_OVERRIDE_EN_CLR	138h	Writing a 1 to a bit in this register clears the corresponding bit in TRIM_OVERRIDE_EN
TRIM_OVERRIDE_EN_TOG	13Ch	Writing a 1 to a bit in this register toggles the corresponding bit in TRIM_OVERRIDE_EN

63.8.1.19.2 Diagram



63.8.1.19.3 Fields

Field	Description
31-28 TRIM_USBPHY_TX_CAL45DN	TRIM_USBPHY_TX_CAL45DN IFR value of TX_CAL45DN.
27-24 TRIM_USBPHY_TX_CAL45DP	TRIM_USBPHY_TX_CAL45DP IFR value of TX_CAL45DP.

Table continues on the next page...

Field	Description
23-20 TRIM_USBPHY_TX_D_CAL	TRIM_USBPHY_TX_D_CAL IFR value of TX_D_CAL.
19-18 TRIM_USB_REG_ENV_TAIL_ADJ_VD	TRIM_USB_REG_ENV_TAIL_ADJ_VD IFR value of ENV_TAIL_ADJ.
17-15 TRIM_PLL_CTRL0_DIV_SEL	TRIM_PLL_CTRL0_DIV_SEL IFR value of PLL_DIV_SEL.
14-13 TRIM_USB2_REFBIAS_TST	TRIM_USB2_REFBIAS_TST Bias current control for usb2_phy
12-10 TRIM_USB2_REFBIAS_VBGADJ	TRIM_USB2_REFBIAS_VBGADJ Adjustment bits for bandgap
9-7 —	Reserved Reserved. This bit field must remain at value 1'b0.
6 TRIM_REFBIAS_TST_OVERRIDE	Override enable for bias current control When this field is set, the register value in DEBUG1[USB2_REFBIAS_TST] will be used.
5 TRIM_REFBIAS_VBGADJ_OVERRIDE	Override enable for bandgap adjustment. When this field is set, the register value in DEBUG1[USB2_REFBIAS_VBGADJ] will be used.
4 TRIM_TX_CAL45DN_OVERRIDE	TRIM_TX_CAL45DN_OVERRIDE Override enable for TX_CAL45DN, when set, the register value in TX[TXCAL45DN] will be used.
3 TRIM_TX_CAL45DP_OVERRIDE	TRIM_TX_CAL45DP_OVERRIDE Override enable for TX_CAL45DP, when set, the register value in TX[TXCAL45DP] will be used.
2 TRIM_TX_D_CAL_OVERRIDE	TRIM_TX_D_CAL_OVERRIDE Override enable for TX_D_CAL, when set, the register value in TX[D_CAL] will be used.
1 TRIM_ENV_TAIL_ADJ_VD_OVERRIDE	TRIM_ENV_TAIL_ADJ_VD_OVERRIDE Override enable for ENV_TAIL_ADJ, when set, the register value in DEBUG1[ENTAILADJVD] will be used.
0 TRIM_DIV_SEL_OVERRIDE	TRIM_DIV_SEL_OVERRIDE Override enable for PLL_DIV_SEL, when set, the register value in PLL_SIC[PLL_DIV_SEL] will be used.

Chapter 64
USB Device Charger Detection Module (USBDCD)

Signal multiplexing	IOMUX	External Signals and Pin Multiplexing IOMUX
Interrupts, DMA Events and XBAR Assignments	-	Interrupts, DMA Events and XBAR Assignments

64.2 Overview

The USBDCD module works with the USB transceiver to detect whether the USB device is attached to a Charging Port, either a Dedicated Charging Port (DCP) or a Charging Downstream Port (CDP). System software coordinates the detection activites of the module and controls an off-chip integrated circuit that performs the battery charging.

There can be separate instantiations of the USBDCD module for each USB port. The instantiation for the High-Speed capable USB port is named USBHSDCD, so that it can be differentiated from the instantiation for Full-Speed/Low-Speed USB port which retains the name USBDCD. See the chip-specific information for the specific instantiation of your device.

The use of the term "USB transceiver" in this module documentation applies to the USB physical layer instance on the chip, whether it is a FS/LS only transceiver or a HS/FS/LS capable PHY.

64.2.1 Block diagram

The following figure is a high level block diagram of the module.

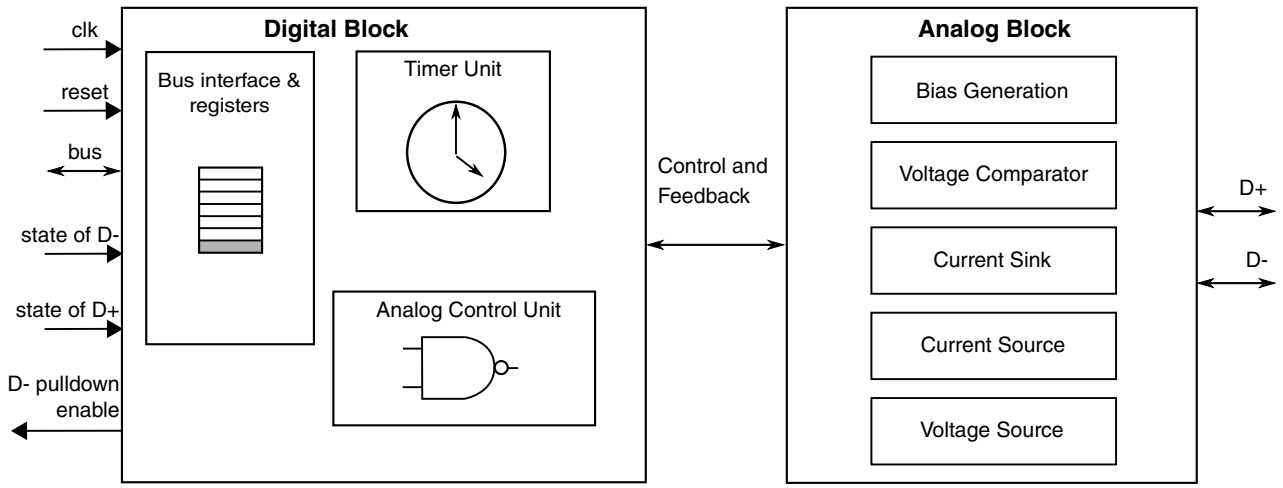

Figure 64-1. Block diagram

The USBDCD module consists of two main blocks:

- A digital block provides the programming interface (memory-mapped registers) and includes the timer unit and the analog control unit.
- An analog block provides the circuitry for the physical detection of the charger, including the bias generation, voltage source, current source, current sink, and voltage comparator circuitry. This block also contains necessary muxes between the source/sink circuits and the D- and D+ pins.

64.2.2 Features

The USBDCD module offers the following features:

- Compliant with the latest industry standard specifications: *USB Battery Charging Specification, Revisions 1.1 and 1.2*
- Programmable timing parameters default to values required by the industry standards:

- Having standard default values allows for easy configuration - simply set the clock frequency before enabling the module.
- Programmability allows the flexibility to meet future updates of the standards.

64.3 Functional description

The sequence of detecting the presence of charging port and type of charging port involves several hardware components, coordinated by system software. This collection of interacting hardware and software is called the USB Battery Charging Subsystem. The following figure shows the USBDCD module as a component of the subsystem. The following table describes the components.

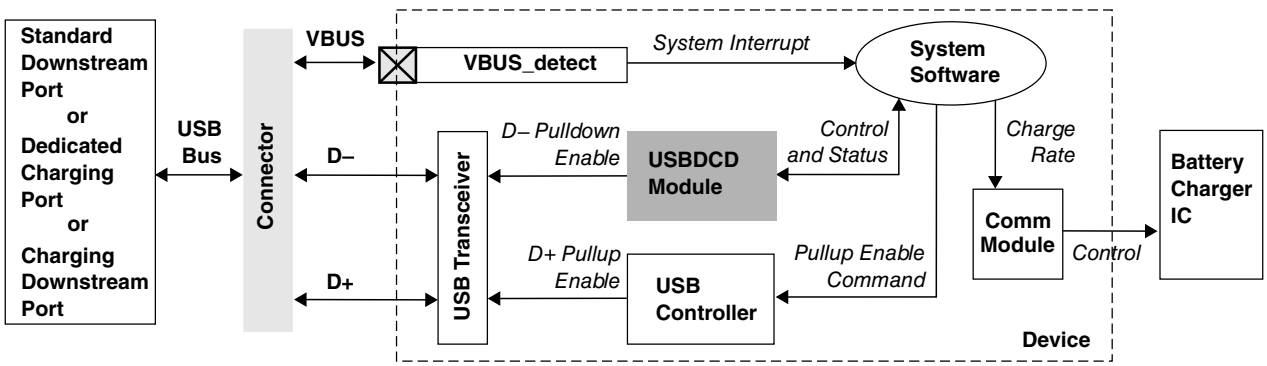

Figure 64-2. USB battery charging subsystem

Table 64-2. USB battery charger subsystem components

Component	Description
Battery Charger IC	The external battery charger IC regulates the charge rate to the rechargable battery. System software is responsible for communicating the appropriate charge rates. **Charger** / **Maximum current drawn** Standard Downstream Port (SDP) / up to 500 mA (I_{CFG_MAX}) Charging Downstream Port (CDP) / up to 1500 mA (I_{DEV_CHG}) Dedicated Charging Port (DCP) / up to 1500 mA (I_{DEV_CHG}) 1. If a USB SDP host has suspended the USB device, current drawn by the device has to follow the rules of the Dead Battery Provision in the *USB Battery Charging Specification, Rev. 1.2*.
Comm Module	A communications module on the device can be used to control the charge rate of the battery charger IC.
System software	Coordinates the detection activities of the subsystem.

Table continues on the next page...

Table 64-2. USB battery charger subsystem components (continued)

Component	Description
USB Controller	The D+ pullup enable control signal plays a role during the charger type detection phase. System software must issue a command to the USB controller to assert this signal. After this pullup is enabled, the device is considered to be connected to the USB bus. The host then attempts to enumerate it. **NOTE:** The USB controller must be used only for USB device applications when using the USBDCD module. For USB host applications, the USBDCD module must be disabled.
USB Transceiver	The USB transceiver contains the pullup resistor for the USB D+ signal and the pulldown resistors for the USB D+ and D– signals. The D+ pullup and the D– pulldown are both used during the charger detection sequence in BC1.1, but it is not used during charger detection in BC1.2. The USB transceiver also outputs the digital state of the D+ and D– signals from the USB bus. The pullup and pulldown enable signals are controlled by other modules during the charger detection sequence in BC1.1: The D+ pullup enable is output from the USB controller and is under software control. The USBDCD module controls the D– pulldown enable.
USBDCD Module	Detects whether the device has been plugged into either an SDP, a CDP, or a DCP.
VBUS_detect	This interrupt pin connected to the USB VBUS signal detects when the device has been plugged into or unplugged from the USB bus. If the system requires waking up from a low power mode on being plugged into the USB port, this interrupt should also be a low power wake up source. If this pin multiplexes other functions, such as GPIO, the pin can be configured as an interrupt so that the USB plug or unplug event can be detected.

1. If a USB SDP host has suspended the USB device, current drawn by the device has to follow the rules of the Dead Battery Provision in the *USB Battery Charging Specification, Rev. 1.2*.

64.3.1 Modes of operation

The operating modes of the USBDCD module are shown in the following table.

Table 64-3. Module modes and their conditions

Module mode	Description	Conditions when used
Enabled for Charger Detection	The module performs the charger detection sequence.	System software should enable the module only when *all* of the following conditions are true: • The system uses a rechargeable battery or is otherwise capable of being powered up by an SDP or a Charging Port. • The device is being used in a USB device application. • The device has detected that it is attached to the USB cable.
Enabled for Signal Overrides	Module bias circuits are enabled for special signaling on DP/DM pins.	See description for SIGNAL_OVERRIDE[PS] bit field.
Disabled	The module is not active and is held in a low power state.	System software should disable the module when *either* of the following conditions is true:

Table continues on the next page...

Table 64-3. Module modes and their conditions (continued)

Module mode	Description	Conditions when used
		• The charger detect sequence is complete. • The conditions for being enabled are not met.
Powered Off	The digital supply voltage dvdd is removed.	Low system performance requirements allow putting the device into a very low-power stop mode.

Operating mode transitions are shown in the following table.

Table 64-4. Entering and exiting module modes

Module mode	Entering	Exiting	Mode after exiting
Enabled	Set CONTROL[START].	Set CONTROL[SR].[1]	Disabled
Disabled	Take *either* of the following actions: • Set CONTROL[SR].[1] • Reset the module. By default, the module is disabled.	Set CONTROL[START].	Enabled
Powered Off	Perform the following actions: 1. Put the device into very low-power stop mode. 2. Adjust the supply voltages.	Perform the following actions: 1. Restore the supply voltages. 2. Take the device out of very low-power stop mode.	Disabled

1. The effect of setting the SR bit is immediate; that is, the module is disabled even if the sequence has not completed.

64.3.2 The charger detection sequence

The following figure illustrates the charger detection sequence in a simplified timing diagram based on the *USB Battery Charging Specification, Rev. 1.2*.

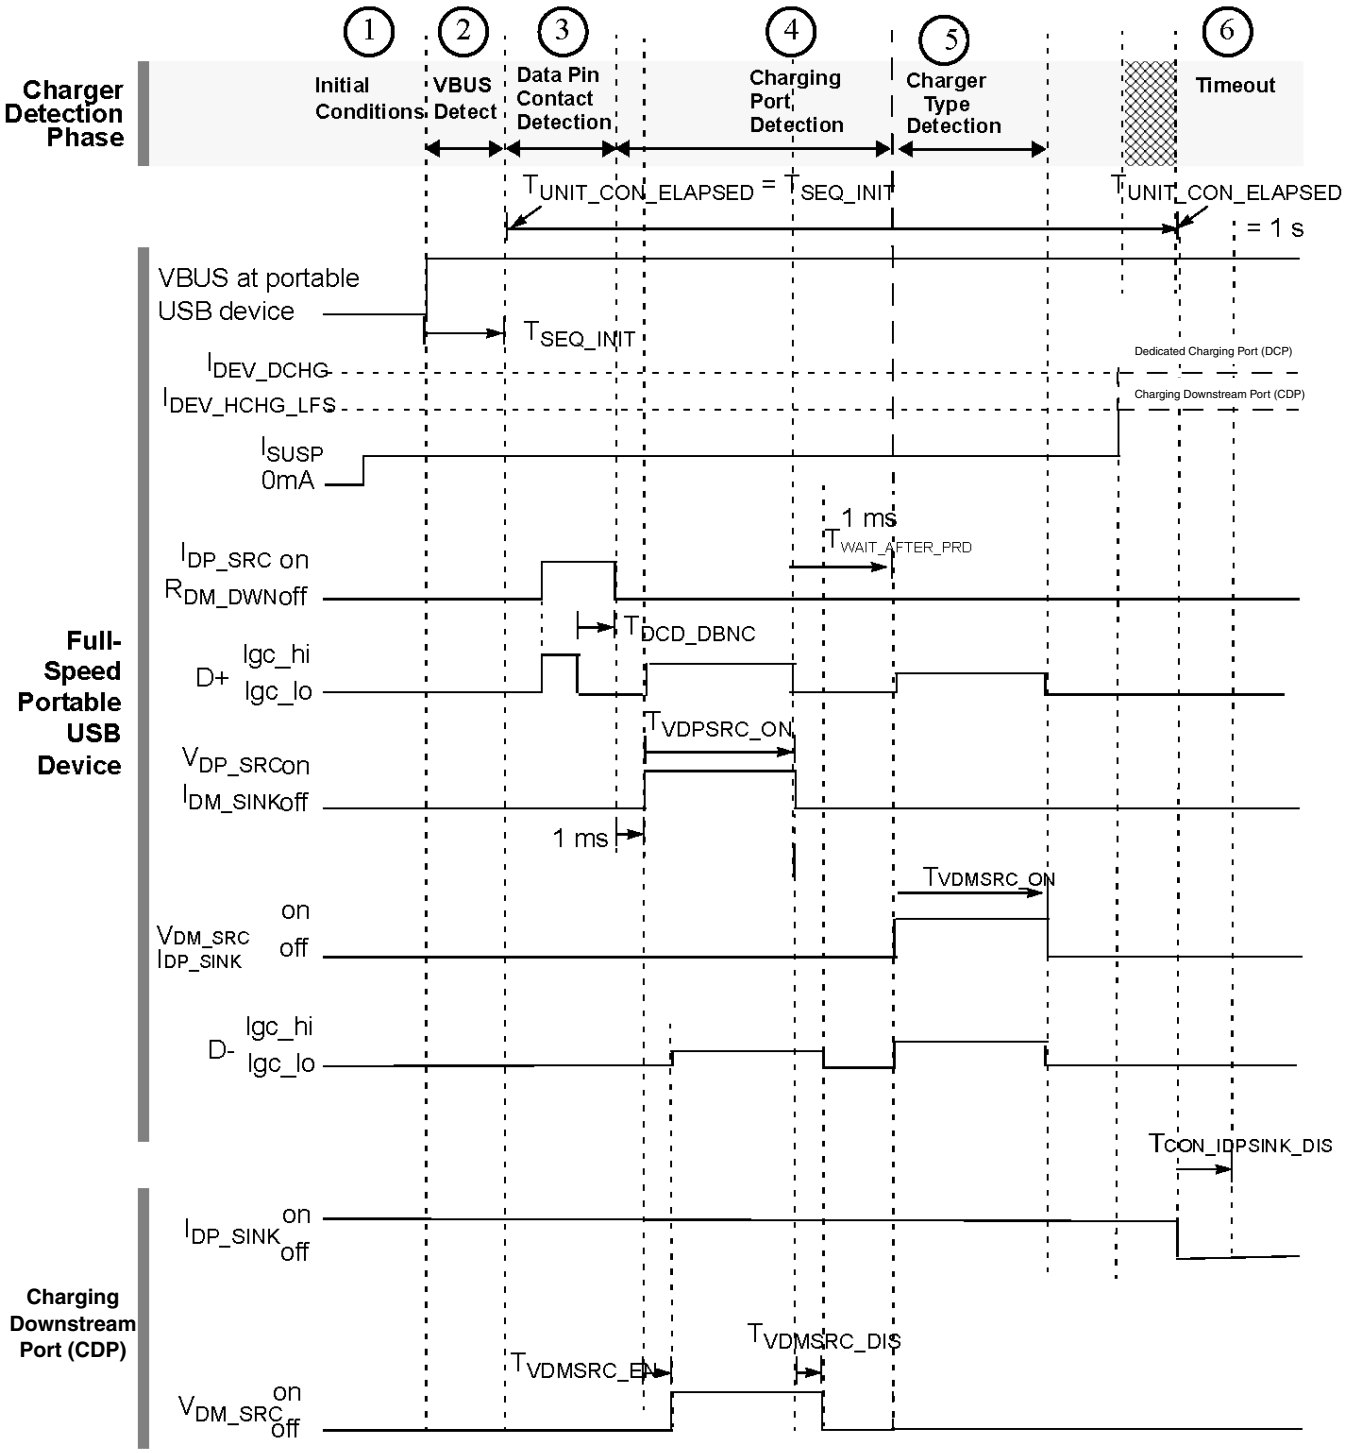

Figure 64-3. Full speed charger detection timing for BC1.2

Timing parameter values used in this module for BC1.2 are listed in the following table.

Table 64-5. Timing parameters for the charger detection sequence for BC1.2

Parameter	USB Battery Charging Spec	Module default	Module programmable range
$T_{DCD_DBNC'}$ [1]	10 ms min (no max)	10 ms	0– 1023 ms
T_{VDPSRC_ON} [1]	40 ms min (no max)	40 ms	0 –1023 ms
$T_{WAIT_AFTER_PRD}$	N/A	1 ms	0– 1023 ms
T_{VDMSRC_ON}	40 ms	40 ms	0 –1023 ms
T_{SEQ_INIT}	N/A	16 ms	0 –1023 ms
T_{UNIT_CON} [1]	1 s	N/A	N/A
T_{VDMSRC_EN} [1]	1– 20 ms	From the USB host	N/A
T_{VDMSRC_DIS} [1]	0 – 20 ms	From the USB host	N/A
$T_{CON_IDPSINK_DIS}$ [1]	0 – 10 ms	From the USB host	N/A

1. This parameter is defined by the *USB Battery Charging Specification, Rev. 1.2*.

The following figure illustrates the charger detection sequence in a simplified timing diagram based on the *USB Battery Charging Specification, Rev. 1.1*.

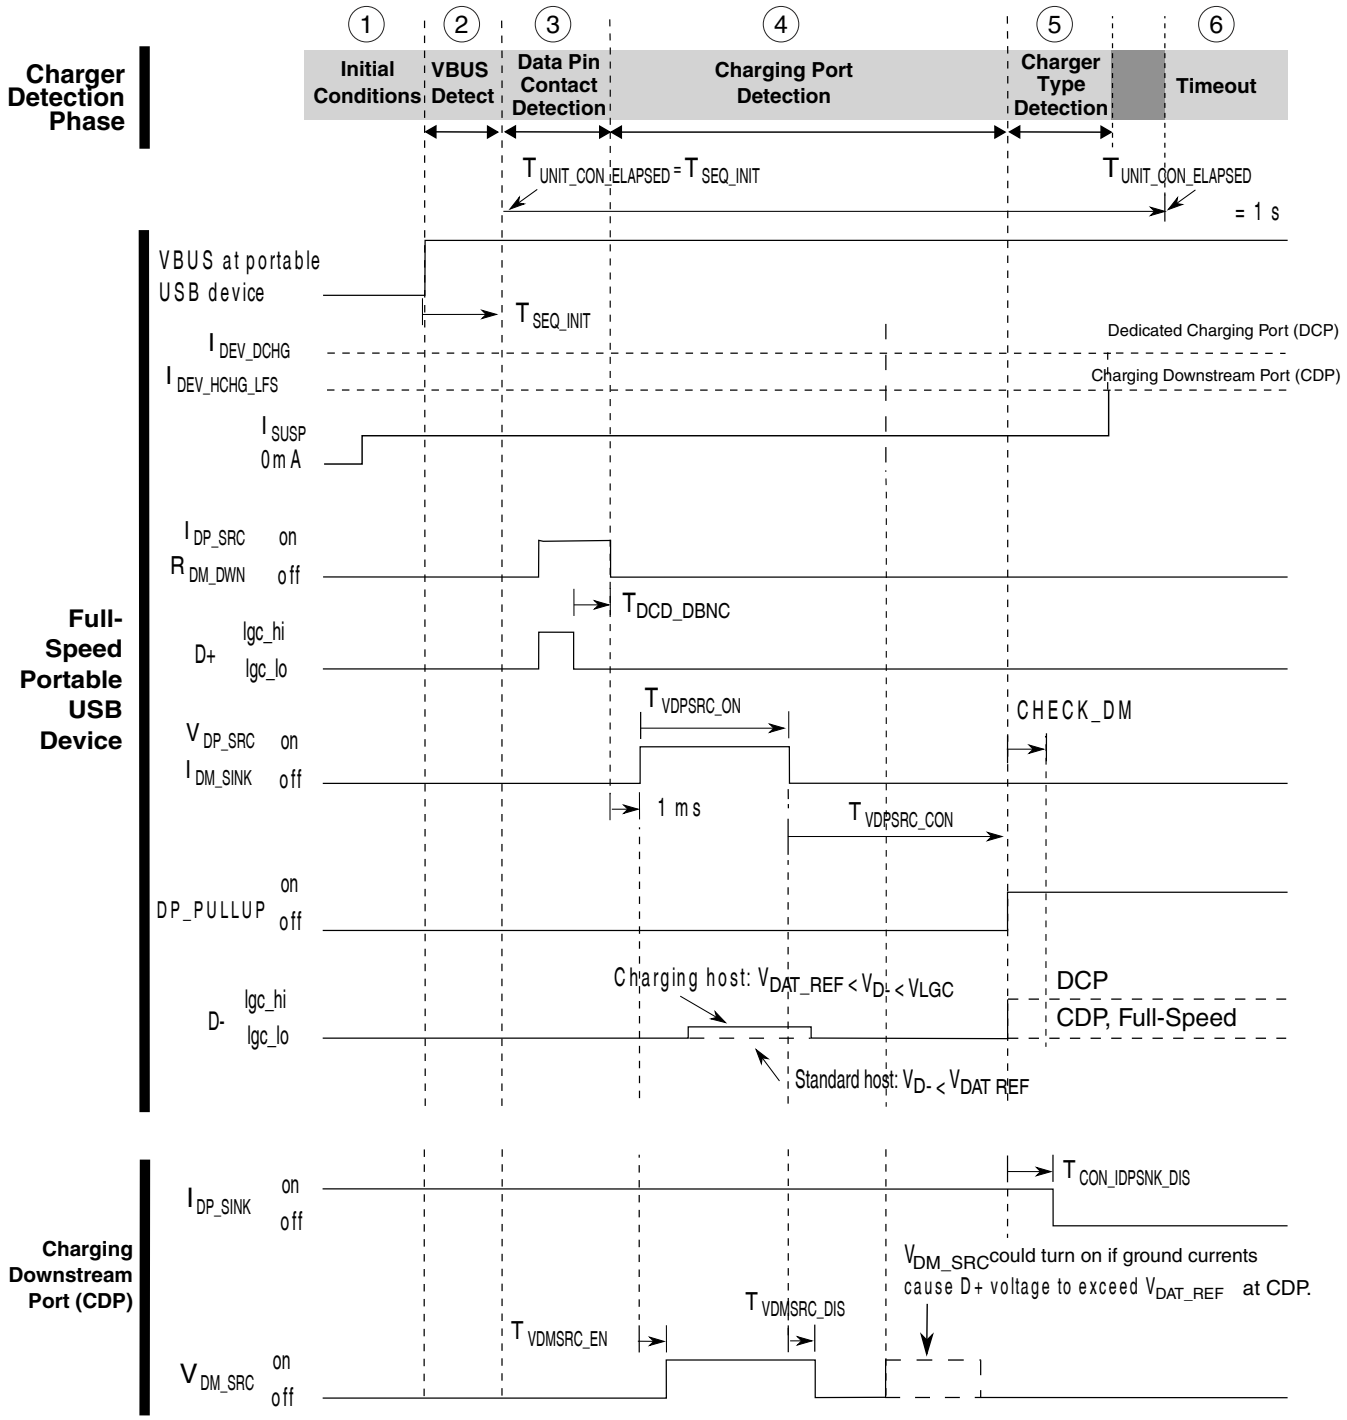

Figure 64-4. Full speed charger detection timing for BC1.1

Timing parameter values used in this module for BC1.1 are listed in the following table.

Table 64-6. Timing parameters for the charger detection sequence for BC1.1

Parameter	USB Battery Charging Spec	Module default	Module programmable range
$T_{DCD_DBNC'}$ [1]	10 ms min (no max)	10 ms	0– 1023 ms
T_{VDPSRC_ON} [1]	40 ms min (no max)	40 ms	0 –1023 ms
T_{VDPSRC_CON} [1]	40 ms min (no max)	40 ms	0 –1023 ms
CHECK_DM	N/A	1 ms	0– 15 ms
T_{SEQ_INIT}	N/A	16 ms	0 –1023 ms
T_{UNIT_CON} [1]	1 s	N/A	N/A
T_{VDMSRC_EN} [1]	1– 20 ms	From the USB host	N/A
T_{VDMSRC_DIS} [1]	0 –20 ms	From the USB host	N/A
$T_{CON_IDPSINK_DIS}$ [1]	0– 20 ms	From the USB host	N/A

1. This parameter is defined by the *USB Battery Charging Specification, Rev. 1.1*.

The following table provides an overview description of the charger detection sequence shown in the preceding figure.

Table 64-7. Overview of the charger detection sequence

Phase		Overview description	Full description
1	Initial Conditions	Initial system conditions that need to be met before the detection sequence is initiated.	Initial System Conditions
2	VBUS Detection	System software detects contact of the VBUS signal with the system interrupt pin VBUS_detect.	VBUS contact detection
3	Data Pin Contact Detection	The USBDCD module detects that the USB data pins D+ and D– have made contact with the USB port.	Data pin contact detection
4	Charging Port Detection	The USBDCD module detects if the port is an SDP or either type of charging port, that is CDP or DCP.	Charging port detection
5	Charger Type Detection	The USBDCD module detects the type of charging port, if applicable.	Charger type detection
6	Sequence Timeout	The USBDCD module did not finish the detection sequence within the timeout interval. The sequence will continue until halted by software.	Charger detection sequence timeout

64.3.2.1 Initial System Conditions

The USBDCD module is intended for use with USB device applications using a rechargable battery. The module does not have support for interfacing with ACA or ACA-Dock equipment as defined in the *USB Battery Charging Specification, Revision 1.2*. It cannot be used with USB applications that are embedded host or OTG.

In addition, before the USBDCD module's charger detection sequence can be initiated, the system must be:

- Powered-up and in run mode. The USBDCD instantiation of this module for the High-Speed port does not directly depend on the VBUS voltage and can operate as long as the avdd33 supply is in a valid range.
- Recently plugged into a USB port.
- Drawing not more than 2.5 mA total system current from the USB bus, except as allowed by the *USB 2.0 Connect Timing Update ECN*.

Examples of allowable precursors to this set of initial conditions include:

- A powered-down device is subsequently powered-up upon being plugged into the USB bus.
- A device in a low power mode subsequently enters run mode upon being plugged into the USB bus.

64.3.2.2 VBUS contact detection

Once the device is plugged into a USB port, the VBUS_detect system interrupt is triggered. System software must do the following to initialize the module and start the charger detection sequence:

1. Restore power if the module is powered-off.
2. Set CONTROL[SR] to initiate a software reset.
3. Configure the USBDCD module by programming the CLOCK register and the timing parameters as needed.
4. Set CONTROL[IE] to enable interrupts, or clear the bit if software polling method is used.
5. Program CONTROL[BC12] based on which revision of the USB Battery Charging Specification is needed.
6. Set CONTROL[START] to start the charger detection sequence.

64.3.2.3 Data pin contact detection

The module must ensure that the data pins have made contact because the detection sequence depends upon the state of the USB D+ and D- signals. USB plugs and receptables are designed such that when the plug is inserted into the receptable, the power pins make contact before the data pins make contact. See the following figure.

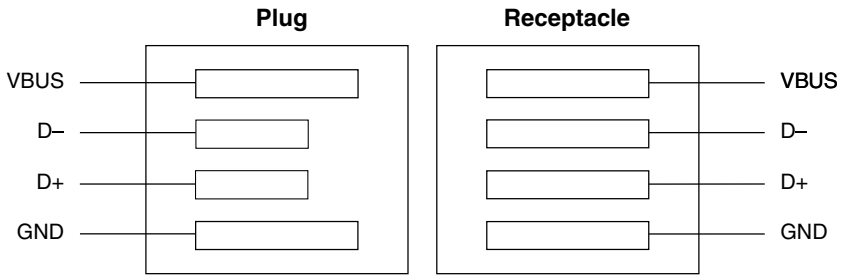

Figure 64-5. Relative pin positions in USB plugs and receptacles

As a result, when a portable USB device is attached to an upstream port, the portable USB device detects VBUS before the data pins have made contact. The time between power pins and data pins making contact depends on how fast the plug is inserted into the receptable. Delays of several hundred milliseconds are possible.

64.3.2.3.1 Debouncing the data pin contact

When system software has initiated the charger detection sequence, as described in Initial System Conditions, the USBDCD module turns on the I_{DP_SRC} current source and enables the R_{DM_DWN} pulldown resistor. If the data pins have not made contact, the D+ line remains high. After the data pins make contact, the D+ line goes low and debouncing begins.

After the D+ line goes low, the module continuously samples the D+ line over the duration of the T_{DCD_DBNC} debounce time interval.By deafult, T_{DCD_DBNC} is 10 ms, but it can be programmed in the TIMER0[TDCD_DBNC] field. See the description of the TIMER0 Register for register information.

When it has remained low for the entire interval, the debouncing is complete. However, if the D+ line returns high during the debounce interval, the module waits until the D+ line goes low again to restart the debouncing. This cycle repeats until either of the following happens:

- The data pin contact has been successfully debounced (see Success in detecting data pin contact (phase completion)).
- A timeout occurs (see Charger detection sequence timeout).

64.3.2.3.2 Success in detecting data pin contact (phase completion)

After successfully debouncing the D+ state, the module does the following:

- Updates the STATUS register to reflect phase completion (See Table 64-12 for field values.)
- Directly proceeds to the next step in the sequence: detection of a charging port (See Charging port detection.)

64.3.2.4 Charging port detection

After it detects that the data pins have made contact, the module waits for a fixed delay of 1 ms, and then attempts to detect whether it is plugged into a charging port. The module connects the following analog units to the USB D+ or D– lines during this phase:

- The voltage source V_{DP_SRC} connects to the D+ line
- The current sink I_{DM_SINK} connects to the D– line
- The voltage comparator connects to the USB D– line, comparing it to the voltage V_{DAT_REF}.

After a time of T_{VDPSRC_ON}, the module samples the D– line. The T_{VDPSRC_ON} parameter is programmable and defaults to 40 ms. After sampling the D– line, the module disconnects the voltage source, current sink, and comparator.

The next steps in the sequence depend on the voltage on the D– line as determined by the voltage comparator. See the following table.

Table 64-8. Sampling D– in the charging port detection phase

If the voltage on D- is...	Then...	See...
Below V_{DAT_REF}	The port is an SDP that does not support using charging currents above I_{CFG_MAX}.	Standard downstream port
Above V_{DAT_REF} but below V_{LGC}	The port is a charging port.	Charging port
Above V_{LGC}	This is an error condition.	Error in charging port detection

64.3.2.4.1 Standard downstream port

As part of the charger detection handshake with a standard USB host, the module does the following without waiting for the interval ($T_{WAIT_AFTER_PRD}$ or T_{VDPSRC_CON}) to elapse:

- Updates the STATUS register to reflect that a standard downstream port (SDP) has been detected with SEQ_RES = 01. See Table 64-12 for field values.
- Sets CONTROL[IF].
- Generates an interrupt if enabled in CONTROL[IE].

At this point, control has been passed to system software via the interrupt. The rest of the sequence, which detects the type of charging port, is not applicable, so software should perform the following steps:

1. Read the STATUS register.
2. Set CONTROL[IACK] to acknowledge the interrupt.
3. Set CONTROL[SR] to issue a software reset to the module.
4. Disable the module.
5. Communicate the appropriate charge rate to the external battery charger IC; see Table 64-2.

64.3.2.4.2 Charging port

As part of the charger detection handshake with any type of USB host, the module waits until the interval ($T_{WAIT_AFTER_PRD}$ or T_{VDPSRC_CON}) has elapsed before it does the following:

For *USB Battery Charging Specification, Rev. 1.2*:

- Enables V_{DM_SRC}.
- Updates the STATUS register to reflect that a charging port has been detected with SEQ_RES = 10. See Table 64-12 for field values.
- At this point the detection sequence progresses to Charger type detection without needing software interaction.

For *USB Battery Charging Specification, Rev. 1.1*:

- Updates the STATUS register to reflect that a charging port has been detected with SEQ_RES = 10. See Table 64-12 for field values.
- Sets CONTROL[IF].

- Generates an interrupt if enabled in CONTROL[IE].
- At this point, control has passed to system software via the interrupt. Software should:

1. Read the STATUS register.
2. Set CONTROL[IACK] to acknowledge the interrupt.
3. Issue a command to the USB controller to pullup the USB D+ line.
4. Wait for the module to complete the final phase of the sequence. See Charger type detection.

64.3.2.4.3 Error in charging port detection

For this error condition, the module does the following:

- Updates the STATUS register to reflect the error with SEQ_RES = 00. See Table 64-12 for field values.
- Sets CONTROL[IF].
- Generates an interrupt if enabled in CONTROL[IE].

Note that in this case the module does not wait for the interval ($T_{WAIT_AFTER_PRD}$ or T_{VDPSRC_CON}) to elapse.

At this point, control has been passed to system software via the interrupt. The rest of the sequence (detecting the type of charging port) is not applicable, so software should:

1. Read the STATUS register.
2. Set CONTROL[IACK] to acknowledge the interrupt.
3. Set CONTROL[SR] to issue a software reset to the module.
4. Disable the module.

64.3.2.5 Charger type detection

For *USB Battery Charging Specification, Rev. 1.2*:

After the USBDCD module enables the V_{DM_SRC}, the module starts the T_{VDMSRC_ON} timer counting down the time interval programmed into the TIMER2[T_{VDMSRC_ON}] field.

Once the T_{VDMSRC_ON} timer has elapsed, the module samples the USB D+ line to determine the type of charger. See the following table.

Table 64-9. Sampling D+ in the charger type detection phase (BC1.2)

If the voltage on D+ is...	Then...	See...
High (D+>V_{DAT_REF})	The port is a DCP. [1]	Dedicated charging port
Low (D+<V_{DAT_REF})	The port is a CDP. [2]	Charging downstream port

1. In a DCP, the D+ and D– lines are shorted together through a small resistor.
2. In a CDP, the D+ and D– lines are not shorted.

For *USB Battery Charging Specification, Rev. 1.1*:

After software enables the D+ pullup resistor, the module is notified automatically (via internal signaling) to start the CHECK_DM timer counting down the time interval programmed in the TIMER2[CHECK_DM] field.

After the CHECK_DM time has elapsed, the module samples the USB D– line to determine the type of charger. See the following table.

Table 64-10. Sampling D– in the charger type detection phase (BC1.1)

If the voltage on D– is...	Then...	See...
High	The port is a DCP. [-1]	Dedicated charging port
Low	The port is a CDP. [-1]	Charging downstream port

64.3.2.5.1 Dedicated charging port

For a dedicated charging port (DCP), the module does the following:

- Updates the STATUS register to reflect that a dedicated charging port has been detected with SEQ_RES = 11. See Table 64-12 for field values.
- Sets CONTROL[IF].
- Generates an interrupt if enabled in CONTROL[IE] bit.

The *USB Battery Charging Specification, Rev. 1.2* indicates that additionally if the detection sequence determines an attachment to a DCP, then the USB device should signal on the D+ pin by either enabling the D+ pullup resistor or enabling V_{DP_SRC}.

At this point, control has been passed to system software via the interrupt. Software should:

1. Read the STATUS register.
2. Disable the USB controller to prevent transitions on the USB D+ or D– lines from causing spurious interrupt or wakeup events to the system.
3. Set CONTROL[IACK] to acknowledge the interrupt.
4. Set CONTROL[SR] to issue a software reset to the module.
5. Disable the module.
6. Enable signaling on the D+ pin. This can be done by enabling the Transceiver D+ pullup resistor through configuration of register bit fields in the USB controller instance for this USB port. On this product this signaling can alternatively be done by enabling V_{DP_SRC} through setting the SIGNAL_OVERRIDE[PS] bit field to a value of 2'b10.
7. Communicate the appropriate charge rate to the external battery charger IC; see Table 64-2.

64.3.2.5.2 Charging downstream port

For a charging downstream port (CDP), the module does the following:

- Updates the STATUS register to reflect that a CDP has been detected with SEQ_RES = 10. See Table 64-12 for field values.
- Sets CONTROL[IF].
- Generates an interrupt if enabled in CONTROL[IE].

At this point, control has been passed to system software via the interrupt. Software should:

1. Read the STATUS register.
2. Set CONTROL[IACK] to acknowledge the interrupt.
3. Set CONTROL[SR] to issue a software reset to the module.
4. Disable the module.
5. Communicate the appropriate charge rate to the external battery charger IC; see Table 64-2.

64.3.2.6 Charger detection sequence timeout

The maximum time allowed to connect according to the *USB Battery Charging Specification* is one second. If the Unit Connection Timer reaches the one second limit and the sequence is still running as indicated by the STATUS[ACTIVE] bit, the module does the following:

- Updates the STATUS register to reflect that a timeout error has occured. See Table 64-12 for field values.
- Sets the CONTROL[IF] bit.
- Generates an interrupt if enabled in CONTROL[IE].
- The detection sequence continues until explicitly halted by software setting the CONTROL[SR] bit.
- The Unit Connection Timer continues counting. See the description of the TIMER0 Register.

At this point, control has been passed to system software via the interrupt, which has two options: ignore the interrupt and allow more time for the sequence to complete, or halt the sequence. To halt the sequence, software should:

1. Read the STATUS register.
2. Set the CONTROL[IACK] bit to acknowledge the interrupt.
3. Set the CONTROL[SR] bit to issue a software reset to the module.
4. Disable the module.

This timeout function is also useful in case software does not realize that the USB device is unplugged from USB port during the charger detection sequence. If the interrupt occurs but the V_{BUS_DETECT} input is low, software can disable and reset the module.

System software might allow the sequence to run past the timeout interrupt under these conditions:

1. The USB Battery Charging Spec is amended to allow more time. In this case, software should poll TIMER0[$T_{UNITCON}$] periodically to track elapsed time after 1s; or
2. For debug purposes.

Note that the $T_{UNITCON}$ register field will stop incrementing when it reaches its maximum value so it will not rollover to zero and start counting up again.

64.3.2.7 Dead Battery Provision signaling

If the system needs to operate under the Dead Battery Provision of the *USB Battery Charging Specification, Revision 1.2*, the USBDCD module must be configured to signal V_{DP_SRC} on the USB_DP pin.

For information on Dead Battery Provision conditions and signaling, see the Dead or weak battery later in this chapter.

64.3.3 Resets

There are two ways to reset various register contents in this module: hardware resets and a software reset.

64.3.3.1 Hardware resets

Hardware resets originate at the system or device level and propagate down to the individual module level. They include start up reset, low-voltage reset, and all other hardware reset sources.

Hardware resets cause the register contents to be restored to their default state as listed in the register descriptions.

64.3.3.2 Software reset

A software reset re-initializes the module's status information, but leaves configuration information unchanged. The software reset allows software to prepare the module without needing to reprogram the same configuration each time the USB device is plugged into a USB port.

Setting CONTROL[SR] initiates a software reset. The following table shows all register fields that are reset to their default values by a software reset.

Table 64-11. Software reset and register fields affected

Register	Fields affected	Fields not affected
CONTROL[1]	IF	IE, START
STATUS	All	None
CLOCK	None	All

Table continues on the next page...

Table 64-11. Software reset and register fields affected (continued)

Register	Fields affected	Fields not affected
TIMER*n*	TUNITCON	All other

1. CONTROL[SR] and CONTROL[IACK] are self-clearing.

A software reset also returns all internal logic, timers, and counters to their reset states. If the module is already active (STATUS[ACTIVE] = 1), a software reset stops the sequence.

Note

Software must always initiate a software reset before starting the sequence to ensure the module is in a known state.

64.3.4 Interrupts

The USBDCD module has an interrupt to alert system software of certain events, which are listed in the following table. All events except the Phase Complete event for the Data Pin Detection phase can trigger an interrupt.

Table 64-12. Events triggering an interrupt by sequence phase

Sequence phase	Event	Event description	STATUS fields [1]	Phase description
Data Pin Detection	Phase Complete	The module has detected data pin contact. *No interrupt occurs*: CONTROL[IF] = 0.	ERR = 0 SEQ_STAT = 01 SEQ_RES = 00 TO = 0	VBUS contact detection
Charging Port Detection	Phase Complete	The module has completed the process of identifying if the USB port is a charging port or not. **NOTE:** An interrupt is triggered at completion of this phase for BC 1.1 operation whether an SDP or a Charging port is detected. For BC 1.2 operation, if an SDP is detected an interrupt is triggered but if a Charging port is detected the sequence goes directly to the Charger Type Detection phase.	ERR = 0 SEQ_STAT = 10 SEQ_RES = 01 or 10 TO = 0	Charging port detection
	Error	The module cannot identify the type of port because the D– line is above the USB's VLGC threshold.	ERR = 1 SEQ_STAT = 10 SEQ_RES = 00 TO = 0	Error in charging port detection
Charger Type Detection	Phase Complete	The module has completed the process of identifying the charger type detection.	ERR = 0 SEQ_STAT = 11	Charger type detection

Table continues on the next page...

Table 64-12. Events triggering an interrupt by sequence phase (continued)

Sequence phase	Event	Event description	STATUS fields [1]	Phase description
		NOTE: The ERR flag always reads zero because no known error conditions are checked during this phase.	SEQ_RES = 11 or 10 TO = 0	
Sequence Timeout	Error	The timeout interval from the time the USB device attaches to a USB port until it connects has elapsed.	ERR = 1 SEQ_STAT = last value [2] SEQ_RES = last value [2] TO = 1	Charger detection sequence timeout

1. See the description of the Status register for register information.
2. The SEQ_STAT and SEQ_RES fields retain the values held at the time of the timeout error.

64.3.4.1 Interrupt Handling

Software can read which event caused the interrupt from the STATUS register during the interrupt service routine.

An interrupt is generated only if CONTROL[IE] is set. The CONTROL[IF] bit is always set under interrupt conditions, even if CONTROL[IE] is cleared. In this case, software can poll CONTROL[IF] to determine if an interrupt condition is pending.

Writes to CONTROL[IF] are ignored. To reset CONTROL[IF], set CONTROL[IACK] to acknowledge the interrupt. Writing to CONTROL[IACK] when CONTROL[IF] is cleared has no effect.

64.4 External Signals

This section describes the module signals. The following table shows a summary of module signals that interface with the pins of the device.

Table 64-13. Signal descriptions

Signal	Description	I/O
USB_DM	USB D– analog data signal. The analog block interfaces directly to the D– signal on the USB bus.	I/O
USB_DP	USB D+ analog data signal. The analog block interfaces directly to the D+ signal on the USB bus.	I/O
avdd33 [1]	3.3 V regulated analog supply	I
vss_bulk	Digital/Analog ground	I
dvdd	Core voltage digital supply	I

1. Voltage must be 3.3 V ± 10% for full functionality of the module. That is, the charger detection function does not work when this voltage is below 3.0 V, and the CONTROL[START] bit should not be set.

NOTE

The transceiver module also interfaces to the USB_DM and USB_DP signals. Both modules and the USB host/hub use these signals as bidirectional, tristate signals.

Information about the signal integrity aspects of the lines including shielding, isolated return paths, input or output impedance, packaging, suggested external components, ESD, and other protections can be found in the USB 2.0 Specification and in Application information.

64.5 Initialization information

This module has been designed for minimal configuration while retaining significant programmability. The CLOCK register needs to be initialized to the actual system clock frequency, unless the default value already matches the system requirements.

The proper operation of the USBHSDCD instantiation of this module requires that the USBPHY_ANACTRL[DEV_PULLDOWN] bit field be reset to value 1'b0 during the period when this module is in use.

The other registers generally do not need to be modified, because they default to values that comply with the USB Battery Charging Specification. However, several timing parameters can be changed for a great deal of flexibility if a particular system requires it.

All module configuration must occur *before* initiating the charger detection sequence. Configuration changes made *after* setting CONTROL[START] result in undefined behavior.

64.6 Application information

This section provides application information.

64.6.1 External pullups

Any external pullups applied to the USB D+ or D- data lines must be capable of being disabled to prevent incorrect pullup values or incorrect operation of the USB subsystem.

64.6.2 Dead or weak battery

According to the *USB Battery Charging Specification, Revision 1.2*, a USB device with a dead or weak battery that is attached to an SDP can draw charging current from VBUS without connecting for several minutes, until the battery is charged to the point that the USB device can connect. The conditions for this operation are referred to as the Dead Battery Provision.

The *USB Battery Charging Specification, Revision 1.2* limits this charging condition to 100mA for a duration of 45 minutes. The later *USB 2.0 Connect Timing Update ECN* modifies this charging condition to 500mA for a duration of 2 minutes. Customers designing systems to take advantage of the Dead Battery Provision should study both specifications closely.

The USBDCD module is compatible with systems that do not check the strength of the battery. Therefore, this module assumes that the battery is good, so the USB device must immediately connect to the USB bus by pulling the USB_DP pin high after the USBDCD module has determined that the device is attached to an SDP or CDP. (By definition, a DCP does not support connection but still requires a signaling event, see Dedicated charging port.)

The module is also compatible with systems that have other circuitry to check the strength of the battery. In these systems, if it is known that the battery is weak or dead, software can delay connecting to the USB while charging using the Dead Battery Provision. Once the battery is charged to the good battery threshold, software must then connect to the USB host by pulling the USB_DP pin high.

While using the Dead Battery Provision, the USB_DP pin must signal by enabling V_{DP_SRC}. On this product that signaling can be done most simply by setting the SIGNAL_OVERRIDE[PS] bit field to value 2'b10.

64.6.3 Handling unplug events

If the device is unplugged from the USB bus during the charger detection sequence, the contents of the STATUS register must be ignored and the USBDCD module must get a Software Reset, as described in Software reset.

64.7 Memory map/Register definition

This section describes the memory map and registers for the USBHSDCD module.

64.7.1 USBDCD register descriptions

64.7.1.1 USBDCD memory map

USBHSDCD1 base address: 4043_4800h

USBHSDCD2 base address: 4043_8800h

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)
0	Control register (CONTROL)	32	RW	0001_0000
4	Clock register (CLOCK)	32	RW	0000_00C1
8	Status register (STATUS)	32	RO	0000_0000
C	Signal Override Register (SIGNAL_OVERRIDE)	32	RW	0000_0000
10	TIMER0 register (TIMER0)	32	RW	0010_0000
14	TIMER1 register (TIMER1)	32	RW	000A_0028
18	TIMER2_BC11 register (TIMER2_BC11)	32	RW	0028_0001
18	TIMER2_BC12 register (TIMER2_BC12)	32	RW	0001_0028

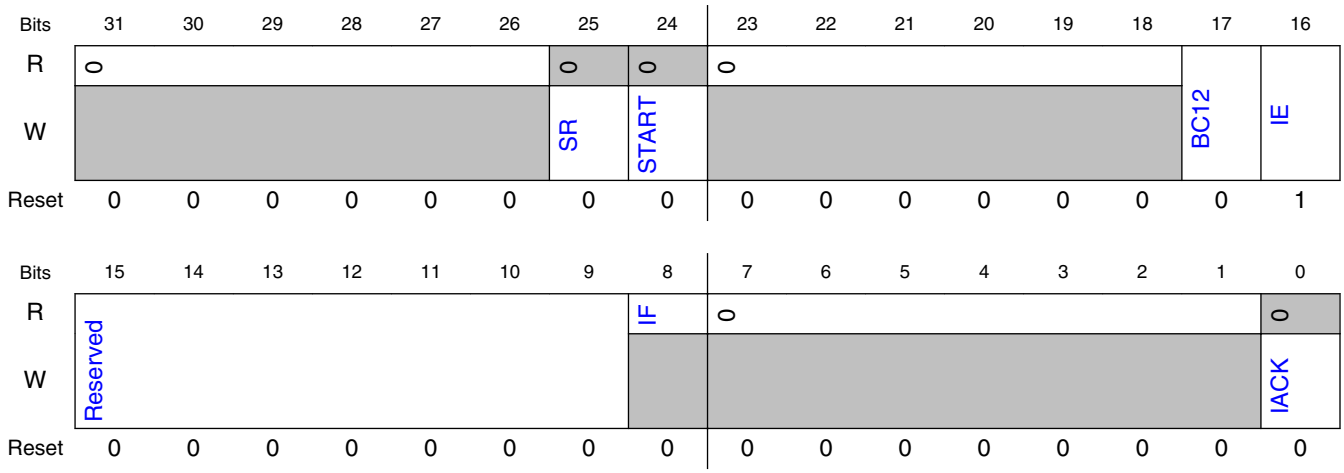
64.7.1.2 Control register (CONTROL)

This register controls various global functions, such as software reset, initiating the charger detection sequence, BC12 compatibility, and interrupt enablement.

64.7.1.2.1 Offset

Register	Offset
CONTROL	0h

64.7.1.2.2 Diagram



64.7.1.2.3 Fields

Field	Description
31-26 —	Reserved
25 SR	Software Reset Determines whether a software reset is performed. 0 - Do not perform a software reset. 1 - Perform a software reset.
24 START	Start Change Detection Sequence Determines whether the charger detection sequence is initiated. 0 - Do not start the sequence. Writes of this value have no effect. 1 - Initiate the charger detection sequence. If the sequence is already running, writes of this value have no effect.
23-18 —	Reserved
17 BC12	BC12 BC1.2 compatibility. This bit cannot be changed after start detection. 0 - Compatible with BC1.1 (default) 1 - Compatible with BC1.2
16 IE	Interrupt Enable Enables/disables interrupts to the system. 0 - Disable interrupts to the system. 1 - Enable interrupts to the system.
15-9 —	Reserved

Table continues on the next page...

Field	Description
8 IF	Interrupt Flag Determines whether an interrupt is pending. 0 - No interrupt is pending. 1 - An interrupt is pending.
7-1 —	Reserved
0 IACK	Interrupt Acknowledge Determines whether the interrupt is cleared. 0 - Do not clear the interrupt. 1 - Clear the IF bit (interrupt flag).

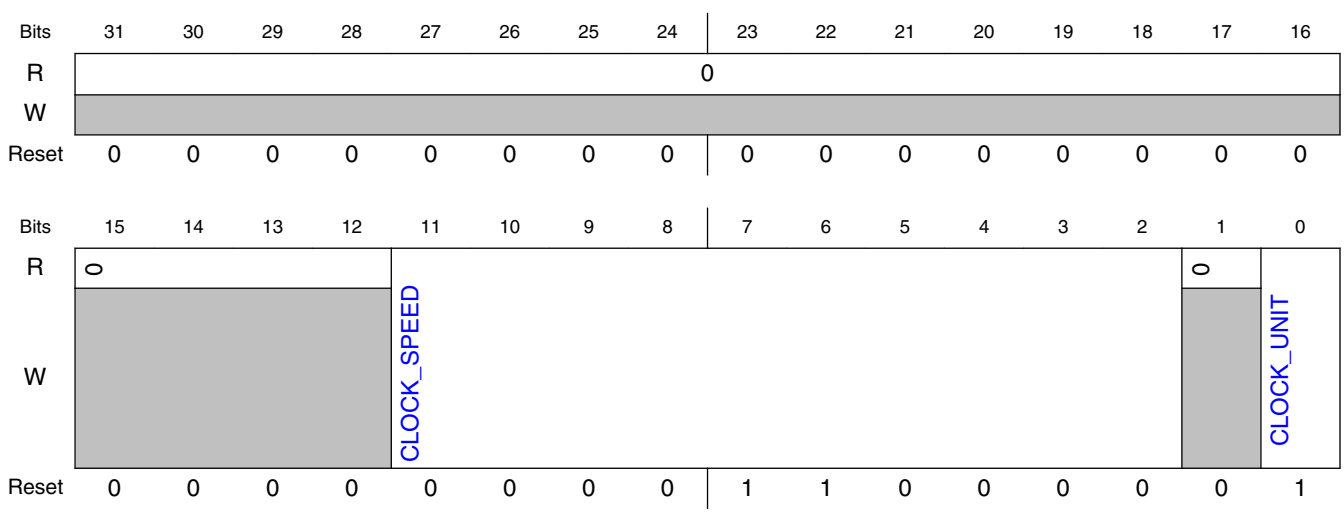
64.7.1.3 Clock register (CLOCK)

This register controls the clock speed.

64.7.1.3.1 Offset

Register	Offset
CLOCK	4h

64.7.1.3.2 Diagram



64.7.1.3.3 Fields

Field	Description
31-12 —	Reserved
11-2 CLOCK_SPEED	Numerical Value of Clock Speed in Binary The unit of measure is programmed in CLOCK_UNIT. The valid range is from 1 to 1023 when clock unit is MHz and 4 to 1023 when clock unit is kHz. Examples with CLOCK_UNIT = 1: • For 48 MHz: 0b00_0011_0000 (48) (Default) • For 24 MHz: 0b00_0001_1000 (24) Examples with CLOCK_UNIT = 0: • For 100 kHz: 0b00_0110_0100 (100) • For 500 kHz: 0b01_1111_0100 (500)
1 —	Reserved
0 CLOCK_UNIT	Unit of Measurement Encoding for Clock Speed Specifies the unit of measure for the clock speed. 0 - kHz Speed (between 1 kHz and 1023 kHz) 1 - MHz Speed (between 1 MHz and 1023 MHz)

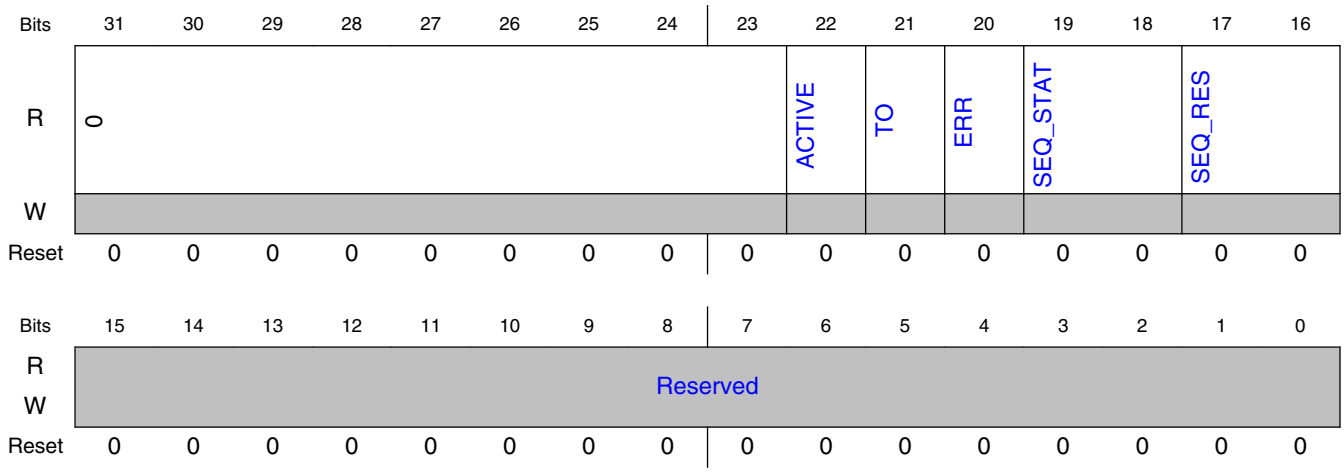
64.7.1.4 Status register (STATUS)

This register stores the current state of the module for system software monitoring.

64.7.1.4.1 Offset

Register	Offset
STATUS	8h

64.7.1.4.2 Diagram



64.7.1.4.3 Fields

Field	Description
31-23 —	Reserved
22 ACTIVE	Active Status Indicator Indicates whether the sequence is running. 0 - The sequence is not running. 1 - The sequence is running.
21 TO	Timeout Flag Indicates whether the detection sequence has passed the timeout threshhold. 0 - The detection sequence has not been running for over 1s. 1 - It has been over 1 s since the data pin contact was detected and debounced.
20 ERR	Error Flag Indicates whether there is an error in the detection sequence. 0 - No sequence errors. 1 - Error in the detection sequence. See the SEQ_STAT field to determine the phase in which the error occurred.
19-18 SEQ_STAT	Charger Detection Sequence Status Indicates the status of the charger detection sequence. 00 - The module is either not enabled, or the module is enabled but the data pins have not yet been detected. 01 - Data pin contact detection is complete. 10 - Charging port detection is complete. 11 - Charger type detection is complete.
17-16	Charger Detection Sequence Results

Table continues on the next page...

Field	Description
SEQ_RES	Reports how the charger detection is attached. 00 - No results to report. 01 - Attached to an SDP. Must comply with USB 2.0 by drawing only 2.5 mA (max) until connected. 10 - Attached to a charging port. The exact meaning depends on bit 18 (value 0: Attached to either a CDP or a DCP. The charger type detection has not completed. value 1: Attached to a CDP. The charger type detection has completed.) 11 - Attached to a DCP.
15-0 —	Reserved **NOTE:** Bits do not always read as 0.

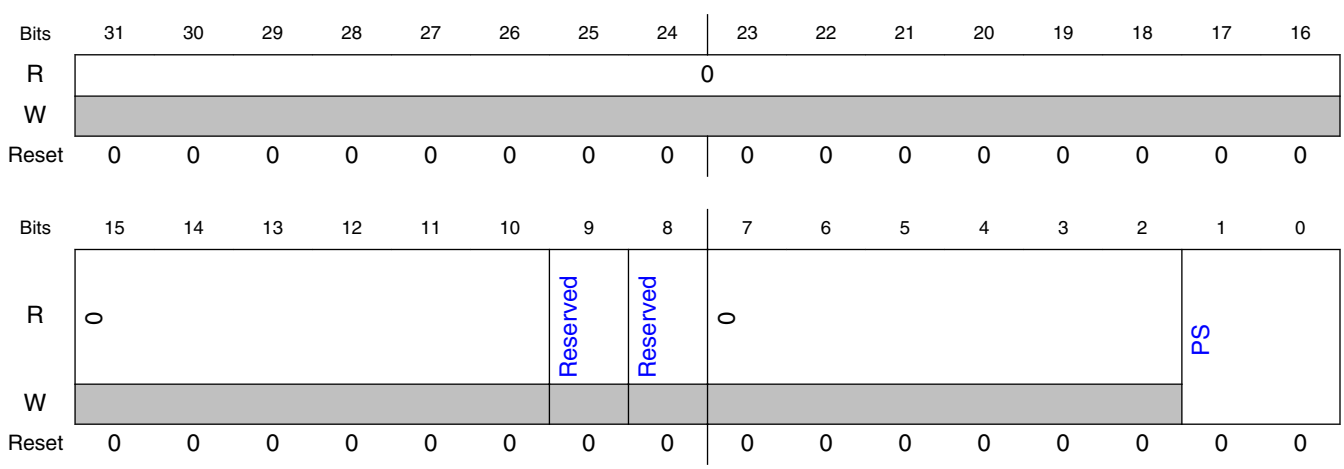
64.7.1.5 Signal Override Register (SIGNAL_OVERRIDE)

This register provides a way for the customer to enable signaling required by the USB BC Rev. 1.2 Specification after the battery charger detection sequences have completed.

64.7.1.5.1 Offset

Register	Offset
SIGNAL_OVERRIDE	Ch

64.7.1.5.2 Diagram



64.7.1.5.3 Fields

Field	Description
31-10 —	Reserved
9 —	Reserved Reserved, not for customer use. The value of this bit field may change during module operation.
8 —	Reserved Reserved, not for customer use. The value of this bit field may change during module operation.
7-2 —	Reserved
1-0 PS	Phase Selection Used to enable specified voltage and current source circuits on the USB_DP and USB_DM pins. Use of the override value below enables the charger detection bias circuits without needing to set the CONTROL[START] bit. Customers may set this bit field to 2'b10 for required signaling if attached to a Dedicated Charging Port, or during operation under the Dead Battery Provision. 00 - No overrides. Bit field must remain at this value during normal USB data communication to prevent unexpected conditions on USB_DP and USB_DM pins. (Default) 01 - Reserved, not for customer use. 10 - Enables VDP_SRC voltage source for the USB_DP pin and IDM_SINK current source for the USB_DM pin. 11 - Reserved, not for customer use.

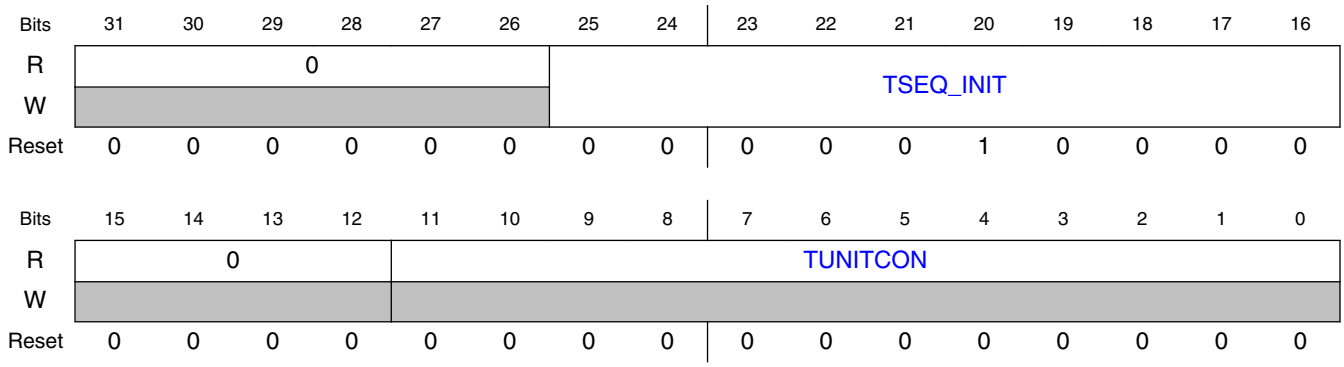
64.7.1.6 TIMER0 register (TIMER0)

This register has an TSEQ_INIT field that represents the system latency in ms. Latency is measured from the time when VBUS goes active until the time system software initiates charger detection sequence in USBDCD module. When software sets the CONTROL[START] bit, the Unit Connection Timer (TUNITCON) is initialized with the value of TSEQ_INIT. Valid values are 0-1023, however the USB Battery Charging Specification requires the entire sequence, including TSEQ_INIT, to be completed in 1s or less.

64.7.1.6.1 Offset

Register	Offset
TIMER0	10h

64.7.1.6.2 Diagram



64.7.1.6.3 Fields

Field	Description
31-26 —	Reserved
25-16 TSEQ_INIT	Sequence Initiation Time TSEQ_INIT represents the system latency (in ms) measured from the time VBUS goes active to the time system software initiates the charger detection sequence in the USBDCD module. When software sets the CONTROL[START] bit, the Unit Connection Timer (TUNITCON) is initialized with the value of TSEQ_INIT. Valid values are 0-1023, but the USB Battery Charging Specification requires the entire sequence, including TSEQ_INIT, to be completed in 1s or less. 0000000000-1111111111 - 0ms - 1023ms
15-12 —	Reserved
11-0 TUNITCON	Unit Connection Timer Elapse (in ms) Displays the amount of elapsed time since the event of setting the CONTROL[START] bit plus the value of TSEQ_INIT. The timer is automatically initialized with the value of TSEQ_INIT before starting to count. This timer enables compliance with the maximum time allowed to connect T_{UNIT_CON} under the USB Battery Charging Specification. If the timer reaches the one second limit, the module triggers an interrupt and sets the error flag STATUS[ERR]. The timer continues counting throughout the charger detection sequence, even when control has been passed to software. As long as the module is active, the timer continues to count until it reaches the maximum value of 0xFFF (4095 ms). The timer does not rollover to zero. A software reset clears the timer.

64.7.1.7 TIMER1 register (TIMER1)

This register contains timing parameters.

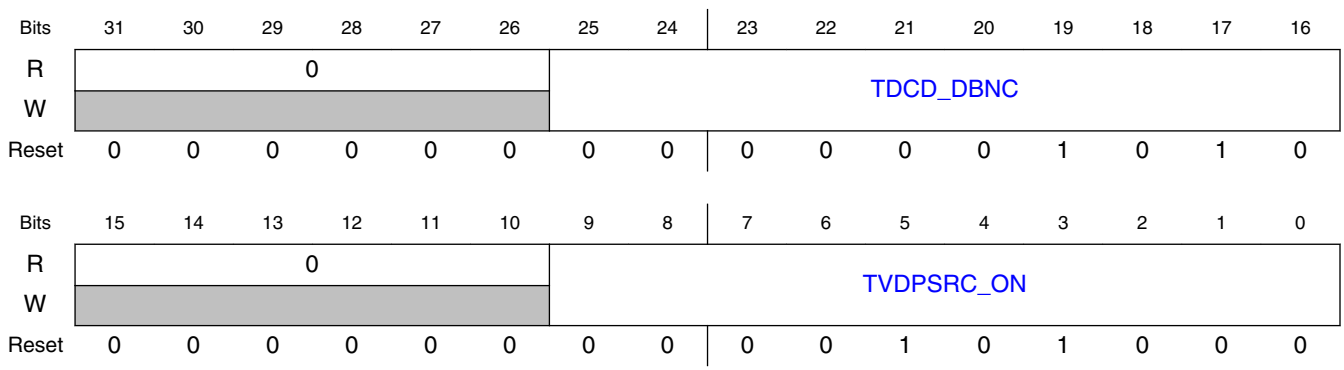
NOTE

Register values can be written that are not compliant with the USB Battery Charging Specification, so care should be taken when overwriting the default values.

64.7.1.7.1 Offset

Register	Offset
TIMER1	14h

64.7.1.7.2 Diagram



64.7.1.7.3 Fields

Field	Description
31-26 —	Reserved
25-16 TDCD_DBNC	Time Period to Debounce D+ Signal Sets the time period (ms) to debounce the D+ signal during the data pin contact detection phase. See "Debouncing the data pin contact" Valid values are 1-1023, but the USB Battery Charging Specification requires a minimum value of 10 ms. 0000000001-1111111111 - 1ms - 1023ms
15-10 —	Reserved
9-0 TVDPSRC_ON	Time Period Comparator Enabled This timing parameter is used after detection of the data pin. See "Charging Port Detection". Valid values are 1-1023, but the USB Battery Charging Specification requires a minimum value of 40 ms. 0000000001-1111111111 - 1ms - 1023ms

64.7.1.8 TIMER2_BC11 register (TIMER2_BC11)

TIMER2_BC11 contains timing parameters for *USB Battery Charging Specification, Rev 1.1*.

NOTE

Register values can be written that are not compliant with the USB Battery Charging Specification, so care should be taken when overwriting the default values.

64.7.1.8.1 Offset

15-10 —	Reserved
9-0 TVDMSRC_ON	TVDMSRC_ON Sets the amount of time (in ms) that the module enables the V_{DM_SRC} . Valid values are 0-40ms. 0000000000-0000101000 - 0ms - 40ms

Chapter 65
Euro, MasterCard, Visa Subscriber Identification Module (EMVSIM)

65.1 Chip-specific EMVSIM information

Table 65-1. Reference links to related information

Topic	Related module(s)	Reference
System memory map	-	System Memory Map
Clocking	CCM	Clock Management Clock Control Module (CCM)
Power management	PMU	Power Management Power Management Unit
Signal multiplexing	IOMUX	External Signals and Pin Multiplexing IOMUX
Interrupts, DMA Events and XBAR Assignments	-	Interrupts, DMA Events and XBAR Assignments

NOTE

Each EMVSIM has two EVENT IRQ assignments. The first EVENT IRQ maps to the data_irq OR'd together (TC, ETC, TFE, and RDT). The second EVENT IRQ maps to all the local interrupts OR'd together, including the data_irq. See the INT_MASK register for more information.

65.2 Overview

The Euro, MasterCard, Visa Subscriber Identification Module (EMVSIM) is designed to facilitate communication to Smart Cards compatible to the EMV v4.3 standard (Book 1) and Smart Cards compatible with ISO/IEC 7816-3 Standard.

65.2.1 Block Diagram

The figure below shows the block diagram for the EMVSIM module.

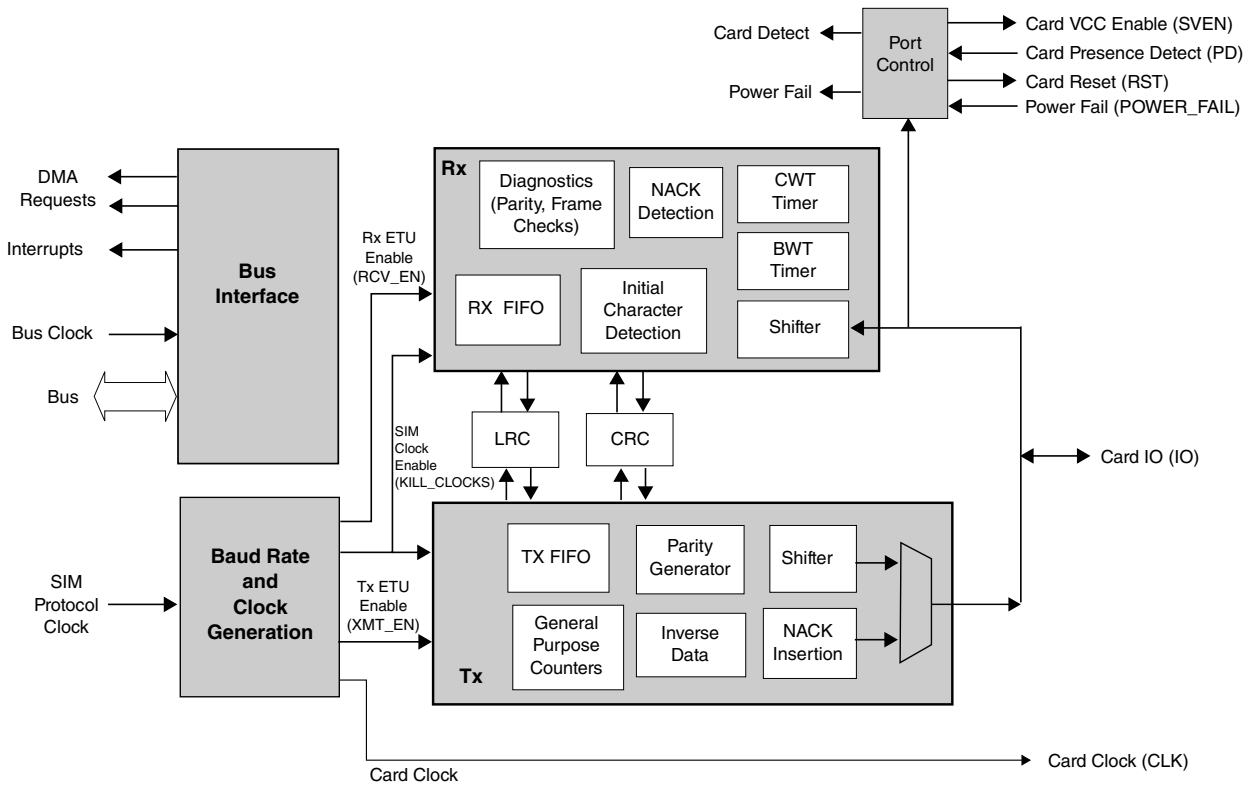

Figure 65-1. EMVSIM Block Diagram

65.2.2 Features

The EMVSIM module supports the following features:

- Independent clock for SIM logic (transmitter + receiver) and independent clock for register read-write interface
- 16 byte deep FIFO for transmitter and receiver
- Automatic NACK generation on parity error and receiver FIFO overflow error
- Support for both Inverse and Direct conventions
- Re-transmission of byte upon Smart Card NACK request with programmable threshold of re-transmissions
- Auto detection of Initial Character in receiver and setting of data format (inverse or direct)

- NACK detection in receiver
- Independent timers to measure character wait time, block wait time and block guard time
- Two general purpose counters are available for use by software application with programmable clock selection for the counters
- DMA support is available to transfer data to/from FIFOs. Programmable option is available to select interrupt or DMA feature
- Programmable Prescaler generates the desired frequency for Card Clock and Baud Rate Divisor generates the internal ETU clocks for transmitter and receiver for any F/D ratio
- Deep sleep wake-up via Smart Card presence detect interrupt
- Manual control of all Smart Card interface signals
- Automatic power down of port logic on Smart Card presence detect
- Support 8-bit LRC and 16-bit CRC generation for bytes sent out from transmitter and check incoming message checksum for receiver

65.3 Functional Description

65.3.1 Bus Interface

The EMVSIM module is a block that is configured via the device's peripheral bus interface. The module has 32-bit aligned memory mapped registers that are used to configure and control the operations of the module. The software can write the transmit bytes or read the received bytes using either interrupt operation or DMA operation. The module can generate necessary DMA requests for the operation.

65.3.2 Smart Card Interface and Control

The EMVSIM module controls all the interface signals for the Smart Card. The Smart Card clock is generated by using the prescaler (CLKCFG[CLK_PRSC]) and the ETU periods are generated by using the baud rate divisor (DIVISOR register). The Smart Card Reset and Voltage Enable are controlled by software through the PCSR register. The message bytes are transmitted and received on the Card IO device pin (IO) which is used in open drain configuration.

The Smart Card interface signals, except IO (controlled by the transmitter and receiver), are generated by the port control block which controls the assertion and de-assertion of the clock, reset and VCC signals to Smart Card. It can do so manually (software needs to explicitly write the necessary bits) or using auto power down wherein the module can

itself power down the Smart Card when configured to do so by software. The port control block can also detect the Smart Card presence and generate necessary interrupts to indicate the same.

For more information about powering up and automatic power down, see Powering Up and Automatic Power Down sections.

65.3.2.1 Smart Card Presence Detect

The Smart Card Presence Detect pin (PD) allows for detection of the insertion or removal of a Smart Card. The PCSR[SPDES] bit allows the software to configure which edge of the PD pin causes a presence detect interrupt flag to be asserted.

An internal pull-down is required on PD pin to allow a high to low transition on this pin when the Smart Card is removed.

65.3.3 EMVSIM Receiver

The EMVSIM Receiver is designed to receive all message bytes and store valid bytes into the receive FIFO. It performs checks on the incoming messages and indicates the transmitter to enable NACK insertion for each message. In addition, the receiver automatically detects NACKs received when the transmitter is sending out message bytes.

The receiver comprises a 16-byte deep FIFO to store the correctly received bytes from the Smart Card. Software must ensure that it reads out the data from FIFO to prevent any overflow when more bytes are sent from the card. The receiver can be configured to detect the initial character. When configured to do so, the data format (direct or inverse convention) is also determined by the receiver and appropriate bit is set in the register map. Internal timers in the receiver measure the various wait times (Character, Block and Guard). On reception of a byte, the receiver checks the byte for Parity Error (in T=0 mode) and Framing Error. It can then direct the transmitter to insert NACK on parity error detection. For a block of bytes received, the receiver checks for LRC or CRC errors (in T=1 mode). See LRC and CRC for more LRC and CRC information. Other errors are stored as status for software to be aware of their occurrence. The status of the receiver operation is intimated to software via maskable interrupts.

65.3.3.1 Data Sampling

The incoming data is internally synchronized and sampled by using a 16x oversampled clock, called the EMVSIM logic clock. The frequency of this clock is 16 times the ETU Clock (1/ETU Period). The whole receiver works on this EMVSIM logic clock.

65.3.3.2 Initial Character Detection

The EMVSIM module supports the detection of the Initial Character and determine the data format when it is placed in the initial character mode by setting the CTRL[ICM] bit. When placed in this mode, the EMVSIM module samples in the input line and waits for one of the initial characters to be detected. Once detected, the CTRL[ICM] bit is cleared and the data format bit, CTRL[IC] bit, is set to appropriate value depending on the data format detected using the initial character.

The two possible data formats are inverse convention and direct convention. Figures below illustrate the differences between the two formats. Essentially, inverse convention differs from direct convention in that the order of the bits is flipped (i.e. MSB for LSB) and the data bits and parity bit are logically inverted. When receiving inverse convention data, the transformation of the data back to direct convention format is done in hardware, including the inversion of the data and parity bits.

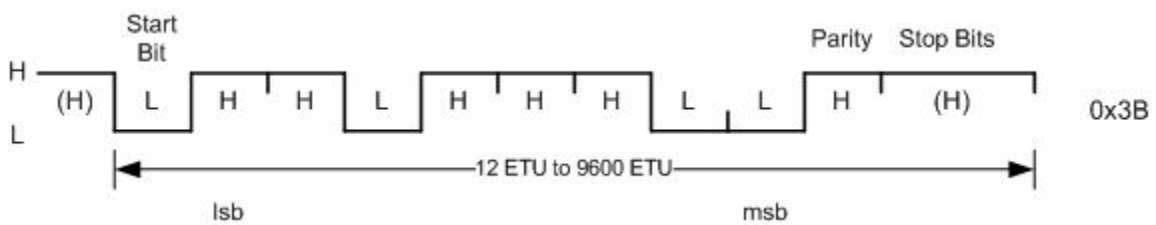

Figure 65-2. Initial Character in Direct Conversion

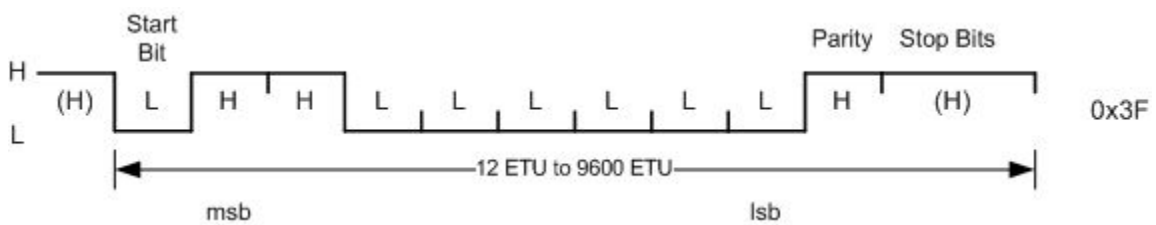

Figure 65-3. Initial Character in Inverse Conversion

To place the EMVSIM into initial character mode, set the CTRL[ICM] bit. Once a valid initial character is received, the CTRL[IC] bit is set accordingly by the hardware, and the CTRL[ICM] bit is cleared. Software can read the state of the CTRL[IC] bit to determine which mode the EMVSIM is currently using. The 0x3B (as decoded by direct

convention) with parity bit high causes direct convention to be used (IC set to logic 0), whereas a 0x3F (as decoded by inverse convention) with parity bit high causes inverse convention to be used (IC set to logic 1).

The receiver remains in initial character mode until disabled by software or a valid initial character is detected. Upon detection of valid character, the receiver enters data receive mode. It is recommended to use one of the general purpose counter as a timeout during initial character mode.

When the receiver is in initial character mode, all received bytes continues to be placed into the receive FIFO whether they are valid initial characters or not. If a valid initial character is received that causes the data format being used to change, all subsequent bytes are decoded with that format before being placed into the FIFO, including the initial character byte itself. That is, if the CTRL[IC] bit is low, and the correct initial character for setting inverse convention is received, that character and all subsequently received characters are stored in the FIFO after having been decoded using inverse convention (for example, the initial character is stored as 0x3F).

NOTE

There is a condition where a parity error in the initial byte for direct convention (0x3B) could be decoded as what appears to be a valid initial character for inverse convention (that is, 0x3F). The EMVSIM module does not recognize this as a valid initial character for inverse convention and sets the PEF flag.

65.3.3.3 Receiver Diagnostics

The EMVSIM module performs diagnostic checks on the incoming messages. These checks include parity check and message frame checks.

Parity Error Detection: The receiver is responsible for detecting parity errors in the received data. Data is always transmitted with even parity, except in inverse convention mode. In inverse convention mode, all data bits and the parity bit are complemented making the data appear to be odd parity. The parity bit is defined as the 10th bit of the received data. The parity of the 2nd through 10th received bits is calculated by the receiver parity logic. This logic determines if the parity of the 9 received bits is correct.

When a parity error is detected on a given byte, the parity error flag (PEF bit) is asserted in the RX_STATUS register if NACK generation on errors is disabled (ANACK = 0 in CTRL register). The parity error flag does not generate an interrupt to the system, however, the module can cause the transmitter to transmit a NACK (if ANACK = 1 in CTRL register) without software needed to enable transmitter for this and request re-transmission of the current byte.

Framing Error Detection: The receiver is responsible for detecting framing errors in the received data. Data is always transmitted with 2 STOP bits, except in 11 ETU mode, where there is one STOP bit. The STOP bits are defined as high state at the 11th and 12th bit positions in the received data. In either mode, the receiver expects to see a high at the 11th bit position in the received data. If a low is detected at the 11th bit position, the receiver indicates a framing error for that byte.

When a framing error is detected on a given byte, the FEF bit is set in the RX_STATUS register. A framing error can not cause an interrupt, nor create a NACK pulse to the Smart Card asking for a retransmission of the corrupted data.

LRC & CRC: The receiver also checks the LRC or CRC on the incoming block of bytes (if LRC or CRC is enabled). The result of the CRC or LRC check is updated in the RX_STATUS register once the complete message block is received. See LRC and CRC for more LRC and CRC information.

65.3.3.4 NACK Detection

During transmission of message bytes, the receiver automatically checks for NACKs sent by the Smart Card. The software does not need to enable receiver for this. The NACK is detected by sampling the IO line at 11 ETUs after the falling edge of the START bit. Once a NACK is detected, the transmitter is signaled and the transmitter retransmits the current byte after two ETU time (as per ISO 7816 specification).

65.3.3.5 Using EMVSIM Receiver with "T=1" Smart Cards

The EMVSIM module provides hardware support for “T=1” type Smart Cards. These type of cards present several requirements above and beyond the standard “T=0” cards. The features provided to meet the requirements that pertain to the EMVSIM receiver are as follows:

- 11 ETU Characters
  - “T=1” cards can transmit with character lengths of 11 ETUs (that is, one STOP bit). The EMVSIM module provides the CTRL[RCVR_11] bit in order to configure the receiver state machine to accept 11 ETU characters.
- Character Wait Time Counter
  - The character waiting time (CWT) is defined as the time between the start bits of two consecutive characters received from the Smart Card. The value of CWT can range from 12 ETU to 32779 ETU. The EMVSIM module provides a 16-bit counter with programmable comparator clocked at the ETU bit rate to identify when the CWT has been exceeded by the Smart Card.
- Block Wait Time

    - The block waiting time (BWT) is defined as the maximum time between the start bits of the last character of a transmitted block and the first character of the next received block. The block wait time must not exceed a value that is programmable. The EMVSIM module provides a 32-bit Block Wait Timer that can be used to identify when the BWT has been violated.
- Block Guard Time
    - The block guard time (BGT) is defined as the minimum delay between the start bits of the last character of a transmitted block and the first character of the next received block. The block guard must be greater than a value that is programmable. The EMVSIM module provides a 16-bit Block Guard Timer that can be used to identify when the BGT has been violated.
- Error Detection Code
    - “T=1” cards can specify LRC or CRC error detection codes to be used. The EMVSIM module provides hardware support for both the LRC and CRC operations.

65.3.4 EMVSIM Transmitter

The transmitter is responsible for reading the message bytes from the Tx FIFO, adding the LRC or CRC at the end of the message block and re-transmit any byte on reception of a NACK. It assists the receive operation by inserting NACKs when directed by the receiver.

The transmitter comprises a 16-byte deep FIFO to store the bytes sent to the Smart Card. These bytes are sent to the Smart Card serially by the transmitter. The data format (i.e. inverse or direct conversion) is supported and the byte is converted into the right data format before being shifted out serially. The transmitter also supports retransmission of the current byte on the reception of a NACK. The transmitter automatically inserts NACK when the receiver indicates a parity or FIFO overflow error, if configured to do so by software. The transmitter is not required to be enabled for this. The transmitter also includes timer to insert the programmable guard time between the transmitter bytes and general purpose timers to allow software to perform certain measurements. The status of the transmitter operation is intimated to software via maskable interrupts.

65.3.4.1 Message Transmission

The transmitter operation does not start until the Tx FIFO is empty. Software can configure the EMVSIM module and enable the transmitter, but no transmission starts unless a byte is written into the Tx FIFO. Clearing the XMT_EN bit while the transmitter is in operation halts any transmission in progress, and flushes the transmit FIFO. See the Transmit FIFO section for more details on using the Tx FIFO.

The transmitter continuously transmits the messages from the Tx FIFO. Upon NACK detection, the transmitter resends the same byte until the Transmitter NACK Threshold limit is reached. When TNTE is set, the EMVSIM transmitter is halted, all pending transfers are aborted, TC, ETC and TFE flags are set. All bytes remaining in the transmit FIFO are lost. There is no way to restart the transmission on the next byte in the FIFO. The transmitter remains frozen until TNTE is cleared by software. The only way to clear TNTE is to write a 1 to the TX_STATUS[TNTE] bit. It is possible to disable the detection of NACKs from the Smart Card by setting TNCK_THD[3:0] to 0x0. By setting TNCK_THD[3:0] to 0x1, it is possible to disable all retransmissions while still setting TNTE on the first NACK received. In general, TNTE is set on the NACK that causes the threshold set by TNCK_THD[3:0] to be reached. This final NACK does not cause a retransmission, whereas all previous NACKs causes a retransmission.

If all bytes are successfully transmitted and the Tx FIFO is empty, the transmitter send the check byte (i.e. LRC or CRC) if the XMT_CRC_LRC and LRC_EN or CRC_EN bits are set. The transmitter sends each byte to the LRC or CRC block to allow the check byte generation.

At the end of each byte, the transmitter inserts the programmed Guard ETUs. Refer to Transmit Guard Time section for more details on Guard Time Counter.

65.3.4.2 NACK Insertion

The transmitter is responsible for driving the output low during the STOP bit time to signify an error was detected in the received data from the Smart Card. This logic responds to a NACK request generated by the receiver block.

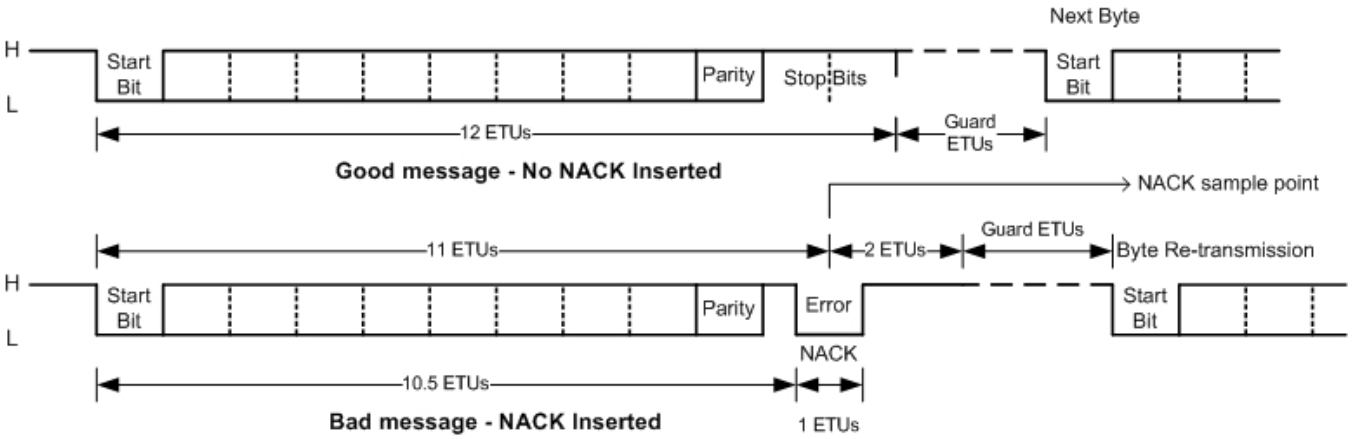

Figure 65-4. NACK Insertion

The NACK generation logic is also responsible for keeping track of the number of NACKs received during a transmit operation. The receiver detects NACKs generated by the Smart Card, and reports them to the transmit NACK logic. Once the number of detected NACKs has reached the programmed threshold (TNCK_THD[3:0]), an interrupt flag (TNTE) is generated, the transmit FIFO is flushed, and the transmitter is disabled.

65.3.4.3 Using EMVSIM Transmitter with "T=1" Smart Cards

The EMVSIM module provides hardware support for “T=1” type Smart Cards. These type of cards present several requirements above and beyond the standard “T=0” cards. The features provided to meet the requirements that pertain to the EMVSIM transmitter are as follows:

- 11 ETU Characters
  - The EMVSIM module transmitter has a programmable guard time register that allows the programmer to specify the number of ETUs between character transmissions. Programming a value of 255 (0xFF) in the TX_GETU[GETU] bits sets the number of ETUs per character transmitted to 11.
- Character Waiting Time
  - The character waiting time (CWT) is defined as the time between the start bits of two consecutive characters. The value of CWT can range from 12 ETU to 32779 ETU. The time between transmitted characters is controlled by the programmable guard time in the TX_GETU register. However, the time between the last byte in the transmit FIFO, and the next transmitted byte can be largely affected by software response time to the transmit interrupts. The EMVSIM transmitter provides a Transmit FIFO threshold (TDTF) interrupt to signal the system when the expected number of characters have been transmitted from the transmit FIFO. The minimum CWT is achieved only if the software can respond

to the TDTF interrupt and write new data to the transmit FIFO before the last character in the Transmit FIFO has been sent.

- Block Waiting Time
  - The block waiting time (BWT) is defined as the maximum time between the start bits of the last character of a transmitted block and the first character of the next received block. The value of BWT is always greater than 1800 ETU. The EMVSIM transmitter provides two General Purpose Counter(s) either of which can be used to track the BWT. The BWT is purely determined by software response time to the transmit interrupts.
- Block Guard Time
  - The block guard time (BGT) is defined as the minimum delay between the start bits of the last character of a transmitted block and the first character of the next received block. The value of BGT is 22 ETU. The EMVSIM module supports the BGT by providing the ability to generate an interrupt when the last byte is received, and transmitting within 2 ETU after the XMT_EN bit is set. The BGT is determined by the speed at which the software can react to an interrupt and enable the transmitter.
- Error Detection Code
  - “T=1” cards can specify LRC or CRC error detection codes to be used. The EMVSIM module provides hardware support for both the LRC and CRC operation.

65.3.5 LRC and CRC

The module also contains the 8-bit LRC and the 16-bit CRC blocks that are common to the transmitter and receiver. Both transmitter and receiver can use the LRC and CRC blocks and can insert the LRC or CRC into the byte stream or check the validity of the input stream using the LRC and CRC values received. Since transmit and receive operations are mutually exclusive, common LRC and CRC blocks for the transmitter and receiver can be used.

65.3.5.1 LRC Block

The EMVSIM module provides an 8-bit Linear Redundancy Check (LRC) generator / checker. The block is provided for use with T=1 Smart Cards that support LRC. This block can be enabled through the CTRL[LRC_EN] bit. This block performs an 8-bit exclusive-OR (XOR) on all received or transmitted characters. At the end of the reception of a block of characters, the result is expected to be 00. If so, the LRC_OK bit is set in the RX_STATUS register. During transmission, the LRC block Exclusive-ORs each

character that is transmitted with the current value of the LRC. If the CTRL[XMT_CRC_LRC] bit is set, the LRC value is automatically sent by the transmitter as the final character when the transmit FIFO empties.

The LRC value can be reset in multiple ways. Clearing the CTRL[LCR_EN] bit resets the LRC value. At the end of a transmission (either after the LRC byte is transmitted, or after the last character in the transmit FIFO is sent when XMT_CRC_LRC is clear), the LRC value is automatically reset by the EMVSIM hardware. Finally, when setting the XMT_EN bit, the EMVSIM hardware resets the LRC value.

Summary of configuration needed to use LRC block:

- Use the CTRL[LRC_EN] bit to enable the LRC block
- Use the XMT_CRC_LRC bit to enable the transmission of the LRC Character after the last character in the Transmit FIFO is sent.

65.3.5.2 CRC Block

The EMVSIM module provides an 16-bit Cyclic Redundancy Check (CRC) generator / checker. The block is provided for use with T=1 Smart Cards that support CRC. This block can be enabled through the CTRL[CRC_EN] bit. This block performs a polynomial based check on all received or transmitted characters. The polynomial used for calculating the CRC is $G(x) = x^{16} + x^{12} + x^5 + 1$. The CRC register is initialized to all “1” before the data is shifted in. The CRC block can be configured to compute using the ISO 7816 CRC method or the 16-bit CCITT CRC method. The software can select the following bits: CRC_IN_FLIP, CRC_OUT_FLIP, and INV_CRC_VAL of the CTRL register.

- To select CCITT CRC method, set
  - CRC_IN_FLIP = 1
  - CRC_OUT_FLIP = 1
  - INV_CRC_VAL = 1
- To select normal CRC method (i.e. ISO 7816 CRC method), set
  - CRC_IN_VAL = 0
  - CRC_OUT_VAL = 0
  - INV_CRC_VAL = 1

During transmission, the CRC block updates the current value of the CRC using each character. If the CTRL[XMT_CRC_LRC] bit is set, the CRC value is automatically formatted as per the selected CRC method (CCITT or normal) and sent by the EMVSIM transmitter as the final two characters when the transmit FIFO empties. At the end of the reception of a block of characters, the residual from the CRC calculation is compared and the CRC_OK bit is set in the RX_STATUS register.

NOTE

Setting any other value for CRC_IN_FLIP, CRC_OUT_FLIP and INV_CRC_VAL causes CRC value to be formatted accordingly; however the CRC is not compliant to the standard CRC used in Smart Cards.

The CRC value can be reset/initialized in multiple ways. Clearing the CTRL[CRC_EN] bit resets the CRC value. At the end of a transmission (either after the CRC characters are transmitted, or after the last character in the transmit FIFO is sent when XMT_CRC_LRC is clear), the CRC value is automatically reset by the EMVSIM hardware. Finally, when setting the XMT_EN bit, the EMVSIM hardware resets the CRC value.

Summary of configuration needed to use CRC block:

- Use CRC_IN_FLIP, CRC_OUT_FLIP and INV_CRC_VAL bits in CTRL register to select the desired CRC method (CCITT or normal)
- Use the CTRL[CRC_EN] bit to enable the CRC block
- Use the XMT_CRC_LRC bit to enable the transmission of the CRC Characters after the last character in the Transmit FIFO is sent.

65.3.6 Message Handling

The EMVSIM module has FIFOs on both transmit and receive side for handling all message bytes.

65.3.6.1 Transmit FIFO

A 16-byte deep FIFO is implemented in the transmitter. The transmit FIFO can be written into by the software but reads to this FIFO returns zeros. To take care of clock synchronization, each write access has wait states inserted by the module but this is transparent to the software. The Tx FIFO can be written to while the transmitter is enabled, however, the transmitter does not start transmitting while the FIFO is empty. A write to the Tx FIFO initiates the transmit operation. Software can store more bytes into the Tx FIFO until the programmed threshold is reached. Software can enable DMA operation by setting TX_DMA_EN = 1 in the CTRL register. On setting this bit, a DMA requestis asserted and remain asserted till the number of bytes in FIFO reached the programmed threshold value (TDT[3:0] in the TX_THD register).

The transmit FIFO can be flushed by setting the CTRL[FLSH_TX] bit. A transmit NACK threshold error (TNTE) halts the transmitter, and flush the transmit FIFO. The flush operation resets the transmit read and write pointers to equal values. Everything in

the transmitter block is reset by the transmit flush operation. This does not include the control registers associated with the transmitter. The Transmit data threshold flag (TDTF) does not get cleared by the FLSH_TX operation.

65.3.6.2 Receive FIFO

A 16-byte deep FIFO is implemented in the receiver. Since more than 16-bytes can be received in the FIFO, the software must ensure that the Rx FIFO is periodically read. The Rx FIFO can be read by software via normal CPU accesses on interrupt (RX_DATA interrupt flag) or via DMA by setting the DMA_RX_EN bit in CTRL register. The software can not write to this register. A write access may terminate in a transfer error.

The Rx FIFO is loaded by the receiver when it receives an error free message byte with correct parity. The FIFO stores the message byte only. When the total bytes in the Rx FIFO equals the programmed threshold value (RDT[3:0] in RX_THD register), the RDTF bit is asserted in the RX_STATUS register. An interrupt is asserted if the INT_MASK[RDT_IM] bit is cleared. If DMA access to RX_FIFO is enabled, the DMA request to read the Rx FIFO is asserted when the threshold flag is set and clears when all the bytes are read out from the Rx FIFO.

The receive FIFO can be flushed by setting the CTRL[FLSH_RX] bit. The flush operation resets the receiver except for receiver control registers.

NOTE

Since the register bits and the receiver logic are in different clock domains, the software needs to make sure to allow clock synchronization time when sampling the RDTF bit. One proposed method could be to read one byte at a time (from Rx FIFO) when RDTF is asserted, allow a time of 3 bus clock cycles after Rx FIFO read and then check the status of the RDTF bit and repeat as necessary. Alternatively, one could set the receiver threshold one more than actually needed.

Rx FIFO Overflow Detection: When a byte is received by the receiver and the Rx FIFO is not read and already contains 16 bytes, a FIFO overflow error is asserted (RFO bit set to 1 in RX_STATUS register). The received byte is discarded leaving the FIFO with the first 16 bytes received. If the ONACK bit in the CTRL register is asserted, the transmitter generates a NACK for the overflow condition every time a new byte is received that can not be stored in the Rx FIFO. The EMVSIM module continually sends NACKs till the Rx FIFO is read or NACK transmit threshold is reached.

65.3.7 Protocol Timers

The EMVSIM module has several 16-bit and 32-bit timers to allow the software to perform protocol timing checks and measurements like:

- Transmit Guard Time
- Character Wait Time
- Block Wait Time
- Block Guard Time
- Work Wait Time

In addition to the above, the EMVSIM module also contains two 32-bit general purpose counters which can be used by software for any specific time measurement application.

65.3.7.1 Transmit Guard Time

The Transmit Guard time is the number of ETUs inserted by the transmitter between each character being transmitted. The number of ETUs is controlled by programming the TX_GETU register. The Guard Time is measured as the time (in ETUs) between the STOP bits of previous character and the START bit of next character.

For a Guard Time programmed as 0xFF in TX_GETU[GETU] bits, the transmitter inserts one STOP bit instead of two.

65.3.7.2 Character Wait Time

The EMVSIM receiver block includes a 16-bit counter that counts the number of bit times (ETUs) between received characters (i.e. time between start bits in the consecutive characters received). When enabled, the Character Wait Time Counter (CWT) does not start counting until after the START bit(s) of a valid character has been received. The counter is synchronized to the receive character bit positions so that an accurate count of the number of ETUs between characters can be made. The Character Wait Time Counter has a 16-bit programmable comparator. Software can write the expected number of ETUs between characters to the comparator. If the time between characters exceeds this value, an interrupt flag is set and an interrupt generated if the mask is clear. The CWT can be configured as follows:

- Program the CWT_VAL register to the value that needs to be enforced
- Activate CWT function by setting the CTRL[CWT_EN] bit
- Enable the CWT_ERR interrupt by clearing the INT_MASK[CWT_IM] bit

- If an interrupt occurs, then the software should read the RX_STATUS register to determine if the error was caused by a CWT_ERR violation. The software should clear the CWT_ERR interrupt by writing a “1” to the RX_STATUS[CWT_ERR] bit
- Software can disable the CWT counter by clearing the CTRL[CWT_EN] bit at any time

65.3.7.3 Block Wait Time and Block Guard Time

A 32-bit timer is used to measure both Block Wait Time (BWT) and Block Guard Time (BGT). The BWT and BGT timer are used to measure the delay between the leading edge of the last character of the block received by the card and the leading edge of the first character of the next block sent by the card. If this time measured is larger than the value in BWT_VAL register, then the BWT_ERR flag is set and an interrupt generated. If the time is less than the value in the BGT_VAL register, then the BGT_ERR flag is set and an interrupt generated. The block wait timer can be configured as follows:

- Program the BWT_VAL and BGT_VAL registers to the value that need to be enforced
- Activate the block wait timer by writing '1' to CTRL[BWT_EN] bit
- Enable the BWT_ERR and BGT_ERR interrupts by clearing the INT_MASK[BWT_IM] and INT_MASK[BGT_IM] bits
- If an interrupt occurs, then the software should read the RX_STATUS register to determine if the error was caused by a BWT_ERR or BGT_ERR violation. The software should clear the interrupt status bit by writing a “1” to the BWT_ERR bit or BGT_ERR, respectively, in the RX_STATUS register
- Software can disable the BWT counter by clearing the CTRL[BWT_EN] bit at any time

NOTE

BWT should be enabled after all bytes are written to in Tx FIFO. This is necessary to avoid the condition where writes to Tx FIFO are very slow (more than 1 ETU time apart) and if BWT is enabled earlier, then BWT error can trigger falsely.

65.3.7.4 Work Wait Time

There is no separate counter to measure the work wait time (WWT). Work wait time is a combination of BWT and CWT. To measure WWT, software must configure both CWT_VAL and BWT_VAL to the value to be enforced. When measuring WWT, the BGT timer is not used so it should be masked (inactive) by the BGT_IM bit. Below is the sequence to program the EMVSIM to send and receive data while checking WWT:

- Program both the CWT_VAL and the BWT_VAL registers to the WWT (work wait time) value that needs to be enforced. Set BGT_VAL register to 0 (this is the default value).
- Activate both the CWT and BWT functions by setting the CTRL[CWT_EN] and CTRL[BWT_EN] bits
- Enable the CWT_ERR and BWT_ERR interrupts by clearing the INT_MASK[CWT_IM] and INT_MASK[BWT_IM] bits
- Program the EMVSIM module to enable Receiver or Transmitter as desired by application
- If an interrupt occurs, then the software should consider that a WWT violation if the CWT_ERR or BWT_ERR bits are asserted. The software should clear the CWT_ERR or BWT_ERR interrupt by writing a “1” to the RX_STATUS[BWT_ERR] bit or RX_STATUS[CWT_ERR] bit

65.3.7.5 General Purpose Counters

The EMVSIM module provides two 16-bit counters for use, when timing events during Smart Card communication. The clock source for the counter is selectable between three sources: Card Clock, Receiver Clock (16 times the ETU clock) or ETU Clock (for Transmitter). The CLKCFG[GPCNT0_CLK_SEL] and CLKCFG[GPCNT1_CLK_SEL] bits are used to select the clock input. The counter is enabled as soon as the input clock is selected. The starting of the counter is immediate once the input clock is running. Software can control the three input clock sources by using the SCEN, KILL_CLOCKS, RCV_EN and XMT_EN bits provided in the CTRL register.

To run the counters from the card clock source the following conditions must be met:

- CTRL[KILL_CLOCKS] = 0
- CTRL[RCV_EN] = 1 or CTRL[XMT_EN] = 1
- PCSR[SCEN] = 1
- CLKCFG[GPCNT0/1_CLK_SEL] = 01

The counter begins to count at the card clock rate as soon as these conditions are met.

To run the counters from the receive clock source the following conditions must be met:

- CTRL[KILL_CLOCKS] = 0
- CTRL[RCV_EN] = 1 or CTRL[XMT_EN] = 1
- CLKCFG[GPCNT0/1_CLK_SEL] = 10

The counter begins to count at the receive clock rate as soon as these conditions are met.

To run the counters from the ETU (transmit) clock source the following conditions must be met:

- CTRL[KILL_CLOCKS] = 0

- CTRL[RCV_EN] = 1 or CTRL[XMT_EN] = 1
- CLKCFG[GPCNT0/1_CLK_SEL] = 11

The counters begins to count at the ETU clock rate as soon as these conditions are met.

The counters can be reset by setting GPCNT0/1_CLK_SEL to 00. A 16-bit comparator value (GPCNT0/1_VAL register) is provided that allows the software to select a count value at which the interrupt flags (TX_STATUS[GPCNT0_TO] and TX_STATUS[GPCNT1_TO] bits) can be set and an interrupt generated if the mask (INT_MASK[GPCNT0/1_IM] bits) are clear.

The following sequence should be followed to configure both general purpose timers:

- Program counter comparator using the GPCNT0/1_VAL register
- Enable the conditions described above using the CTRL register
- Select desired clock source for the General Purpose Counter using the CLKCFG register
- Enable interrupts in the INT_MASK register

65.3.8 Answer To Reset (ATR) Detection

The first communication that occurs between the Smart Card and the EMVSIM module is a block of data sent from the Smart Card to the EMVSIM module after the card is powered up and the card reset is removed (As described in Smart Card Interface and Control Section). This block is called the Answer To Reset (ATR). To receive the ATR, the EMV SIM module should be configured for 12 ETU character reception. According to the ISO 7816-3 spec, both “T=0” and “T=1” cards communicate initially using 12 ETU character durations.

For more information about ATR Detect Configuration, see the Configuration for ATR Detect section.

65.3.9 Clocks

The key functional blocks in the module are clocking, transmitter, and receiver which control the interactions with the Smart Card. These blocks function on a clock that is different and asynchronous to the register read/write clock. In order for the transmitter and receiver to function properly, the respective configuration must be done before enabling the transmitter or receiver.

The EMVSIM clocking module generates the following clocks:

- Card clock (output to Smart Card)

    - The prescaler (CLKCFG[CLK_PRSC]) generates the card clock in the range of 1 to 5 MHz with near 50% duty cycle
- Internal clocks for the transmitter and receiver - the internal clocks control the ETU period and the sampling and driving of data on the IO line
    - The receive operation uses an internal over-sampled clock that oversamples the received input at 16x times the ETU rate
    - The baud divider (DIVISOR register) generates the internal ETU clocks for transmitter and receiver.

65.4 External Signals

The module interfaces to the external card (Smart Card) via card clock, card reset, card V_{CC} enable and IO pins. The transmitter output from the module and the receiver input to the module are connected to the same IO pin and used in the open drain configuration.

NOTE

A pull-up resistor must be connected to the IO pin on board to allow proper functioning.

The following table shows the user-accessible signals available on EMVSIM. See the chip-level specification to find out which signals are connected to the external pins.

Table 65-2. EMVSIM Signal Description

Signal	Description	I/O
CLK	Card Clock. Clock to Smart Card.	O
RST	Card Reset. Reset signal to Smart Card	O
SVEN	Card Power Enable. This signal controls the power to Smart Card	O
IO	Card Data Line. Bi-directional data line.	I/O
PD	Card Presence Detect. Signal indicating presence or removal of card	I
POWER_FAIL	External PMIC power fail indication.	I

65.5 Initialization

The first operation that must be done is to configure the EMVSIM interface signals to allow the EMVSIM Transmit or Receive operation to commence. The following steps describe a typical way to enable the Smart Card:

1. Configure prescaler by programming the desired value in CLKCFG register to generate the card clock. The card clock frequency is calculated as:

- f_{SIM} / (CLKCFG[CLK_PRSC]); where f_{SIM} is the EMV SIM Clock Frequency
- Prescaler value must be set such that the maximum card clock frequency specification set by EMV & ISO-7816 specifications are not violated

2. Configure the DIVISOR[DIVISOR_VALUE]. This value determines the ETU period to be used by the transmitter or receiver
3. Enable power to the Smart Card by setting the PCSR[SVCC_EN] bit
4. Enable the Smart Card clock by setting the PCSR[SCEN] bit
5. Release Smart Card reset using the PCSR[SRST] bit to bring the Smart Card out of reset
6. Program the power down functionality i.e. if Auto Power Down of Smart Card is required or not
7. Select the Data Format type for the EMVSIM
   - Either set the CTRL[IC] bit to the desired data format (inverse or direct) OR
   - Set the CTRL[ICM] bit to allow automatic detection of Initial Character. The CTRL[IC] bit is updated to desired data format upon valid Initial Character detection
8. Configure if the EMVSIM module is enabled to run in STOP and DOZE modes by setting the CTRL[STOP_EN] and CTRL[DOZE_EN] bits as desired
9. Enable DMA request generation for Transmitter or Receiver as desired

Once the above configuration is complete, the receiver or transmitter can be configured depending on the operation to be carried out on the Smart Card.

NOTE

XMT_EN and RCV_EN bits should not be changed in the same write cycle. Software should attempt separate write accesses to CTRL register for updating these bits, one by one. For example, if XMT_EN = 1 and RCV_EN = 0 and in order to enable the receiver, first write to CTRL register should make XMT_EN = 0 and second write to CTRL register should make RCV_EN = 1.

NOTE

The Transmit and Receive operations are mutually exclusive and should not be enabled together.

65.5.1 Configuring Receiver

The following is a list of configurations that need to be performed (after the "Configuring EMVSIM" step) in order to configure the EMVSIM receiver for operation:

1. Enable NACK generation capability

- To generate NACK on parity errors and invalid initial characters, set the CTRL[ANACK] bit
- To generate NACK on receiver FIFO overflow error, set the CTRL[ONACK] bit

2. Configure the desired threshold for NACK generation and data threshold in the RX_THD register. These are the thresholds at which the RTE and RDTF flags are set, respectively.
   - If auto power down is desired on RTE flag assertion, then write to SAPD bit PCSR to initiate the Smart Card power down
3. Configure the timeout values for Character Wait Time Counter, the Block Wait Timer Counter and the Block Guard Time Counter
4. Enable necessary interrupts by clearing respective bits in the INT_MASK register
5. Configure the General Purpose Counter as needed and select desired clock source (CLKCFG[GPCNT0/1_CLK_SEL])
6. Enable Receiver by setting CTRL[RCV_EN] bit to 1
7. Receiver enters Initial Character Detection mode if CTRL[ICM] bit is set or enter normal receive mode if CTRL[ICM] bit is not set
8. Enable LRC or CRC as desired

65.5.2 Configuring Transmitter

The following is a list of configurations that need to be performed (after the "Configuring EMVSIM" step) in order to configure the EMVSIM transmitter for operation:

1. Select desired re-transmission threshold for NACKed characters in TX_THD register
   - This is the threshold at which the TNTE flag is set by using the TNACK_THD bits
2. Configure the desired Guard Time between the characters transmitted by writing to the TX_GETU[GETU] bits
3. Configure the desired data threshold in TX_THD register.
4. Enable necessary interrupts by clearing respective bits in the INT_MASK register
5. Configure the General Purpose Counter as needed and select desired clock source (CLKCFG[GPCNT0/1_CLK_SEL])
6. Enable Transmitter by setting the CTRL[XMT_EN]
7. Enable LRC & CRC as desired
8. Program bytes to be transmitted into the Tx FIFO. If DMA is enabled, DMA request is asserted automatically.

NOTE

Tx FIFO can be written to after the transmitter is enabled (XMT_EN = 1). Writing to Tx FIFO while the transmitter is disabled is not successful and write access is ignored.

65.6 Application Information

65.6.1 Powering Up

The first step to communicate with a Smart Card is to provide power and a clock signal to the card. Once the card is detected as present (using the presence detect features, or some other method), the Smart Card should be powered up according to the power up sequence specified in the ISO 7816-3 specification.

1. Apply voltage to the Smart Card by setting the PCSR[SVCC_EN] bit
2. Select the appropriate clock frequency for the Smart Card by programming the CLKCFG and DIVISOR registers
3. Enable the clock to the Smart Card by setting the PCSR[SCEN] bit
4. Card exits reset state by setting the PCSR[SRST] bit

65.6.2 Automatic Power Down

Smart Cards require a proper sequence of operations to power down. The power down sequence as per ISO 7816 specifications is:

1. Smart Card Reset (RST) pin transitions from high to low
2. Smart Card Clock (CLK) is turned off to low
3. Smart Card IO (IO) is transitioned from high impedance to low
4. Smart Card Voltage Enable (SVCC_EN) is turned off (pin driven low)

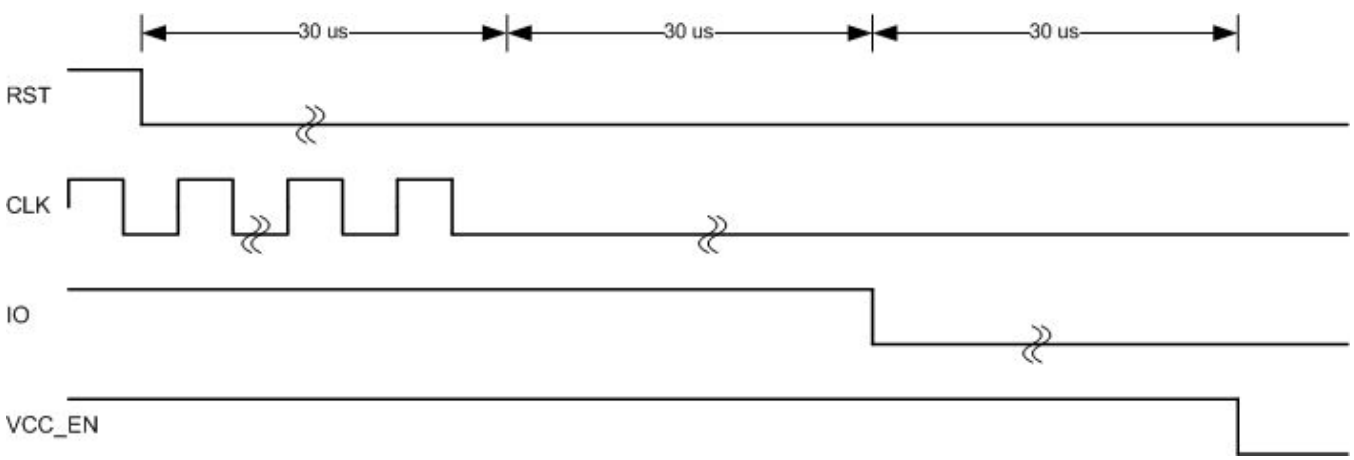

Figure 65-5. Auto Power Down Sequence

These operations can be done manually by software which writes to appropriate bits (SCEN, SRST and SVCC_EN) in the PCSR register or automatically by hardware under the following conditions.

- Setting the PSCR[SPD] bit by software
- Assertion of RX_STATUS[RTE] bit
- Assertion of PCSR[SPDIF] bit when configured to detect card removal
- Power Fail indication from off-chip power management controller

NOTE

The PCSR[SPDES] bit determines which edge transition of the Smart Card Presence Detect pin is used for Smart Card presence detection. Presence detection can be used to determine if the card has been inserted or removed. The occurrence of the edge specified by SPDES bit causes the following: SPDIF to be set; if the SPDIM mask is clear, an interrupt to the CPU; and if SAPD in the PCSR register is set, an auto power down sequence to begin. If Smart card insertion is expected, SAPD can be set low to avoid the auto power down sequence from falsely triggering. The bit SPDP can be used to determine the current state of the Smart Card Presence Detect pin.

NOTE

The auto power down operation requires a low frequency clock (usually 32 kHz clock source) to be active on the device.

The auto power down sequence clears the following register bits upon power down sequence completion:

1. PCSR[SPD] bit
2. PCSR[SCEN] bit
3. PCSR[SRST] bit
4. PCSR[SVCC_EN] bit
5. CTRL[XMT_EN] and CTRL[RCV_EN] bits

65.6.3 Configuration for ATR Detect

The following steps provide a suggested approach to configure the EMVSIM module to receive the ATR.

1. Clear the CTRL[RCVR_11] bit
2. Set the CTRL[ANACK] bit to enable NACK generation. The ISO 7816-3 spec allows the EMVSIM module to NACK any communication errors that occur during the initial communication at 12 ETU.

NOTE

The Europay MasterCard and VISA (EMV) cards are similar to “T=1”, but do not allow the EMVSIM module to NACK during the initial communication

3. Enable RDTF and RFO interrupts by setting RDT_IM and RFO_IM bits in INT_MASK register. These interrupts are enabled to notify the software when characters are received. A threshold can be set for the number of characters to receive before generating an interrupt.
4. Set desired threshold for received characters by writing RDT in RX_THD register

The EMVSIM should be setup to perform in initial character mode during ATR detection. This causes the hardware to identify the first valid character sent during the ATR as an initial character. This character automatically configures the hardware for the data convention used by the Smart Card.

- Set Initial Character Mode by setting the CTRL[ICM] bit

The ISO 7816-3 spec requires that Smart Cards meet certain timing restrictions. One of these is the time from the de-assertion of the card reset to the beginning of the ATR sequence. The General Purpose Counter of EMVSIM module can be used to verify that the Smart Card begins its ATR within the 400 to 40,000 card clock cycle range.

1. Set General Purpose Counter Timeout Value with 0x9C40 by programming GPCNT0/1_VAL register.
2. Enable General Purpose Counter Interrupt by clearing GPCNT0/1_IM bit in INT_MASK register.
3. Enable General Purpose Counter by programming the GPCNT0/1_CLK_SEL bits to 01, so that the card clock is used for counting.

The ISO7816-3 spec states that the maximum allowed time between two characters during the ATR is 9600 ETUs (Initial Waiting Time). The Character Wait Time Counter should be setup to detect any errors for this condition.

1. Set Character Wait Time Counter Comparator to 9600 using the CWT_VAL register
2. Enable the Character Wait Time Counter Interrupt by clearing CWT_ERR_IM in INT_MASK register
3. Enable the Character Wait Time Counter by setting the CTRL[CWT_EN] bit

The last step in preparing for ATR reception is to enable the receiver.

- Set RCV_EN bit in CTRL register

The EMVSIM module generates interrupts once a threshold number of characters is received. The software should react to these interrupts and read the characters from the receive FIFO (RX_BUF) until the complete ATR has been received. If a General Purpose Counter interrupt occurs before the final ATR character is received, then the card should

be deactivated according to the ISO 7816-3 spec (See Section Smart Card Interface and Control). Otherwise, once a valid ATR is received, the software knows from the ATR information the specific characteristics for this card (refer to the ISO 7816-3 spec for details).

65.6.3.1 Programming Considerations for T=0 Smart Cards

For type T=0 card, the software should adjust the following parameters according to the information in the ATR:

- Adjust the baud rate by changing the values of DIVISOR register based on the values of 'F' and 'D' received in the ATR
- Adjust the guard time between characters by changing the value of GETU in the TX_GETU register
- Adjust NACK capability by modifying the values of the ONACK and ANACK bits in the CTRL register
- Adjust the stop clock polarity by modifying the value of the PCSR[SCSP] bit
- Adjust the level of transmit NACK re-transmissions allowed by modifying the value of the TX_THD[TNCK_THD] bits
- Adjust the level for the Receive NACK threshold by modifying the RX_THD[RNCK_THD] bits

If a negotiation with the Smart Card is desired, the software sends a PPS response to the Smart Card. To send the response, the following steps should be performed:

- Set the desired transmit FIFO threshold level by writing the TDT bits in the TX_THD register
- Clear all transmit interrupt flags in the TX_STATUS register by writing a one to the bits of the register
- Enable the transmit interrupts desired by clearing the mask bits in the INT_MASK register. If more than 16 characters are to be sent, it is suggested that the TDTF interrupt be used to signify when to write more characters to the transmit FIFO. This results in the most efficient transfer times to the Smart Card
- Enable the transmitter by setting the CTRL[XMT_EN] bit
- Write the characters to be sent as response (max 16) to the transmit FIFO using the TX_BUF register

At this point, the EMVSIM module transmits the characters in the transmit FIFO. If more than 16 characters are to be sent, the transmit threshold interrupt is set when the threshold number of characters are remaining in the FIFO. The software can then write an additional number of characters to be sent without interrupting transmission to the Smart Card.

Once the transmission is complete, the EMVSIM module should be completely configured for standard operation with the T=0 Smart Card. The software can continue to service RDTF interrupts for received characters, and TDTF interrupts for transmitted characters.

65.6.3.2 Programming Considerations for T=1 Smart Cards

For type T=1 card, the software should adjust the following parameters according to the information in the ATR:

- Adjust the baud rate by changing the values of DIVISOR register based on the values of 'F' and 'D' received in the ATR
- Adjust the guard time between characters by changing the value of GETU in the TX_GETU register. Setting GETU to 0xFF configures the SIM transmitter for 11 ETU transmissions
- Disable NACK capability by clearing the CTRL[ONACK] and CTRL[ANACK] bits. T=1 cards do not allow NACKs
- Adjust the stop clock polarity by modifying the value of the PCSR[SCSP] bit
- Set Character Wait Time Counter Timeout Value to value specified in the ATR by using the CWT_VAL register
- Enable the Character Wait Time Counter Interrupt by clearing CWT_ERR_IM in INT_MASK register
- Enable the Character Wait Time Counter by setting the CTRL[CWT_EN] bit
- Enable CRC or LRC error checking according to the ATR information by setting either the CTRL[CRC_EN] bit or the CTRL[LRC_EN] bit. These bits should never be set at the same time!

For T=1 cards, the ATR is sent using a T=0 type of structure (12 ETU, no LRC or CRC). If a negotiation with the Smart Card is desired, the software sends a PPS response to the Smart Card. Otherwise, the protocol is initiated with a block transfer from the EMVSIM module. In order to send the response or the first block, the following steps should be performed:

- Set the desired transmit FIFO threshold level by writing the TDT[3:0] bits in the TX_THD register
- Clear all transmit interrupt flags in the TX_STATUS register by writing a one to the bits of the register
- Enable the transmit interrupts desired by clearing the mask bits in the INT_MASK register. If more than 16 characters are to be sent, it is suggested that the TDTF interrupt be used to signify when to write more characters to the transmit FIFO. This results in the most efficient transfer times to the Smart Card
- Enable the transmission of the error checking characters (LRC or CRC) by setting the CTRL[XMT_CRC_LRC] bit

NOTE

If the card supports PPS, the software may not be allowed to send the LRC/CRC information until the PPS exchange is completed. If so, do not set the XMT_CRC_LRC bit during the PPS exchange.

- Enable the transmitter by setting the CTRL[XMT_EN] bit
- Write the characters to be sent as response (max 16) to the transmit FIFO using the TX_BUF register

At this point, the EMVSIM module transmits the characters in the transmit FIFO. If more than 16 characters are to be sent, the transmit threshold interrupt is set when the threshold number of characters are remaining in the FIFO. The software can then write an additional number of characters to be sent without interrupting transmission to the Smart Card.

Once the transmission is complete, the EMVSIM module should be completely configured for standard operation with the T=1 Smart Card. The software can continue to service RDTF interrupts for received characters, and TDTF interrupts for transmitted characters.

65.7 Memory Map and Registers

65.7.1 EMVSIM register descriptions

The memory map comprises 32-bit aligned registers which can be accessed via 8-bit, 16-bit, or 32-bit accesses. Write access to reserved locations generate transfer error. Read access to reserved locations also generate transfer error and the read data bus show all 0s.The module not check for correctness of programmed values in the registers and software must ensure that correct values are being written.

7-0 RX_FIFO_DEPTH	Receive FIFO Depth Value of parameter for Receive FIFO Depth (in Bytes)

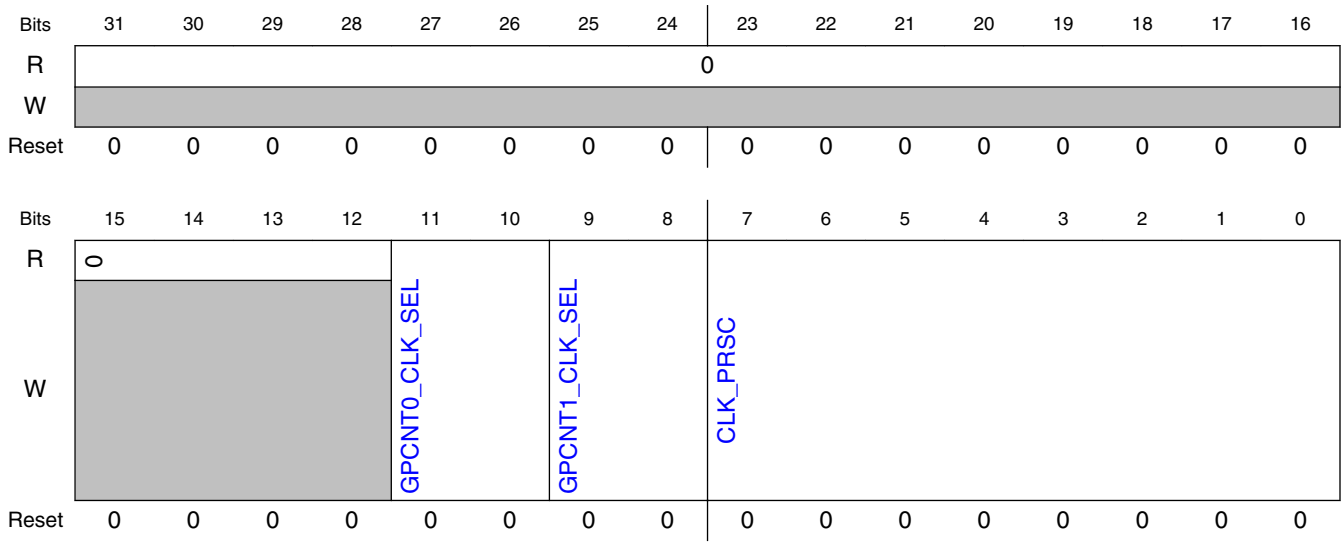
65.7.1.4 Clock Configuration Register (CLKCFG)

This register provides configuration details to enable the right clock frequency of clocks used by EMVSIM module.

65.7.1.4.1 Offset

Register	Offset
CLKCFG	8h

65.7.1.4.2 Diagram



65.7.1.4.3 Fields

Field	Description
31-12 —	Reserved
11-10 GPCNT0_CLK_SEL	General Purpose Counter 0 Clock Select Selects which clock source is used by EMVSIM Module general purpose counter 0. The only way to reset the counter is to set these bits to zero. The counter begins counting as soon as the clock input is selected and the clocks are active. These input clocks are enabled through other register bits of the EMVSIM module (KILL_CLOCK, RCV_EN, and XMT_EN). Counter is active while RCV_EN or XMT_EN are set. 00 - Disabled / Reset 01 - Card Clock 10 - Receive Clock 11 - ETU Clock (transmit clock)
9-8 GPCNT1_CLK_SEL	General Purpose Counter 1 Clock Select Selects which clock source is used by EMVSIM Module general purpose counter 1. The only way to reset the counter is to set these bits to zero. The counter begins counting as soon as the clock input is selected and the clocks are active. These input clocks are enabled through other register bits of the EMVSIM module (KILL_CLOCK, RCV_EN, and XMT_EN). Counter is active while RCV_EN or XMT_EN are set. 00 - Disabled / Reset 01 - Card Clock 10 - Receive Clock 11 - ETU Clock (transmit clock)
7-0 CLK_PRSC	Clock Prescaler Value

Field	Description
	The value written to this register determines the desired card clock frequency. The Card Clock frequency is the EMVSIM Protocol (or logic) clock divided by this prescaler value. The prescaler value should be updated only when card clock is disabled and transmitter and receiver are not operational. When CLK_PRSC = 0 or 1, the maximum prescaler value is used (0xFF). For all other values of CLK_PRSC, the prescaler value = CLK_PRSC.

65.7.1.5 Baud Rate Divisor Register (DIVISOR)

This register configures the divisor value to generate the baud clock which drives the card clock and also generate the transmit and receive clocks and respective ETUs.

65.7.1.5.3 Fields

Field	Description
31-9 —	Reserved
8-0 DIVISOR_VALUE	Divisor (F/D) Value The value written to this register is used to generate the ETU bit period that is used by the transmitter and receiver. The divisor value is the integer result of F/D value. 1 ETU = F / D * 1 / f

Field	Description
	• ETU is Elementary Time Unit, which is the nominal time to transmit a bit (0 or 1) • F is the clock rate conversion integer • D is the baud rate adjustment integer • f is the frequency of the communication clock used between the controller and the smartcard. The value in this register can be changed when no transaction is active with the smart card. When programming this field, the fractional part of F/D should be rounded off the nearest integer. 000000000-000000100 - Invalid. As per ISO 7816 specification, minimum value of F/D is 5 000000101-011111111 - For example, 101110100b = Divisor value for F = 372 and D = 1

65.7.1.6 Control Register (CTRL)

This register provides EMVSIM configuration details.

65.7.1.6.1 Offset

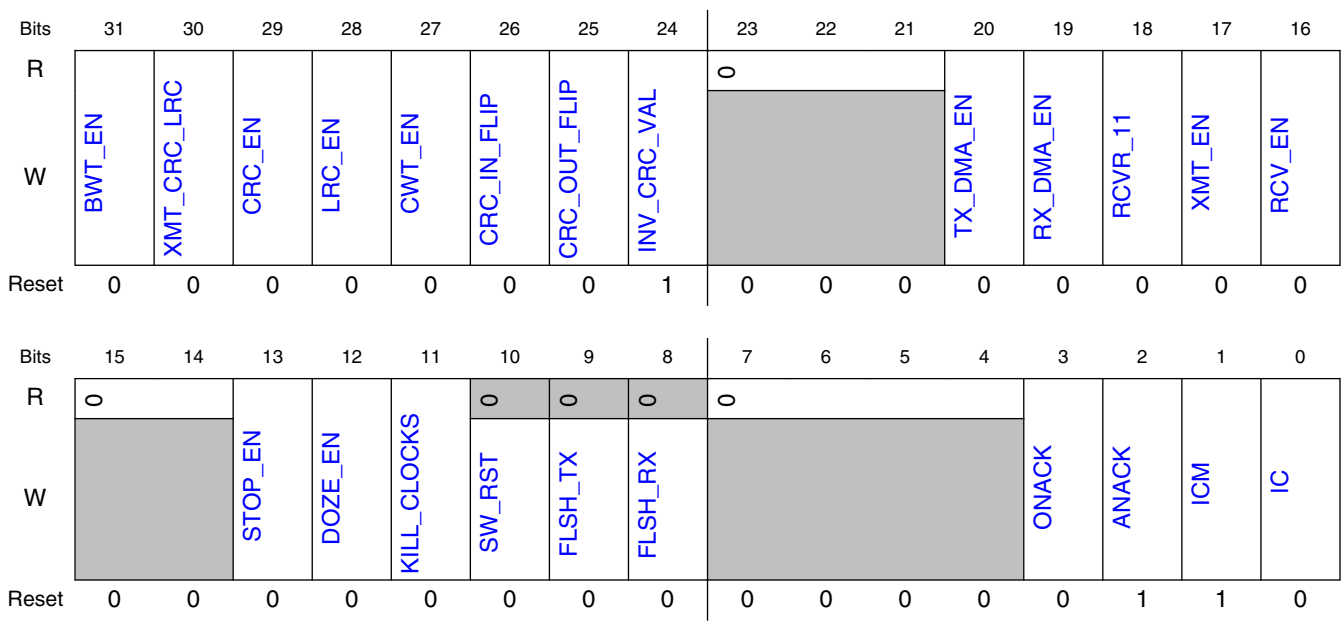
CTRL	10h

65.7.1.6.2 Diagram



65.7.1.6.3 Fields

Field	Description
31 BWT_EN	Block Wait Time Counter Enable Writing a '1' to this bit enables the BWT and BGT functions. The BWT and BGT functions can then be individually selected using the interrupt mask. 0 - Disable BWT, BGT Counters 1 - Enable BWT, BGT Counters
30 XMT_CRC_LRC	Transmit CRC or LRC Enable This bit specifies whether or not to transmit the redundancy checking data (LRC or CRC) at the end of a transmission (that is, when the FIFO becomes empty). 0 - No CRC or LRC value is transmitted 1 - Transmit LRC or CRC info when FIFO empties (whichever is enabled)
29 CRC_EN	CRC Enable This bit enables the calculation of the 16-bit CRC value for both receiver and transmitter. The result of the calculation is continuously compared to the expected remainder and reflected in the RX_STATUS[CRC_OK] bit. Clearing this bit resets the current CRC residual value in the EMVSIM hardware. 0 - 16-bit Cyclic Redundancy Checking disabled 1 - 16-bit Cyclic Redundancy Checking enabled
28 LRC_EN	LRC Enable This bit enables the calculation of the 8-bit LRC value for both receiver and transmitter. The result of the calculation is continuously compared to zero and reflected in the RX_STATUS[LRC_OK] bit. Clearing this bit resets the current LRC value in the EMVSIM hardware. 0 - 8-bit Linear Redundancy Checking disabled 1 - 8-bit Linear Redundancy Checking enabled
27 CWT_EN	Character Wait Time Counter Enable Enables the character wait time counter. Clearing this bit resets the counter to zero. 0 - Character Wait time Counter is disabled 1 - Character Wait time counter is enabled
26 CRC_IN_FLIP	CRC Input Byte's Bit Reversal or Flip Control This bit control whether the bits in the CRC input byte are reversed before CRC calculation or not. When set to '1', the bits within the input byte for CRC changes from 7:0 to 0:7. For CCITT CRC calculation, this bit should be set to '1'. For any other CRC using same polynomial, this bit can be set accordingly. 0 - Bits in the input byte are not reversed (i.e. 7:0 remain 7:0) before the CRC calculation 1 - Bits in the input byte are reversed (i.e. 7:0 becomes 0:7) before CRC calculation
25 CRC_OUT_FLIP	CRC Output Value Bit Reversal or Flip This bit control whether the bits in the CRC output bytes are reversed or not. When set to '1', the bits within the two bytes for CRC Output changes from 15:0 to {8:15,0:7}. For CCITT CRC calculation, this bit should be set to '1'. For any other CRC using same polynomial, this bit can be set accordingly. 0 - Bits within the CRC output bytes are not reversed i.e. 15:0 remains 15:0 1 - Bits within the CRC output bytes are reversed i.e. 15:0 becomes {8:15,0:7}
24 INV_CRC_VAL	Invert bits in the CRC Output Value

Table continues on the next page...

Field	Description
	This bit control whether the bits within the CRC Output value are inverted (1's complement) or not. For CCITT CRC calculation, this bit should be set to '1'. For any other CRC using same polynomial, this bit can be set accordingly. 0 - Bits in CRC Output value are not inverted. 1 - Bits in CRC Output value are inverted.
23-21 —	Reserved
20 TX_DMA_EN	Transmit DMA Enable Enables assertion of DMA write request when Transmit FIFO is empty. Request is held asserted till Transmit FIFO reaches the programmed data threshold value. Transmit Data Threshold Interrupt is not generated when this bit is asserted. 0 - No DMA Write Request asserted for Transmitter 1 - DMA Write Request asserted for Transmitter
19 RX_DMA_EN	Receive DMA Enable Enables assertion of DMA read request when Receive FIFO reaches the programmed data threshold value. Request is held asserted till all the programmed threshold bytes are read out. Receiver Data Interrupt is not be generated when this bit is asserted. 0 - No DMA Read Request asserted for Receiver 1 - DMA Read Request asserted for Receiver
18 RCVR_11	Receiver 11 ETU Mode Enable Used to configure the EMVSIM module receiver for 11 ETU operation (that is, 1 Stop bit). This bit is provided for support of T=1 cards. 0 - Receiver configured for 12 ETU operation mode 1 - Receiver configured for 11 ETU operation mode
17 XMT_EN	Transmitter Enable Used to enable/disable the EMVSIM transmitter block. It can be set to 0 during the auto power down sequence. **Note:** Setting this bit (transition from 0 to 1) resets the CRC and LRC values. 0 - EMVSIM Transmitter disabled 1 - EMVSIM Transmitter enabled
16 RCV_EN	Receiver Enable Used to enable/disable the EMVSIM receiver block. Once the transmitter has completed its operation, the software must enable the receiver using this bit. It can be set to 0 during the auto power down sequence. 0 - EMVSIM Receiver disabled 1 - EMVSIM Receiver enabled
15-14 —	Reserved
13 STOP_EN	STOP Enable Used to configure the operation of the EMVSIM module when a processor STOP instruction is executed. This bit is added to provide support for Smart Cards that do not allow the Smart Card clock to be stopped while power is applied. 0 - STOP instruction shuts down all EMVSIM clocks

Table continues on the next page...

Field	Description
	1 - STOP instruction shuts down all clocks except for the Smart Card Clock (SCK) (clock provided to Smart Card)
12 DOZE_EN	Doze Enable Used to configure the operation of the EMVSIM module when a processor DOZE instruction is executed. 0 - DOZE instruction gates all internal EMVSIM clocks as well as the Smart Card clock when the transmit FIFO is empty 1 - DOZE instruction has no effect on EMVSIM module
11 KILL_CLOCKS	Kill all internal clocks Used to enable/disable the clock input to the EMVSIM module. This bit gates all clocks including the Smart Card clock regardless of the state of the STOP bit described above. **Note:** This bit has no effect on the register read write clock. Only EMVSIM logic clock is gated. 0 - EMVSIM input clock enabled 1 - EMVSIM input clock is disabled
10 SW_RST	Software Reset Bit Used to reset the entire EMVSIM module. This acts the same as a hardware reset for the EMVSIM module. This bit is self-clearing and always reads 0. **Note:** Software should allow a minimum of 4 Protocol clock cycles before attempting to access the EMVSIM module after a software reset. 0 - EMVSIM Normal operation 1 - EMVSIM held in Reset
9 FLSH_TX	Flush Transmitter Bit This bit operates as an EMVSIM transmitter reset. The receive portion of the EMVSIM module is not affected. This bit clears automatically and always reads 0. 0 - EMVSIM Transmitter normal operation 1 - EMVSIM Transmitter held in Reset
8 FLSH_RX	Flush Receiver Bit This bit operates as an EMVSIM receiver reset. The transmit portion of the EMVSIM module is not affected. This bits clears automatically and always reads 0. 0 - EMVSIM Receiver normal operation 1 - EMVSIM Receiver held in Reset
7-4 —	Reserved
3 ONACK	Overrun NACK Enable Enables NACK generation when Rx FIFO is full and another message is ready for writing into the FIFO. 0 - NACK generation on overrun is disabled 1 - NACK generation on overrun is enabled
2 ANACK	Auto NACK Enable Enables NACK generation for parity errors in receieved messages or when invalid initial characters are received in ICM mode. 0 - NACK generation on errors disabled 1 - NACK generation on errors enabled
1	Initial Character Mode

Table continues on the next page...

Field	Description
ICM	Enables initial character mode. It is automatically cleared by hardware once a valid initial character is received. 0 - Initial Character Mode disabled 1 - Initial Character Mode enabled
0 IC	Inverse Convention Used to configure the EMVSIM to use either inverse convention or direct convention for its data format. The IC bit can be controlled by software, but it is normally set by hardware as a result of the interpretation of the initial character when in ICM mode. 0 - Direction convention transfers enabled 1 - Inverse convention transfers enabled

65.7.1.7 Interrupt Mask Register (INT_MASK)

This register provides interrupt masking configuration details.

65.7.1.7.1 Offset

Register	Offset
INT_MASK	14h

Field	Description
31-16 —	Reserved
15 PEF_IM	Parity Error Interrupt Mask Used to enable/disable the ability of the RX_STATUS[PEF] flag to generate EMVSIM interrupts. 0 - PEF interrupt enabled 1 - PEF interrupt masked
14 RX_DATA_IM	Receive Data Interrupt Mask Used to enable/disable the ability of the RX_STATUS[RX_DATA] flag to generate EMVSIM interrupts. 0 - RX_DATA interrupt enabled 1 - RX_DATA interrupt masked
13 GPCNT1_IM	General Purpose Counter 1 Timeout Interrupt Mask Used to enable/disable the ability of the TX_STATUS[GPCNT1_TO] flag to generate EMVSIM interrupts. 0 - GPCNT1_TO interrupt enabled 1 - GPCNT1_TO interrupt masked
12 BGT_ERR_IM	Block Guard Time Error Interrupt Used to enable/disable the ability of the RX_STATUS[BGT_ERR] flag to generate EMVSIM interrupts. 0 - BGT_ERR interrupt enabled 1 - BGT_ERR interrupt masked
11 BWT_ERR_IM	Block Wait Time Error Interrupt Mask Used to enable/disable the ability of the RX_STATUS[BWT_ERR] flag to generate EMVSIM interrupts. 0 - BWT_ERR interrupt enabled 1 - BWT_ERR interrupt masked
10 RNACK_IM	Receiver NACK Threshold Interrupt Mask Used to enable/disable the ability of the RX_STATUS[RTE] flag to generate EMVSIM interrupts. 0 - RTE interrupt enabled 1 - RTE interrupt masked
9 CWT_ERR_IM	Character Wait Time Error Interrupt Mask Used to enable/disable the ability of the RX_STATUS[CWT_ERR] flag to generate EMVSIM interrupts. 0 - CWT_ERR interrupt enabled 1 - CWT_ERR interrupt masked
8 GPCNT0_IM	General Purpose Timer 0 Timeout Interrupt Mask Used to enable/disable the ability of the TX_STATUS[GPCNT0_TO] flag to generate EMVSIM interrupts. 0 - GPCNT0_TO interrupt enabled 1 - GPCNT0_TO interrupt masked
7 TDT_IM	Transmit Data Threshold Interrupt Mask Used to enable/disable the ability of the TX_STATUS[TDTF] flag to generate EMVSIM interrupts. 0 - TDTF interrupt enabled

Table continues on the next page...

Field	Description
	1 - TDTF interrupt masked
6 TFF_IM	Transmit FIFO Full Interrupt Mask Used to enable/disable the ability of the TX_STATUS[TFF] flag to generate EMVSIM interrupts. 0 - TFF interrupt enabled 1 - TFF interrupt masked
5 TNACK_IM	Transmit NACK Threshold Interrupt Mask Used to enable/disable the ability of the TX_STATUS[TNTE] flag to generate EMVSIM interrupts. 0 - TNTE interrupt enabled 1 - TNTE interrupt masked
4 TFE_IM	Transmit FIFO Empty Interrupt Mask Used to enable/disable the ability of the TX_STATUS[TFE] flag to generate EMVSIM interrupts. 0 - TFE interrupt enabled 1 - TFE interrupt masked
3 ETC_IM	Early Transmit Complete Interrupt Mask Used to enable/disable the ability of the TX_STATUS[ETC] flag to generate EMVSIM interrupts. 0 - ETC interrupt enabled 1 - ETC interrupt masked
2 RFO_IM	Receive FIFO Overflow Interrupt Mask Used to enable/disable the ability of the RX_STATUS[RFO] flag to generate EMVSIM interrupts. 0 - RFO interrupt enabled 1 - RFO interrupt masked
1 TC_IM	Transmit Complete Interrupt Mask Used to enable/disable the ability of the TX_STATUS[TCF] flag to generate EMVSIM interrupts. 0 - TCF interrupt enabled 1 - TCF interrupt masked
0 RDT_IM	Receive Data Threshold Interrupt Mask Used to enable/disable the ability of the RX_STATUS[RDTF] flag to generate EMVSIM interrupts. 0 - RDTF interrupt enabled 1 - RDTF interrupt masked

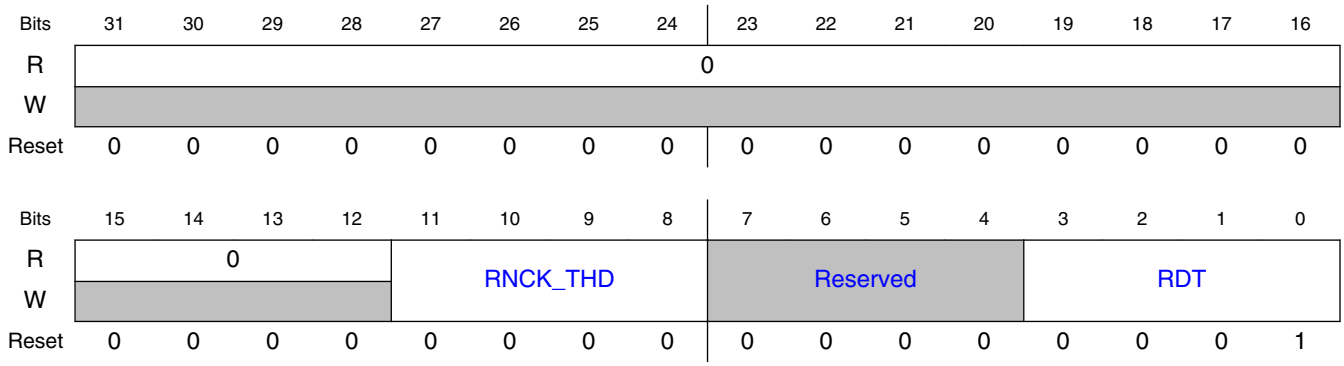
65.7.1.8 Receiver Threshold Register (RX_THD)

This register provides receiver threshold configuration details.

65.7.1.8.1 Offset

Register	Offset
RX_THD	18h

65.7.1.8.2 Diagram



65.7.1.8.3 Fields

Field	Description
31-12 —	Reserved
11-8 RNCK_THD	Receiver NACK Threshold Value Used to specify the number of consecutive NACK's transmitted by the EMVSIM module, for a given character, before the receive threshold error (RTE) flag is triggered. A value of 0 indicates that RTE is never set. When a valid character is received by the EMV SIM, the internal counter keeping track of the NACK count resets to zero for the subsequent byte being received. If the ANACK bit is clear in the CTRL register, RNCK_THD has no effect. 0000 - Zero Threshold. RTE is not set 0001 - RTE is triggered after 1 nack is transmitted 0010 - RTE is triggered after 2 nacks are transmitted 0011 - RTE is triggered after 3 nacks are transmitted ... 1111 - RTE is triggered after 15 nacks are transmitted
7-4 —	Reserved
3-0 RDT	Receiver Data Threshold Value Determines the number of bytes that must exist in the Receive FIFO to trigger the receive data threshold interrupt flag (RDTF). Value must not exceed the total bytes that can be stored in the Receive FIFO.

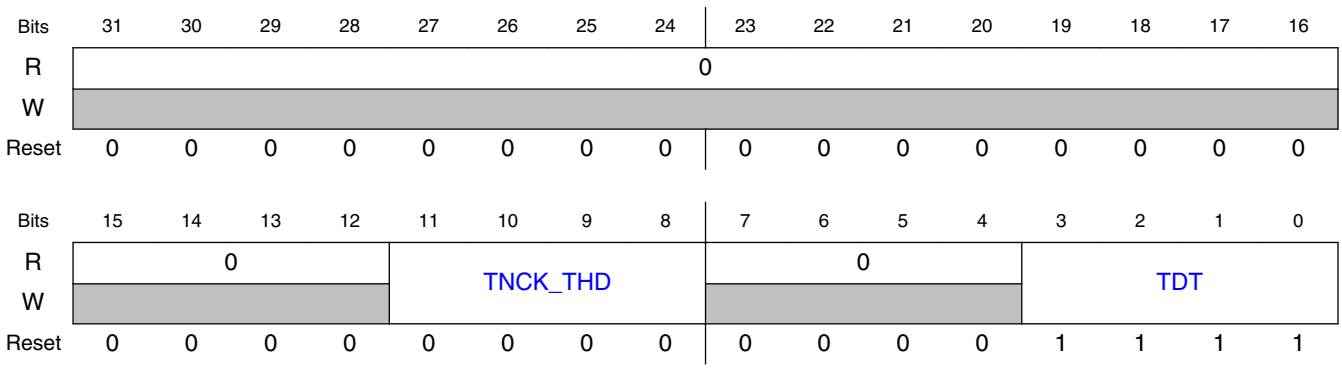
65.7.1.9 Transmitter Threshold Register (TX_THD)

This register provides transmitter threshold configuration details.

65.7.1.9.1 Offset

Register	Offset
TX_THD	1Ch

65.7.1.9.2 Diagram



65.7.1.9.3 Fields

Field	Description
31-12 —	Reserved
11-8 TNCK_THD	Transmitter NACK Threshold Value Used to set the NACK threshold for the transmitter. Once the threshold number set by TNCK_THD has been reached for the current byte being transmitted, the error flag TNTE in the TX_STATUS register is set. Setting of TNTE causes the remaining transmissions queued in the transmit FIFO to be aborted and no more transmissions to occur until software clears TNTE. To trigger TNTE, a given byte being transmitted must reach the TNCK_THD threshold itself. Transmit NACKs accumulated on one byte are not carried over to the next. 0000 - TNTE is never set; retransmission after NACK reception is disabled 0001 - TNTE is set after 1 nack is received; 0 retransmissions occurs 0010 - TNTE is set after 2 nacks are received; at most 1 retransmission occurs 0011 - TNTE is set after 3 nacks are received; at most 2 retransmissions occurs ... 1111 - TNTE is set after 15 nacks are received; at most 14 retransmissions occurs
7-4 —	Reserved
3-0 TDT	Transmitter Data Threshold Value Used to set the threshold value for the Transmit FIFO at which the TX_STATUS[TDTF] bit is set. When the number of bytes in the Transmit FIFO is less than or equal to TDT, TDTF is set.

65.7.1.10 Receive Status Register (RX_STATUS)

This register provides receive status details.

65.7.1.10.1 Offset

Register	Offset
RX_STATUS	20h

65.7.1.10.2 Diagram

65.7.1.10.3 Fields

Field	Description
31-28 —	Reserved
27-24 RX_CNT	Receive FIFO Byte Count These bits indicate the number of bytes stored in the receive FIFO. 0000 - FIFO is emtpy
23-20 —	Reserved
19-16 RX_WPTR	Receive FIFO Write Pointer Value Value of write pointer of Receive FIFO
15-14 —	Reserved
13	Frame Error Flag

Table continues on the next page...

Field	Description
FEF	Used to indicate if the current received byte did not have proper STOP bits. This does not cause a NACK transmission. This bit does not cause an interrupt assertion. It is simply an indication that a framing error has occured. 0 - No frame error detected 1 - Frame error detected
12 PEF	Parity Error Flag Used to indicate if a received byte had a parity error or not. A parity error causes transmission of NACK if ANACK bit is set in CTRL register and PEF bit is not asserted. When ANACK is *not* set, PEF is asserted. This bit also does not assert when the ICM bit is set; however parity is checked in ICM = 1 mode. It is simply an indication that a parity error has occured. 0 - No parity error detected 1 - Parity error detected
11 BGT_ERR	Block Guard Time Error Flag Used to indicate if the block guard time was too small. The threshold is set by the BGT_VAL register. 0 - Block guard time was sufficient 1 - Block guard time was too small
10 BWT_ERR	Block Wait Time Error Flag Used to indicate if the block wait time has been exceeded. The threshold is set by the BWT_VAL registers. 0 - Block wait time not exceeded 1 - Block wait time was exceeded
9 RTE	Received NACK Threshold Error Flag Used to indicate whether the number of consecutive NACK's generated by the EMVSIM module in response to receive parity errors, for the byte being received, equals the value programmed in the RX_THD[RNCK_THD]. This bit is never set unless the ANACK bit is set in the CTRL register. The PCSR[SAPD] bit must be set to enable the threshold error to trigger the auto power down sequence. RTE is a write once clear bit. Clearing this bit also resets the internal counter for consecutive NACKs being transmitted for a given byte. 0 - Number of NACKs generated by the receiver is less than the value programmed in RNCK_THD 1 - Number of NACKs generated by the receiver is equal to the value programmed in RNCK_THD
8 CWT_ERR	Character Wait Time Error Flag Used to indicate when the time between received characters is equal to or greater than the value programmed in the CWT_VAL register. 0 - No CWT violation has occurred 1 - Time between two consecutive characters has exceeded the value in CWT_VAL.
7 CRC_OK	CRC Check OK Flag Used to indicate when the calculated 16-bit CRC value matches the expected value for the current input data stream. The value is calculated across all received characters from the point the CRC_EN bit is set in the CTRL register. The current CRC residual can be reset by three mechanisms: • Clear CTRL[CRC_EN] bit • Set CTRL[XMT_EN] bit • Automatically by hardware when ETC flag is set at the end of a transmission. 0 - Current CRC value does not match remainder. 1 - Current calculated CRC value matches the expected result.

Table continues on the next page...

Field	Description
6 LRC_OK	LRC Check OK Flag Used to indicate when the calculated 8-bit LRC value is correct for the current input data stream. The value is calculated across all received characters from the point the LRC_EN bit is set in the CTRL register. The current LRC residual can be reset by three mechanisms: • Clear CTRL[LRC_EN] bit • Set CTRL[XMT_EN] bit • Automatically by hardware when ETC flag is set at the end of a transmission. 0 - Current LRC value does not match remainder. 1 - Current calculated LRC value matches the expected result (i.e. zero).
5 RDTF	Receive Data Threshold Interrupt Flag Interrupt flag asserted when total bytes in the Receive FIFO equal or is greater than the programmed receive threshold RDT. The RDTF flag is set any time the number of unread bytes in the receive FIFO is equal to or greater than the value set by RDT. The flag can be cleared by reading enough bytes out of the receive FIFO so as to bring the number of bytes left in the FIFO below the RDT level. Another way to clear the flag is to set the RDT level higher than the number of unread bytes currently in the FIFO. The RDTF flag creates an interrupt if the INT_MASK[RDT_IM] bit is cleared. 0 - Number of unread bytes in receive FIFO less than the value set by RDT 1 - Number of unread bytes in receive FIFO greater or than equal to value set by RDT.
4 RX_DATA	Receive Data Interrupt Flag Interrupt asserted when a new data byte is received and entered into the Receive FIFO. 0 - No new byte is received 1 - New byte is received ans stored in Receive FIFO
3-1 —	Reserved
0 RFO	Receive FIFO Overflow Flag Used to indicate that the EMVSIM was unable to store received data due to already unread bytes in the FIFO (FIFO full or almost full). It does not necessarily indicate that data has been lost. If the CTRL[ONACK] control bit is set, there is a NACK pulse generated on bytes that would otherwise cause a loss of data due to a full FIFO. These bytes should be retransmitted by the Smart Card which implies that no data has actually been lost. In this case, the RFO flag is just an indicator that this situation has occurred which may be helpful in system debug. For the case where ONACK is not set, a set RFO flag does indicate a loss of data since all bytes received with the OEF flag set is indeed lost (including the byte that caused the bit to be set). The RFO flag causes an interrupt if the INT_MASK[RFO_IM] bit is enabled (RFO_IM=0). The RFO flag is a write-one-to-clear bit. 0 - No overrun error has occurred 1 - A byte was received when the received FIFO was already full

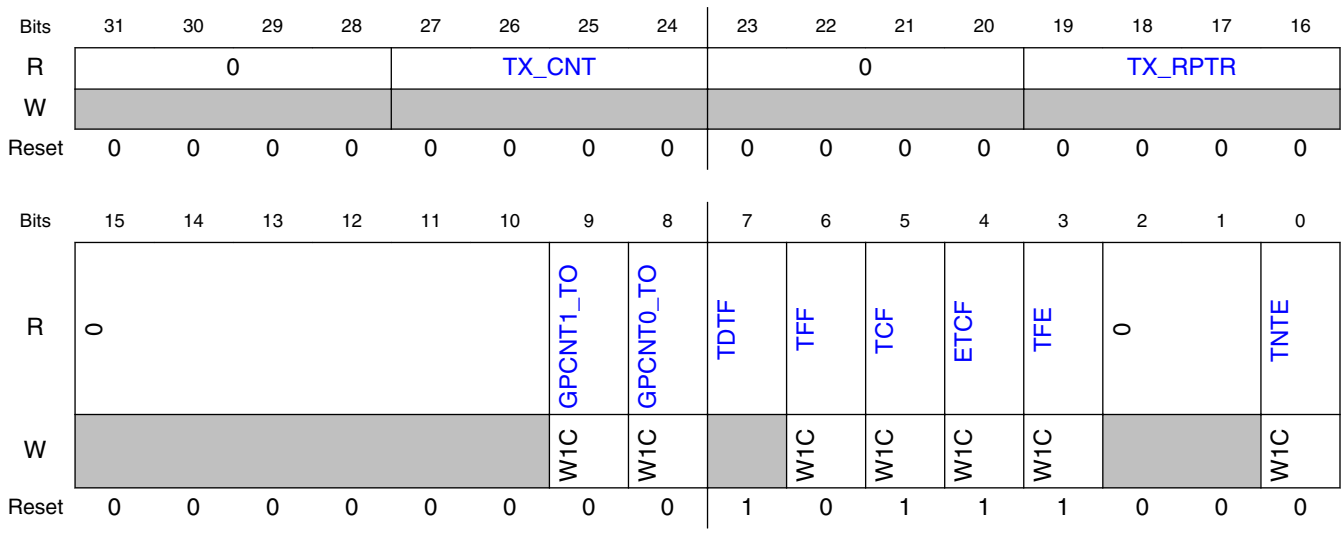
65.7.1.11 Transmitter Status Register (TX_STATUS)

This register provides transmitter status details.

65.7.1.11.1 Offset

Register	Offset
TX_STATUS	24h

65.7.1.11.2 Diagram



65.7.1.11.3 Fields

Field	Description
31-28 —	Reserved
27-24 TX_CNT	Transmit FIFO Byte Count These bits indicate the number of bytes stored in the transmit FIFO. 0000 - FIFO is emtpy
23-20 —	Reserved
19-16 TX_RPTR	Transmit FIFO Read Pointer Value of the read pointer of transmit FIFO.
15-10 —	Reserved
9 GPCNT1_TO	General Purpose Counter 1 Timeout Flag Used to indicate when the General Purpose Counter 1 has reached the GPCNT1 value in the GPCNT1_VAL register. 0 - GPCNT1 time not reached, or bit has been cleared.

Table continues on the next page...

Field	Description
	1 - General Purpose counter has reached the GPCNT1 value
8 GPCNT0_TO	General Purpose Counter 0 Timeout Flag Used to indicate when the General Purpose Counter 0 has reached the GPCNT0 value in the GPCNT0_VAL register. 0 - GPCNT0 time not reached, or bit has been cleared. 1 - General Purpose counter has reached the GPCNT0 value
7 TDTF	Transmit Data Threshold Flag Interrupt flag asserted when total bytes in the Transmit FIFO is less than or equal to the programmed transmit data threshold TDT. The TDTF flag is set any time the number of bytes in the transmit FIFO is less than or equal to the value set by TDT. The flag can be cleared by writing enough bytes into the transmit FIFO so as to take the number of bytes in the FIFO above the TDT level. Another way to clear the flag is to set the TDT level lower than the number of bytes currently in the FIFO.The TDTF flag creates an interrupt if the INT_MASK[TDT_IM] bit is cleared. 0 - Number of bytes in FIFO is greater than TDT, or bit has been cleared 1 - Number of bytes in FIFO is less than or equal to TDT
6 TFF	Transmit FIFO Full Flag Used to indicate when the Transmit FIFO has been written with maximum number of bytes that it can store. Subsequent writes may get ignored. The TFF bit can only be cleared by writing 1 to this bit or setting the CTRL[SW_RST] bit. 0 - Transmit FIFO Full condition has not occurred 1 - A Transmit FIFO Full condition has occurred
5 TCF	Transmit Complete Flag Used to indicate whether the EMVSIM transmitter is ready for a new transmission. The TC flag becomes set when the guard time has expired after the last byte in the transmit FIFO (if XMT_CRC_LRC = 0) or the LRC or CRC byte (if XMT_CRC_LRC bit = 1) has been transmitted. The TC flag creates an interrupt if TC_IM in the INT_MASK register is low. The TC bit is a write-one-to-clear bit. 0 - Transmit pending or in progress 1 - Transmit complete
4 ETCF	Early Transmit Complete Flag Used to indicate that the EMVSIM transmitter has finished sending the last byte in transmit FIFO (if XMT_CRC_LRC = 0) or finished sending the LRC or CRC byte (if XMT_CRC_LRC = 1). This bit differs from the TC bit in that it is set before the guard time of the last byte has elapsed. The ETC flag creates an interrupt if ETC_IM in the INT_MASK register is low. The ETC bit is a write-one-to-clear bit. 0 - Transmit pending or in progress 1 - Transmit complete
3 TFE	Transmit FIFO Empty Flag Used to indicate that the EMVSIM transmit FIFO has been emptied. This bit is set when the last byte in the transmit FIFO has been transferred out of the EMVSIM transmitter to the Smart Card successfully. TFE is also set when the TNTE flag is set. The TFE flag creates an interrupt if TFE_IM in the INT_MASK register is low. The TFE bit is a write-one-to-clear bit. 0 - Transmit FIFO is not empty 1 - Transmit FIFO is empty
2-1 —	Reserved
0	Transmit NACK Threshold Error Flag

Field	Description
TNTE	Used to indicate the transmit NACK threshold has been reached. When TNTE is high, no further transmissions are done until the TNTE flag is cleared. Any data transmissions still pending in the transmit FIFO are aborted, and the TC, ETC, and TFE flags are set. The TNTE flag creates an interrupt if TNACK_IM in the INT_MASK register is low. The TNTE bit is a write-one-to-clear bit. 0 - Transmit NACK threshold has not been reached 1 - Transmit NACK threshold reached; transmitter frozen

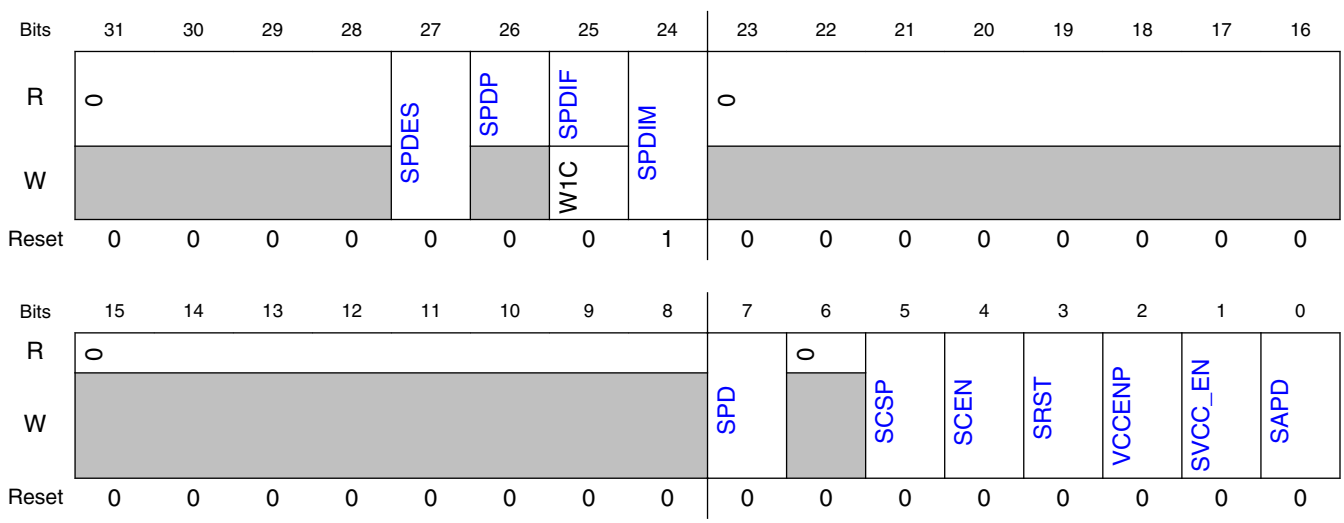
65.7.1.12 Port Control and Status Register (PCSR)

This register provides control and status details related to the smart card port.

65.7.1.12.1 Offset

Register	Offset
PCSR	28h

65.7.1.12.2 Diagram



65.7.1.12.3 Fields

Field	Description
31-28 —	Reserved

Table continues on the next page...

Field	Description
27 SPDES	SIM Presence Detect Edge Select Controls which edge of the Smart Card Presence Detect pin is used to detect the presence of the Smart Card. 0 - Falling edge on the pin 1 - Rising edge on the pin
26 SPDP	Smart Card Presence Detect Pin Status This bit reflects the state of the Smart Card Presence Detect pin. It is not a latched register bit, but instead a synchronized version of the state of the pin itself. 0 - SIM Presence Detect pin is logic low 1 - SIM Presence Detectpin is logic high
25 SPDIF	Smart Card Presence Detect Interrupt Flag Status flag to indicate that an insertion or removal of a Smart Card has been detected on port. Can create an interrupt to the MCU if SPDIM is low and/or initiate the auto power down sequence if SAPD bit is '1'. Write a '1' to this bit to clear. 0 - No insertion or removal of Smart Card detected on Port 1 - Insertion or removal of Smart Card detected on Port
24 SPDIM	Smart Card Presence Detect Interrupt Mask Interrupt mask for the presence detect interrupt flag (SPDIF). 0 - SIM presence detect interrupt is enabled 1 - SIM presence detect interrupt is masked
23-8 —	Reserved
7 SPD	Auto Power Down Control Writing a '1' to this location starts the autopower down sequence provided the auto power down feature is enabled by writing '1' to SAPD bit of this register. The SPD bit autoclears when power down is complete. 0 - No effect 1 - Start Auto Powerdown or Power Down is in progress
6 —	Reserved
5 SCSP	Smart Card Clock Stop Polarity Used to control the polarity of the idle EMVSIM clock when the clock is disabled by SCEN. 0 - Clock is logic 0 when stopped by SCEN 1 - Clock is logic 1 when stopped by SCEN
4 SCEN	Clock Enable for Smart Card Used to enable/disable the clock to the Smart Card. It can be forced low by hardware during the auto power down sequence. 0 - Smart Card Clock Disabled 1 - Smart Card Clock Enabled
3 SRST	Reset to Smart Card Used to control state of reset line to the Smart Card. It can be forced low by hardware during the auto power down sequence. Smart Card reset signals are active low.

Table continues on the next page...

Field	Description
	0 - Smart Card Reset is asserted 1 - Smart Card Reset is de-asserted
2 VCCENP	VCC Enable Polarity Control Used to control the polarity of the SVEN output pad via the SVCC_EN bit. When set to '1', this bit inverts the value of SVCC_EN bit of this register and output to SVEN output pad of device. 0 - SVCC_EN is active high. Polarity of SVCC_EN is unchanged. 1 - SVCC_EN is active low. Polarity of SVCC_EN is inverted.
1 SVCC_EN	Vcc Enable for Smart Card Used to control the state of the SVEN pin on Smart Card port. The SVEN pin controls the Smart Card Vcc enable in the power management chip. It can be forced low by hardware during the auto power down sequence. This bit is XORed with the VCCENP bit to control the polarity of the SVEN output pad. 0 - Smart Card Voltage disabled 1 - Smart Card Voltage enabled
0 SAPD	Auto Power Down Enable Used to enable/disable the auto power down feature. This bit must be set prior to the auto power conditions are met. This bit returns to 0 at the end of the auto power down sequence. This bit controls the auto power down function which can be initiated by: • Setting the SPD bit in this register by software • Assertion of the RX_STATUS[RTE] bit • Assertion of the SPDIF bit when the interrupt is used for detecting card removal Manual Power Down via software by writing to the SCEN, SRST, and SVCC_EN bits in PCSR register can still be carried out irrespective of this bit. 0 - Auto power down disabled 1 - Auto power down enabled

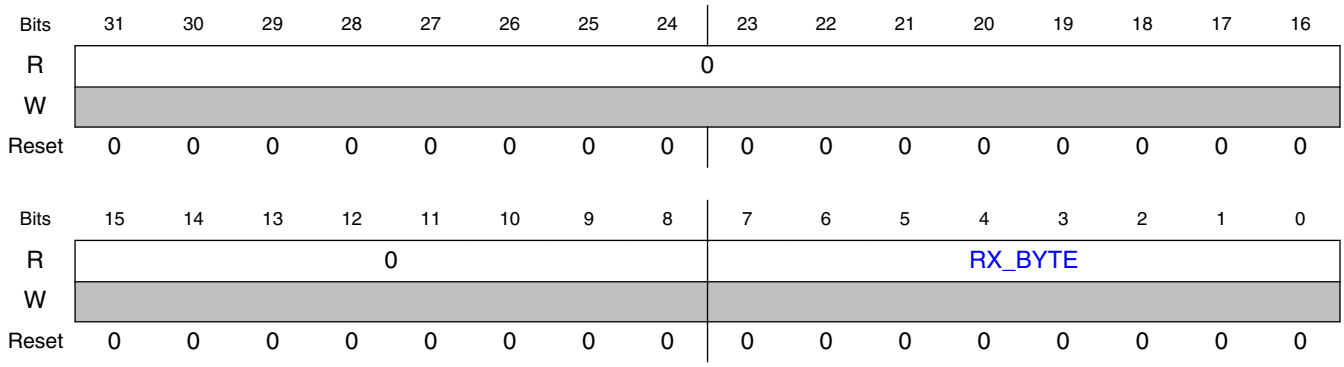
65.7.1.13 Receive Data Read Buffer (RX_BUF)

This register provides the byte value from the top of the receive FIFO.

65.7.1.13.1 Offset

Register	Offset
RX_BUF	2Ch

65.7.1.13.2 Diagram



65.7.1.13.3 Fields

Field	Description
31-8 —	Reserved
7-0 RX_BYTE	Receive Data Byte Read Provides the byte value from the top of the receive FIFO. Each read access to this register increments the read pointer of the Receive FIFO.

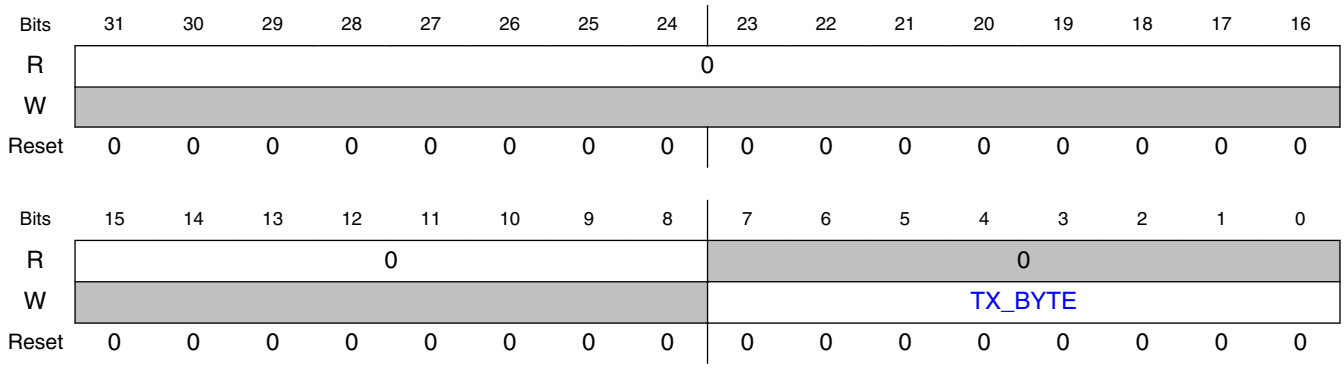
65.7.1.14 Transmit Data Buffer (TX_BUF)

This register is written to fill the transmit FIFO with the bytes to be transmitted.

65.7.1.14.1 Offset

Register	Offset
TX_BUF	30h

65.7.1.14.2 Diagram



65.7.1.14.3 Fields

Field	Description
31-8 —	Reserved
7-0 TX_BYTE	Transmit Data Byte Write to this register to fill the transmit FIFO with the bytes to be transmitted. The Tx FIFO can be written to only when the transmitter is enabled. Writing to this register while transmitter is disabled leads to ignoring of all write accesses to this register. Reads to this register returns zeros. **NOTE:** Writing more data to the transmit FIFO than it can hold, causes a Transmit FIFO Full (TFF) error.

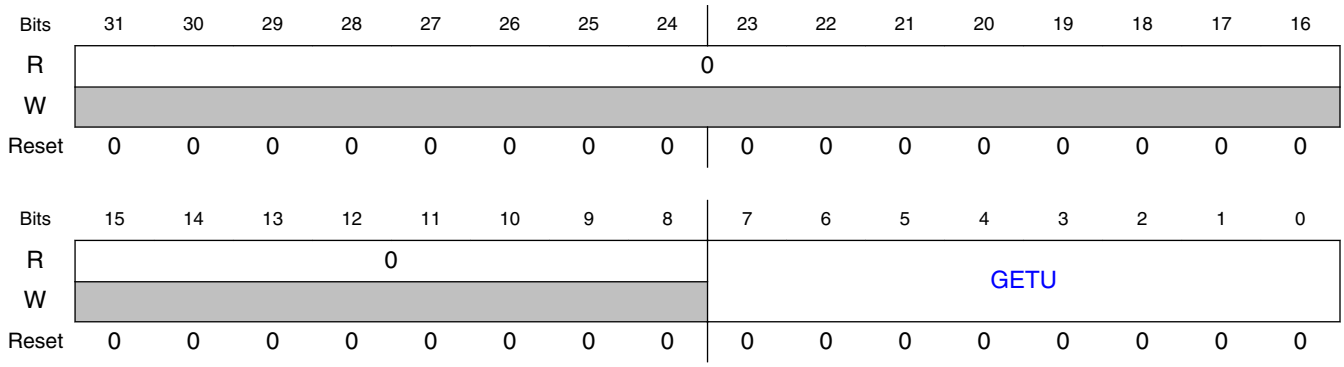
65.7.1.15 Transmitter Guard ETU Value Register (TX_GETU)

This register is used to control the number of additional Elementary Time Units (ETUs) inserted between bytes transmitted by the EMV SIM transmitter.

65.7.1.15.1 Offset

Register	Offset
TX_GETU	34h

65.7.1.15.2 Diagram



65.7.1.15.3 Fields

Field	Description
31-8 —	Reserved
7-0 GETU	Transmitter Guard Time Value in ETU Used to control the number of additional Elementary Time Units (ETUs) inserted between bytes transmitted by the EMVSIM transmitter. An ETU is equivalent to one bit time at the given baud rate (for example, the length of a START bit). The guard time has no effect on the EMVSIM receiver. A value of 0x00 inserts no additional ETUs, while a value of 0xFE inserts 254 additional ETUs. A value of 0xFF subtracts one ETU by reducing the number of STOP bits from two to one. 00000000 - No additional ETUs inserted 00000001 - 1 additional ETU inserted ... 11111110 - 254 additional ETUs inserted 11111111 - Subtracts one ETU by reducing the number of STOP bits from two to one

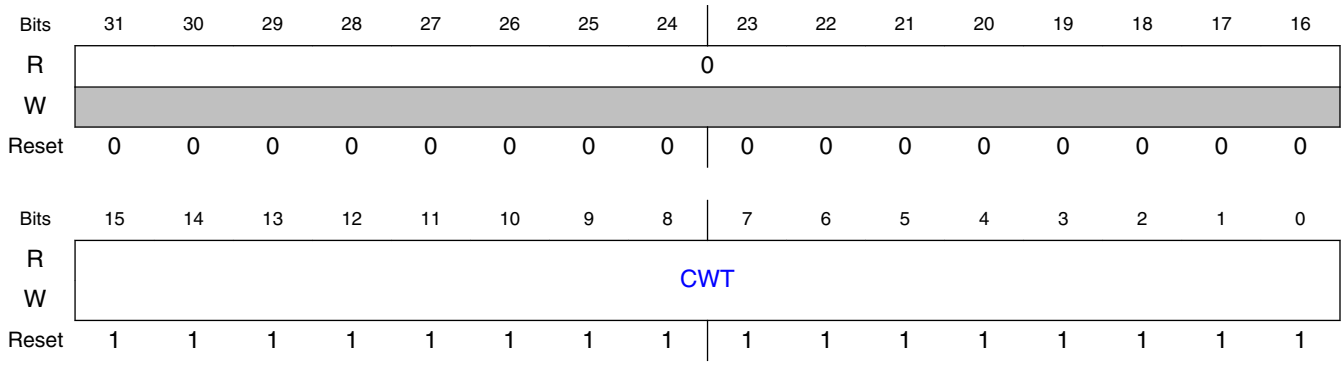
65.7.1.16 Character Wait Time Value Register (CWT_VAL)

This register is used to specify the number of ETU times allowed between characters.

65.7.1.16.1 Offset

Register	Offset
CWT_VAL	38h

65.7.1.16.2 Diagram



65.7.1.16.3 Fields

Field	Description
31-16 —	Reserved
15-0 CWT	Character Wait Time Value The value written to this register specifies the number of ETU times allowed between characters. Default is 0xFFFF

65.7.1.17 Block Wait Time Value Register (BWT_VAL)

This register is used to specify the maximum time between the time from the START bit of last byte sent from the EMVSIM module to the START bit of the first byte sent from the Smart Card.

65.7.1.17.1 Offset

Register	Offset
BWT_VAL	3Ch

15-0 BGT	Block Guard Time Value The value in this register is the block guard time. Time from START bit of last byte sent from the EMVSIM module to the START bit of the first byte sent from the SmartCard must be greater than this value. If it is not, then the BGT flag is set.

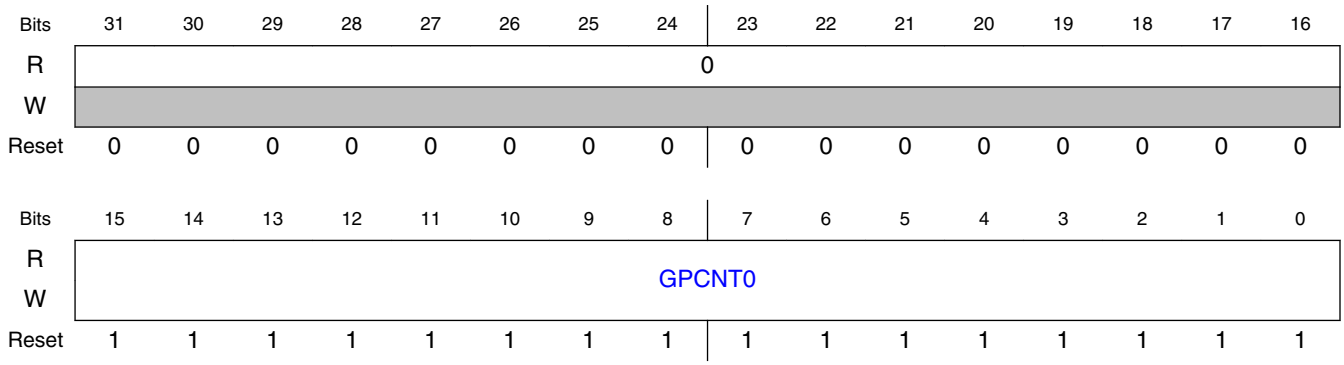
65.7.1.19 General Purpose Counter 0 Timeout Value Register (GPCNT0_VAL)

The value written to this register is used to compare to the general purpose counter 0 in the EMVSIM module.

65.7.1.19.1 Offset

Register	Offset
GPCNT0_VAL	44h

65.7.1.19.2 Diagram



65.7.1.19.3 Fields

Field	Description
31-16 —	Reserved
15-0 GPCNT0	General Purpose Counter 0 Timeout Value The value written to this register is used to compare to the general purpose counter 0 in the EMVSIM module. Once the General purpose counter reaches this value, the GPCNT0_TO flag in the TX_STATUS register is set. This counter is intended to be used for any events that must be monitored for duration based on the card clock, receiver sample rate, or ETU rate (transmit clock). Example: ATR arrival time and ATR duration.

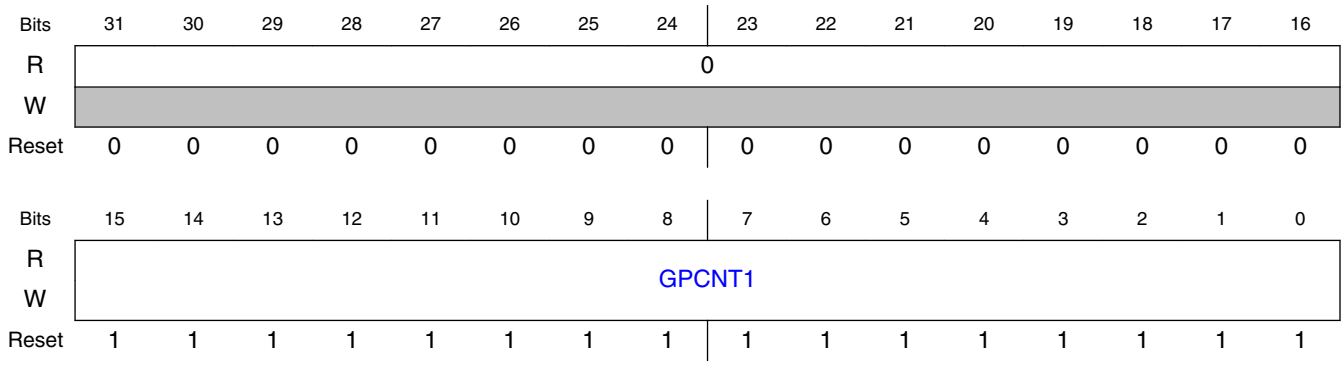
65.7.1.20 General Purpose Counter 1 Timeout Value (GPCNT1_VAL)

The value written to this register is used to compare to the general purpose counter in the EMVSIM module.

65.7.1.20.1 Offset

Register	Offset
GPCNT1_VAL	48h

65.7.1.20.2 Diagram



65.7.1.20.3 Fields

Field	Description
31-16 —	Reserved
15-0 GPCNT1	General Purpose Counter 1 Timeout Value The value written to this register is used to compare to the general purpose counter in the EMVSIM module. Once the General purpose counter reaches this value, the GPCNT1_TO flag in the TX_STATUS register is set. This counter is intended to be used for any events that must be monitored for duration based on the card clock, receiver sample rate, or ETU rate (transmit clock). Example: ATR arrival time and ATR duration.

CAN2 external timer tick: XBAR1_OUT133

CAN3 external timer tick: PIT2 trigger[0]

66.2 Overview

The FlexCAN module is a communication controller implementing the CAN protocol according to the ISO 11898-1 standard and CAN 2.0 B protocol specifications. A general block diagram is shown in Figure 66-1, which describes the main subblocks implemented in the FlexCAN module, including:

- One associated memory for storing message buffers
- Receive Global Mask registers
- Receive Individual Mask registers
- Receive FIFO filters
- Receive FIFO ID filters

NOTE

Rx FIFO cannot be used in FD mode.

The CAN protocol was primarily designed to be used as a vehicle serial data bus, meeting the specific requirements of this field:

- Real-time processing
- Reliable operation in the EMI environment of a vehicle
- Cost-effectiveness
- Required bandwidth

The FlexCAN module is a full implementation of the CAN protocol specification, the CAN with Flexible Data rate (CAN FD) protocol, and the CAN 2.0 version B protocol, which supports both standard and extended message frames and long payloads up to 64 bytes, transferred at faster rates (up to 8 Mb/s—Note that this baud rate can be reached only in the Rx and Tx digital pins, and also depends on the physical layer of the application). The message buffers are stored in an embedded RAM dedicated to the FlexCAN module. See the chip-specific FlexCAN information for the actual number of message buffers configured in the chip.

The Protocol Engine (PE) submodule manages the serial communication on the CAN bus:

- Requesting RAM access for receiving and transmitting message frames
- Validating received messages
- Performing error handling
- Detecting CAN FD messages

The Controller Host Interface (CHI) submodule manages message buffer selection for reception and transmission, taking care of arbitration and ID matching algorithms for both CAN FD and non-CAN FD message formats.

The Bus Interface Unit (BIU) submodule controls access to and from the internal interface bus, in order to establish connection to the CPU and to other blocks. Clocks, address and data buses, interrupt outputs, DMA and test signals are accessed through the BIU.

66.2.1 Block diagram

The following figure illustrates the block diagram of FLEXCAN.

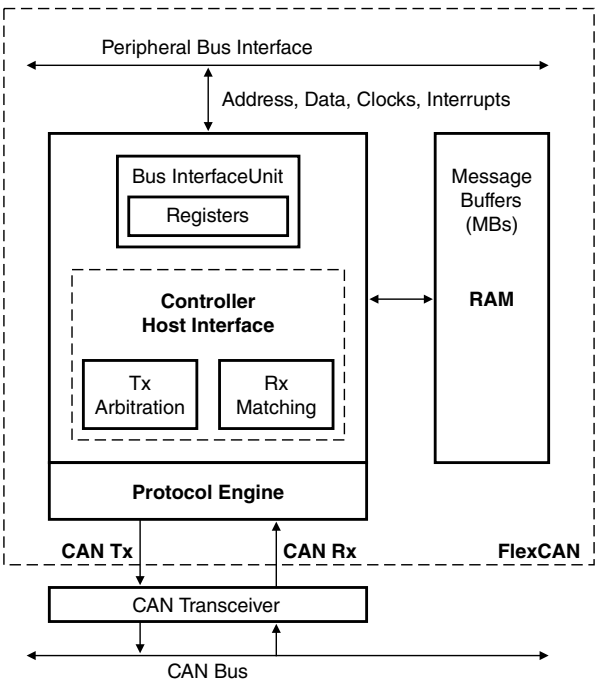

Figure 66-1. FlexCAN block diagram

66.2.2 Features

The FlexCAN module includes these distinctive features:

- Full implementation of the CAN with Flexible Data Rate (CAN FD) protocol specification and CAN protocol specification, Version 2.0 B
  - Standard data frames
  - Extended data frames
  - Zero to sixty four bytes data length
  - Programmable bit rate (see the chip-specific FlexCAN information for the specific maximum rate configuration)
  - Content-related addressing

- Compliant with the ISO 11898-1 standard
- Flexible mailboxes configurable to store 0 to 8, 16, 32, or 64 bytes data length
- Each mailbox configurable as receive or transmit, all supporting standard and extended messages
- Individual Rx Mask registers per mailbox
- Full-featured Rx FIFO with storage capacity for up to six frames and automatic internal pointer handling with DMA support
- Transmission abort capability
- Flexible message buffers (MBs), totaling 64 message buffers of 8 bytes data length each, configurable as Rx or Tx
- Programmable clock source to the CAN Protocol Interface, either peripheral clock or oscillator clock
- RAM not used by reception or transmission structures can be used as general purpose RAM space
- Listen-Only mode capability
- Programmable Loop-Back mode supporting self-test operation
- Programmable transmission priority scheme: lowest ID, lowest buffer number, or highest priority
- Time stamp based on 16-bit free running timer, with an optional external time tick
- Global network time, synchronized by a specific message
- Maskable interrupts
- Independence from the transmission medium (an external transceiver is assumed)
- Short latency time due to an arbitration scheme for high-priority messages
- Low power modes, with programmable wakeup on bus activity
- Transceiver delay compensation feature when transmitting CAN FD messages at faster data rates
- Remote request frames may be managed automatically or by software
- CAN bit time settings and configuration bits can only be written in Freeze mode
- Tx mailbox status (Lowest priority buffer or empty buffer)
- Identifier Acceptance Filter Hit Indicator (IDHIT) register for received frames
- SYNCH bit available in Error in Status 1 register to indicate that the module is synchronous with CAN bus
- CRC status for transmitted message
- Rx FIFO Global Mask register
- Selectable priority between mailboxes and Rx FIFO during matching process
- Powerful Rx FIFO ID filtering, capable of matching incoming IDs against either 128 extended, 256 standard, or 512 partial (8 bit) IDs, with up to 32 individual masking capability
- 100% backward compatibility with previous FlexCAN version
- Supports detection and correction of errors in memory read accesses

Each byte of FlexCAN memory is associated to 5 parity bits, and the error correction mechanism ensures that in this 13-bit word, errors in one bit can be corrected (correctable errors) and errors in 2 bits can be detected but not corrected (non-correctable errors).

66.3 Functional description

The FlexCAN module is a CAN protocol engine with a very flexible mailbox system for transmitting and receiving CAN frames. The mailbox system is composed of a set of message buffers (MB) that store configuration and control data, time stamp, message ID, and data (see Message buffer structure).

For Classical CAN frames, simultaneous reception through FIFO and mailbox is supported. For CAN FD frames, reception is supported through mailboxes only. For mailbox reception, a matching algorithm makes it possible to store received frames only into MBs that have the same ID programmed in the ID field. A masking scheme makes it possible to match the ID programmed on the MB with a range of IDs on received CAN frames. For transmission, an arbitration algorithm decides the prioritization of MBs to be transmitted based on the message ID (optionally augmented by 3 local priority bits) or the MB ordering.

Before proceeding with the functional description, an important concept must be explained. A message buffer is said to be active at a given time if it can participate in both the matching and arbitration processes. An Rx MB with a 0b code is inactive (see Table 66-26). Similarly, a Tx MB with a 1000b or 1001b code is also inactive (see Table 66-27).

The FlexCAN module is also able to receive and transmit messages in CAN FD format. The message buffers are sized to adequately store the quantity of data bytes selected by the FDCTRL[MBDSRn] fields. The quantity of FD MBs available for a given quantity of data bytes is described in the FDCTRL register. See also FlexCAN memory partition for CAN FD.

66.3.1 Modes of operation

The FlexCAN module has these functional modes:

- Normal mode (User or Supervisor):

In Normal mode, the module operates receiving and/or transmitting message frames, errors are managed normally, and all CAN Protocol functions are enabled. User and Supervisor modes differ in the access to some restricted control registers.

- Freeze mode:

  Freeze mode is enabled when MCR[FRZ] is asserted. If enabled, Freeze mode is entered when MCR[HALT] is set or when is requested at chip level and MCR[FRZ_ACK] is asserted by the FlexCAN. In this mode, no transmission or reception of frames is done and synchronicity to the CAN bus is lost. See Freeze mode for more information.

- Loop-Back mode:

  The module enters this mode when CTRL1[LPB] is asserted. In this mode, FlexCAN performs an internal loop back that can be used for self-test operation. The bit stream output of the transmitter is internally fed back to the receiver input. The Rx CAN input pin is ignored and the Tx CAN output goes to the recessive state (logic '1'). FlexCAN behaves as it normally does when transmitting and treats its own transmitted message as a message received from a remote node. In this mode, FlexCAN ignores the bit sent during the ACK slot in the CAN frame acknowledge field to ensure proper reception of its own message. Both transmit and receive interrupts are generated.

- Listen-Only mode:

  The module enters this mode when CTRL1[LOM] is asserted. In this mode, transmission is disabled, all error counters are frozen, and the module operates in a CAN Error Passive mode. Only messages acknowledged by another CAN station will be received. If FlexCAN detects a message that has not been acknowledged, it will flag a BIT0 error (without changing the REC), as if it was trying to acknowledge the message.

- CAN FD Active mode:

  In this mode, FlexCAN is capable of transmitting and receiving all messages formatted according to the CAN FD Protocol and CAN 2.0 Protocol 2.0 in an interleaved fashion. The CPU can set the FlexCAN into CAN FD Active mode by configuring MCR[FDEN] in Freeze mode.

  It is important to know which features are available in CAN FD active mode. This table lists the differences between FD and classical modes.

Table 66-2. Differences between CAN classical and CAN FD

Feature	CAN classical	CAN FD
Rx FIFO DMA	Yes	No
Rx FIFO	Yes	No

For low-power operation, the FlexCAN module has:

- Module Disable mode:

  This low-power mode is entered when MCR[MDIS] is asserted by the CPU and MCR[LPM_ACK] is asserted by FlexCAN. When disabled, the module issues a request to disable the clocks to the CAN Protocol Engine and Controller Host Interface submodules. Exit from this mode is done by negating MCR[MDIS]. See Module Disable mode for more information.

- Doze mode:

  This low power mode is entered when MCR[DOZE] is asserted and Doze mode is requested at chip level, and MCR[LPM_ACK] is asserted by FlexCAN. When in Doze mode, the module issues a request to disable the clocks to the CAN Protocol Engine and the CAN Controller-Host Interface submodules. Exit from this mode happens when MCR[DOZE] is negated, when the chip is removed from Doze mode, or when activity is detected on the CAN bus and the Self Wake Up mechanism is enabled. See Doze mode for more information.

- Stop mode:

  This low power mode is entered when Stop mode is requested at chip level and MCR[LPM_ACK] is asserted by the FlexCAN. When in Stop Mode, the module puts itself in an inactive state and then informs the CPU that the clocks can be shut down globally. Exit from this mode happens when the Stop mode request is removed, or when activity is detected on the CAN bus and the Self Wake Up mechanism is enabled. See Stop mode for more information.

66.3.1.1 Modes of operation details

The FlexCAN module has functional modes and low-power modes. See Modes of operation for an introductory description of all the modes of operation. The following sub-sections contain functional details on Freeze mode and the low-power modes.

CAUTION

"Permanent Dominant" failure on CAN Bus line is not supported by FlexCAN. If a Low-Power request or Freeze mode request is done during a "Permanent Dominant", the corresponding acknowledge can never be asserted.

66.3.1.1.1 Freeze mode

This mode is requested either by the CPU through the assertion of MCR[HALT] or when the chip is put into Debug mode. In both cases it is also necessary that MCR[FRZ] be asserted and the module not be in a low-power mode. This mode is also requested by FlexCAN through the automatic assertion of both MCR[HALT] and MCR[FRZ] when MECR[NCEFAFRZ] is set and a non-correctable error is detected in a memory read access performed by FlexCAN internal processes (see Response to errors).

The acknowledgement is obtained through the assertion by the FlexCAN of MECR[FRZ_ACK]. The CPU must only consider the FlexCAN in Freeze mode when both request and acknowledgement conditions are satisfied.

When Freeze mode is requested, FlexCAN does the following:

- Waits to be in either Intermission, Passive Error, Bus Off, or Idle state.
- Waits for all internal activities like arbitration, matching, move-in, and move-out to finish. A pending move-in does not prevent entering Freeze mode.
- Ignores the Rx input pin and drives the Tx pin as recessive.
- Stops the prescaler, thus halting all CAN protocol activities.
- Grants write access to the Error Counters register, which is read-only in other modes.
- Sets MCR[NOTRDY] and MCR[FRZACK].

After requesting Freeze mode, the user must wait for MCR[FRZ_ACK] to be asserted before executing any other action; otherwise FlexCAN may operate in an unpredictable way. In Freeze mode, all memory-mapped registers are accessible, except for CTRL1[CLKSRC], which can be read but cannot be written.

Exiting Freeze mode is done in one of the following ways:

- CPU negates MCR[FRZ].
- The chip is removed from Debug mode and/or the HALT bit is negated.

MCR[FRZ_ACK] is negated after the protocol engine recognizes the negation of the freeze request. When out of Freeze mode, FlexCAN tries to resynchronize to the CAN bus by waiting for 11 consecutive recessive bits.

66.3.1.1.2 Module Disable mode

This low-power mode is normally used to temporarily disable a complete FlexCAN block, with no power consumption. It is requested by the CPU through the assertion of MCR[MDIS], and the acknowledgement is obtained through the assertion by the FlexCAN of MCR[LPMACK]. The CPU must only consider the FlexCAN in Disable mode when both request and acknowledgement conditions are satisfied.

If the module is disabled during Freeze mode, it requests to disable the clocks to the PE and CHI submodules, sets MCR[LPMACK] and negates MCR[FRZACK].

If the module is disabled during transmission or reception, FlexCAN does the following:

- Waits to be in either Idle or Bus Off state, or else waits for the third bit of Intermission and then checks it to be recessive.
- Waits for all internal activities like arbitration, matching, move-in, and move-out to finish. A pending move-in is not taken into account.
- Ignores its Rx input pin and drives its Tx pin as recessive.
- Shuts down the clocks to the PE and CHI submodules
- Sets MCR[NOTRDY] and MCR[LPMACK].

The Bus Interface Unit continues to operate, enabling the CPU to access memory-mapped registers, except the Rx Mailboxes Global Mask registers, the Rx Buffer 14 Mask register, the Rx Buffer 15 Mask register,. The message buffers, the Rx Individual Mask registers, and the reserved words within RAM may not be accessed when the module is in Disable mode. Exiting from this mode is done by negating the MDIS bit by the CPU, which causes the FlexCAN to request to resume the clocks and negate the LPMACK bit after the CAN protocol engine recognizes the negation of disable mode requested by the CPU.

66.3.1.1.3 Doze mode

This is a system low power mode in which the CPU bus is kept alive and a global Doze mode request is sent to all peripherals asking them to enter low-power mode. When Doze mode is globally requested, MCR[DOZE] needs to have been asserted previously for

Doze mode to be triggered. The acknowledgement is obtained through the assertion by the FlexCAN of MCR[LPMACK]. The CPU must only consider the FlexCAN to be in Doze mode when both request and acknowledgement conditions are satisfied.

If Doze mode is triggered during Freeze mode, FlexCAN requests to shut down the clocks to the PE and CHI submodules, sets MCR[LPMACK] and negates MCR[FRZACK]. If Doze mode is triggered during transmission or reception, FlexCAN does the following:

- Waits to be in either Idle or Bus Off state, or else waits for the third bit of Intermission and checks it to be recessive.
- Waits for all internal activities like arbitration, matching, move-in, and move-out to finish. A pending move-in is not taken into account.
- Ignores its Rx input pin and drives its Tx pin as recessive.
- Shuts down the clocks to the PE and CHI submodules.
- Sets MCR[NOTRDY] and MCR[LPMACK].

The Bus Interface Unit continues to operate, enabling the CPU to access memory-mapped registers, except the Rx Mailboxes Global Mask registers, the Rx Buffer 14 Mask register, the Rx Buffer 15 Mask register. The the message buffers, the Rx Individual Mask registers, and the reserved words within RAM may not be accessed when the module is in Doze mode.

Exiting Doze mode is done in one of the following ways:

- CPU removing the Doze mode request
- CPU negating MCR [DOZE]
- Self Wake mechanism

In the Self Wake mechanism, if MCR[SLFWAK] was set at the time FlexCAN entered Doze mode, then upon detection of a recessive to dominant transition on the CAN bus, FlexCAN negates the DOZE bit, requests to resume its clocks and negates the LPMACK after the CAN protocol engine recognizes the negation of the Doze mode request. It also sets ESR [WAKINT] and, if enabled by MCR[WAKMSK], generates a Wake-Up interrupt to the CPU. FlexCAN will then wait for 11 consecutive recessive bits to synchronize to the CAN bus. As a consequence, it will not receive the frame that woke it up. The following table details the effect of SLFWAK and WAKMSK upon wakeup from Doze mode.

Table 66-3. Wakeup from Doze mode

SLFWAK	WAKINT	WAKMSK	FlexCAN clocks enabled	Wakeup interrupt generated
0	—	—	No	No
0	—	—	No	No
1	0	0	No	No
1	0	1	No	No
1	1	0	Yes	No
1	1	1	Yes	Yes

The sensitivity to CAN bus activity can be modified by applying a low-pass filter function to the Rx CAN input line when in Doze mode. (See MCR[WAKSRC].) This feature can be used to protect FlexCAN from waking up due to short glitches on the CAN bus lines. Such glitches can result from electromagnetic interference within noisy environments.

66.3.1.1.4 Stop mode

This is a system low-power mode in which all chip clocks can be stopped for maximum power savings. The Stop mode is globally requested by the CPU and acknowledgement is obtained through the assertion by the FlexCAN of a Stop Acknowledgement signal. The CPU must only consider the FlexCAN in Stop mode when both request and acknowledgement conditions are satisfied.

If FlexCAN receives the global Stop mode request during Freeze mode, it sets MCR[LPMACK], negates MCR[FRZACK], and then sends the Stop Acknowledge signal to the CPU, in order to shut down the clocks globally.

If Stop mode is requested during transmission or reception, FlexCAN does the following:

- Waits to be in either Idle or Bus Off state, or else waits for the third bit of Intermission and checks it to be recessive
- Waits for all internal activities like arbitration, matching, move-in, and move-out to finish. A pending move-in is not taken into account.
- Ignores its Rx input pin and drives its Tx pin as recessive
- Sets MCR[NOTRDY] and MCR[LPMACK]
- Sends a Stop Acknowledge signal to the CPU, so that it can shut down the clocks globally

Stop mode is exited when the CPU resumes the clocks and removes the Stop mode request. This can be as a result of the Self Wake mechanism.

In the Self Wake mechanism, if MCR[SLFWAK] was set at the time FlexCAN entered Stop mode, then upon detection of a recessive to dominant transition on the CAN bus, FlexCAN sets ESR[WAKINT] and, if enabled by MCR[WAKMSK], generates a Wake Up interrupt to the CPU. Upon receiving the interrupt, the CPU should resume the clocks and remove the Stop mode request. FlexCAN will then wait for 11 consecutive recessive bits to synchronize to the CAN bus. As a consequence, it will not receive the frame that woke it up. The following table details the effect of MCR[SLFWAK] and MCR[WAKMSK] upon wakeup from Stop mode. Note that wakeup from Stop mode only works when both bits are asserted.

After the CAN protocol engine recognizes the negation of the Stop mode request, the FlexCAN negates MCR[LPMACK]. FlexCAN will then wait for 11 consecutive recessive bits to synchronize to the CAN bus. As a consequence, it will not receive the frame that woke it up.

Table 66-4. Wakeup from Stop mode

SLFWAK	WAKINT	WAKMSK	Chip clocks enabled	Wakeup interrupt generated
0	—	—	No	No
0	—	—	No	No
1	0	0	No	No
1	0	1	No	No
1	1	0	No	No
1	1	1	Yes	Yes

The sensitivity to CAN bus activity can be modified by applying a low-pass filter function to the Rx CAN input line when in Stop mode. (See the description in MCR[WAKSRC].) This feature can be used to protect FlexCAN from waking up due to short glitches on the CAN bus lines. Such glitches can result from electromagnetic interference within noisy environments.

66.3.2 Transmit process

To transmit a CAN frame, the CPU must prepare a message buffer for transmission by executing the following procedure:

1. Check whether the respective interrupt bit is set and clear it.
2. If the MB is active (transmission pending), write the ABORT code (1001b) to the CODE field of the Control and Status word to request an abort of the transmission.
3. Wait for the corresponding IFLAG bit to be asserted by polling the IFLAG register, or by the interrupt request if enabled by the respective IMASK bit.

4. Read back the CODE field to check if the transmission was aborted or transmitted (see Transmission abort mechanism).
5. Clear the corresponding interrupt flag.
6. Write the ID register (containing the local priority if enabled via MCR[LPRIO_EN]).
7. Write payload data bytes.
8. Configure the Control and Status word with the desired configuration.
   a. Set ID type via MB_CS[IDE].
   b. Set Remote Transmission Request (if needed) via MB_CS[RTR].
   c. If MCR[FDEN] is enabled, also configure the MB_CS[EDL] and MB_CS[BRS] fields. For details about the relationship between the written value and transmitted value of the MB_CS[ESI] field, see Table 66-8.[1]
   d. Set Data Length Code in bytes via MB_CS[DLC]. See Table 66-28 for detailed information.
   e. Activate the message buffer to transmit the CAN frame by setting MB_CS[CODE] to Ch.

NOTE

It is strongly recommended that all the fields in MB_CS word be configured in only one 32-bit write operation to maximize software performance. If the fields are configured in separate writes, the MB_CS[CODE] must be the last write in the C/S word.

When the MB is activated, it participates in the arbitration process and is eventually transmitted according to its priority. When the DLC value stored in the MB selected for transmission is larger than the respective MB payload size, FlexCAN adds the necessary number of bytes with constant CCh pattern to complete the expected DLC.

At the end of the successful transmission:

- The value of the free running timer is written into the Time Stamp field.
- The CODE field in the Control and Status word is updated.
- Both CRC and FDCRC registers are updated.
- A status flag is set in the Interrupt Flag register.
- An interrupt is generated if allowed by the corresponding Interrupt Mask Register bit.

The new CODE field after transmission depends on the code that was used to activate the MB (see Table 66-26 and Table 66-27 in Message buffer structure).

1. The ESI field does not need to be written, and will automatically be transmitted dominant by error active nodes and recessive by error passive nodes. Note that there is an exception if the FlexCAN is operating as a network gateway: In that case, the CPU writes the MB_CS[ESI] bit according to the error status of the node which sent the message.

When the Abort feature is enabled (MCR[AEN] is asserted), after the Interrupt flag is asserted for a mailbox configured as transmit buffer, the mailbox is blocked. Therefore the CPU is not able to update it until the Interrupt Flag is negated by the CPU. This means that the CPU must clear the corresponding IFLAG bit before starting to prepare this MB for a new transmission or reception.

NOTE

If backwards compatibility is desired (MCR[AEN] is negated), write the INACTIVE code (1000b) to the CODE field to inactivate the MB. However, in this case the pending frame may be transmitted without notification (see Mailbox inactivation).

66.3.3 Arbitration process

The arbitration process scans the mailboxes, searching for the Tx mailbox that holds the message to be sent in the next opportunity. This mailbox is called the arbitration winner.

The scan starts from the lowest number mailbox and runs toward the higher ones.

The arbitration process is triggered in the following events:

- From the CRC field of the CAN frame. The start point depends on the value of CTRL2[TASD].
- During the Error Delimiter field of a CAN frame.
- During the Overload Delimiter field of a CAN frame.
- When the winner is inactivated and the CAN bus has still not reached the first bit of the Intermission field.
- When there is a CPU write to the C/S word of a winner MB and the CAN bus has still not reached the first bit of the Intermission field.
- When CHI is in Idle state and the CPU writes to the C/S word of any MB.
- When FlexCAN exits Bus Off state.
- Upon leaving Freeze mode or Low Power mode.

If the arbitration process does not manage to evaluate all mailboxes before the CAN bus has reached the first bit of the Intermission field, the temporary arbitration winner is invalidated and the FlexCAN will not compete for the CAN bus in the next opportunity.

The arbitration process selects the winner among the active Tx mailboxes at the end of the scan according to the settings of both CTRL1[LBUF] and MCR[LPRIOEN].

66.3.3.1 Lowest-number mailbox first

If CTRL1[LBUF] is asserted, the first (lowest number) active Tx mailbox found is the arbitration winner. MCR[LPRIOEN] has no effect when CTRL1[LBUF] is asserted.

66.3.3.2 Highest-priority mailbox first

If CTRL1[LBUF] is negated, then the arbitration process searches the active Tx mailbox with the highest priority, which means that this mailbox's frame would have a higher probability to win the arbitration on CAN bus when multiple external nodes compete for the bus at the same time.

The sequence of bits considered for this arbitration is called the *arbitration value* of the mailbox. The highest-priority Tx mailbox is the one that has the lowest arbitration value among all Tx mailboxes.

If two or more mailboxes have equivalent arbitration values, the mailbox with the lowest number is the arbitration winner.

The composition of the arbitration value depends on the MCR[LPRIOEN] setting.

66.3.3.2.1 Local priority disabled

If MCR[LPRIOEN] is negated the arbitration value is built in the exact sequence of bits as they would be transmitted in a CAN frame (see the following table) in such a way that the local priority is disabled.

Table 66-5. Composition of the arbitration value when local priority is disabled

Format	Mailbox arbitration value (32 bits)				
Standard (IDE = 0)	Standard ID (11 bits)	RTR (1 bit)	IDE (1 bit)	- (18 bits)	- (1 bit)
Extended (IDE = 1)	Extended ID[28:18] (11 bits)	SRR (1 bit)	IDE (1 bit)	Extended ID[17:0] (18 bits)	RTR (1 bit)

66.3.3.2.2 Local priority enabled

To enable local priority, MCR[LPRIOEN] must be asserted. In this case the mailbox PRIO field is included at the very left of the arbitration value (see the following table).

Table 66-6. Composition of the arbitration value when local priority is enabled

Format	Mailbox arbitration value (35 bits)					
Standard (IDE = 0)	PRIO (3 bits)	Standard ID (11 bits)	RTR (1 bit)	IDE (1 bit)	- (18 bits)	- (1 bit)
Extended (IDE = 1)	PRIO (3 bits)	Extended ID[28:18] (11 bits)	SRR (1 bit)	IDE (1 bit)	Extended ID[17:0] (18 bits)	RTR (1 bit)

Because the PRIO field is the most significant part of the arbitration value, mailboxes with low PRIO values have higher priority than mailboxes with high PRIO values regardless of the rest of their arbitration values.

Note that the PRIO field is not part of the frame on the CAN bus. Its purpose is only to affect the internal arbitration process.

66.3.3.3 Arbitration process (continued)

After the arbitration winner is found, its content is copied to a hidden auxiliary MB called Tx Serial Message Buffer (Tx SMB), which has the same structure as a normal MB but is not user accessible. This operation is called move-out and after it is done, write access to the C/S word of the corresponding MB is blocked (if MCR[AEN] is asserted). Write access is restored in the following events:

- After the MB is transmitted and the corresponding IFLAG bit is cleared by the CPU.
- FlexCAN enters Freeze mode or Bus Off.
- FlexCAN loses the bus arbitration or there is an error during the transmission.

At the first opportunity window on the CAN bus, the message on the Tx SMB is transmitted according to the CAN protocol rules.

Arbitration process can be triggered in the following situations:

- During Rx and Tx frames from CAN CRC field to end of frame. CTRL2[TASD] value may be changed to optimize the arbitration start point.
- During CAN Bus Off state from TX_ERR_CNT=124 to 128. CTRL2[TASD] value may be changed to optimize the arbitration start point.
- During C/S write by CPU in Bus Idle. First C/S write starts arbitration process, and a second C/S write during this same arbitration restarts the process. If other C/S writes are performed, Tx arbitration process is pending. If there is no arbitration winner after the arbitration process has finished, then the TX arbitration machine begins a new arbitration process. If there is a pending arbitration and Bus Idle state starts, then an arbitration process is triggered. In this case the first and second C/S write in Bus Idle will not restart the arbitration process. It is possible that there is not enough time

to finish arbitration in Wait For Bus Idle state and the next state is Idle. In this case the scan is not interrupted, and it is completed during Bus Idle state. During this arbitration C/S write does not cause arbitration restart.
- Arbitration winner deactivation during a valid arbitration window.
- Upon exiting Freeze mode (first bit of the Wait For Bus Idle state). If there is a re-synchronization during Wait For Bus Idle, the arbitration process is restarted.

Arbitration process stops in the following situations:

- All mailboxes were scanned.
- A Tx active mailbox is found if lowest buffer feature is enabled.
- Arbitration winner inactivation or abort during any arbitration process.
- There was not enough time to finish Tx arbitration process (for instance, when a deactivation was performed near the end of frame). In this case arbitration process is pending.
- Error or overload flag in the bus.
- Low Power or Freeze mode request in Idle state.

Arbitration is considered pending as described below:

- It was not possible to finish arbitration process in time.
- C/S write during arbitration if write is performed in a MB whose number is lower than the Tx arbitration pointer.
- Any C/S write if there is no Tx arbitration process in progress.
- Rx Match has just updated a Rx code to Tx code.
- Entering Bus Off state.

C/S write during arbitration has the following effect:

- If C/S write is performed in the arbitration winner, a new process is restarted immediately.
- If C/S write is performed in a MB whose number is higher than the Tx arbitration pointer, the ongoing arbitration process will scan this MB as normal.

66.3.4 Receive process

To be able to receive CAN frames into a mailbox, the CPU must prepare it for reception by executing the following steps:

1. If the mailbox is active (either Tx or Rx) inactivate the mailbox (see Mailbox inactivation), preferably with a safe inactivation (see Transmission abort mechanism).
2. Write the ID word into the mailbox.

3. Write the EMPTY code (0100b) to the CODE field of the Control and Status word to activate the mailbox. No setup is required for EDL, BRS, and ESI bits—they are overwritten by the respective bit fields in the received message.

After the MB is activated, it will be able to receive frames that match the programmed filter. At the end of a successful reception, the mailbox is updated by the move-in process (see Move-in) as follows:

1. The received data field (8 bytes at most for Classical CAN message format and up to 64 bytes for CAN FD message format) is stored.
2. The received Identifier field is stored.
3. The value of the Free Running Timer at the time of the second bit of frame's Identifier field is written into the mailbox's Time Stamp field.
4. The received SRR, IDE, RTR, EDL, BRS, ESI, and DLC fields are stored.
5. The CODE field in the Control and Status word is updated (see Table 66-26 and Table 66-27 in Section Message buffer structure).
6. A status flag is set in the Interrupt Flag Register and an interrupt is generated if allowed by the corresponding Interrupt Mask Register bit.

The recommended way for the CPU to service (read) the frame received in a mailbox is by the following procedure:

1. Read the Control and Status word of that mailbox.
2. Check if the BUSY bit is deasserted, indicating that the mailbox is locked. Repeat step 1) while it is asserted. See Mailbox lock mechanism.
3. Read the contents of the mailbox. After the mailbox is locked, its contents won't be modified by FlexCAN move-in processes. See Move-in.
4. Acknowledge the proper flag at IFLAG registers.
5. Read the free running timer to unlock the mailbox.

The CPU should poll for frame reception by the status flag bit for the specific mailbox in one of the IFLAG registers and not by the CODE field of that mailbox. Polling the CODE field does not work because after a frame is received and the CPU services the mailbox (by reading the C/S word followed by unlocking the mailbox), the CODE field will not return to EMPTY. It will remain FULL, as explained in Table 66-26. If the CPU tries to work around this behavior by writing to the C/S word to force an EMPTY code after reading the mailbox without a prior safe inactivation, a newly received frame matching the filter of that mailbox may be lost.

CAUTION

In summary: never do polling by reading directly the C/S word of the mailboxes. Instead, read the IFLAG registers.

Note that the received frame's Identifier field is always stored in the matching mailbox, thus the contents of the ID field in a mailbox may change if the match was due to masking. When MCR[SRXDIS] is asserted, FlexCAN will not store frames transmitted by itself in any MB, even if it contains a matching Rx mailbox, and no interrupt flag or interrupt signal will be generated. Otherwise, when MCR[SRXDIS] is deasserted, FlexCAN can receive frames transmitted by itself if a matching Rx mailbox exists.

When MCR[DMA] is asserted, upon receiving a frame in FIFO, IFLAG1[BUF5I] generates a DMA request and does not generate a CPU interrupt (see Rx FIFO under DMA operation). The IMASK1 bits in Rx FIFO region are not used.

The DMA controller must service the received frame using the following procedure:

1. Read the Control and Status word (read 80h address, optional).
2. Read the ID field (read 84h address, optional).
3. Read all data bytes (start read at 88h address, optional).

66.3.5 Matching process

The matching process scans the MB memory looking for Rx MBs programmed with the same ID as the one received from the CAN bus. . The matching starts from the lowest number message buffer toward the higher ones.

For Rx FIFO see Rx FIFO.

As the frame is being received, it is stored in a hidden auxiliary MB called Rx Serial Message Buffer (Rx SMB).

The matching process start point depends on the following conditions:

- If the received frame is a remote frame, the start point is the CRC field of the frame.
- If the received frame is a data frame with DLC field equal to zero, the start point is the CRC field of the frame.
- If the received frame is a data frame with DLC field different than zero, the start point is the DATA field of the frame.

If a matching ID is found in one of the mailboxes, the contents of the Rx SMB are transferred to to the matched mailbox by the move-in process. If any CAN protocol error is detected then no match results are transferred to the matched mailbox at the end of reception.

The matching process scans all matching elements of the active Rx mailboxes (CODE is EMPTY, FULL, OVERRUN, or RANSWER) in search of a successful comparison with the matching elements of the Rx SMB that is receiving the frame on the CAN bus. The Rx SMB has the same structure as a mailbox. The reception structures (mailboxes) associated with the matching elements that had a successful comparison are the *matched structures*. The *matching winner* is selected at the end of the scan among those matched structures and depends on conditions described ahead. See the following table.

Table 66-7. Matching architecture

Structure	SMB[RTR]	CTRL2[RRS]	CTRL2[EACEN]	MB[IDE]	MB[RTR]	MB[ID[1]]	MB[CODE]
Mailbox	0	—	0	cmp[2]	no_cmp[3]	cmp_msk[4]	EMPTY or FULL or OVERRUN
Mailbox	0	—	1	cmp_msk	cmp_msk	cmp_msk	EMPTY or FULL or OVERRUN
Mailbox	1	0	—	cmp	no_cmp	cmp	RANSWER
Mailbox	1	1	0	cmp	no_cmp	cmp_msk	EMPTY or FULL or OVERRUN
Mailbox	1	1	1	cmp_msk	cmp_msk	cmp_msk	EMPTY or FULL or OVERRUN

1. For mailbox structure, If SMB[IDE] is asserted, the ID is 29 bits (ID Standard + ID Extended). If SMB[IDE] is negated, the ID is only 11 bits (ID Standard). For FIFO structure, the ID depends on IDAM.
2. cmp: Compares the Rx SMB contents with the MB contents regardless the masks.
3. no_cmp: The Rx SMB contents are not compared with the MB contents.
4. cmp_msk: Compares the Rx SMB contents with MB contents taking into account the masks.

A reception structure is free-to-receive when any of the following conditions is satisfied:

- The CODE field of the mailbox is EMPTY.
- The CODE field of the mailbox is either FULL or OVERRUN and it has already been serviced (the C/S word was read by the CPU and unlocked as described in Mailbox lock mechanism).
- The CODE field of the mailbox is either FULL or OVERRUN and an inactivation (see Mailbox inactivation) is performed.

The scan order for mailboxes is from the matching element with lowest number to the higher ones.

The matching winner search for mailboxes is affected by MCR[IRMQ]. If it is negated, the matching winner is the first matched mailbox regardless if it is free-to-receive or not. If it is asserted, the matching winner is selected according to the priority below:

1. the first free-to-receive matched mailbox;

2. the last non free-to-receive matched mailbox.

If a non-safe mailbox inactivation (see Mailbox inactivation) occurs during matching process and the mailbox inactivated is the temporary matching winner, then the temporary matching winner is invalidated. The matching elements scan is not stopped nor restarted—it continues normally. The consequence is that the current matching process works as if the matching elements compared before the inactivation did not exist, therefore a message may be lost.

Suppose, for example, that IRMQ is enabled, there are two MBs with the same ID, and FlexCAN starts receiving messages with that ID. Let us say that these MBs are the second and the fifth in the array. When the first message arrives, the matching algorithm finds the first match in MB number 2. The code of this MB is EMPTY, so the message is stored there. When the second message arrives, the matching algorithm finds MB number 2 again, but it is not "free-to-receive", so it keeps looking, finds MB number 5 and stores the message there. If yet another message with the same ID arrives, the matching algorithm finds out that there are no matching MBs that are "free-to-receive", so it decides to overwrite the last matched MB, which is number 5. In doing so, it sets the CODE field of the MB to indicate OVERRUN.

The ability to match the same ID in more than one MB can be exploited to implement a reception queue to allow more time for the CPU to service the MBs. By programming more than one MB with the same ID, received messages are queued into the MBs. The CPU can examine the Time Stamp field of the MBs to determine the order in which the messages arrived.

Matching to a range of IDs is possible by using ID acceptance masks. FlexCAN supports individual masking per MB (see the description of Rx Individual Mask registers [RXIMR0-RXIMR63]). During the matching algorithm, if a mask bit is asserted, then the corresponding ID bit is compared. If the mask bit is negated, the corresponding ID bit is a "don't care". Note that the Individual Mask Registers are implemented in RAM, so they are not initialized out of reset. Also, they can only be programmed when the module is in Freeze mode; otherwise, they are blocked by hardware.

FlexCAN also supports an alternate masking scheme with only four mask registers (RXMGMASK, RX14MASK, and RX15MASK) for backwards compatibility with legacy applications. This alternate masking scheme is enabled when the IRMQ bit in the MCR register is negated.

66.3.6 Move process

There are two types of move process: move-in and move-out.

66.3.6.1 Move-in

The move-in process is the copy of a message received by an Rx SMB to an Rx mailbox that has matched it. Each Rx SMB has its own move-in process, but only one is performed at a given time as described ahead. The move-in starts only when the message held by the Rx SMB has a corresponding matching winner (see Matching process) and all of the following conditions are true:

- The CAN bus has either reached or already gone past:
  - The second bit of Intermission field next to the frame that carried the message that is in the Rx SMB.
  - The first bit of an overload frame next to the frame that carried the message that is in the Rx SMB.
- There is no ongoing matching process.
- The destination mailbox is not locked by the CPU.
- There is no ongoing move-in process from another Rx SMB. If more than one move-in process is to be started at the same time, both are performed and the newest substitutes for the oldest.

The term pending move-in is used throughout the documentation and stands for a move-to-be that still does not satisfy all of the aforementioned conditions.

The move-in is cancelled and the Rx SMB is able to receive another message if any of the following conditions is satisfied:

- The destination mailbox is inactivated after the CAN bus has reached the first bit of Intermission field next to the frame that carried the message and its matching process has finished.
- There is a previous pending move-in to the same destination mailbox.
- The Rx SMB is receiving a frame transmitted by the FlexCAN itself and self-reception is disabled (MCR[SRXDIS] is asserted).
- Any CAN protocol error is detected.

Note that the pending move-in is not cancelled if the module enters Freeze or Low-Power mode. It stays on hold, only waiting for Freeze and Low-Power mode to be exited and the module to be unlocked. If an MB is unlocked during Freeze mode, the move-in happens immediately.

The move-in process is the execution by the FlexCAN of the following steps:

1. Read all data words from the Rx SMB in accordance with the selected payload size for the Rx storage element.

2. Write all data words to the Rx mailbox in accordance with the selected payload size for the Rx storage element. If the data size of the storage element is smaller than the original payload size described in the message's DLC field, the payload is truncated and the high order bytes that do not fit the destination size are lost.
3. Read the Control/Status and ID words from the Rx SMB.
4. Write Control/Status and ID words to the Rx mailbox, and update the CODE field.

The move-in process is not atomic, in such a way that it is immediately cancelled by the inactivation of the destination mailbox (see Mailbox inactivation). In this case the mailbox may remain partially updated, thus incoherent.

The BUSY Bit (least significant bit of the CODE field) of the destination message buffer is asserted while the move-in is being performed to alert the CPU that the message buffer content is temporarily incoherent.

66.3.6.2 Move-out

The move-out process is the copy of the content from a Tx Mailbox to the Tx SMB when a message for transmission is available (see Arbitration process). The move-out occurs in the following conditions:

- The first bit of Intermission field
- During Bus Off state when TX Error Counter is in the 124 to 128 range
- During Bus Idle state
- During Wait For Bus Idle state

The move-out process is not atomic. Only the CPU has priority to access the memory concurrently out of Bus Idle state. In Bus Idle, the move-out has the lowest priority to the concurrent memory accesses.

66.3.7 Data coherence

In order to maintain data coherency and FlexCAN proper operation, the CPU must obey the rules described in Transmit process and Receive process.

66.3.7.1 Transmission abort mechanism

The abort mechanism provides a safe way to request the abort of a pending transmission. A feedback mechanism is provided to inform the CPU if the transmission was aborted or if the frame could not be aborted and was transmitted instead.

Two primary conditions must be fulfilled in order to abort a transmission:

- MCR[AEN] must be asserted.
- The first CPU action must be the writing of abort code (1001b) into the CODE field of the Control and Status word.

Active MBs configured for transmission must be aborted first before they can be updated. If the abort code is written to a Mailbox that is currently being transmitted or to a Mailbox that was already loaded into the Tx SMB for transmission, the write operation is blocked and the transmission is not disturbed. However, the abort request is captured and kept pending until one of the following conditions is satisfied:

- The module loses the bus arbitration.
- There is an error during the transmission.
- The module is put into Freeze mode.
- The module enters Bus Off state.
- There is an overload frame.

If none of the conditions above are reached:

- The MB is transmitted correctly.
- The interrupt flag is set in the IFLAG register.
- An interrupt to the CPU is generated (if enabled).

The abort request is automatically cleared when the interrupt flag is set. On the other hand, if only one of the above conditions is reached, the frame is not transmitted; therefore:

- The abort code is written into the CODE field.
- The interrupt flag is set in the IFLAG.
- An interrupt is (optionally) generated to the CPU.

If the CPU writes the abort code before the transmission begins internally, then the write operation is not blocked; therefore, the MB is updated and the interrupt flag is set. In this way the CPU only needs to read the abort code to make sure the active MB was safely inactivated. Although the AEN bit is asserted and the CPU wrote the abort code, in this case the MB is inactivated and not aborted, because the transmission did not start yet. One Mailbox is aborted only when the abort request is captured and kept pending until one of the previous conditions is satisfied.

66.3.7.2 Mailbox inactivation

Inactivation is a mechanism provided to protect the mailbox against updates by the FlexCAN internal processes, thus allowing the CPU to rely on mailbox data coherence after having updated it, even in Normal mode.

Inactivation of transmission mailboxes must be performed just when MCR[AEN] is deasserted.

If a mailbox is inactivated, it participates in neither the arbitration process nor the matching process until it is reactivated. See Transmit process and Receive process for more detailed instructions on how to inactivate and reactivate a mailbox.

To inactivate a mailbox, the CPU must update its CODE field to INACTIVE (either 0b or 1000b).

Because you will not be able to synchronize the CODE field update with the FlexCAN internal processes, an inactivation can have the following consequences:

- A frame in the bus that matches the filtering of the inactivated Rx mailbox may be lost without notice, even if there are other mailboxes with the same filter.
- A frame containing the message within the inactivated Tx mailbox may be transmitted without setting the respective IFLAG.

In order to perform a safe inactivation and avoid the above consequences for Tx mailboxes, the CPU must use the transmission abort mechanism (see Transmission abort mechanism).

The inactivation automatically unlocks the mailbox (see Mailbox lock mechanism).

66.3.7.3 Mailbox lock mechanism

Other than mailbox inactivation, FlexCAN has another data coherence mechanism for the receive process. When the CPU reads the Control and Status word of an Rx MB with codes FULL or OVERRUN, FlexCAN assumes that the CPU wants to read the whole MB in an atomic operation, and therefore it sets an internal lock flag for that MB. The lock is released when the CPU reads the free running timer (global unlock operation), or when it reads the Control and Status word of another MB regardless of its code. A CPU write into the C/S word also unlocks the MB, but this procedure is not recommended for normal unlock use because it cancels a pending move and potentially may lose a received message. The MB locking prevents a new frame from being written into the MB while the CPU is reading it.

NOTE

The locking mechanism applies only to Rx MBs that have a code different than INACTIVE (0b) or EMPTY[1] (0100b). Also, Tx MBs cannot be locked.

1. In previous FlexCAN versions, reading the C/S word locked the MB even if it was EMPTY. This behavior is maintained when the IRMQ bit is negated.

Suppose, for example, that the second and the fifth MBs of the array are programmed with the same ID, and FlexCAN has already received and stored messages into these two MBs. Suppose now that the CPU decides to read MB number 5 and at the same time another message with the same ID is arriving. When the CPU reads the Control and Status word of MB number 5, this MB is locked. The new message arrives and the matching algorithm finds out that there are no free-to-receive MBs, so it decides to override MB number 5. However, this MB is locked, so the new message cannot be written there. It will remain in the Rx SMB waiting for the MB to be unlocked, and only then will be written to the MB.

If the MB is not unlocked in time and yet another new message with the same ID arrives, then the new message overwrites the one on the Rx SMB and there will be no indication of lost messages either in the CODE field of the MB or in the Error and Status Register.

While the message is being moved in from the Rx SMB to the MB, the BUSY bit on the CODE field is asserted. If the CPU reads the Control and Status word and finds out that the BUSY bit is set, it should defer accessing the MB until the BUSY bit is negated.

Note

If the BUSY bit is asserted or if the MB is empty, then reading the Control and Status word does not lock the MB.

Inactivation takes precedence over locking. If the CPU inactivates a locked Rx MB, then its lock status is negated and the MB is marked as invalid for the current matching round. Any pending message on the Rx SMB will not be transferred anymore to the MB. An MB is unlocked when the CPU reads the Free Running Timer Register (see #d46445e1851a1310), or the C/S word of another MB.

Lock and unlock mechanisms have the same functionality in both Normal and Freeze modes.

An unlock during Normal or Freeze mode results in the move-in of the pending message. However, the move-in is postponed if an unlock occurs during a low power mode (see Modes of operation), and it takes place only when the module returns to Normal or Freeze modes.

66.3.8 Rx FIFO

The Rx FIFO is receive-only and is enabled by asserting MCR[RFEN]. The reset value of this bit is zero to maintain software backward compatibility with previous versions of the module that did not have the FIFO feature.

CAUTION

Rx FIFO must not be enabled when CAN FD feature is enabled.

The FIFO is 6-message deep. The memory region occupied by the FIFO structure (both message buffers and FIFO engine) is described in Rx FIFO structure. The CPU can read the received messages sequentially, in the order they were received, by repeatedly reading a message buffer structure at the output of the FIFO.

IFLAG1[BUF5I] (Frames available in Rx FIFO) is asserted when there is at least one frame available to be read from the FIFO. An interrupt is generated if it is enabled by the corresponding mask bit. Upon receiving the interrupt, the CPU can read the message (accessing the output of the FIFO as a message buffer) and the RXFIR register, and then clear the interrupt. If there are more messages in the FIFO the act of clearing the interrupt updates the output of the FIFO with the next message and updates RXFIR with the attributes of that message, reissuing the interrupt to the CPU. Otherwise, the flag remains negated. The output of the FIFO is valid only while IFLAG1[BUF5I] is asserted.

IFLAG1[BUF6I] (Rx FIFO Warning) is asserted when the number of unread messages within the Rx FIFO is increased to five from four due to the reception of a new one, meaning that the Rx FIFO is almost full. The flag remains asserted until the CPU clears it.

IFLAG1[BUF7I] (Rx FIFO Overflow) is asserted when an incoming message was lost because the Rx FIFO is full. Note that the flag will not be asserted when the Rx FIFO is full and the message was captured by a Mailbox. The flag remains asserted until the CPU clears it.

Clearing one of those three flags does not affect the state of the other two.

An interrupt is generated if an IFLAG bit is asserted and the corresponding mask bit is asserted too.

A powerful filtering scheme is provided to accept only frames intended for the target application, reducing the interrupt servicing workload. The filtering criteria is specified by programming a table of up to 128 32-bit registers, according to CTRL2[RFFN] setting, that can be configured to one of the following formats (see also Rx FIFO structure):

- Format A: 128 IDAFs (extended or standard IDs including IDE and RTR)
- Format B: 256 IDAFs (standard IDs or extended 14-bit ID slices including IDE and RTR)
- Format C: 512 IDAFs (standard or extended 8-bit ID slices)

Note

A chosen format is applied to all entries of the filter table. It is not possible to mix formats within the table.

Every frame available in the FIFO has a corresponding IDHIT (Identifier Acceptance Filter Hit Indicator) that can be read in the IDHIT field from C/S word, as shown in the Rx FIFO Structure description. Another way the CPU can obtain this information is by accessing the RXFIR register. RXFIR[IDHIT] refers to the message at the output of the FIFO and is valid while the IFLAG1[BUF5I] flag is asserted. The RXFIR register must be read only before clearing the flag, which guarantees that the information refers to the correct frame within the FIFO.

Up to 32 elements of the filter table are individually affected by the Individual Mask Registers (RXIMRx), according to the setting of CTRL2[RFFN], allowing very powerful filtering criteria to be defined. If MCR[IRMQ] is negated, then the FIFO filter table is affected by RXFGMASK.

NOTE

For more information about the difference between FD and non-FD regarding this feature, see Table 66-2.

66.3.8.1 Rx FIFO under DMA operation

The receive-only FIFO can support DMA. This feature is enabled by asserting both MCR[RFEN] and MCR[DMA]. The reset value of MCR[DMA] is zero to maintain backward compatibility with previous versions of the module that did not have the DMA feature.

The DMA controller can read the received message by reading a message buffer structure at the FIFO output port at the 80h–8Ch address range.

When MCR[DMA] is asserted the CPU must not access the FIFO output port address range. Before enabling MCR[DMA], the CPU must service the IFLAGs asserted in the Rx FIFO region. Otherwise, these IFLAGs may show that the FIFO has data to be serviced, and mistakenly generate a DMA request. Before disabling MCR[DMA], the CPU must perform a clear FIFO operation.

IFLAG1[BUF5I] (Frames available in Rx FIFO) is asserted when there is at least one frame available to be read from the FIFO. Consequently a DMA request is generated simultaneously. Upon receiving the request, the DMA controller can read the message (accessing the output of the FIFO as a message buffer). The DMA reading process must end by reading address 8Ch, which clears IFLAG1[BUF5I] and updates both the FIFO output with the next message (if FIFO is not empty) and the RXFIR register with the

attributes of the new message. If there are more messages stored in the FIFO, IFLAG1[BUF5I] will be re-asserted and another DMA request is issued. Otherwise, the flag remains negated.

IFLAG1[BUF6I] and IFLAG1[BUF7I] are not used when the DMA feature is enabled.

When FlexCAN is working with DMA, the CPU does not receive any Rx FIFO interruption and must not clear the related IFLAGs. In addition, the related IMASKs are not used to mask the generation of DMA requests.

NOTE

For more information about the difference between FD and non-FD regarding this feature, see Table 66-2.

66.3.8.2 Clear FIFO operation

When MCR[RFEN] is asserted, the clear FIFO operation is a feature used to empty FIFO contents. With MCR[RFEN] asserted the Clear FIFO occurs when the CPU writes one in IFLAG1[BUF0I]. This operation can only be performed in Freeze mode and is blocked by hardware in other modes. This operation does not clear the FIFO IFLAGs; consequently the CPU must service all FIFO IFLAGs before executing the clear FIFO task.

When Rx FIFO is working with DMA, the clear FIFO operation clears IFLAG1[BUF5I] and the DMA request is canceled.

CAUTION

Clear FIFO operation does not clear IFLAGs, except when MCR[DMA] is asserted; in this case only IFLAG1[BUF5I] is cleared.

66.3.9 CAN protocol related features

This section describes the CAN protocol related features.

66.3.9.1 CAN FD ISO compliance

The CAN FD protocol has been improved to increase the failure detection capability that was in the original CAN FD protocol, which is also called non-ISO CAN FD, by CAN in Automation (CiA). A three-bit stuff counter and a parity bit have been introduced in the improved CAN FD protocol, now called ISO CAN FD. The CRC calculation has also

been modified. All these improvements make the ISO CAN FD protocol incompatible with the non-FD CAN FD protocol. The non-ISO CAN FD is still supported by FlexCAN so that it can be used mainly during an intermediate phase, for evaluation and development purposes.

Therefore, it is strongly recommended to configure FlexCAN to the ISO CAN FD protocol by setting the ISOCANFDEN field in the CTRL2 register.

66.3.9.2 CAN FD frames

The ISO 11898-1 standard specifies the Classical Frame format compliant to ISO 11898-1 (2003) and introduces the CAN Flexible Data Rate Frame format. The Classical Frame format allows bit rates up to 1 Mbit/s and payloads up to 8 bytes per frame. The Flexible Data Rate Frame format allows bit rates higher than 1 Mbit/s and payloads longer than 8 bytes per frame. FlexCAN can receive and transmit CAN FD messages interleaved with Classical CAN messages.

There are three additional control bits in the CAN FD frame. The Extended Data Length (EDL) bit enables a longer data payload with different data length coding. The Bit Rate Switch (BRS) bit decides whether the bit rate is switched inside a CAN FD format frame. The Error State Indicator (ESI) flag is transmitted dominant by error active nodes, and recessive by error passive nodes. There are no Remote Frames (see Remote frames) in the CAN FD format. A message configured to transmit a Remote Frame is always sent out in the Classical CAN format. When an FD frame is received and matches a mailbox, the RTR bit in the receiving message buffer is negated. The RTR bit must be considered in classical frames only.

CAN FD messages may be formatted as long frames where the data field exceeds 8 bytes, and may range from 12 up to 64 bytes. They can also be configured to support bit rate switching, where the control field, the data field, and the CRC field of a CAN frame are transmitted with a higher bit rate than the beginning and the end of the frame. Messages in Classical CAN format are limited to transport a maximum payload of 8 bytes at nominal rate. The following figure illustrates the message formats for Classical and FD frames with either standard or extended ID.

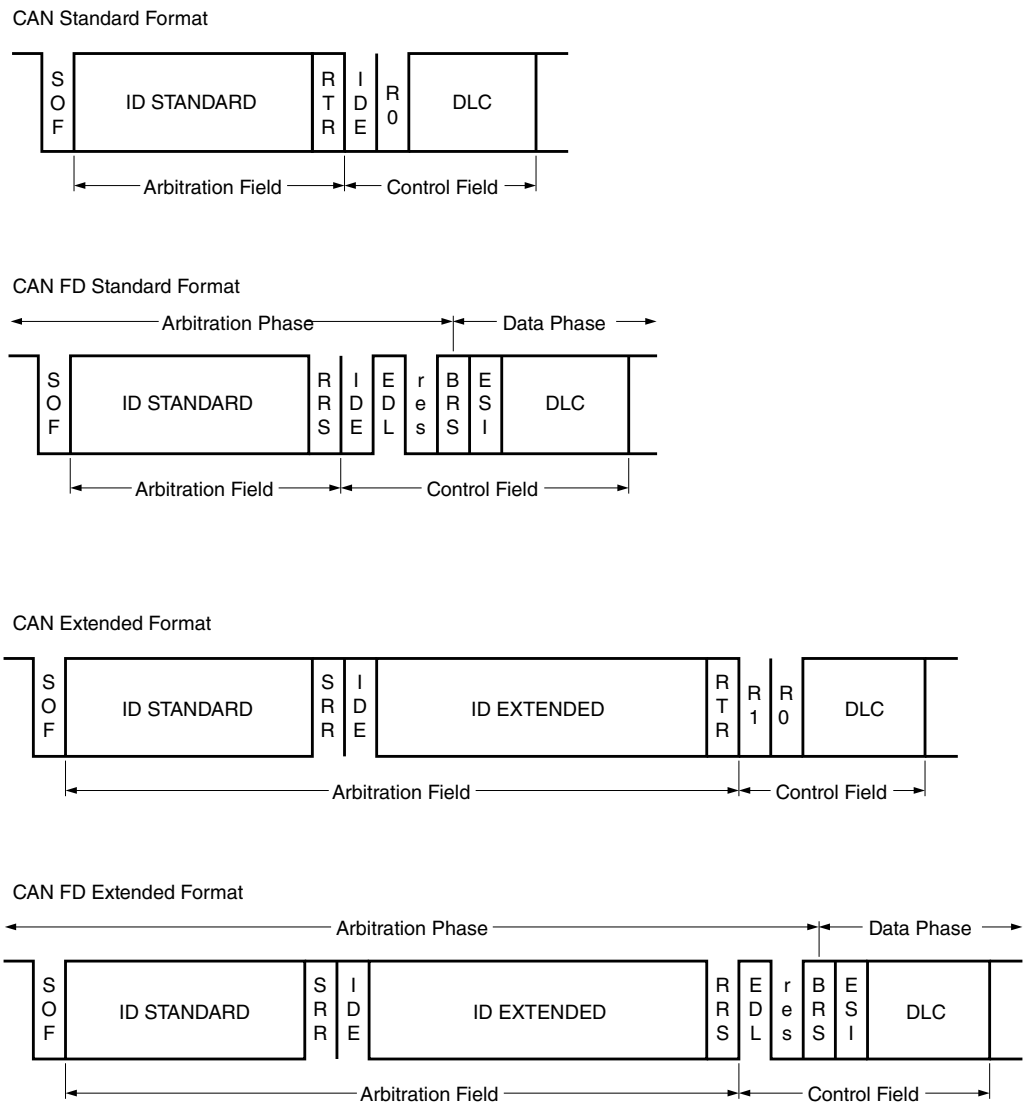

Figure 66-2. CAN message formats

The ability to receive and transmit CAN FD messages is enabled by MCR[FDEN]. Either a recessive R0 bit in CAN frames with 11-bit identifiers or a recessive R1 bit in CAN frames with 29-bit identifiers are decoded as an EDL bit (not a reserved one). A CAN FD frame is recognized by a recessive EDL bit, and a Classical CAN frame is recognized by a dominant EDL bit. The BRS bit specifies whether this frame switches the bit rate in its data phase. A long frame is decoded in accordance with the DLC field value (see DLC definition in Message buffer structure).

CAN FD messages can be transmitted with two different bit rates. The first part of a CAN FD frame, from the Start Of Frame (SOF) bit until the Bit Rate Switch (BRS) bit, also called the arbitration phase, is transmitted with the nominal bit rate based on a set of nominal CAN bit timing configuration values. The second part, from the BRS bit until the CRC Delimiter bit, also named the data phase, is transmitted with the data bit rate

defined by a second set of CAN data bit timing configuration values. Finally, from the CRC Delimiter until the Intermission bits, the transmission returns to nominal bit rate. In CAN FD frames with bit rate switching, the bit timing is changed inside the frame at the sample point of the BRS bit if this bit is recessive. Before the BRS bit, in the CAN FD arbitration phase, the nominal CAN bit timing is used as defined by the CBT register (also by CTRL1 register for backward compatibility). Upon detecting a recessive BRS bit, the CAN data bit timing is used as defined by the FDCBT register.

NOTE

If the length of the time quantum in the nominal bit timing and the length of the time quantum in the data bit timing are not identical, a quantization error of up to one time quantum of the arbitration phase may be present as a phase error. This situation can occur after the switch from arbitration to data phase and will last until the next synchronization event. Thus, the length of the time quantum should be the same in nominal and data bit timing in order to minimize the chance of error frames on the CAN bus, and to optimize the clock tolerance in networks that use FD frames.

FDCTRL[FDRATE] enables the transmission of all frames with bit rate switching if the BRS bit in the selected Tx MB is set. If FDRATE is negated, the transmission is performed at nominal rate regardless of the BRS bit value. FDCTRL[FDRATE] can be written any time but takes effect only for the next message transmitted or received.

The nominal bit timing is resumed at either the sample point of the CRC Delimiter bit or when an error is detected, whichever occurs first. The following figure describes the mechanism for entering and leaving the data phase when BRS bit is recessive.

CAN FD Frame

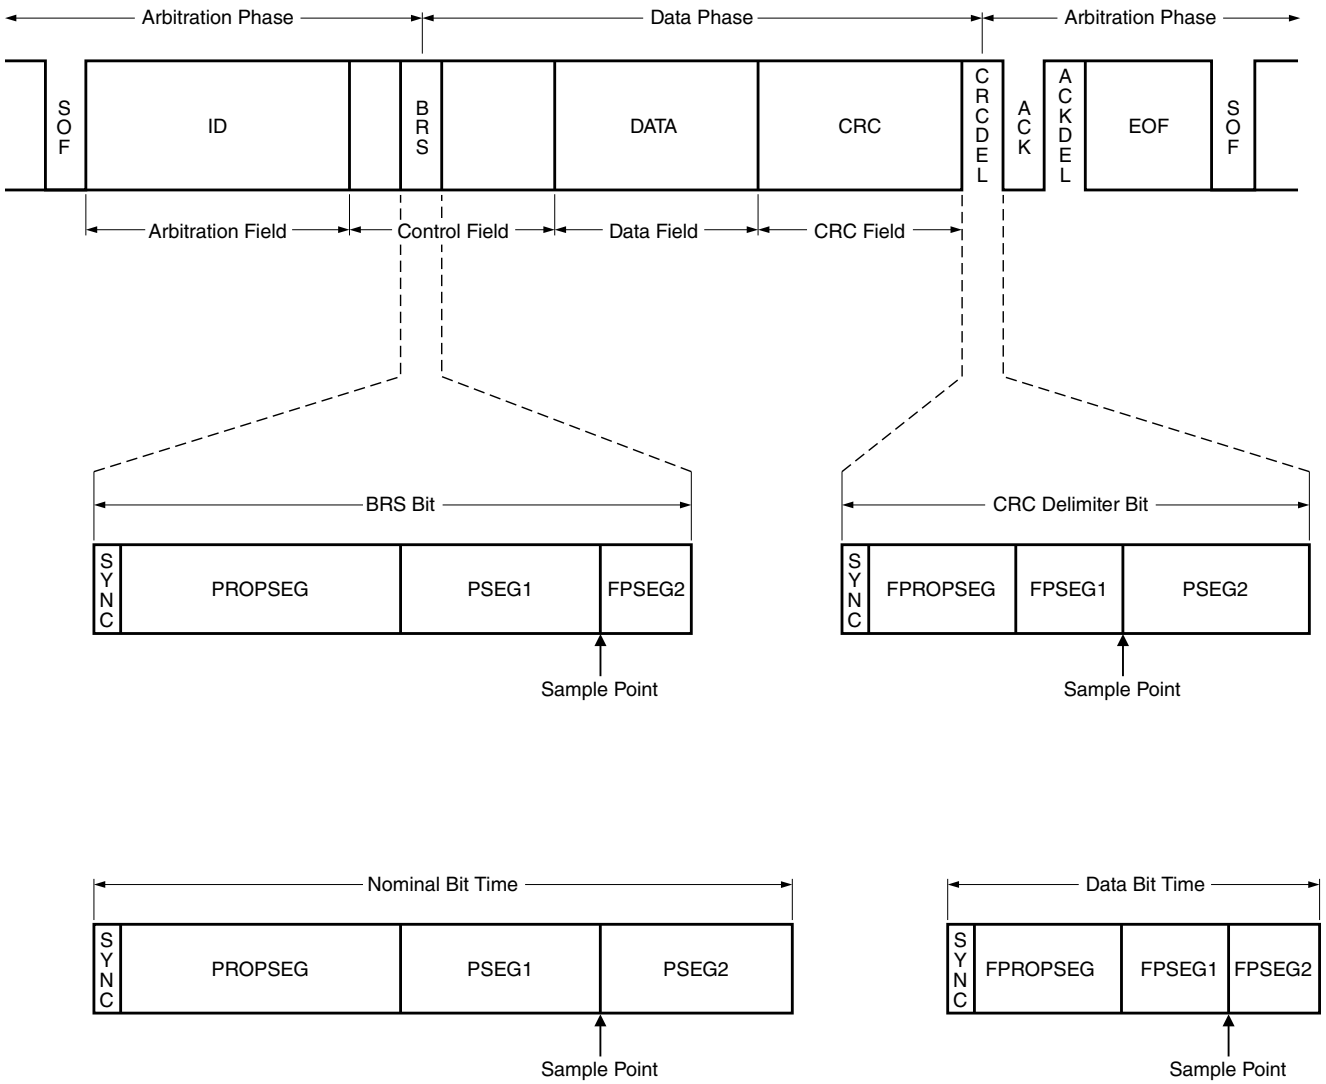

Figure 66-3. Bit rate switching mechanism for CAN FD messages

NOTE

In Classical CAN frames, the CRC delimiter is one single recessive bit. In CAN FD frames, the CRC delimiter may consist of one or two recessive bits. FlexCAN sends only one recessive bit as the CRC delimiter, but it accepts two recessive bits before the edge from recessive to dominant that starts the acknowledge slot. As a receiver, FlexCAN sends its acknowledge bit after the first CRC delimiter bit. In CAN FD frames, FlexCAN accepts a two-bit dominant ACK slot as a valid ACK to compensate for phase shifts between the receivers.

The maximum configurable bit rate in the CAN FD data phase depends on the clock frequency of CAN_PE subblock. For example, with a CAN_PE clock frequency of 40 MHz and the shortest configurable bit time of 5 time quanta, the bit rate in the data phase is 8 Mbit/s.[3]

The value of the ESI bit is determined either by the transmitter's error state at the start of the transmission, if the frame is originated in the FlexCAN node, or by the original transmitting node in case FlexCAN is acting as a gateway for the message. If the transmitter is error passive, ESI is transmitted recessive; otherwise, it is transmitted dominant. The permutations of the relationship between the written value and the transmitted value of the ESI are shown in this table.

Table 66-8. Written versus transmitted values of ESI field

FlexCAN fault confinement status at start of frame	ESI bit Of Tx MB	Transmitted ESI
Error active	0	0 (Error Active)
Error passive	0	1 (Error Passive)
Error active	1	1 (Error Passive)
Error passive	1	1 (Error Passive)

There are different CRC polynomials for different CAN frame formats. The first polynomial, CRC_15, is used for all frames in Classical CAN format. The second, CRC_17, is used for frames in CAN FD format with a data field up to sixteen bytes long. The third, CRC_21, is used for frames in CAN FD format with a data field longer than sixteen bytes. Each polynomial results in a Hamming distance of 6. At the start of the frame, all three CRC polynomials are calculated concurrently. The CRC sequence to be transmitted is selected by the values of the EDL bit and the DLC bit field. When receiving a message, FlexCAN decodes EDL and DLC to select the adequate CRC polynomial to check for a CRC error.

In CAN FD format frames, stuff bits are included in the bit stream for CRC calculation. In Classical CAN format frames, stuff bits are not included. After the transmission of the last bit relevant to the CRC calculation, the FDCRC register stores the calculated CRC for the transmitted message, with the adequate length in accordance to the type of message, for both CAN FD and non-FD messages. The CRCR register reports a valid CRC for Classical CAN messages only.

In CAN FD format frames, the CAN bit stuffing method is changed for the CRC sequence so that the stuff bits are inserted at fixed positions. When FlexCAN is transmitting a CAN FD frame, a fixed stuff bit is inserted just before the first bit of the CRC sequence, even if the last bits of the preceding field do not fulfill the CAN stuff

3. The frequency used in this example may not be supported on this chip; it is shown only to demonstrate how the maximum configurable bit rate is calculated.

condition. Additional stuff bits are inserted after each fourth bit of the CRC sequence. The value of any fixed stuff bit is the inverse value of its preceding bit. When FlexCAN is receiving a CAN FD frame, it discards the fixed stuff bits from the bit stream for the CRC check. A stuff error is detected if the fixed stuff bit has the same value as its preceding bit.

FlexCAN detects errors in CAN FD frames the same way as in Classical CAN frames. The error counters RXERRCNT and TXERRCNT in the ECR register accumulate the counts of Rx and Tx errors, respectively, for both FD and non-FD frames indiscriminately. There are two extra error counters (RXERRCNT_FAST and TXERRCNT_FAST) that accumulate Rx and Tx errors occurring in the data phase of CAN FD frames with the BRS bit set only. The rules for updating the error counters are the same for both CAN FD and non-FD frames (see ECR register).

Error Flags BITERR1, BITERR0, ACKERR, CRCERR, FRMERR, and STFERR in the ESR1 register report errors in both CAN FD and non-FD frames. They also generate the ERRINT interrupt if CTRL1[ERRMSK] is asserted. The ESR1 register has additional error flags (BITERR1_FAST, BITERR0_FAST, CRCERR_FAST, FRMERR_FAST, and STFERR_FAST) to individually indicate the occurrence of errors in the data phase of CAN FD frames with the BRS bit set. There is no ACKERR detected in the data phase of a CAN FD frame. Fault confinement status reported in ESR1[FLTCONF] is the same for both CAN FD and Classical CAN frames, and is based on RXERRCNT and TXERRCNT error counters only. Information contained in RXERRCNT_FAST and TXERRCNT_FAST counters may be considered as status to help detect the error nature related to the bit rate value.

When FlexCAN is in the data phase, either transmitting or receiving a CAN FD message, and detects an error, it immediately switches back to the arbitration phase and to the nominal rate to start an error flag.

Resynchronization and hard synchronization occur in CAN FD frames in the same way as in Classical CAN ones. Additionally, a hard synchronization is also performed at the recessive to dominant edge from EDL to R0 in CAN FD format frames. FlexCAN does not resynchronize while transmitting in the CAN FD data phase.

66.3.9.3 Transceiver delay compensation

The CAN FD protocol allows the transmission and reception of data at a higher bit rate than the nominal rate used in the arbitration phase when the message's BRS bit is set. This feature enables the use of rates up to 8 Mbps.

During the data phase of a CAN FD frame, the transmitter detects a bit error if it cannot receive its own latest transmitted bit at the sample point of that bit. When bit rate switching is enabled (BRS bit is asserted), the length of the CAN bit time in the data phase can become shorter than the transceiver's loop delay, thus impeding the correct comparison between the transmitted bit and the received bit within the current CAN bit time interval.

Note that the TDC process defines a secondary sample point where the transmitted bit is correctly compared with the received bit in order to check for bit errors.

The TDC mechanism can be enabled by FDCTRL[TDCEN] and is effective only during the data phase of FD frames having the BRS bit set. It has no effect either on non-FD frames, or on FD frames transmitted at normal bit rate. The TDC is active from the sample point of the BRS bit until the sample point of the CRC Delimiter bit, provided the respective message under transmission has the BRS bit set. When it is active, a comparison is done between the real received bit and the delayed transmitted bit, where the delay is calculated based on the measured transceiver loop delay.

NOTE

The actual value of the CRC Delimiter bit is disregarded by transmitters using the transceiver delay compensation mechanism. A global error at the end of the CRC field will cause the receivers to send error frames that the transmitter will detect during Acknowledge or End of Frame.

For every transmitted FD frame having the BRS bit set, the delay measurement is triggered by the transition from the recessive EDL bit to the dominant R0 bit (as shown in the next figure). The loop delay is measured in Protocol Engine (PE) clock periods (CANCLK, see Protocol timing), from the transmitted EDL-R0 edge to the received EDL-R0 edge. The position of the secondary sample point is defined by the measured loop delay time added to an offset value specified in FDCTRL[TDCOFF]. FDCTRL[TDCVAL] stores the result of this calculation. The TDCVAL value saturates at its maximum value of 63 CANCLK when the delay measurement is too long.

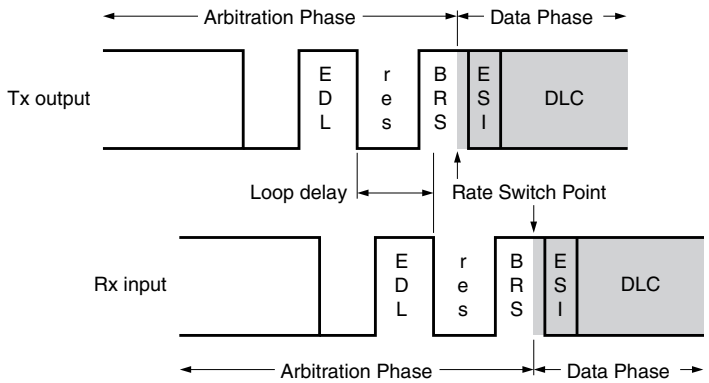

Figure 66-4. Transceiver loop delay measurement

The measured loop delay is not enough to be used to define the secondary sample point because it relates to the CAN bit edges. The transceiver delay compensation offset TDCOFF is used to shift the secondary sample point from the edge to an intermediate point inside the bit time, far away from its edges. Therefore, the TDCOFF value cannot be larger than the CAN bit duration in the data phase.

If the secondary sample point is set very near the CAN bit edge (SYNC field), then problems may occur during the bit sampling in the data phase. For the TDC to work reliably, the offset has to use optimal settings. To be sure the bit sampling is performed in the best region, the TDC offset should be configured as shown in this equation:

$$\text{Offset} = (\text{FPSEG1} + \text{FPROPSEG} + 2) \times (\text{FPRESDIV} + 1)$$

The following figure shows the SSP position when these settings are used.

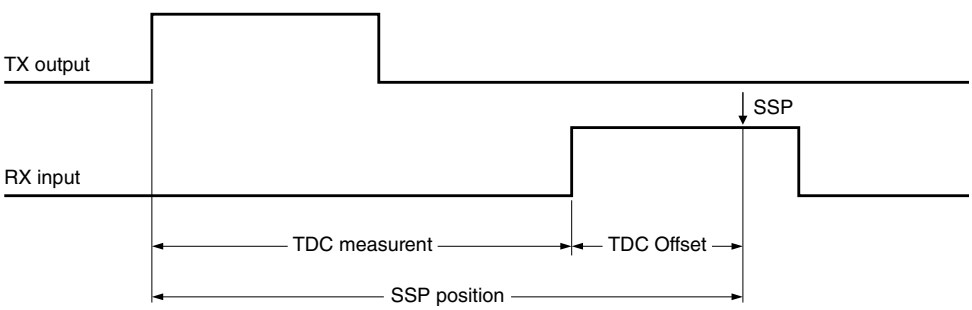

Figure 66-5. SSP position with optimal values

During the data phase of CAN FD frames with bit rate switching enabled, at the onset of every Tx CAN bit, the transmitted Tx bit value is temporarily stored in a buffer and a time countdown based on FDCTRL[TDCVAL] is started which ends with the comparison of the received Rx bit (delayed by the external loop delay plus the specified offset) with the stored Tx bit. If a bit error is detected at the secondary sample point, the FlexCAN issues an error flag to the CAN bus at the next sample point.

During the arbitration phase the delay compensation is always disabled. The maximum delay which can be compensated by the FlexCAN's transceiver delay compensation during the data phase is 3 CAN bit times – 2 Tq. Beyond this limit, the FDCTRL[TDCFAIL] flag is set to indicate when the transceiver delay compensation mechanism is out of range, unable to compensate the transceiver loop delay.

66.3.9.4 Remote frames

A remote frame is a special kind of frame. You can program a mailbox to be a remote request frame by configuring the mailbox as Transmit with the RTR bit set to one. After the remote request frame is transmitted successfully, the mailbox becomes a receive message buffer, with the same ID as before.

When a remote request frame is received by FlexCAN, it can be treated in three ways, depending on remote request storing (CTRL2[RRS]) and Rx FIFO Enable (MCR[RFEN]):

- If RRS is negated the frame's ID is compared to the IDs of the transmit message buffers with the CODE field 1010b. If there is a matching ID, then this mailbox frame will be transmitted. Note that if the matching mailbox has the RTR bit set, then FlexCAN will transmit a remote frame as a response. The received remote request frame is not stored in a receive buffer. It is only used to trigger a transmission of a frame in response. The mask registers are not used in remote frame matching, and all ID bits (except RTR) of the incoming received frame should match. In the case that a remote request frame is received and matches a mailbox, this message buffer immediately enters the internal arbitration process, but is considered as a normal Tx mailbox, with no higher priority. The data length of this frame is independent of the DLC field in the remote frame that initiated its transmission.
- If RRS is asserted the frame's ID is compared to the IDs of the receive mailboxes with the CODE field 0100b, 0010b, or 0110b. If there is a matching ID, then this mailbox will store the remote frame in the same fashion of a data frame. No automatic remote response frame will be generated. The mask registers are used in the matching process.
- If RFEN is asserted FlexCAN will not generate an automatic response for remote request frames that match the FIFO filtering criteria. If the remote frame matches one of the target IDs, it will be stored in the FIFO and presented to the CPU. Note that for filtering formats A and B, it is possible to select whether remote frames are accepted or not. For format C, remote frames are always accepted (if they match the ID). Remote request frames are considered as normal frames, and generate a FIFO overflow when a successful reception occurs and the FIFO is already full.

NOTE

There is no remote frame in the CAN FD format. The RTR bit is replaced by a fixed dominant RRS bit. FlexCAN receives and transmits remote frames in the Classical CAN format.

66.3.9.5 Overload frames

FlexCAN does transmit overload frames when the following conditions are detected on the CAN bus:

- Detection of a dominant bit in the first/second bit of Intermission
- Detection of a dominant bit at the 7th bit (last) of End of Frame field (Rx frames)
- Detection of a dominant bit at the 8th bit (last) of Error Frame Delimiter or Overload Frame Delimiter

66.3.9.6 Time stamp

The value of the free running timer is sampled at the beginning of the Identifier field on the CAN bus, and is stored at the end of move-in in the TIME STAMP field, providing network behavior with respect to time.

When CTRL2[TIMER_SRC] is asserted, the free running timer is continuously clocked by an external time tick.

When CTRL2[TIMER_SRC] is negated, the free running timer is clocked by the FlexCAN bit-clock, which defines the baud rate on the CAN bus. During a message transmission/reception, it increments by one for each bit that is received or transmitted. When there is no message on the bus, it counts using the previously programmed baud rate.

The free running timer is not incremented during Disable, Doze, Stop, and Freeze modes. It can be reset upon a specific frame reception, enabling network time synchronization. See the TSYN description in Control 1 register (CTRL1).

66.3.9.7 Protocol timing

The following figure shows the structure of the clock generation circuitry that feeds the CAN Protocol Engine (PE) submodule. The clock source field CTRL1[CLKSRC] defines whether the internal clock is connected to the output of a crystal oscillator (oscillator clock) or to the peripheral clock. In order to guarantee reliable operation, the clock source should be selected when the module is in Disable mode (MCR[MDIS] is set).

NOTE

Please see the clock distribution chapter (module clocks table) to identify the proper clock source.

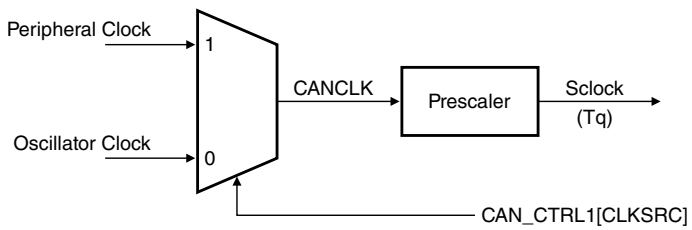

Figure 66-6. CAN engine clocking scheme

The oscillator clock should be selected whenever a tight tolerance (up to 0.1%) is required in the CAN bus timing. The crystal oscillator clock has better jitter performance than the peripheral clock.

The FlexCAN module supports a variety of means to set up bit timing parameters that are required by the CAN protocol. The Control 1 register (CTRL1) has various fields used to control bit timing parameters: PRESDIV, PROPSEG, PSEG1, PSEG2, and RJW.

The CAN Bit Timing register (CBT) extends the range of the CAN bit timing variables in CTRL1. The CAN FD Bit Timing register (FDCBT) provides a second set of CAN bit timing variables to be applied at the data phase of CAN FD frames with the Bit Rate Switch (BRS) set.

NOTE

When the CAN FD feature is enabled, always set CBT[BTF] and configure the CAN bit timing variables in CBT. See #d46445e7780a1310.

The PRESDIV field (as well as its extended range EPRESDIV and FDPRESDIV for the data phase bits of CAN FD messages) defines the prescaler value (see the equation below) that generates the serial clock (Sclock), whose period defines the time quantum used to compose the CAN waveform. A time quantum (Tq) is the atomic unit of time managed by the CAN engine.

$$Tq = \frac{(PRESDIV + 1)}{f_{CANCLK}}$$

The bit rate, which defines the rate the CAN message is either received or transmitted, is given by the formula:

$$\text{CAN Bit Time} = (\text{Number of Time Quanta in 1 bit time}) * Tq$$

$$\text{Bit Rate} = \frac{1}{\text{CAN Bit Time}}$$

A bit time is subdivided into three segments[1] (see Figure 66-7, Figure 66-8 and Table 66-9):

- SYNC_SEG: This segment has a fixed length of one time quantum. Signal edges are expected to happen within this section.
- Time Segment 1: This segment includes the propagation segment and the phase segment 1 of the CAN standard. It can be programmed by setting CTRL1[PROPSEG] and CTRL1[PSEG1] so that their sum (plus 2) is in the range of 2 to 16 time quanta. When CBT[BTF] is asserted, FlexCAN uses EPROPSEG and EPSEG1 fields from CBT register so that their sum (plus 2) is in the range of 2 to 96 time quanta. For messages in CAN FD format with the BRS bit set, FlexCAN uses FDPROPSEG and FDPSEG1 from FDCBT instead, so that their sum (plus 1) is in the range of 2 to 39 time quanta.
- Time Segment 2: This segment represents the phase segment 2 of the CAN standard. It can be programmed by setting CTRL1[PSEG2] (plus 1) to be 2 to 8 time quanta long. When CBT[BTF] is asserted, FlexCAN uses EPSEG2 fields of CBT register so that its value (plus 1) is in the range of 2 to 32 time quanta. For messages in CAN FD format with the BRS bit set, FlexCAN uses FDPSEG2 from FDCBT instead, so that its value (plus 1) is in the range of 2 to 8 time quanta. The time segment 2 cannot be smaller than the Information Processing Time (IPT), which value is 2 time quanta in FlexCAN.

NOTE

The bit time defined by the above time segments must not be smaller than five time quanta. For bit time calculations, use an Information Processing Time (IPT) of two, which is the value implemented in the FlexCAN module.

1. For further explanation of the underlying concepts, see ISO 11898-1. See also the CAN 2.0A/B protocol specification for bit timing.

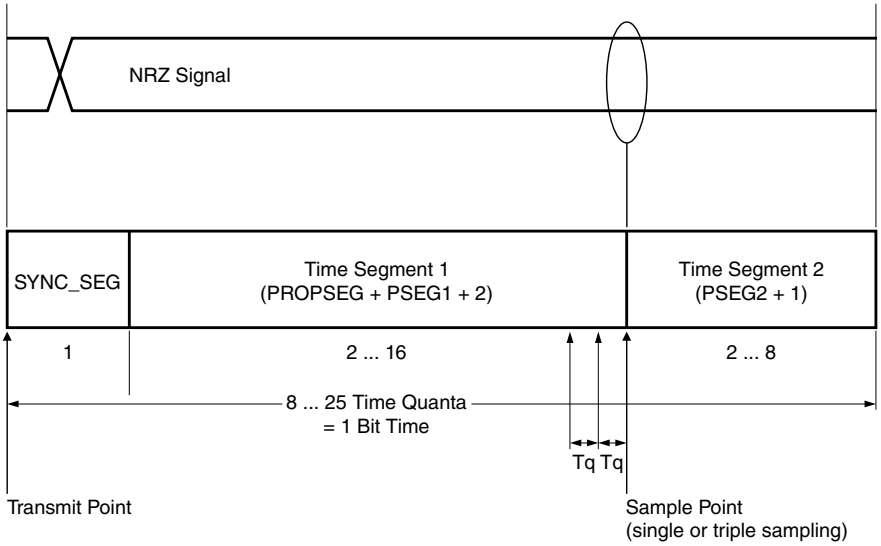

Figure 66-7. Segments within the bit time (example using CTRL1 bit timing variables for Classical CAN format)

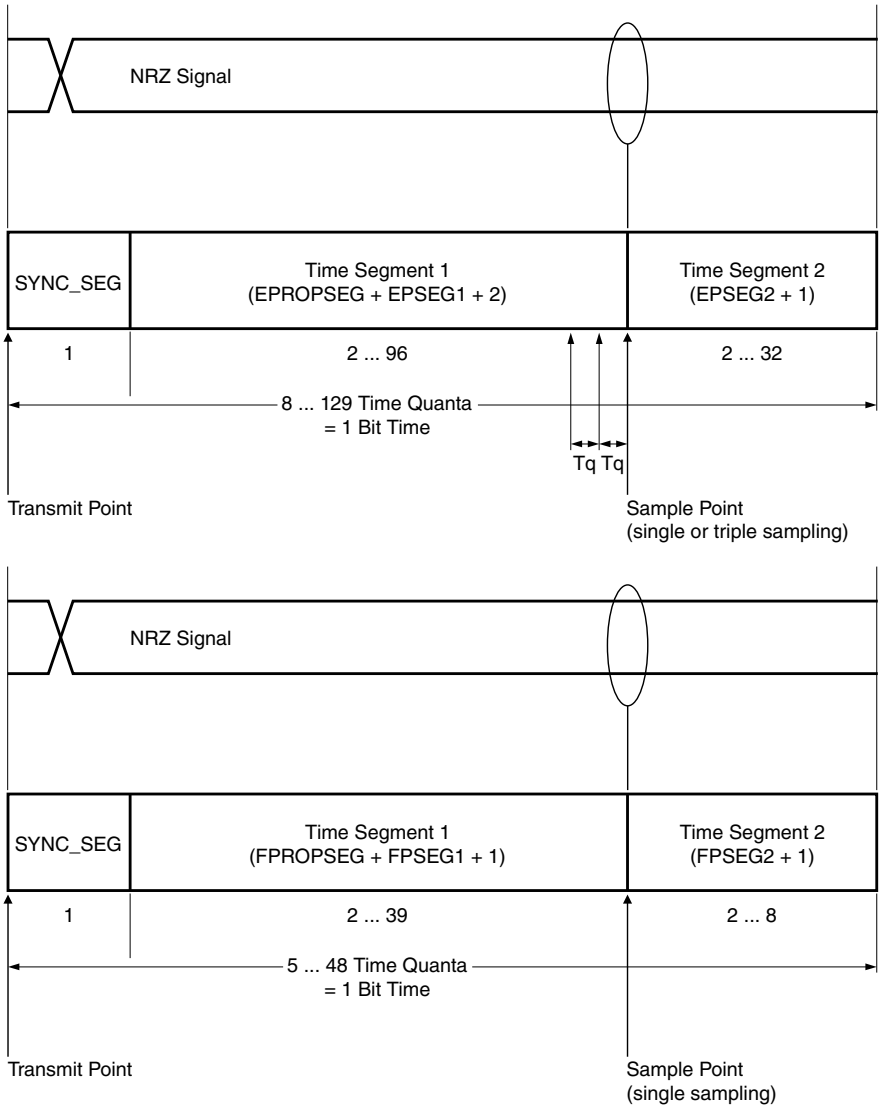

Figure 66-8. Segments within the bit time (example using CBT and FDCBT bit timing variables for CAN FD format)

Table 66-9. Time segment syntax

Syntax	Description
SYNC_SEG	System expects transitions to occur on the bus during this period.
TSEG1	Corresponds to the sum of PROPSEG and PSEG1.
TSEG2	Corresponds to the PSEG2 value.
Transmit point	A node in transmit mode transfers a new value to the CAN bus at this point.
Sample point	A node samples the bus at this point. If the three samples per bit option is selected, then this point marks the position of the third sample.

The following table gives some examples of the CAN compliant segment settings for Classical CAN format (Bosch CAN 2.0B) (non-FD) messages.

Table 66-10. Bosch CAN 2.0B standard compliant bit time segment settings

Time segment 1	Time segment 2	Re-synchronization jump width
5 .. 10	2	1 .. 2
4 .. 11	3	1 .. 3
5 .. 12	4	1 .. 4
6 .. 13	5	1 .. 4
7 .. 14	6	1 .. 4
8 .. 15	7	1 .. 4
9 .. 16	8	1 .. 4

Note

The user must ensure the bit time settings are in compliance with the CAN Protocol standard (ISO 11898-1).

Whenever CAN bit is used as a measure of time duration (for example, estimating the occurrence of a CAN bit event in a message), the number of peripheral clocks in one CAN bit (NumClkBit) can be calculated as:

$$\text{NumClkBit} = \frac{f_{SYS}}{f_{CANCLK}} \times (\text{PRESDIV} + 1) \times (\text{PROPSEG} + \text{PSEG1} + \text{PSEG2} + 4)$$

where:

- NumClkBit is the number of peripheral clocks in one CAN bit.
- f_{CANCLK} is the Protocol Engine (PE) Clock (see Figure 66-6), in Hz.
- f_{SYS} is the frequency of operation of the system (CHI) clock, in Hz.
- PSEG1 is the value in CTRL1[PSEG1] field.
- PSEG2 is the value in CTRL1[PSEG2] field.
- PROPSEG is the value in CTRL1[PROPSEG] field.
- PRESDIV is the value in CTRL1[PRESDIV] field.

The formula above is also applicable to the alternative CAN bit timing variables described in the CAN Bit Timing register (CBT) and also to the CAN FD Bit Timing register (FDCBT).

For example, 180 CAN bits = (180 x NumClkBit) peripheral clock periods.

66.3.9.8 Arbitration and matching timing

During normal reception and transmission, the matching, arbitration, move-in, and move-out processes are executed during certain time windows inside the CAN frame, as shown in the following figures.

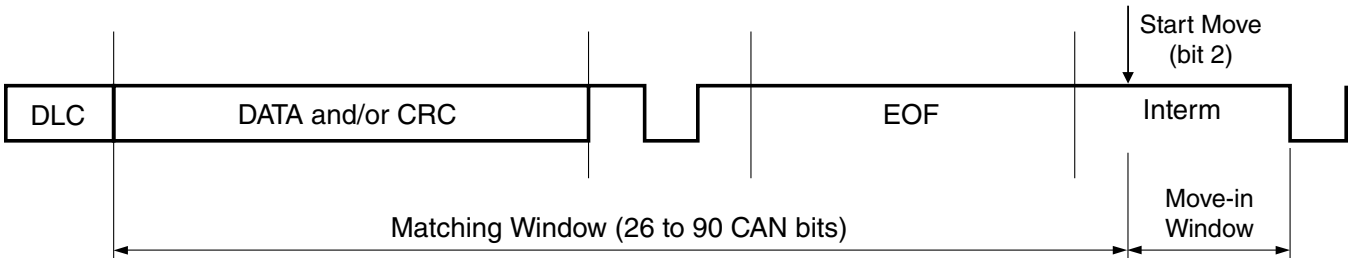

Figure 66-9. Matching and move-in time windows

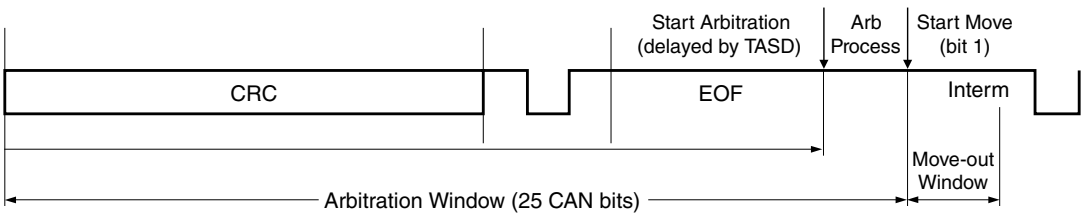

Figure 66-10. Arbitration and move-out time windows

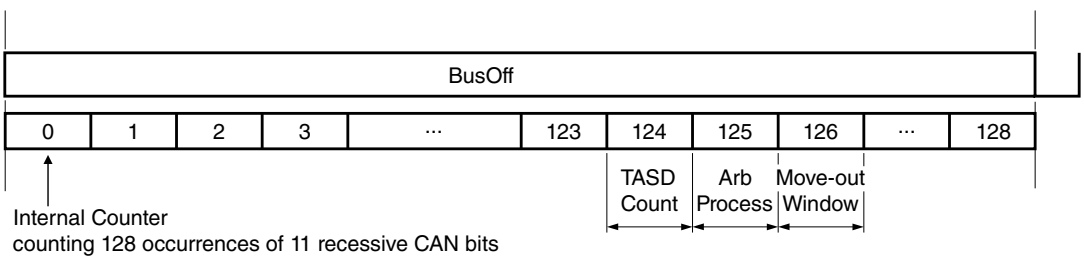

Figure 66-11. Arbitration at the end of bus off and move-out time windows

NOTE

In the preceding figures, the matching and arbitration timing does not take into account the delay caused by the concurrent memory access due to the CPU or other internal FlexCAN subblocks.

66.3.9.9 Tx arbitration start delay

CTRL2[TASD] (Tx Arbitration Start Delay) is a variable that indicates the number of CAN bits used by FlexCAN to delay the Tx arbitration process start point from the first bit of CRC field of the current frame. This variable can be written only in Freeze mode because it is blocked by hardware in other modes.

The transmission performance is impacted by the ability of the CPU to reconfigure message buffers (MBs) for transmission after the end of the internal arbitration process, where FlexCAN finds the winner MB for transmission (see Arbitration process). If the

arbitration ends too early before the first bit of Intermission field, then there is a chance that the CPU reconfigures some Tx MBs and the winner MB is no longer the best candidate to be transmitted.

TASD is useful to optimize the transmission performance by defining the arbitration start point, as shown in the next figure, based on factors such as:

- Peripheral-to-oscillator clock ratio
- CAN bit timing variables that determine the CAN bit rate
- Number of message buffers (MBs) in use by the matching and arbitration processes

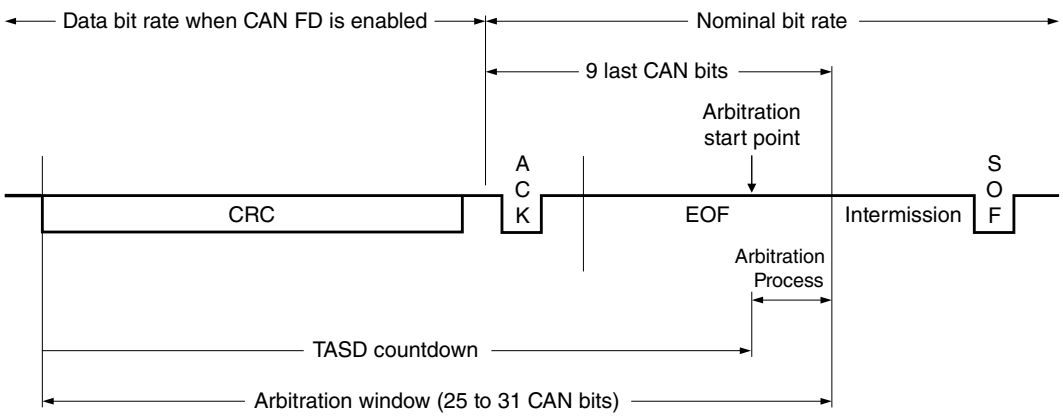

Figure 66-12. Optimal Tx Arbitration start point

The duration of an arbitration process, in terms of CAN bits, is directly proportional to the number of available MBs and to the CAN bit rate, and inversely proportional to the peripheral clock frequency.

The optimal arbitration timing is that in which the last MB is scanned just before the first bit of the Intermission field of a CAN frame. For instance, if there are few MBs and the peripheral/oscillator clock ratio is high and the CAN baud rate is low, then the arbitration can be placed closer to the frame's end, adding more delay to its start point, and vice-versa.

If TASD is set to 0 then the arbitration start is not delayed and more time is reserved for arbitration. On the other hand, if TASD is close to 24 then the CPU can configure a Tx MB later and less time is reserved for arbitration. If too little time is reserved for arbitration the FlexCAN may be not be able to find a winner MB in time to be transmitted with the best chance to win the bus arbitration against external nodes on the CAN bus.

The optimal TASD value can be calculated as follows:

For CAN FD frames and (MAXMB + 1) ≤ NMB_{END}

$$TASD = 31 - \frac{2 * (MAXMB + 1) + 4}{CPCB_N}$$

For CAN FD frames and (MAXMB + 1) > NMB_{END}

$$TASD = 22 - \frac{2 * (MAXMB + 1) - NMB_{END}}{CPCB_F}$$

For non-FD frames

$$TASD = 25 - \frac{2 * (MAXMB + 1) + 4}{CPCB}$$

where:

$$NMB_{END} = \frac{(9 * CPCB_N) - 4}{2}$$

$$BITRATE_N = \left(\frac{f_{CANCLK}}{[1 + (EPSEG1 + 1) + (EPSEG2 + 1) + (EPROPSEG + 1)] \times (EPRESDIV + 1)} \right)$$

$$BITRATE_F = \left(\frac{f_{CANCLK}}{[1 + (FPSEG1 + 1) + (FPSEG2 + 1) + FPROPSEG] \times (FPRESDIV + 1)} \right)$$

$$CPCB_N = \frac{f_{SYS}}{BITRATE_N}$$

$$CPCB_F = \frac{f_{SYS}}{BITRATE_F}$$

$$CPCB = CPCB_N$$

- MAXMB is the value in CTRL1[MAXMB].
- NMB_{END} is the number of message buffers that can be scanned by the arbitration process during the 9 last CAN bits at the end of a frame (see the figure above).
- $BITRATE_N$ is the CAN bit rate in bits per second calculated by the nominal CAN bit time variables.
- $BITRATE_F$ is the CAN bit rate in bits per second calculated by the data CAN bit time variables.
- $CPCB_N$ is the number of peripheral clocks per CAN bit in nominal bit rate for CAN FD frames.
- $CPCB_F$ is the number of peripheral clocks per CAN bit in data bit rate for CAN FD frames.
- CPCB is the number of peripheral clocks per CAN bit for non-FD frames.
- f_{CANCLK} is the oscillator clock, in Hz.
- f_{SYS} is the peripheral clock, in Hz.
- EPSEG1 is the value in CBT[EPSEG1] (CTRL1[PSEG1] can also be used).
- EPSEG2 is the value in CBT[EPSEG2] (CTRL1[PSEG2] can also be used).

- EPROPSEG is the value in CBT[EPROPSEG] (CTRL1[PROPSEG] can also be used).
- EPRESDIV is the value in CBT[EPRESDIV] (CTRL1[PRESDIV] can also be used).
- FPSEG1 is the value in FDCBT[FPSEG1].
- FPSEG2 is the value in FDCBT[FPSEG2].
- FPROPSEG is the value in FDCBT[FPROPSEG].
- FPRESDIV is the value in FDCBT[FPRESDIV].

See also Protocol timing for more details.

The following tables give the TASD value calculated for some configuration cases.

Case 1:

- Clock ratio = 2:1 (example: peripheral clock 80 MHz and oscillator clock 40 MHz)
- Bit rate in arbitration phase = 1 Mbaud

Table 66-11. TASD values:

Number of message buffers	TASD value	Maximum bit rate in data phase (MBd)
16	24	Invalid
32	24	8.0
64	23	8.0

Case 2:

- Clock ratio = 1:1 (example: peripheral clock 40 MHz and oscillator clock 40 MHz)
- Bit rate in arbitration phase = 1 Mbaud

Table 66-12. TASD values:

Number of message buffers	TASD value	Maximum bit rate in data phase (MBd)
16	24	Invalid
32	23	6.67
54	22	5.0
64	21	3.33

Case 3:

- Clock ratio = 2:1 (example: peripheral clock 40 MHz and oscillator clock 20 MHz)
- Bit rate in arbitration phase = 1 Mbaud

Table 66-13. TASD values:

Number of message buffers	TASD value	Maximum bit rate in data phase (MBd)
16	24	Invalid
32	23	4.0
54	22	4.0
64	21	3.33

66.3.10 Clocks

The following table describes the clock sources for FlexCAN. Please see Clock Controller Module (CCM) for clock setting, configuration and gating information.

Table 66-14. FlexCAN clocks

Clock name	Description
ipg_clk	Peripheral clock
ipg_clk_chi	Control Host Interface (CHI) clock
ipg_clk_pe	Protocol Engine (PE) clock
ipg_clk_pe_nogate	Protocol Engine clock (no gating)
ipg_clk_s	Peripheral access clock

66.3.10.1 Clock domains and restrictions

The FlexCAN module has two clock domains asynchronous to each other:

- The bus domain feeds the Control Host Interface (CHI) submodule.
- The oscillator domain feeds the CAN Protocol Engine (PE) submodule.

When CTRL1[CLKSRC] is set, synchronous operation occurs because both domains are connected to the peripheral clock (creating a 1:1 ratio between the peripheral and oscillator clocks).

When the two domains are connected to clocks with different frequencies and/or phases, there are restrictions on the frequency relationship between the two clock domains. In the case of asynchronous operation, the bus domain clock frequency must always be greater than the oscillator domain clock frequency.

NOTE

Asynchronous operation with a 1:1 ratio between peripheral and oscillator clocks is not allowed.

When doing matching and arbitration, FlexCAN needs to scan the whole message buffer memory during the time slot of one CAN frame, comprised of a number of CAN bits. In order to have sufficient time to do that, the following requirements must be observed:

- The peripheral clock frequency cannot be smaller than the oscillator clock frequency.
- There must be a minimum number of peripheral clocks per CAN bit, as specified in the table shown below.

Table 66-15. Minimum number of peripheral clocks per CAN bit for Classical CAN format

Number of mailboxes	Value of MCR[RFEN]	Minimum number of peripheral clocks per CAN bit
16	0	16
32	0	16
64	0	25
16	1	16
32	1	17
64	1	30

For classical frame format, the minimum number of peripheral clocks per CAN bit specified in the preceding table determines the minimum peripheral clock frequency for a given number of mailboxes and for an expected CAN bit rate. The CAN bit rate depends on the number of time quanta in a CAN bit, which can be defined by adjusting one or more of the bit timing values contained in either the Control 1 register (CTRL1) or CAN Bit Time register (CBT). The time quantum (Tq) is defined in Protocol timing. The minimum number of time quanta per CAN bit must be 8; therefore, the oscillator clock frequency should be at least 8 times the CAN bit rate.

For CAN FD frame format, there are some constraints that need to be satisfied. The number of peripheral clocks per CAN bit in nominal bit rate (NumClkNomBit) can be calculated by the equation below.

$$\text{NumClkNomBit} = \frac{f_{SYS}}{f_{CANCLK}} \times (\text{PRESDIV} + 1) \times (\text{PROPSEG} + \text{PSEG1} + \text{PSEG2} + 4)$$

$$= \frac{f_{SYS}}{\text{NomBitRate}}$$

where PRESDIV, PSEG1, and PSEG2 are CAN bit time values in CTRL1 register. Alternatively, EPRESDIV, EPSEG1, and EPSEG2 values in CBT register can be used instead. NumClkNomBit can also be calculated as a function of the expected nominal bit rate used in the arbitration phase (NomBitRate), as shown in the equation above.

The number of CAN bits in the data phase of an FD frame with the BRS bit set (fast CAN bits, in short) depends on the number of data bytes in the payload. The number of fast CAN bits (NumOfFastBits) can be determined in the table below. The fewer the number of data bytes, the fewer the number of fast CAN bits, and less time is available for FlexCAN to scan the whole message buffer memory during the internal matching and arbitration processes.

Table 66-16. Number of fast CAN bits in a CAN FD frame

Minimum number of data bytes	DLC field	NumOfFastBits
0	0h	21
1	1h	29
2	2h	37
3	3h	45
4	4h	53
5	5h	61
6	6h	69
7	7h	77
8	8h	85
12	9h	117
16	Ah	149
20	Bh	186
24	Ch	218
32	Dh	282
48	Eh	410
64	Fh	538

The critical part of a CAN FD frame is during the data phase, where the CAN bit rate is faster than in the arbitration phase. The minimum number of peripheral clocks per fast CAN bit (MinNumClkFastBit) can be calculated to guarantee that enough time is available for FlexCAN to scan the message buffer memory during reception and transmission. The equation below calculates this constraint.

$$\text{MinNumClkFastBit}_A = \frac{(\ 8.5 \times \text{MaxNumOfMb}\ ) + 64 - (\ 9 \times \text{NumClkNomBit}\ )}{\text{NumOfFastBits}}$$

where MaxNumOfMb is the maximum number of available mailboxes defined in MCR[MAXMB].

The clock domain crossing circuit between the CHI and PE subblocks also imposes a minimum number of peripheral clocks per fast CAN bit for the handshake mechanism to work properly without losing status information through the interface, as shown in the equation below.

$$MinNumClkFastBit_B = 3 \times \left(1 + \frac{f_{SYS}}{f_{CANCLK}}\right)$$

Therefore, the minimum number of peripheral clocks per fast CAN bit (MinNumClkFastBit) is determined by the larger of the two values calculated above.

$$MinNumClkFastBit = Maximum\ (\ MinNumClkFastBit_A, MinNumClkFastBit_B\ )$$

Then, the maximum CAN bit rate in the data phase of CAN FD frames (DataBitRateMAX) can be calculated as below.

$$DataBitrate_{MAX} = \frac{f_{CANCLK}}{ROUNDUP\left(\frac{MinNumClkFastBit \times f_{CANCLK}}{f_{SYS}}\right)}$$

The peripheral and oscillator clock frequencies, the maximum number of mailboxes, and the expected nominal bit rate affect the maximum data bit rate attainable by FlexCAN in CAN FD mode. Also, the data bit rate depends on the minimum payload size of FD frames used in a given application.

To illustrate how the CAN FD bit rate is affected by the configuration of FlexCAN variables, an application example with the peripheral and oscillator clock frequencies set to 50 MHz and 40 MHz, respectively, is considered.

1. Considering the nominal bit rate as 1 Mbps, the number of peripheral clocks per CAN bit in nominal bit rate is calculated as below.

$$NumClkNomBit = \frac{50 \times 10^6}{1 \times 10^6} = 50$$

2. The number of fast CAN bits (NumOfFastBits) is determined in the table presented above. For example, if the minimum payload in FD frames is 8 bytes, then there are 85 CAN bits in the data phase.
3. Assuming the maximum number of mailboxes is 96, the minimum number of peripheral clocks per fast CAN bit (MinNumClkFastBit) can be calculated.

$$MinNumClkFastBit_A = \frac{(8.5 \times 96) + 64 - (9 \times 50)}{85} = 5.06$$

$$MinNumClkFastBit_B = 3 \times \left(1 + \frac{50}{40}\right) = 6.75$$

$$MinNumClkFastBit = Maximum\ (5.06, 6.75) = 6.75$$

4. The maximum CAN bit rate in the data phase can finally be found.

$$DataBitRate_{MAX} = \frac{40 \times 10^6}{ROUNDUP\left(\frac{6.75 \times 40 \times 10^6}{50 \times 10^6}\right)} = 6.667 \text{ Mbps}$$

As demonstrated in this example, even though the oscillator clock frequency (40 MHz) is adequate to generate a data rate of 8 Mbps in CAN FD mode, the specific FlexCAN configuration limits this rate to 6.667 Mbps. This limitation is mainly due to the low peripheral clock frequency that imposes the MinNumClkFastBitB bound.

The table below shows the maximum data rate for CAN FD according to clock frequencies, payload size, and number of available mailboxes. See in this table that, for some cases, if the number of available mailboxes is reduced, the FlexCAN can then achieve a data rate up to 8 Mbps.

Table 66-17. Maximum CAN bit rate in data phase on CAN FD frames

Peripheral clock frequency (MHz)	Payload size	Number of available mailboxes	Maximum data rate (Mbps)
40	8	94	6.667
40	8	114	5.0
40	12	117	6.667
40	12	128	5.714
50	12 to 64	128	6.667
60	8	126	8.0
60	12	128	8.0
67	6	128	8.0
80	3	128	8.0
100	0	128	8.0

66.3.11 Reset

You can reset FlexCAN in the following ways:

1. Chip level hard reset, which resets all memory-mapped registers asynchronously.
2. MCR[SOFTRST], which resets some of the memory-mapped registers synchronously. See Table 66-19 to see what registers are affected by soft reset.

Soft reset is synchronous and has to follow an internal request/acknowledge procedure across clock domains. Therefore, it may take some time to fully propagate its effects. MCR[SOFTRST] remains asserted while soft reset is pending, so software can poll this bit to know when the reset has completed. Also, soft reset cannot be applied while clocks are shut down in a low-power mode. The low-power mode should be exited and the clocks resumed before applying soft reset.

The clock source should be selected when the module is in Disable mode (see CTRL1[CLKSRC] description in #d46445e1242a1310). After the clock source is selected and the module is enabled (MCR[MDIS] bit negated), FlexCAN automatically enters Freeze mode. In Freeze mode, FlexCAN is un-synchronized to the CAN bus, MCR[HALT] and MCR[FRZ] are set, the internal state machines are disabled, then MCR[FRZACK] and MCR[NOTRDY] are set. The Tx pin is in recessive state and FlexCAN does not initiate any transmission or reception of CAN frames. Note that the message buffers and the Rx Individual Mask registers are not affected by reset, so they are not automatically initialized.

66.3.12 Interrupts

The module has many interrupt sources: interrupts due to message buffers and interrupts due to the ORed interrupts from MBs, Bus Off, Bus Off Done, Error, Error Fast (errors detected in the data phase of CAN FD format messages with the BRS bit set), Wake Up, Tx Warning, and Rx Warning.

Each one of the message buffers can be an interrupt source, if its corresponding IMASK bit is set. There is no distinction between Tx and Rx interrupts for a particular buffer, under the assumption that the buffer is initialized for either transmission or reception. Each of the buffers has an assigned flag bit in the IFLAG registers. The bit is set when the corresponding buffer completes a successful transfer and is cleared when the CPU writes one to it (unless another interrupt is generated at the same time).

Note

It must be guaranteed that the CPU clears only the bit causing the current interrupt. For this reason, bit manipulation instructions (BSET) must not be used to clear interrupt flags. These instructions may cause accidental clearing of interrupt flags which are set after entering the current interrupt service routine.

If the Rx FIFO is enabled (MCR[RFEN] = 1) and DMA is disabled (MCR[DMA] = 0), the interrupts corresponding to MBs 0 to 7 have different meanings. Bit 7 of the IFLAG1 register becomes the "FIFO Overflow" flag; bit 6 becomes the "FIFO Warning" flag, bit 5 becomes the "Frames Available in FIFO" flag and bits 4-0 are unused. See the description of #d46445e5234a1310 for more information.

If both Rx FIFO and DMA are enabled (MCR[RFEN] and MCR[DMA] = 1) the FlexCAN does not generate any FIFO interrupt. Bit 5 of the IFLAG1 register still indicates "Frames Available in FIFO" and generates a DMA request. Bits 7, 6, 4-0 are unused.

CAUTION

FIFO cannot be enabled when CAN FD feature is enabled.

For a combined interrupt where multiple MB interrupt sources are OR'd together, the interrupt is generated when any of the associated MBs (or FIFO, if applicable) generates an interrupt. In this case, the CPU must read the IFLAG registers to determine which MB or FIFO source caused the interrupt.

The following interrupt sources generate interrupts like the MB interrupt sources, and can be read from ESR1 register

- Bus Off
- Bus Off Done
- Error
- Error Fast
- Wake Up
- Tx Warning
- Rx Warning

The Bus Off, Error, Tx Warning, and Rx Warning interrupt mask bits are located in the CTRL1 register; the Wake-Up interrupt mask bit is located in MCR.

66.3.13 Bus interface

CPU access to FlexCAN registers is subject to the following rules:

- Unrestricted read and write access to supervisor registers (registers identified with S/U in Table 66-19 in Supervisor Mode or with S only) results in an access error.
- Read and write access to implemented reserved address space results in an access error.
- Write access to positions whose bits are all currently read-only results in an access error. If at least one of the bits is not read-only then no access error is issued. Write permission to positions or some of their bits can change depending on the mode of operation or transitory state. See register and field descriptions for details.
- Read and write access to unimplemented address space results in access error.
- Read and write access to RAM located positions during Low Power mode results in an access error.
- It is possible for the RXIMR memory region to be considered as general purpose memory and available for access. There are two ways of doing this:
  a. If MCR[IRMQ] is cleared, the individual masks (RXIMR) are disabled. In this case the RXIMR memory region is considered as general purpose memory.
  b. If MCR[MAXMB] is programmed with a value smaller than the available number of MBs, then the unused memory space can be used as general purpose

RAM space. Note that reserved words within RAM cannot be used. As an example, suppose FlexCAN's RAM can support up to 16 MBs, CTRL2[RFFN] is 0h, and MCR[MAXMB] is programmed with zero. The maximum number of MBs in this case becomes one. The RAM starts at 0080h, and the space 0080h–008Fh is used by the one MB. The memory space 0090h–017Fh is available. The space 0180h–087Fh is reserved. The space 0880h–0883h is used by the one individual mask and the available memory in the mask registers space would be 0884h–08BFh. From 08C0h–09DFh there are reserved words for internal use which cannot be used as general purpose RAM. As a general rule, free memory space for general purpose depends only on MAXMB.

c. If MCR[FDEN] is enabled, general purpose memory can be used out of Freeze mode only.

66.3.14 Detection and correction of memory errors

NOTE

All FlexCAN memory must be initialized before starting its operation in order to have the parity bits in memory properly updated. CTRL2[WRMFRZ] grants write access to all memory positions that require initialization, ranging from 080h–ADFh and from F28h–FFFh when the CAN FD feature is enabled. The RXMGMASK, RX14MASK, RX15MASK, and RXFGMASK registers need to be initialized as well. MCR[RFEN] must not be set during memory initialization.

FlexCAN supports detection and correction of errors in memory read accesses. Each byte of FlexCAN memory is associated to five parity bits that ensure a Hamming distance of four. The error correction mechanism ensures that in this 13-bit word, errors in one bit can be corrected (correctable errors) and errors in two bits can be detected but not corrected (non-correctable errors). Errors in more than two bits may not be detected. In case of non-correctable errors, the corrupted data is not changed by the error correction logic. When a read access is performed, the parity bits are used to calculate a syndrome, which indicates the error in each byte.

FlexCAN detects a noncorrectable error in the event either an all-zeros or an all-ones read occurs. See description of #d46445e10651a1310.

Memory errors are indicated to the host through status register (Error Status Register (ERRSR)) and bus transfer errors, and reported through report registers (Error Report Address register (RERRAR), Error Report Data register (RERRDR) and Error Report Syndrome register (RERRSYNR)).

The error detection and correction mechanism can be activated or not, controlled by MECR[ECCDIS]. When disabled, updates on indications and reporting registers are stopped, but the parity bits are still calculated and written along with data in memory write operations to ensure that memory has consistent parity bits associated with the data.

To avoid accidentally changing the critical error correction configuration, this protocol must be followed to enable the update of the Memory Error Control register (MECR):

1. By default, CTRL2[ECRWRE] is zero and MECR[ECRWRDIS] is one.
2. Set CTRL2[ECRWRE].
3. Clear MECR[ECRWRDIS].
4. All writes to Memory Error Control register (MECR) must keep MECR[ECRWRDIS] cleared.
5. After configuration is done, lock the Memory Error Control register (MECR) by either setting MECR[ECRWRDIS] or clearing CTRL2[ECRWRE].

66.3.14.1 Sources of the memory access

The FlexCAN memory can be accessed by two major sources (or requestors):

- Host (CPU): the largest word accessed is 32-bit.
- FlexCAN internal processes (Rx matching, Tx arbitration, move-in on reception, move-out on transmission): the largest word accessed is 64-bit.

The way that noncorrectable errors are indicated and reported depends on the source of access.

66.3.14.2 Error indication

Memory errors are indicated by flags HANCEIF, FANCEIF, and CEIF in the Error Status Register (ERRSR). Noncorrectable errors detected in memory reads requested by the host are indicated separately than the ones detected in requests by FlexCAN internal processes. FlexCAN makes no distinction of the source of the access when correctable errors are detected. There are three independent flags for these three cases, and each flag will raise an interrupt unless it is masked by mask bits in Memory Error Control Register (MECR). If both noncorrectable and correctable errors are found in different bytes in the same read operation, both flags are set.

A noncorrectable error detected in host access is also indicated as a bus transfer error. A bus wait request may be asserted to extend the memory transaction to the moment the report registers are updated. This indication cannot be masked. If the flag bit ERRSR[HANCEIF] is not masked, the same noncorrectable error will raise a bus transfer error and an interrupt request.

Each indication flag has one overrun flag in Error Status Register (ERRSR). The overrun flags do not request interrupts. Overrun flags for noncorrectable errors indicate that other errors of the same nature were detected after current error being treated; overrun flags for correctable errors indicate that other errors of the same nature were detected before the current error being treated.

This is the recommended handling sequence for error indication:

1. Get error report information from report registers.
2. Use this information to take proper measures in the application.
3. Clear the HANCEIF, FANCEIF, and CEIF flags.
4. If the overrun flag is active:
    a. Alert application that at least one error could not be managed.
    b. Clear the overrun flag.

The FlexCAN internal processes can access memory in transactions larger than 32 bits. For the indication, this kind of access is considered a consecutive sequence of 32-bit accesses. If errors are found in two or more 32-bit words the interrupt and overrun flags are set simultaneously.

66.3.14.3 Error reporting

The report registers Error Report Address register (RERRAR), Error Report Data register (RERRDR), and Error Report Syndrome register (RERRSYNR) provide detailed information about the address read, raw data, and syndrome read with error, and are indicated by the flags described in Error indication. The address, data, and syndrome registers are updated simultaneously along with the error flags, according to these rules:

1. If either of the two non-correctable error flags is currently set, the report registers are not updated (the previous non-correctable error reporting is preserved).
2. Otherwise (either no error flag is currently set or only the correctable error flag is currently set), the report registers are updated according to the new error; or according to the most severe of new errors if non-correctable and correctable errors are simultaneously detected.

Reporting of errors detected in accesses larger than 32-bit follows the rules described in Error indication and in the description of #d46445e9994a1310.

The address reported in RERRAR and defined in ERRIAR are not the same listed in the module memory map. The relation between the reported addresses and the respective ones in the module memory map is shown in the description of #d46445e8929a1310.

Addresses reported when reading memory portions organized as FIFOs, such as the Rx FIFO Structure and the Rx FIFO Information Register (RXFIR), refer to the address of the specific entry accessed in the FIFO, not to the FIFO base address.

To assure coherence of the error report registers it is necessary to turn off the report update by setting MECR[RERRDIS] before reading the report registers.

66.3.14.4 Response to errors

Correctable errors have no consequence on FlexCAN operation because affected data is corrected before its use by the host or FlexCAN internal processes.

For host-initiated reads, a noncorrectable error may affect the host, but does not affect FlexCAN operation.

Non-correctable errors detected on memory reads requested by the FlexCAN internal processes may result in incorrect operation depending on the state of MECR[NCEFAFRZ], as follows:

- During reception (either matching or move-in processes), when a noncorrectable error occurs, an incorrect destination may be selected to store the incoming frame, a corrupted frame may be stored in the correct destination, or both. If MECR[NCEFAFRZ] is set, FlexCAN stops operation automatically and enters in Freeze mode to prevent corrupted data from being treated as valid by FlexCAN internal processes. When MECR[NCEFAFRZ] is negated, FlexCAN continues working and a corrupted frame is received.
- During arbitration process, when a noncorrectable error occurs, either a non-highest priority Tx message buffer may be mistakenly selected for transmission or its data may be corrupted. If MECR[NCEFAFRZ] is set, FlexCAN stops operation automatically and enters Freeze mode before starting the move-out. When MECR[NCEFAFRZ] is negated, FlexCAN proceeds to move-out with a corrupted frame that will be transmitted on the CAN bus.
- During move-out process, when a noncorrectable error occurs, a corrupted frame is copied from the selected Tx MB that won the arbitration to the Tx SMB for transmission. If MECR[NCEFAFRZ] is set, FlexCAN stops operation automatically and enters Freeze mode before starting the transmission. When MECR[NCEFAFRZ]

is negated, the corrupted frame is transferred from the Tx SMB to the Protocol Engine (PE) sub-block and is transmitted on the CAN bus.

- A noncorrectable error can also be detected beyond the move-out process, when Tx data is read from Tx SMB (buffer located in RAM) to be transferred to the PE subblock for transmission. In this case, a frame with corrupted ID and/or data is transmitted on the CAN bus.

  To prevent the frame from being successfully received by the external nodes, FlexCAN inverts all bits in the CRC field (CRC sequence plus CRC delimiter), and transmits an error flag just after CRC delimiter as a result of self-detecting a Bit1 error and a form error due to the CRC field inversion. When MECR[NCEFAFRZ] is set, FlexCAN stops operation automatically and enters Freeze mode just after the error frame. When MECR[NCEFAFRZ] is negated, FlexCAN may attempt to re-transmit the same frame, as long as no other higher priority Tx MB is subsequently configured for transmission.

  In the event the noncorrectable error persists, FlexCAN eventually reaches the Bus Off state because of consecutive error detections. ECR[TXERRCNT] is updated every time FlexCAN inverts the CRC field, causing errors as described above.

When MECR[NCEFAFRZ] is set and FlexCAN enters Freeze mode, only the CPU can cause FlexCAN to exit Freeze mode and resume Normal mode. The assertion of MECR[NCEFAFRZ] is the only way to prevent corrupted frames from being transmitted on the CAN bus up to the move-out internal process.

The error report registers can provide information to the application for customized management of these situations.

66.3.14.5 Error injection

The error injection registers ERRIAR, ERRIDPR, and ERRIPPR are used to inject errors in memory reads in order to force errors and consequently update the indication and reporting registers. The relation between the error injection addresses and the respective ones in the module memory map is shown in the description of #d46445e8929a1310.

The injection is done by flipping the data and parity bits correspondent to the bits in 1 in ERRIDPR and ERRIPPR. Injection can be selected specifically for memory accesses requested by the host or by FlexCAN internal processes.

In case of accesses larger than 32-bits, the EXTERRIE bit in Memory Error Control register (MECR) extends the injection pattern, replicating it in 32-bit words to fill the width of the access.

NOTE

It is very unlikely, but error injection may correct a bit with error. This will not raise the error flags and reports as expected.

To ensure coherence among error injection registers and avoid spurious error injections, MECR[HAERRIE] and MECR[FAERRIE] must be cleared when configuring the memory injection registers.

66.4 FlexCAN signal descriptions

The FlexCAN module has two I/O signals connected to the external chip pins. These signals are summarized in the following table and described in more detail in the next subsections.

Table 66-18. FlexCAN signal descriptions

Signal	Description	I/O
CAN Rx	CAN receive pin	Input
CAN Tx	CAN transmit pin	Output

66.4.1 CAN Rx

This pin is the receive pin from the CAN bus transceiver. Dominant state is represented by logic level 0. Recessive state is represented by logic level 1.

66.4.2 CAN Tx

This pin is the transmit pin to the CAN bus transceiver. Dominant state is represented by logic level 0. Recessive state is represented by logic level 1.

66.5 Initialization/application information

This section provides instructions for initializing the FlexCAN module.

66.5.1 FlexCAN initialization sequence

For any configuration change/initialization it is required that FlexCAN be put into Freeze mode (see Freeze mode). Note that the module needs to be initialized after every reset.

The following is a generic initialization sequence applicable to the FlexCAN module:

1. Initialize the Module Configuration register (MCR).
   a. Enable the individual filtering per MB and reception queue features by setting IRMQ.
   b. Enable the warning interrupts by setting WRNEN.
   c. If required, disable frame self reception by setting SRXDIS.
   d. Enable the Rx FIFO by setting RFEN.
   e. If Rx FIFO is enabled and DMA is required, set DMA.
   f. Enable the abort mechanism by setting AEN.
   g. Enable the local priority feature by setting LPRIOEN.
2. Initialize the Control 1 register (CTRL1) and optionally the CAN Bit Timing register (CBT). Initialize also the CAN FD CAN Bit Timing register (FDCBT).
   a. Determine the bit timing parameters: PROPSEG, PSEG1, PSEG2, and RJW.
   b. Optionally determine the bit timing parameters: EPROPSEG, EPSEG1, EPSEG2, and ERJW.
   c. Determine the CAN FD bit timing parameters: FPROPSEG, FPSEG1, FPSEG2, and FRJW.
   d. Determine the bit rate by programming the PRESDIV field and optionally the EPRESDIV field.
   e. Determine the CAN FD bit rate by programming the FPRESDIV field.
   f. Determine the internal arbitration mode (LBUF).
3. All FlexCAN memory must be initialized if Error Code Correction (ECC) is enabled. See Detection and correction of memory errors.
4. Initialize the message buffers.
   a. The control and status word of all message buffers must be initialized.
   b. If Rx FIFO was enabled, the ID filter table must be initialized.
   c. Other entries in each message buffer should be initialized as required.
5. Initialize the Rx Individual Mask registers (RXIMRn).
6. Set required interrupt mask bits in
   - IMASK registers (for all MB interrupts)
   - MCR register (for Wake-Up interrupt)
   - CTRL1 / CTRL2 registers (for Bus Off and Error interrupts)
7. Negate MCR[HALT].

After the last step listed above, FlexCAN attempts to synchronize to the CAN bus.

66.6 Memory map/register definition

This section describes the registers and data structures in the FlexCAN module. The base address of the module depends on the particular memory map of the chip.

66.6.1 FlexCAN memory mapping

The address space occupied by FlexCAN has 128 bytes for registers starting at the module base address, followed by embedded RAM starting at address offset 0080h.

Each individual register is identified by its complete name and the corresponding mnemonic . The access type can be Supervisor (S) or Unrestricted (U). Most of the registers can be configured to have either Supervisor or Unrestricted access by programming MCR[SUPV]. These registers are identified as S/U in the Access column of Table 66-19.

NOTE

An invalid register access will result in a bus error. This includes reading a write-only register, writing a read-only register, or accessing an invalid address.

Table 66-19. Register access and reset information

Register	Access type	Affected by hard reset	Affected by soft reset
Module Configuration Register (MCR)	S	Yes	Yes
Control 1 register (CTRL1)	S/U	Yes	No
Free Running Timer register (TIMER)	S/U	Yes	Yes
Rx Mailboxes Global Mask register (RXMGMASK)	S/U	No	No
Rx Buffer 14 Mask register (RX14MASK)	S/U	No	No
Rx Buffer 15 Mask register (RX15MASK)	S/U	No	No
Error Counter Register (ECR)	S/U	Yes	Yes
Error and Status 1 Register (ESR1)	S/U	Yes	Yes
Interrupt Masks 2 register (IMASK2)	S/U	Yes	Yes
Interrupt Masks 1 register (IMASK1)	S/U	Yes	Yes
Interrupt Flags 2 register (IFLAG2)	S/U	Yes	Yes
Interrupt Flags 1 register (IFLAG1)	S/U	Yes	Yes
Control 2 Register (CTRL2)	S/U	Yes	No
Error and Status 2 Register (ESR2)	S/U	Yes	Yes
CRC Register (CRCR)	S/U	Yes	Yes
Rx FIFO Global Mask register (RXFGMASK)	S/U	No	No

Table continues on the next page...

Table 66-19. Register access and reset information (continued)

Register	Access type	Affected by hard reset	Affected by soft reset
Rx FIFO Information Register (RXFIR)	S/U	No	No
CAN Bit Timing Register (CBT)	S/U	Yes	No
Message buffers	S/U	No	No
Rx Individual Mask Registers	S/U	No	No
Memory Error Control register (MECR)	S/U	Yes	Yes
Error Injection Address register (ERRIAR)	S/U	Yes	Yes
Error Injection Data Pattern register (ERRIDPR)	S/U	Yes	Yes
Error Injection Parity Pattern register (ERRIPPR)	S/U	Yes	Yes
Error Report Address register (RERRAR)	S/U	Yes	Yes
Error Report Data register (RERRDR)	S/U	Yes	Yes
Error Report Syndrome register (RERRSYNR)	S/U	Yes	Yes
Error Status register (ERRSR)	S/U	Yes	Yes
CAN FD Control register (FDCTRL)	S/U	Yes	No
CAN FD Bit Timing register (FDCBT)	S/U	Yes	No
CAN FD CRC register (FDCRC)	S/U	Yes	Yes

The FlexCAN module can store CAN messages for transmission and reception using mailboxes and Rx FIFO structures.

66.6.2 CAN register descriptions

The table below shows the FlexCAN memory map.

The address range from offset 80h–47Fh allocates the sixty-four 128-bit message buffers (MBs).

The memory maps for the message buffers are in FlexCAN message buffer memory map.

66.6.2.1 CAN memory map

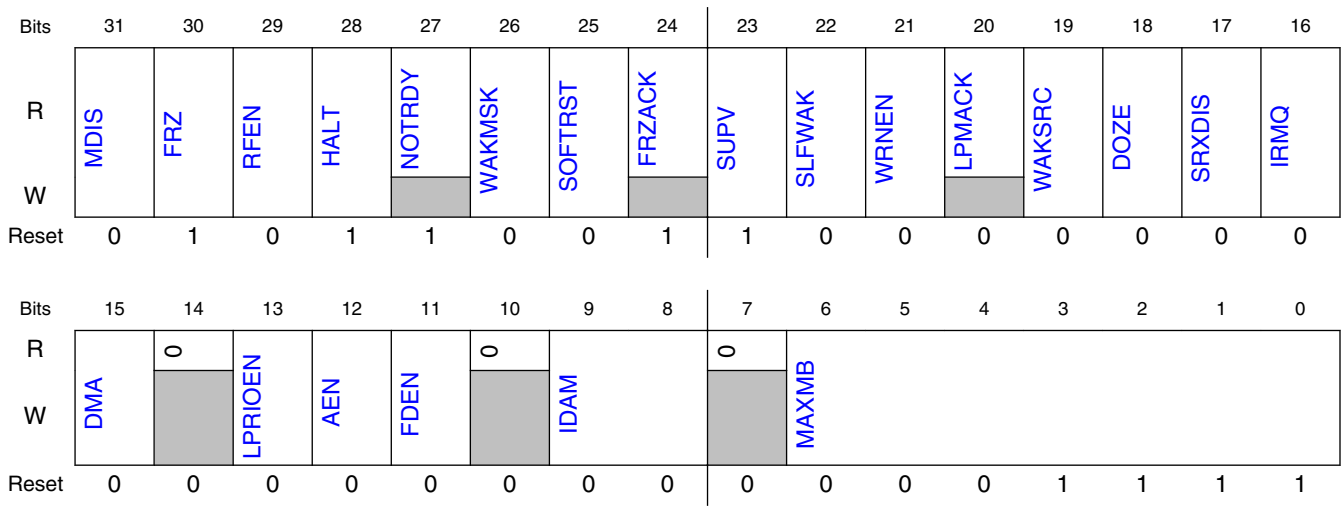
66.6.2.2 Module Configuration register (MCR)

This register defines global system configurations, such as the module operation modes and the maximum message buffer configuration.

66.6.2.2.1 Offset

Register	Offset
MCR	0h

66.6.2.2.2 Diagram



66.6.2.2.3 Fields

Field	Description
31 MDIS	Module Disable This bit controls whether FlexCAN is enabled or not. When disabled, FlexCAN disables the clocks to the CAN Protocol Engine and Controller Host Interface submodules. This bit is not affected by soft reset. 0 - Enable the FlexCAN module. 1 - Disable the FlexCAN module.
30 FRZ	Freeze Enable The FRZ bit specifies the FlexCAN behavior when MCR[HALT] is set or when Debug mode is requested at chip level. When FRZ is asserted, FlexCAN is enabled to enter Freeze mode. Negation of this bit field causes FlexCAN to exit from Freeze mode. This bit is set by hardware when a non-correctable error is detected (MECR[NCEFAFRZ] is asserted). 0 - Not enabled to enter Freeze mode. 1 - Enabled to enter Freeze mode.
29 RFEN	Rx FIFO Enable This bit controls whether the Rx FIFO feature is enabled or not. When RFEN is set, MBs 0 to 5 cannot be used for normal reception and transmission because the corresponding memory region (80h–DCh) is used by the FIFO engine as well as additional MBs (up to 32, depending on CTRL2[RFFN] setting) which

Table continues on the next page...

Field	Description
	are used as Rx FIFO ID filter table elements. RFEN also impacts the definition of the minimum number of peripheral clocks per CAN bit as described in Table 66-15. This bit can be written in Freeze mode only, because it is blocked by hardware in other modes. **NOTE:** This bit cannot be set when CAN FD operation is enabled (see FDEN bit). 0 - Rx FIFO not enabled. 1 - Rx FIFO enabled.
28 HALT	Halt FlexCAN Assertion of this bit puts the FlexCAN module into Freeze mode. The CPU should clear it after initializing the message buffers and the Control registers CTRL1 and CTRL2. No reception or transmission is performed by FlexCAN before this bit is cleared. Freeze mode cannot be entered when FlexCAN is in a low power mode. The HALT bit is set by hardware when a non-correctable error is detected and MECR[NCEFAFRZ] is asserted. 0 - No Freeze mode request. 1 - Enters Freeze mode if the FRZ bit is asserted.
27 NOTRDY	FlexCAN Not Ready This read-only bit indicates that FlexCAN is either in Disable mode, Doze mode, Stop mode or Freeze mode. It is negated when FlexCAN has exited these modes. This bit is not affected by soft reset. 0 - FlexCAN module is either in Normal mode, Listen-Only mode, or Loop-Back mode. 1 - FlexCAN module is either in Disable mode, Doze mode, Stop mode, or Freeze mode.
26 WAKMSK	Wake Up Interrupt Mask This bit enables the Wake Up interrupt generation under Self Wake Up mechanism. 0 - Wake Up interrupt is disabled. 1 - Wake Up interrupt is enabled.
25 SOFTRST	Soft Reset When SOFTRST is asserted, FlexCAN resets its internal state machines and some of the memory-mapped registers. SOFTRST can be asserted directly by the CPU when it writes to the MCR register. Because soft reset is synchronous and has to follow a request/acknowledge procedure across clock domains, it may take some time to fully propagate its effect. The SOFTRST bit remains asserted when reset is pending, and is automatically negated when reset completes. Therefore, software can poll this bit to know when the soft reset has completed. Soft reset cannot be applied when clocks are shut down in a low power mode. The module should be first removed from low power mode, and then soft reset can be applied. This bit is not affected by soft reset. 0 - No reset request. 1 - Resets the registers affected by soft reset.
24 FRZACK	Freeze Mode Acknowledge This read-only bit indicates that FlexCAN is in Freeze mode and its prescaler is stopped. The Freeze mode request cannot be granted until current transmission or reception processes have finished. Therefore the software can poll the FRZACK bit to know when FlexCAN has actually entered Freeze mode. If Freeze mode request is negated, then this bit is negated after the FlexCAN prescaler is running again. If Freeze mode is requested when FlexCAN is in a low power mode, then the FRZACK bit will be set only when the low-power mode is exited. See Freeze mode. This bit is not affected by soft reset. **NOTE:** FRZACK will be asserted within 178 CAN bits from the Freeze mode request by the CPU, and negated within 2 CAN bits after the Freeze mode request removal (see Protocol timing). 0 - FlexCAN not in Freeze mode, prescaler running.

Table continues on the next page...

Field	Description
	1 - FlexCAN in Freeze mode, prescaler stopped.
23 SUPV	Supervisor Mode This bit configures the FlexCAN to be either in Supervisor or User mode. The registers affected by this bit are marked as S/U in the "Access type" column of Table 66-19. Reset value of this bit is 1, so the affected registers start with Supervisor access allowance only. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. 0 - FlexCAN is in User mode. Affected registers allow both Supervisor and Unrestricted accesses. 1 - FlexCAN is in Supervisor mode. Affected registers allow only Supervisor access. Unrestricted access behaves as though the access was done to an unimplemented register location.
22 SLFWAK	Self Wake Up This bit enables the Self Wake Up feature when FlexCAN is in a low-power mode other than Disable mode. When this feature is enabled, the FlexCAN module monitors the bus for wakeup event, that is, a recessive-to-dominant transition. If a wakeup event is detected during Doze mode, FlexCAN requests to resume its clocks and, if enabled to do so, generates a Wake Up interrupt to the CPU. If a wakeup event is detected during Stop mode, then FlexCAN generates, if enabled to do so, a Wake Up interrupt to the CPU so that it can exit Stop mode globally and FlexCAN can request to resume the clocks. When FlexCAN is in a low-power mode other than Disable mode, this bit cannot be written as it is blocked by hardware. 0 - FlexCAN Self Wake Up feature is disabled. 1 - FlexCAN Self Wake Up feature is enabled.
21 WRNEN	Warning Interrupt Enable When asserted, this bit enables the generation of the TWRNINT and RWRNINT flags in the Error and Status Register 1 (ESR1). If WRNEN is negated, the TWRNINT and RWRNINT flags will always be zero, independent of the values of the error counters, and no warning interrupt will ever be generated. This bit can be written in Freeze mode only, because it is blocked by hardware in other modes. 0 - TWRNINT and RWRNINT bits are zero, independent of the values in the error counters. 1 - TWRNINT and RWRNINT bits are set when the respective error counter transitions from less than 96 to greater than or equal to 96.
20 LPMACK	Low-Power Mode Acknowledge This read-only bit indicates that FlexCAN is in a low-power mode (Disable mode, Doze mode, Stop mode). A low-power mode cannot be entered until all current transmission or reception processes have finished, so the CPU can poll the LPMACK bit to know when FlexCAN has actually entered low power mode. This bit is not affected by soft reset. **NOTE:** LPMACK will be asserted within 180 CAN bits from the low-power mode request by the CPU, and negated within 2 CAN bits after the low-power mode request removal (see Protocol timing). 0 - FlexCAN is not in a low-power mode. 1 - FlexCAN is in a low-power mode.
19 WAKSRC	Wake Up Source This bit defines whether the integrated low-pass filter is applied to protect the Rx CAN input from spurious wakeup. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. 0 - FlexCAN uses the unfiltered Rx input to detect recessive to dominant edges on the CAN bus. 1 - FlexCAN uses the filtered Rx input to detect recessive to dominant edges on the CAN bus.
18	Doze Mode Enable

Table continues on the next page...

Field	Description
DOZE	This bit defines whether FlexCAN is allowed to enter low-power mode when Doze mode is requested at chip level. This bit is automatically reset when FlexCAN wakes up from Doze mode upon detecting activity on the CAN bus (self wakeup enabled). 0 - FlexCAN is not enabled to enter low-power mode when Doze mode is requested. 1 - FlexCAN is enabled to enter low-power mode when Doze mode is requested.
17 SRXDIS	Self Reception Disable This bit defines whether FlexCAN is allowed to receive frames transmitted by itself. If this bit is asserted, frames transmitted by the module will not be stored in any MB, regardless if the MB is programmed with an ID that matches the transmitted frame, and no interrupt flag or interrupt signal will be generated due to the frame reception. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. 0 - Self-reception enabled. 1 - Self-reception disabled.
16 IRMQ	Individual Rx Masking And Queue Enable This bit indicates whether Rx matching process will be based either on individual masking and queue or on masking scheme with RXMGMASK, RX14MASK, RX15MASK, and RXFGMASK. This bit can be written in Freeze mode only because it is blocked by hardware in other modes. 0 - Individual Rx masking and queue feature are disabled. For backward compatibility with legacy applications, the reading of C/S word locks the MB even if it is EMPTY. 1 - Individual Rx masking and queue feature are enabled.
15 DMA	DMA Enable DMA controls whether the DMA feature is enabled or not. The DMA feature can only be used in Rx FIFO, so consequently MCR[RFEN] must be asserted. When DMA and RFEN are set, IFLAG1[BUF5I] generates the DMA request and no RX FIFO interrupt is generated. This bit can be written in Freeze mode only as it is blocked by hardware in other modes. 0 - DMA feature for RX FIFO disabled. 1 - DMA feature for RX FIFO enabled.
14 —	Reserved
13 LPRIOEN	Local Priority Enable This bit is provided for backwards compatibility with legacy applications. It controls whether the local priority feature is enabled or not. It is used to expand the ID used during the arbitration process. With this expanded ID concept, the arbitration process is done based on the full 32-bit word, but the actual transmitted ID still has 11-bit for standard frames and 29-bit for extended frames. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. 0 - Local Priority disabled. 1 - Local Priority enabled.
12 AEN	Abort Enable When asserted, this bit enables the Tx abort mechanism. This mechanism guarantees a safe procedure for aborting a pending transmission, so that no frame is sent in the CAN bus without notification. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. **NOTE:** When MCR[AEN] is asserted, only the abort mechanism (see Transmission abort mechanism) must be used for updating mailboxes configured for transmission. **CAUTION:** Writing the Abort code into Rx mailboxes can cause unpredictable results when MCR[AEN] is asserted. 0 - Abort disabled.

Table continues on the next page...

Field	Description
	1 - Abort enabled.
11 FDEN	CAN FD operation enable This bit enables the CAN with Flexible Data rate (CAN FD) operation. This bit can be written in Freeze mode only. **NOTE:** FlexCAN is able to transmit FD frame format according to ISO 11898-1. **NOTE:** The Rx FIFO Enable (RFEN) bit cannot be set if FDEN is asserted. 0 - CAN FD is disabled. FlexCAN is able to receive and transmit messages in CAN 2.0 format. 1 - CAN FD is enabled. FlexCAN is able to receive and transmit messages in both CAN FD and CAN 2.0 formats.
10 —	Reserved
9-8 IDAM	ID Acceptance Mode This 2-bit field identifies the format of the Rx FIFO ID filter table elements. Note that all elements of the table are configured at the same time by this field (they are all the same format). See Rx FIFO structure. This field can be written only in Freeze mode because it is blocked by hardware in other modes. 00 - Format A: One full ID (standard and extended) per ID filter table element. 01 - Format B: Two full standard IDs or two partial 14-bit (standard and extended) IDs per ID filter table element. 10 - Format C: Four partial 8-bit standard IDs per ID filter table element. 11 - Format D: All frames rejected.
7 —	Reserved
6-0 MAXMB	Number Of The Last Message Buffer This 7-bit field defines the number of the last message buffers that will take part in the matching and arbitration processes. The reset value (0Fh) is equivalent to a 16 MB configuration. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Number of the last MB = MAXMB **NOTE:** MAXMB must be programmed with a value smaller than or equal to the number of available message buffers, as described in FlexCAN memory partition for CAN FD. Additionally, the definition of MAXMB value must take into account the region of MBs occupied by Rx FIFO and its ID filters table space defined by CTRL2[RFFN]. MAXMB also impacts the definition of the minimum number of peripheral clocks per CAN bit as described in Table 66-15.

66.6.2.3 Control 1 register (CTRL1)

This register is defined for specific FlexCAN control features related to the CAN bus, such as bit rate, programmable sampling point within an Rx bit, Loop Back mode, Listen-Only mode, Bus Off recovery behavior, and interrupt enabling (Bus-Off, Error, Warning). It also determines the division factor for the clock prescaler.

The CAN bit timing variables (PRESDIV, PROPSEG, PSEG1, PSEG2, and RJW) can also be configured in the CBT register, which extends the range of all these variables. If CBT[BTF] is set, PRESDIV, PROPSEG, PSEG1, PSEG2, and RJW fields of CTRL1 become read only.

NOTE

When the CAN FD feature is enabled, do not use the PRESDIV, RJW, PSEG1, PSEG2, and PROPSEG fields of the CTRL1 register for CAN bit timing. Instead use the CBT register's EPRESDIV, ERJW, EPSEG1, EPSEG2, and EPROPSEG fields.

The contents of this register are not affected by soft reset.

NOTE

The CAN bit variables in CTRL1 and in CBT are stored in the same register.

66.6.2.3.1 Offset

66.6.2.3.3 Fields

Field	Description
31-24	Prescaler Division Factor

Table continues on the next page...

Field	Description
PRESDIV	This 8-bit field defines the ratio between the PE clock frequency and the serial clock (Sclock) frequency. The Sclock period defines the time quantum of the CAN protocol. For the reset value, the Sclock frequency is equal to the PE clock frequency. The maximum value of this field is FFh, which gives a minimum Sclock frequency equal to the PE clock frequency divided by 256. See Protocol timing for more information. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Sclock frequency = PE clock frequency / (PRESDIV + 1).
23-22 RJW	Resync Jump Width This 2-bit field defines the maximum number of time quanta that a bit time can be changed by one resynchronization. One time quantum is equal to the Sclock period. The valid programmable values are 0–3. See Protocol timing for more information. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Resync Jump Width = RJW + 1.
21-19 PSEG1	Phase Segment 1 This 3-bit field defines the length of phase segment 1 in the bit time. The valid programmable values are 0–7. See Protocol timing for more information. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Phase Buffer Segment 1 = (PSEG1 + 1) × Time-Quanta.
18-16 PSEG2	Phase Segment 2 This 3-bit field defines the length of phase segment 2 in the bit time. The valid programmable values are 1–7. See Protocol timing for more information. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Phase Buffer Segment 2 = (PSEG2 + 1) × Time-Quanta.
15 BOFFMSK	Bus Off Interrupt Mask This bit provides a mask for the Bus Off interrupt ESR1[BOFFINT]. 0 - Bus Off interrupt disabled. 1 - Bus Off interrupt enabled.
14 ERRMSK	Error Interrupt Mask This bit provides a mask for the Error interrupt ESR1[ERRINT]. 0 - Error interrupt disabled. 1 - Error interrupt enabled.
13 CLKSRC	CAN Engine Clock Source This bit selects the clock source to the CAN Protocol Engine (PE) to be either the peripheral clock or the oscillator clock. The selected clock is the one fed to the prescaler to generate the serial clock (Sclock). In order to guarantee reliable operation, this bit can be written only in Disable mode because it is blocked by hardware in other modes. See Protocol timing. **NOTE:** The user must ensure the protocol engine clock tolerance according to the CAN Protocol standard (ISO 11898-1). **NOTE:** See the clock distribution chapter (module clocks table) to identify the proper clock source. 0 - The CAN engine clock source is the oscillator clock. Under this condition, the oscillator clock frequency must be lower than the bus clock. 1 - The CAN engine clock source is the peripheral clock.
12 LPB	Loop Back Mode

Table continues on the next page...

Field	Description
	This bit configures FlexCAN to operate in Loop-Back mode. In this mode, FlexCAN performs an internal loop back that can be used for self-test operation. The bit stream output of the transmitter is fed back internally to the receiver input. The Rx CAN input pin is ignored and the Tx CAN output goes to the recessive state (logic 1). FlexCAN behaves as it normally does when transmitting, and treats its own transmitted message as a message received from a remote node. In this mode, FlexCAN ignores the bit sent during the ACK slot in the CAN frame acknowledge field, generating an internal acknowledge bit to ensure proper reception of its own message. Both transmit and receive interrupts are generated. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. **NOTE:** In this mode, MCR[SRXDIS] cannot be asserted because this will impede the self-reception of a transmitted message. **NOTE:** FDCTRL[TDCEN] must be disabled when LPB is asserted. 0 - Loop Back disabled. 1 - Loop Back enabled.
11 TWRNMSK	Tx Warning Interrupt Mask This bit provides a mask for the Tx Warning interrupt associated with the TWRNINT flag in the Error and Status Register 1 (ESR1). This bit is read as zero when MCR[WRNEN] is negated. This bit can be written only if MCR[WRNEN] is asserted. 0 - Tx Warning interrupt disabled. 1 - Tx Warning interrupt enabled.
10 RWRNMSK	Rx Warning Interrupt Mask This bit provides a mask for the Rx Warning interrupt associated with the RWRNINT flag in the Error and Status Register 1 (ESR1). This bit is read as zero when MCR[WRNEN] bit is negated. This bit can be written only if MCR[WRNEN] bit is asserted. 0 - Rx Warning interrupt disabled. 1 - Rx Warning interrupt enabled.
9 —	Reserved
8 —	Reserved
7 SMP	CAN Bit Sampling This bit defines the sampling mode of CAN bits at the Rx input. It can be written in Freeze mode only, because it is blocked by hardware in other modes. **NOTE:** For proper operation, to assert SMP it is necessary to guarantee a minimum value of two TQs in CTRL1[PSEG1] (or CBT[EPSEG1]).This bit cannot be asserted when CAN FD is enabled (MCR[FDEN] = 1). 0 - Just one sample is used to determine the bit value. 1 - Three samples are used to determine the value of the received bit: the regular one (sample point) and two preceding samples; a majority rule is used.
6 BOFFREC	Bus Off Recovery This bit defines how FlexCAN recovers from Bus Off state. If this bit is negated, automatic recovering from Bus Off state occurs according to the CAN Specification 2.0B. If the bit is asserted, automatic recovering from Bus Off is disabled and the module remains in Bus Off state until the bit is negated by the user. If the negation occurs before 128 sequences of 11 recessive bits are detected on the CAN bus, then Bus Off recovery happens as if the BOFFREC bit had never been asserted. If the negation occurs after 128 sequences of 11 recessive bits occurred, then FlexCAN will resynchronize to the bus by waiting

Table continues on the next page...

Field	Description
	for 11 recessive bits before joining the bus. After negation, the BOFFREC bit can be reasserted again during Bus Off, but it will be effective only the next time the module enters Bus Off. If BOFFREC was negated when the module entered Bus Off, asserting it during Bus Off will not be effective for the current Bus Off recovery. **NOTE:** See Bus off in the CAN Protocol standard (ISO 11898-1) for details. 0 - Automatic recovering from Bus Off state enabled. 1 - Automatic recovering from Bus Off state disabled.
5 TSYN	Timer Sync This bit enables a mechanism that resets the free running timer each time a message is received in message buffer 0. This feature provides means to synchronize multiple FlexCAN stations with a special “SYNC” message, that is, global network time. If MCR[RFEN] is set (Rx FIFO enabled), the first available mailbox, according to CTRL2[RFFN] setting, is used for timer synchronization instead of MB0. This bit can be written in Freeze mode only because it is blocked by hardware in other modes. 0 - Timer sync feature disabled 1 - Timer sync feature enabled
4 LBUF	Lowest Buffer Transmitted First This bit defines the ordering mechanism for message buffer transmission. When asserted, MCR[LPRIOEN] does not affect the priority arbitration. This bit can be written in Freeze mode only, because it is blocked by hardware in other modes. 0 - Buffer with highest priority is transmitted first. 1 - Lowest number buffer is transmitted first.
3 LOM	Listen-Only Mode This bit configures FlexCAN to operate in Listen-Only mode. In this mode, transmission is disabled, all error counters described in the ECR register are frozen, and the module operates in a CAN Error Passive mode. Only messages acknowledged by another CAN station will be received. If FlexCAN detects a message that has not been acknowledged, it will flag a BIT0 error without changing the receive error counter (ECR[RXERRCNT]), as if it was trying to acknowledge the message. Listen-Only mode is acknowledged by the state of ESR1[FLTCONF] indicating Passive Error. There can be some delay between the Listen-Only mode request and acknowledge. This bit can be written in Freeze mode only because it is blocked by hardware in other modes. 0 - Listen-Only mode is deactivated. 1 - FlexCAN module operates in Listen-Only mode.
2-0 PROPSEG	Propagation Segment This 3-bit field defines the length of the propagation segment in the bit time. The valid programmable values are 0–7. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Propagation segment time = (PROPSEG + 1) × time-quanta. Time-quantum = one Sclock period.

66.6.2.4 Free Running Timer (TIMER)

This register represents a 16-bit free-running counter that can be read and written by the CPU. The timer starts from 0h after Reset, counts linearly to FFFFh, and wraps around.

When CTRL2[TIMER_SRC] is asserted, the timer is continuously incremented by an external time tick. The time tick must be synchronous to the peripheral clock, with a minimum pulse width of one clock cycle.

When CTRL2[TIMER_SRC] is negated, the timer is incremented by the CAN bit clock, which defines the baud rate on the CAN bus. During a message transmission/reception, it increments by one for each bit that is received or transmitted. When there is no message on the bus, it counts using the previously programmed baud rate. The timer is not incremented during Disable, Doze, Stop and Freeze modes.

The timer value is captured when the second bit of the identifier field of any frame is on the CAN bus. This captured value is written into the time stamp entry in a message buffer after a successful reception or transmission of a message.

If CTRL1[TSYN] is asserted, the timer is reset whenever a message is received in the first available mailbox, according to CTRL2[RFFN] setting.

The CPU can write to this register anytime. However, if the write occurs at the same time that the timer is being reset by a reception in the first mailbox, then the write value is discarded.

Reading this register affects the mailbox unlocking procedure (see Mailbox lock mechanism).

15-0 TIMER	Timer Value Contains the free-running counter value.

66.6.2.5 Rx Mailboxes Global Mask register (RXMGMASK)

This register is located in RAM.

RXMGMASK is provided for legacy application support.

- When MCR[IRMQ] is negated, RXMGMASK is always in effect (the bits in the MG field will mask the mailbox filter bits).
- When MCR[IRMQ] is asserted, RXMGMASK has no effect (the bits in the MG field will not mask the mailbox filter bits).

RXMGMASK is used to mask the filter fields of all Rx MBs, excluding MBs 14-15, which have individual mask registers.

This register can only be written in Freeze mode as it is blocked by hardware in other modes.

66.6.2.5.1 Offset

1	1	1	MG[31]	MG[30]	MG[28:0]	MG[29]

0b - The corresponding bit in the filter is "don't care."
1b - The corresponding bit in the filter is checked.

66.6.2.6 Rx 14 Mask register (RX14MASK)

This register is located in RAM.

RX14MASK is provided for legacy application support. When MCR[IRMQ] is asserted, RX14MASK has no effect.

RX14MASK is used to mask the filter fields of message buffer 14.

This register can only be programmed when the module is in Freeze mode as it is blocked by hardware in other modes.

66.6.2.6.1 Offset

Register	Offset

66.6.2.6.3 Fields

Field	Description
31-0 RX14M	Rx Buffer 14 Mask Bits Each mask bit masks the corresponding mailbox 14 filter field in the same way that RXMGMASK masks other mailboxes' filters. See the description of the RXMGMASK register. 0b - The corresponding bit in the filter is "don't care." 1b - The corresponding bit in the filter is checked.

66.6.2.7 Rx 15 Mask register (RX15MASK)

This register is located in RAM.

RX15MASK is provided for legacy application support. When MCR[IRMQ] is asserted, RX15MASK has no effect.

RX15MASK is used to mask the filter fields of message buffer 15.

This register can be programmed only when the module is in Freeze mode because it is blocked by hardware in other modes.

66.6.2.7.3 Fields

Field	Description
31-0 RX15M	Rx Buffer 15 Mask Bits Each mask bit masks the corresponding mailbox 15 filter field in the same way that RXMGMASK masks other mailboxes' filters. See the description of the RXMGMASK register. 0b - The corresponding bit in the filter is "don't care." 1b - The corresponding bit in the filter is checked.

66.6.2.8 Error Counter (ECR)

This register has four 8-bit fields reflecting the value of the FlexCAN error counters:

- Transmit Error Counter (TXERRCNT field)
- Receive Error Counter (RXERRCNT field)

- Transmit Error Counter for errors detected in the data phase of CAN FD messages with the BRS bit set (TXERRCNT_FAST field)
- Receive Error Counter for errors detected in the data phase of CAN FD messages with the BRS bit set (RXERRCNT_FAST field)

The TXERRCNT and RXERRCNT counters take into account all errors in both CAN FD and non-FD message formats. TXERRCNT_FAST and RXERRCNT_FAST are dedicated to count only the errors that occur in the data phase of CAN FD frames with the BRS bit set.

The Fault Confinement state (ESR1[FLTCONF]) is updated based on TXERRCNT and RXERRCNT counters only. TXERRCNT and RXERRCNT counters can be written in Freeze mode only. TXERRCNT_FAST and RXERRCNT_FAST counters are read-only except in Freeze mode when the CPU can write value zero. The rules for increasing and decreasing these counters are described in the CAN protocol and are completely implemented in the FlexCAN module.

The following are the basic rules for FlexCAN bus state transitions:

- If the value of TXERRCNT or RXERRCNT becomes greater than or equal to 128, ESR1[FLTCONF] is updated to reflect Error Passive state.
- If the FlexCAN state is Error Passive, and either TXERRCNT or RXERRCNT decrements to a value less than or equal to 127 when the other already satisfies this condition, ESR1[FLTCONF] is updated to reflect Error Active state.
- If the value of TXERRCNT becomes greater than 255, ESR1[FLTCONF] is updated to reflect Bus Off state, and an interrupt may be issued. The value of TXERRCNT is then reset to zero.
- If FlexCAN is in Bus Off state, then TXERRCNT is cascaded together with another internal counter to count the 128th occurrences of 11 consecutive recessive bits on the bus. Hence, TXERRCNT is reset to zero and counts in a manner where the internal counter counts 11 such bits and then wraps around when incrementing the TXERRCNT. When TXERRCNT reaches the value of 128, ESR1[FLTCONF] is updated to be Error Active and both error counters are reset to zero. At any instance of dominant bit following a stream of less than 11 consecutive recessive bits, the internal counter resets itself to zero without affecting the TXERRCNT value. The TXERRCNT_FAST counter is frozen during Bus Off.
- If during system startup only one node is operating, then its TXERRCNT increases in each message it is trying to transmit, as a result of acknowledge errors (indicated by the ACKERR bit in the Error and Status Register). After the transition to Error Passive state, TXERRCNT does not increment anymore by acknowledge errors. Therefore the device never goes to the Bus Off state.
- If RXERRCNT increases to a value greater than 127, it is not incremented further, even if more errors are detected when being a receiver. At the next successful

message reception, the counter is set to a value between 119 and 127 to return to Error Active state.

- TXERRCNT_FAST and RXERRCNT_FAST error counter values increment and decrement based on errors detected only in the data phase of CAN FD frames with the BRS bit set, following the same increment and decrement rules as TXERRCNT and RXERRCNT counters. These counters do not wrap around and get stuck at their maximum value (255). They stop counting and keep their values frozen when FlexCAN is in Bus Off state. They are reset when FlexCAN leaves Bus Off state and restart counting after FlexCAN returns to Error Active state.

NOTE

See Fault confinement in the CAN Protocol standard (ISO 11898-1) for details.

66.6.2.8.3 Fields

Field	Description
31-24 RXERRCNT_FAST	Receive Error Counter for fast bits Receive error counter for errors detected in the data phase of received CAN FD messages with the BRS bit set. The RXERRCNT_FAST counter is read-only except in Freeze mode, where the CPU can write an 8-bit zero value only.
23-16	Transmit Error Counter for fast bits

Table continues on the next page...

Field	Description
TXERRCNT_FAST	Transmit error counter for errors detected in the data phase of transmitted CAN FD messages with the BRS bit set. The TXERRCNT_FAST counter is read-only except in Freeze mode, where the CPU can write an 8-bit zero value only.
15-8 RXERRCNT	Receive Error Counter Receive error counter for all errors detected in received messages. The RXERRCNT counter is read-only except in Freeze mode, where it can be written by the CPU.
7-0 TXERRCNT	Transmit Error Counter Transmit error counter for all errors detected in transmitted messages. The TXERRCNT counter is read-only except in Freeze mode, where it can be written by the CPU.

66.6.2.9 Error and Status 1 register (ESR1)

This register reports various error conditions detected in the reception and transmission of a CAN frame, some general status of the device, and is the source of some interrupts to the CPU. The reported error conditions are:

- Errors detected in CAN frames of any format:
  - BIT1ERR
  - BIT0ERR
  - ACKKERR
  - CRCERR
  - FRMERR
  - STFERR
- Errors detected in the data phase of CAN FD frames with the BRS bit set only:
  - BIT1ERR_FAST
  - BIT0ERR_FAST
  - CRCERR_FAST
  - FRMERR_FAST
  - STFERR_FAST

An error detected in a single CAN frame may be reported by one or more error flags. Also, error reporting is cumulative, in case more error events happen in the next frames when the CPU does not attempt to read this register.

Status bits:
- TXWRN
- RXWRN
- IDLE
- TX
- FLTCONF

- RX
- SYNCH

Interrupt bits:

- BOFFINT
- BOFFDONEINT
- ERRINT
- ERRINT_FAST
- WAKINT
- TWRNINT
- RWRNINT

It is recommended that the CPU use the following procedure when servicing interrupt requests generated by these bits:

1. Read this register to capture all error condition and status bits. This action clears the respective bits that were set since the last read access.
2. Write 1 to clear the interrupt bit that has triggered the interrupt request.
3. Write 1 to clear the ERR_OVR bit, if it is set.

Starting from all error flags cleared, a first error event sets either the ERRINT or the ERRINT_FAST (provided the corresponding mask bit is asserted). If other error events in subsequent frames happen before the CPU serves the interrupt request, the ERR_OVR bit is set to indicate that errors from different frames have accumulated.

SYNCH	IDLE	TX	RX	FlexCAN state
0	0	0	0	Not synchronized to CAN bus
1	1	x	x	Idle
1	0	1	0	Transmitting
1	0	0	1	Receiving

NOTE

See Fault confinement in the CAN Protocol standard (ISO 11898-1) for details.

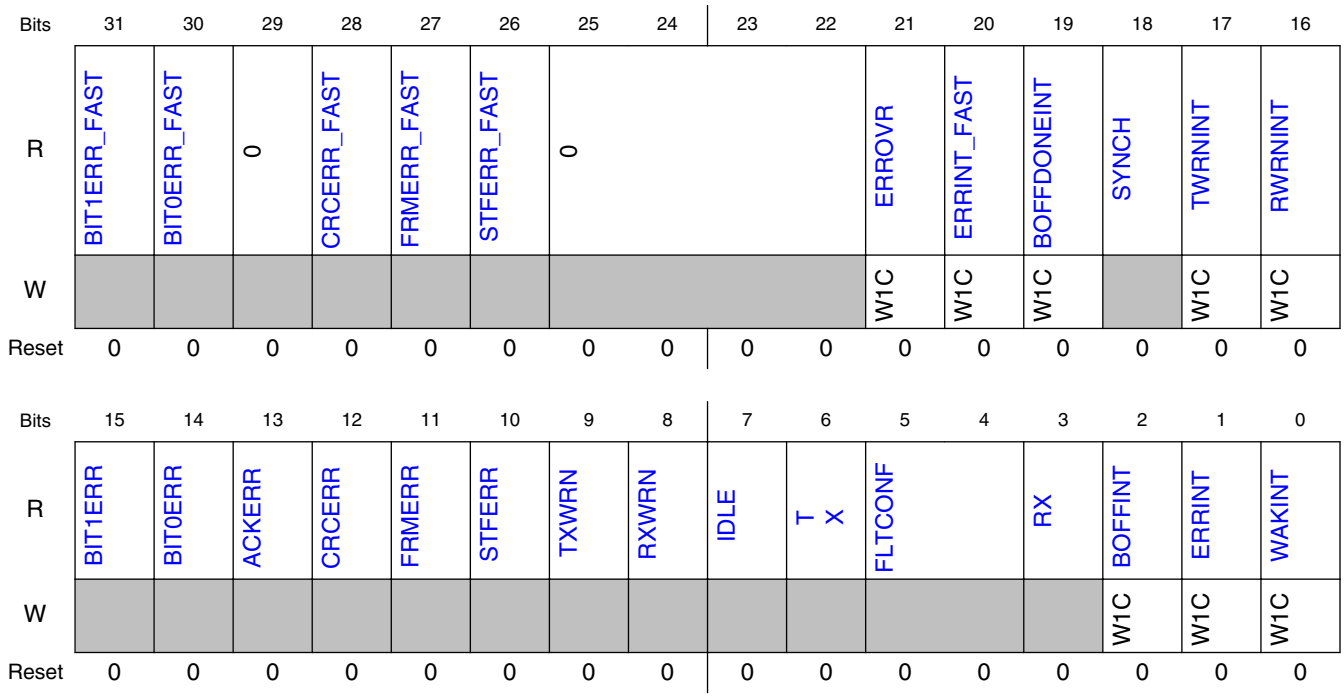
Register	Offset
ESR1	20h

66.6.2.9.2 Diagram



66.6.2.9.3 Fields

Field	Description
31 BIT1ERR_FAST	Bit1 Error in the Data Phase of CAN FD frames with the BRS bit set This bit indicates when an inconsistency occurs between the transmitted and the received bit in the data phase of CAN FD frames with the BRS bit set. After a read operation, the field's value clears to 0. 0 - No such occurrence. 1 - At least one bit sent as recessive is received as dominant.
30 BIT0ERR_FAST	Bit0 Error in the Data Phase of CAN FD frames with the BRS bit set This bit indicates when an inconsistency occurs between the transmitted and the received bit in the data phase of CAN FD frames with the BRS bit set. After a read operation, the field's value clears to 0. 0 - No such occurrence. 1 - At least one bit sent as dominant is received as recessive.
29 —	Reserved
28 CRCERR_FAST	Cyclic Redundancy Check Error in the CRC field of CAN FD frames with the BRS bit set This bit indicates that a CRC error has been detected by the receiver node in the CRC field of CAN FD frames with the BRS bit set, that is, the calculated CRC is different from the received. After a read operation, the field's value clears to 0.

Table continues on the next page...

Field	Description
	0 - No such occurrence. 1 - A CRC error occurred since last read of this register.
27 FRMERR_FAST	Form Error in the Data Phase of CAN FD frames with the BRS bit set This bit indicates that a form error has been detected by the receiver node in the data phase of CAN FD frames with the BRS bit set, that is, a fixed-form bit field contains at least one illegal bit. After a read operation, the field's value clears to 0. 0 - No such occurrence. 1 - A form error occurred since last read of this register.
26 STFERR_FAST	Stuffing Error in the Data Phase of CAN FD frames with the BRS bit set This bit indicates that a stuffing error has been detected in the data phase of CAN FD frames with the BRS bit set. After a read operation, the field's value clears to 0. 0 - No such occurrence. 1 - A stuffing error occurred since last read of this register.
25-22 —	Reserved
21 ERROVR	Error Overrun This bit indicates that an error condition occurred when any error flag is already set. This bit is cleared by writing it to 1. 0 - Overrun has not occurred. 1 - Overrun has occurred.
20 ERRINT_FAST	Error interrupt for errors detected in Data Phase of CAN FD frames with BRS bit set This bit indicates that at least one of the error bits detected in the data phase of CAN FD frames with the BRS bit set (BIT1ERR_FAST, BIT0ERR_FAST, CRCERR_FAST, FRMERR_FAST, or STFERR_FAST) is set. If the corresponding mask bit CTRL2[ERRMSK_FAST] is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. Writing 0 has no effect. 0 - No such occurrence. 1 - Indicates setting of any error bit detected in the data phase of CAN FD frames with the BRS bit set.
19 BOFFDONEINT	Bus Off Done Interrupt This bit is set when the Tx Error Counter (TXERRCNT) has finished counting 128 occurrences of 11 consecutive recessive bits on the CAN bus and is ready to leave Bus Off. If the corresponding mask bit in the Control 2 Register (BOFFDONEMSK) is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. Writing 0 has no effect. 0 - No such occurrence. 1 - FlexCAN module has completed Bus Off process.
18 SYNCH	CAN Synchronization Status This read-only flag indicates whether the FlexCAN is synchronized to the CAN bus and able to participate in the communication process. It is set and cleared by the FlexCAN. See the table in the overall ESR1 register description. 0 - FlexCAN is not synchronized to the CAN bus. 1 - FlexCAN is synchronized to the CAN bus.
17 TWRNINT	Tx Warning Interrupt Flag

Table continues on the next page...

Field	Description
	If MCR[WRNEN] is asserted, TWRNINT is set when the TXWRN flag transitions from 0 to 1, meaning that the Tx error counter reached 96. If the corresponding mask bit in the Control 1 Register (CTRL1[TWRNMSK]) is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. When MCR[WRNEN] is negated, this flag is masked. CPU must clear this flag before disabling MCR[WRNEN]. Otherwise it will be set when MCR[WRNEN] is set again. Writing 0 has no effect. This flag is not generated during Bus Off state. This bit is not updated during Freeze mode. 0 - No such occurrence. 1 - The Tx error counter transitioned from less than 96 to greater than or equal to 96.
16 RWRNINT	Rx Warning Interrupt Flag If MCR[WRNEN] is asserted, RWRNINT is set when the RXWRN flag transitions from 0 to 1, meaning that the Rx error counters reached 96. If the corresponding mask bit in the Control 1 Register (CTRL1[RWRNMSK]) is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. When WRNEN is negated, this flag is masked. CPU must clear this flag before disabling the bit. Otherwise it will be set when WRNEN is set again. Writing 0 has no effect. This bit is not updated during Freeze mode. 0 - No such occurrence. 1 - The Rx error counter transitioned from less than 96 to greater than or equal to 96.
15 BIT1ERR	Bit1 Error This bit indicates when an inconsistency occurs between the transmitted and the received bit in a non-CAN FD message or in the arbitration or data phase of a CAN FD message. **NOTE:** This bit is not set by a transmitter in case of arbitration field or ACK slot, or in case of a node sending a passive error flag that detects dominant bits. After a read operation, the field's value clears to 0. 0 - No such occurrence. 1 - At least one bit sent as recessive is received as dominant.
14 BIT0ERR	Bit0 Error This bit indicates when an inconsistency occurs between the transmitted and the received bit in a non-CAN FD message or in the arbitration or data phase of a CAN FD message. After a read operation, the field's value clears to 0. 0 - No such occurrence. 1 - At least one bit sent as dominant is received as recessive.
13 ACKERR	Acknowledge Error This bit indicates that an Acknowledge Error has been detected by the transmitter node, that is, a dominant bit has not been detected during the ACK SLOT. After a read operation, the field's value clears to 0. 0 - No such occurrence. 1 - An ACK error occurred since last read of this register.
12 CRCERR	Cyclic Redundancy Check Error This bit indicates that a Cyclic Redundancy Check (CRC) error has been detected by the receiver node either in a non-FD message or in the arbitration or data phase of a frame in CAN FD format, that is, the calculated CRC is different from the received. After a read operation, the field's value clears to 0. 0 - No such occurrence. 1 - A CRC error occurred since last read of this register.

Table continues on the next page...

Field	Description
11 FRMERR	Form Error This bit indicates that a form error has been detected in a non-FD message or else in an FD message's arbitration or data phase by the receiver node, that is, a fixed-form bit field contains at least one illegal bit. After a read operation, the field's value clears to 0. 0 - No such occurrence. 1 - A Form Error occurred since last read of this register.
10 STFERR	Stuffing Error This bit indicates that a stuffing error has been detected in a non-FD message or else in an FD message's arbitration or data phase by the receiver node. After a read operation, the field's value clears to 0. 0 - No such occurrence. 1 - A stuffing error occurred since last read of this register.
9 TXWRN	TX Error Warning This bit indicates when repetitive errors are occurring during message transmission and is affected by the value of TXERRCNT in ECR register only. This bit is not updated during Freeze mode. After a read operation, the field's value clears to 0. 0 - No such occurrence. 1 - TXERRCNT is greater than or equal to 96.
8 RXWRN	Rx Error Warning This bit indicates when repetitive errors are occurring during message reception and is affected by the value of RXERRCNT in ECR register only. This bit is not updated during Freeze mode. After a read operation, the field's value clears to 0. 0 - No such occurrence. 1 - RXERRCNT is greater than or equal to 96.
7 IDLE	IDLE This bit indicates when CAN bus is in IDLE state. See the table in the overall ESR1 register description. 0 - No such occurrence. 1 - CAN bus is now IDLE.
6 TX	FlexCAN In Transmission This bit indicates if FlexCAN is transmitting a message. See the table in the overall ESR1 register description. 0 - FlexCAN is not transmitting a message. 1 - FlexCAN is transmitting a message.
5-4 FLTCONF	Fault Confinement State This 2-bit field indicates the confinement state of the FlexCAN module. If CTRL1[LOM] is asserted, after a delay that depends on the CAN bit timing, ESR1[FLTCONF] will indicate Error Passive. The very same delay affects the way that ESR1[FLTCONF] reflects an update to ECR register by the CPU. It may be necessary to wait up to one CAN bit time to get them coherent again. This bit field is affected by soft reset, but if the LOM bit is asserted, its reset value lasts just one CAN bit. After this time, ESR1[FLTCONF] reports Error Passive. 00 - Error Active

Table continues on the next page...

Field	Description
	01 - Error Passive 1x - Bus Off
3 RX	FlexCAN In Reception This bit indicates if FlexCAN is receiving a message. See the table in the overall ESR1 register description. 0 - FlexCAN is not receiving a message. 1 - FlexCAN is receiving a message.
2 BOFFINT	Bus Off Interrupt This bit is set when FlexCAN enters Bus Off state. If the corresponding mask bit in the Control Register 1 (CTRL1[BOFFMSK]) is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. Writing 0 has no effect. 0 - No such occurrence. 1 - FlexCAN module entered Bus Off state.
1 ERRINT	Error Interrupt This bit indicates that at least one of the error bits (BIT1ERR, BIT0ERR, ACKERR, CRCERR, FRMERR, or STFERR) is set. If the corresponding mask bit CTRL1[ERRMSK] is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. Writing 0 has no effect. 0 - No such occurrence. 1 - Indicates setting of any error bit in the Error and Status register.
0 WAKINT	Wake-Up Interrupt This field applies when FlexCAN is in low-power mode under Self Wake Up mechanism: • Doze mode • Stop mode When a recessive-to-dominant transition is detected on the CAN bus and if MCR[WAKMSK] is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. When MCR[SLFWAK] is negated, this flag is masked. The CPU must clear this flag before disabling the bit. Otherwise it will be set when SLFWAK is set again. Writing 0 has no effect. 0 - No such occurrence. 1 - Indicates a recessive to dominant transition was received on the CAN bus.

66.6.2.10 Interrupt Masks 2 register (IMASK2)

This register allows any number of a range of the 32 message buffer interrupts to be enabled or disabled for MB63 to MB32. It contains one interrupt mask bit per buffer, enabling the CPU to determine which buffer generates an interrupt after a successful transmission or reception, that is, when the corresponding IFLAG2 bit is set.

66.6.2.10.3 Fields

Field	Description
31-0 BUF63TO32M	Buffer MBi Mask Each bit enables or disables the corresponding FlexCAN message buffer interrupt for MB63 to MB32. **NOTE:** Setting or clearing a bit in the IMASK2 Register can assert or negate an interrupt request, if the corresponding IFLAG2 bit is set. 0b - The corresponding buffer interrupt is disabled. 1b - The corresponding buffer interrupt is enabled.

66.6.2.11 Interrupt Masks 1 register (IMASK1)

This register allows any number of a range of the 32 message buffer interrupts to be enabled or disabled for MB31 to MB0. It contains one interrupt mask bit per buffer, enabling the CPU to determine which buffer generates an interrupt after a successful transmission or reception, that is, when the corresponding IFLAG1 bit is set.

Field	Description
31-0 BUF31TO0M	Buffer MBi Mask Each bit enables or disables the corresponding FlexCAN message buffer interrupt for MB31 to MB0. **NOTE:** Setting or clearing a bit in the IMASK1 Register can assert or negate an interrupt request, if the corresponding IFLAG1 bit is set. 0b - The corresponding buffer interrupt is disabled. 1b - The corresponding buffer interrupt is enabled.

66.6.2.12 Interrupt Flags 2 register (IFLAG2)

This register defines the flags for the 32 message buffer interrupts for MB63 to MB32. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the respective IFLAG2 bit. If the corresponding IMASK2 bit is set, an interrupt will be generated. The interrupt flag must be cleared by writing 1 to it. Writing 0 has no effect.

Before updating MCR[MAXMB], CPU must service the IFLAG2 bits whose MB value is greater than the MAXMB to be updated; otherwise, they will remain set and be inconsistent with the number of MBs available.

66.6.2.12.3 Fields

Field	Description
31-0 BUF63TO32I	Buffer MBi Interrupt Each bit flags the corresponding FlexCAN message buffer interrupt for MB63 to MB32. 0b - The corresponding buffer has no occurrence of successfully completed transmission or reception. 1b - The corresponding buffer has successfully completed transmission or reception.

66.6.2.13 Interrupt Flags 1 register (IFLAG1)

This register defines the flags for the 32 message buffer interrupts for MB31 to MB0. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the corresponding IFLAG1 bit. If the corresponding IMASK1 bit is set, an interrupt will be generated. The interrupt flag must be cleared by writing 1 to it. Writing 0 has no effect. There is an exception when DMA for Rx FIFO is enabled, as described below.

The BUF7I to BUF5I flags are also used to represent FIFO interrupts when the Rx FIFO is enabled. When MCR[RFEN] is set and MCR[DMA] is negated, the function of the eight least significant interrupt flags changes: BUF7I, BUF6I, and BUF5I indicate operating conditions of the FIFO , BUF0I is used to empty FIFO, and BUF4I to BUF1I bits are reserved.

Before enabling MCR[RFEN], the CPU must service the IFLAG bits asserted in the Rx FIFO region; see Rx FIFO. Otherwise, these IFLAG bits will mistakenly show the related MBs now belonging to FIFO as having contents to be serviced. When MCR[RFEN] is negated, the FIFO flags must be cleared. The same care must be taken when a CTRL2[RFFN] value is selected, extending Rx FIFO filters beyond MB7. For example, when RFFN is 8h, the MB0–23 range is occupied by Rx FIFO filters and related IFLAG bits must be cleared.

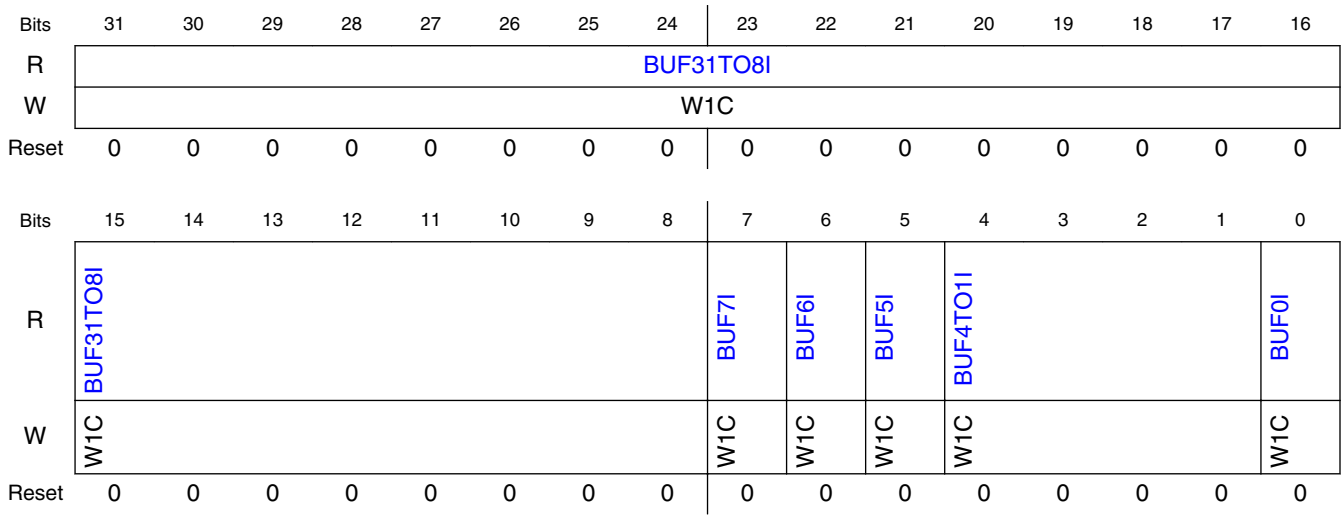
When both the MCR[RFEN] and MCR[DMA] bits are asserted (DMA feature for Rx FIFO enabled), the function of the eight least significant interrupt flags (BUF7I–BUF0I) are changed to support the DMA operation. BUF7I and BUF6I are not used, as well as BUF4I–BUF1I. BUF5I indicates operating condition of FIFO, and BUF0I is used to empty FIFO. Moreover, BUF5I does not generate a CPU interrupt, but generates a DMA request. IMASK1 bits in Rx FIFO region are not considered when bit MCR[DMA] is enabled. In addition the CPU must not clear the flag BUF5I when DMA is enabled. Before enabling MCR[DMA], the CPU must service the IFLAGs asserted in the Rx FIFO region. When MCR[DMA] is negated, the FIFO must be empty. FIFO must be disabled when MCR[FDEN] is enabled.

Before updating MCR[MAXMB], CPU must service the IFLAG1 bits whose MB value is greater than the MCR[MAXMB] to be updated; otherwise, they will remain set and be inconsistent with the number of MBs available.

66.6.2.13.1 Offset

Register	Offset
IFLAG1	30h

66.6.2.13.2 Diagram



66.6.2.13.3 Fields

Field	Description
31-8 BUF31TO8I	Buffer MBi Interrupt Each bit flags the corresponding FlexCAN message buffer interrupt for MB31 to MB8. 0b - The corresponding buffer has no occurrence of successfully completed transmission or reception. 1b - The corresponding buffer has successfully completed transmission or reception.
7 BUF7I	Buffer MB7 Interrupt Or Rx FIFO Overflow When MCR[RFEN] is cleared (Rx FIFO disabled), this bit flags the interrupt for MB7. **NOTE:** This flag is cleared by the FlexCAN whenever MCR[RFEN] is changed by CPU writes. The BUF7I flag represents Rx FIFO overflow when MCR[RFEN] is set. In this case, the flag indicates that a message was lost because the Rx FIFO is full. Note that the flag will not be asserted when the Rx FIFO is full and the message was captured by a mailbox. 0 - No occurrence of MB7 completing transmission/reception when MCR[RFEN]=0, or of Rx FIFO overflow when MCR[RFEN]=1 1 - MB7 completed transmission/reception when MCR[RFEN]=0, or Rx FIFO overflow when MCR[RFEN]=1
6 BUF6I	Buffer MB6 Interrupt Or Rx FIFO Warning When MCR[RFEN] is cleared (Rx FIFO disabled), this bit flags the interrupt for MB6. **NOTE:** This flag is cleared by the FlexCAN whenever MCR[RFEN] is changed by CPU writes. The BUF6I flag represents Rx FIFO warning when MCR[RFEN] is set. In this case, the flag indicates when the number of unread messages within the Rx FIFO is increased to five from four due to the reception of a new one, meaning that the Rx FIFO is almost full. Note that if the flag is cleared when the number of unread messages is greater than four, it does not assert again until the number of unread messages within the Rx FIFO is decreased to be equal to or less than four. 0 - No occurrence of MB6 completing transmission/reception when MCR[RFEN]=0, or of Rx FIFO almost full when MCR[RFEN]=1

Table continues on the next page...

Field	Description
	1 - MB6 completed transmission/reception when MCR[RFEN]=0, or Rx FIFO almost full when MCR[RFEN]=1
5 BUF5I	Buffer MB5 Interrupt Or Frames available in Rx FIFO When MCR[RFEN] is cleared (Rx FIFO disabled), this field flags the interrupt for MB5. **NOTE:** This flag is cleared by the FlexCAN whenever MCR[RFEN] is changed by CPU writes. When MCR[RFEN] is set (Rx FIFO enabled), the BUF5I flag represents "Frames available in Rx FIFO" and indicates that at least one frame is available to be read from the Rx FIFO. When the MCR[DMA] bit is enabled, this flag generates a DMA request and the CPU must not clear this bit by writing 1 in BUF5I. 0 - No occurrence of MB5 completing transmission/reception when MCR[RFEN]=0, or of frame(s) available in the FIFO, when MCR[RFEN]=1 1 - MB5 completed transmission/reception when MCR[RFEN]=0, or frame(s) available in the Rx FIFO when MCR[RFEN]=1. It generates a DMA request in case of MCR[RFEN] and MCR[DMA] are enabled.
4-1 BUF4TO1I	Buffer MBi Interrupt Or Reserved When MCR[RFEN] is cleared (Rx FIFO disabled), these bits flag the interrupts for MB4 to MB1. **NOTE:** These flags are cleared by the FlexCAN whenever MCR[RFEN] is changed by CPU writes. The BUF4TO1I flags are reserved when MCR[RFEN] is set. 0b - The corresponding buffer has no occurrence of successfully completed transmission or reception when MCR[RFEN]=0. 1b - The corresponding buffer has successfully completed transmission or reception when MCR[RFEN]=0.
0 BUF0I	Buffer MB0 Interrupt Or Clear FIFO bit When MCR[RFEN] is cleared (Rx FIFO disabled), this field flags the interrupt for MB0. If the Rx FIFO is enabled, this bit is used to trigger the clear FIFO operation. This operation empties FIFO contents. Before performing this operation the CPU must service all FIFO related IFLAGs. When MCR[DMA] is enabled this operation also clears the BUF5I flag and consequently aborts the DMA request. The clear FIFO operation occurs when the CPU writes 1 in BUF0I. It is only allowed in Freeze mode and is blocked by hardware in other conditions. 0 - The corresponding buffer has no occurrence of successfully completed transmission or reception when MCR[RFEN]=0. 1 - The corresponding buffer has successfully completed transmission or reception when MCR[RFEN]=0.

66.6.2.14 Control 2 register (CTRL2)

This register complements Control1 register, providing control bits for memory write access in Freeze mode, for extending FIFO filter quantity, and to adjust the operation of internal FlexCAN processes like matching and arbitration.

The contents of this register are not affected by soft reset.

This table shows how the Rx FIFO filter structure is determined by the value of CTRL2[RFFN]. See the CTRL2[RFFN] field description for more information.

Table 66-20. Rx FIFO filter: possible structures

RFFN[3:0]	Number of Rx FIFO filter elements	Message buffers occupied by Rx FIFO and ID filter table	Remaining available mailboxes	Rx FIFO ID filter table elements affected by Rx individual masks	Rx FIFO ID filter table elements affected by Rx FIFO global mask

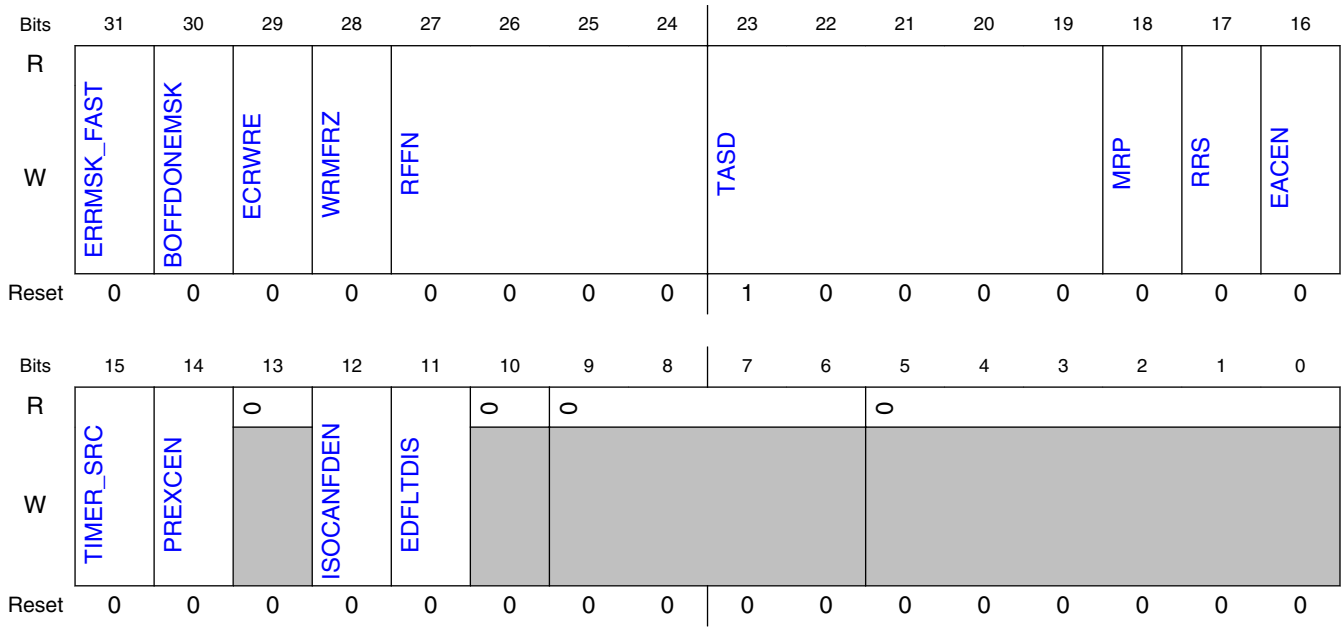
66.6.2.14.1 Offset

Register	Offset
CTRL2	34h

66.6.2.14.2 Diagram



66.6.2.14.3 Fields

Field	Description
31 ERRMSK_FAST	Error Interrupt Mask for errors detected in the data phase of fast CAN FD frames This bit provides a mask for the ERRINT_FAST interrupt in ESR1 register. 0 - ERRINT_FAST error interrupt disabled. 1 - ERRINT_FAST error interrupt enabled.
30 BOFFDONEMSK	Bus Off Done Interrupt Mask This bit provides a mask for the bus off done interrupt in ESR1 register. 0 - Bus off done interrupt disabled. 1 - Bus off done interrupt enabled.
29 ECRWRE	Error-correction Configuration Register Write Enable This bit enables the MECR register to be updated. This bit is automatically set to 0 if the protocol described in Detection and correction of memory errors is not followed. 0 - Disable update. 1 - Enable update.
28 WRMFRZ	Write-Access To Memory In Freeze Mode Enable unrestricted write access to FlexCAN memory in Freeze mode. This bit can only be written in Freeze mode and has no effect out of Freeze mode. MCR[RFEN] must not be set during FlexCAN memory initialization. 0 - Maintain the write access restrictions. 1 - Enable unrestricted write access to FlexCAN memory.

Table continues on the next page...

Field	Description
27-24 RFFN	Number Of Rx FIFO Filters This 4-bit field defines the number of Rx FIFO filters, as shown in Table 66-20. The maximum selectable number of filters is determined by the chip. This field can only be written in Freeze mode as it is blocked by hardware in other modes. This field must not be programmed with values that cause the number of message buffers occupied by Rx FIFO and ID Filter to exceed the number of mailboxes present, as defined by MCR[MAXMB]. **NOTE:** Each group of eight filters occupies a memory space equivalent to two message buffers, which means that the more filters are implemented the fewer mailboxes will be available. Considering that the Rx FIFO occupies the memory space originally reserved for MB0-5, RFFN should be programmed with a value corresponding to a number of filters not greater than the number of available memory words, which can be calculated as follows: (SETUP_MB - 6) × 4 where SETUP_MB is the smaller of the parameter NUMBER_OF_MB and MCR[MAXMB]. The number of remaining mailboxes available will be: (SETUP_MB - 8) - (RFFN × 2) If the number of Rx FIFO filters programmed through RFFN exceeds the SETUP_MB value (memory space available), then the exceeding ones will not be functional. **NOTE:** • The number of the last remaining available mailboxes is defined by the smaller of NUMBER_OF_MB minus 1 and MCR[MAXMB]. • If Rx Individual Mask registers are not enabled then all Rx FIFO filters are affected by the Rx FIFO Global Mask.
23-19 TASD	Tx Arbitration Start Delay This 5-bit field indicates how many CAN bits the Tx arbitration process start point can be delayed from the first bit of CRC field on CAN bus. See Tx arbitration start delay for more details. This field can be written only in Freeze mode because it is blocked by hardware in other modes.
18 MRP	Mailboxes Reception Priority If this bit is set the matching process starts from the mailboxes and if no match occurs the matching continues on the Rx FIFO. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. 0 - Matching starts from Rx FIFO and continues on mailboxes. 1 - Matching starts from mailboxes and continues on Rx FIFO.
17 RRS	Remote Request Storing If this bit is asserted a remote request frame is submitted to a matching process and stored in the corresponding message buffer in the same fashion as a data frame. No automatic remote response frame will be generated. If this bit is negated the remote request frame is submitted to a matching process and an automatic remote response frame is generated if a message buffer with CODE = 1010b is found with the same ID. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. 0 - Remote response frame is generated. 1 - Remote request frame is stored.
16 EACEN	Entire Frame Arbitration Field Comparison Enable For Rx Mailboxes This bit controls the comparison of IDE and RTR bits within Rx mailbox filters with their corresponding bits in the incoming frame by the matching process. This bit does not affect matching for Rx FIFO. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. 0 - Rx mailbox filter's IDE bit is always compared and RTR is never compared despite mask bits.

Table continues on the next page...

Field	Description
	1 - Enables the comparison of both Rx mailbox filter's IDE and RTR bit with their corresponding bits within the incoming frame. Mask bits do apply.
15 TIMER_SRC	Timer Source Selects the time tick source used for incrementing the free running timer counter. This bit can be written in Freeze mode only. 0 - The free running timer is clocked by the CAN bit clock, which defines the baud rate on the CAN bus. 1 - The free running timer is clocked by an external time tick. The period can be either adjusted to be equal to the baud rate on the CAN bus, or a different value as required. See the device-specific section for details about the external time tick.
14 PREXCEN	Protocol Exception Enable This bit enables the protocol exception feature. This field is writable only in Freeze mode. **NOTE:** See Protocol exception event in the CAN Protocol standard (ISO 11898-1) for details. 0 - Protocol exception is disabled. 1 - Protocol exception is enabled.
13 —	Reserved
12 ISOCANFDEN	ISO CAN FD Enable This field enables the CAN FD protocol according to ISO specification (ISO 11898-1) (see CAN FD ISO compliance). This field is writable only in Freeze mode. **NOTE:** FlexCAN is able to transmit FD frame format according to CAN Protocol standard (ISO 11898-1). 0 - FlexCAN operates using the non-ISO CAN FD protocol. 1 - FlexCAN operates using the ISO CAN FD protocol (ISO 11898-1).
11 EDFLTDIS	Edge Filter Disable This bit disables the edge filter used during the bus integration state. When the Edge Filter is enabled, two consecutive nominal time quanta with dominant bus state are required to detect an edge that causes synchronization. When synchronization occurs, the counting of the sequence of eleven consecutive recessive bits is restarted. The edge filter prevents the dominant pulses that are shorter than a nominal bit time (present during the data phase of an FD frame) from being mistaken for an idle condition. This field is writable only in Freeze mode. **NOTE:** See Bus Integration state in the CAN Protocol standard (ISO 11898-1) for details. 0 - Edge filter is enabled 1 - Edge filter is disabled
10 —	Reserved
9-6 —	Reserved
5-0 —	Reserved

66.6.2.15 Error and Status 2 register (ESR2)

This register reports some general status information.

66.6.2.15.1 Offset

Register	Offset
ESR2	38h

66.6.2.15.2 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	0	VPS	IMB	0												
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

66.6.2.15.3 Fields

Field	Description
31-23 —	Reserved
22-16 LPTM	Lowest Priority Tx Mailbox If ESR2[VPS] is asserted, this field indicates the lowest number inactive mailbox (see the ESR2[IMB] bit description). If there is no inactive mailbox then the mailbox indicated depends on the value of CTRL1[LBUF]. If CTRL1[LBUF] is negated, then the mailbox indicated is the one that has the greatest arbitration value (see Highest-priority mailbox first). If CTRL1[LBUF] is asserted then the mailbox indicated is the highest number active Tx mailbox. If a Tx mailbox is being transmitted it is not considered in LPTM calculation. If ESR2[IMB] is not asserted and a frame is transmitted successfully, LPTM is updated with its mailbox number.
15 —	Reserved
14 VPS	Valid Priority Status This bit indicates whether ESR2[IMB] and ESR2[LPTM] contents are currently valid or not. It is asserted upon every complete Tx arbitration process unless the CPU writes to Control and Status word of a mailbox that has already been scanned, that is, it is behind Tx Arbitration Pointer, during the Tx

Table continues on the next page...

Field	Description
	arbitration process. If there is no inactive mailbox and only one Tx mailbox that is being transmitted then VPS is not asserted. This bit is negated upon the start of every Tx arbitration process or upon a write to Control and Status word of any mailbox. **NOTE:** ESR2[VPS] is not affected by any CPU write into Control Status (C/S) of an MB that is blocked by abort mechanism. When MCR[AEN] is asserted, the abort code write in C/S of an MB that is being transmitted (pending abort), or any write attempt into a Tx MB with IFLAG set is blocked. 0 - Contents of IMB and LPTM are invalid. 1 - Contents of IMB and LPTM are valid.
13 IMB	Inactive Mailbox If ESR2[VPS] is asserted, this bit indicates whether there is any inactive mailbox (CODE field is either 1000b or 0b). This bit is asserted in the following cases: • During arbitration, if an ESR2[LPTM] is found and it is inactive. • If ESR2[IMB] is not asserted and a frame is transmitted successfully. This bit is always cleared in start of arbitration (see Arbitration process). **NOTE:** ESR2[LPTM] mechanism has the following behavior: if an MB is successfully transmitted and ESR2[IMB]=0 (no inactive mailbox), then ESR2[VPS] and ESR2[IMB] are asserted and the index related to the MB just transmitted is loaded into ESR2[LPTM]. 0 - If ESR2[VPS] is asserted, the ESR2[LPTM] is not an inactive mailbox. 1 - If ESR2[VPS] is asserted, there is at least one inactive mailbox. LPTM content is the number of the first one.
12-0 —	Reserved

66.6.2.16 CRC register (CRCR)

This register provides information about the CRC of transmitted messages for non-FD messages. This register only reports the 15 low order bits of CRC calculations for messages in CAN FD format that require either 17 or 21 bits. For CAN FD format frames, the FDCRC register must be used. This register is updated at the same time the Tx interrupt flag is asserted.

NOTE

See CRC sequence calculation in the CAN Protocol standard (ISO 11898-1) for details.

66.6.2.16.1 Offset

Register	Offset
CRCR	44h

66.6.2.16.2 Diagram

66.6.2.16.3 Fields

Field	Description
31-23 —	Reserved
22-16 MBCRC	CRC Mailbox This field indicates the number of the mailbox corresponding to the value in CRCR[TXCRC] field.
15 —	Reserved
14-0 TXCRC	Transmitted CRC value This field indicates the CRC value of the last transmitted message for non-FD frames. For FD frames, CRC value is reported in FDCRC register.

66.6.2.17 Rx FIFO Global Mask register (RXFGMASK)

This register is located in RAM.

If Rx FIFO is enabled, RXFGMASK is used to mask the Rx FIFO ID filter table elements that do not have a corresponding RXIMR according to CTRL2[RFFN] field setting.

This register can only be written in Freeze mode as it is blocked by hardware in other modes.

The following table shows how the FGM bits correspond to each IDAF field.

Table 66-21. Correspondence of Rx FIFO global mask bits to IDF fields

Rx FIFO ID filter table elements format (MCR[IDAM])	Identifier acceptance filter fields					
	RTR	IDE	RXIDA	RXIDB [1]	RXIDC [2]	Reserved
A	FGM[31]	FGM[30]	FGM[29:1]	—	—	FGM[0]
B	FGM[31], FGM[15]	FGM[30], FGM[14]	—	FGM[29:16], FGM[13:0]		—
C	—	—		—	FGM[31:24], FGM[23:16], FGM[15:8], FGM[7:0]	

1. If MCR[IDAM] is equivalent to format B, only the fourteen most significant bits of the identifier of the incoming frame are compared with the Rx FIFO filter.
2. If MCR[IDAM] is equivalent to format C, only the eight most significant bits of the identifier of the incoming frame are compared with the Rx FIFO filter.

66.6.2.17.1 Offset

66.6.2.17.3 Fields

Field	Description
31-0 FGM	Rx FIFO Global Mask Bits These bits mask the ID filter table elements bits in a perfect alignment. 0b - The corresponding bit in the filter is "don't care." 1b - The corresponding bit in the filter is checked.

66.6.2.18 Rx FIFO Information register (RXFIR)

RXFIR provides information on Rx FIFO.

This register is the port through which the CPU accesses the output of the RXFIR FIFO located in RAM. The RXFIR FIFO is written by the FlexCAN whenever a new message is moved into the Rx FIFO. Also, its output is updated whenever the output of the Rx FIFO is updated with the next message. See Rx FIFO for instructions on reading this register.

NOTE

RXFIR can be written only during memory initialization, due to the error code correction (ECC) feature. In every other case the register is read-only.

66.6.2.18.1 Offset

Register	Offset
RXFIR	4Ch

66.6.2.18.3 Fields

Field	Description
31-9	Reserved

Table continues on the next page...

Field	Description
—	
8-0 IDHIT	Identifier Acceptance Filter Hit Indicator This field indicates which Identifier Acceptance filter was hit by the received message that is in the output of the Rx FIFO. If multiple filters match the incoming message ID then the first matching IDAF found (lowest number) by the matching process is indicated. This field is valid only when IFLAG1[BUF5I] is asserted.

66.6.2.19 CAN Bit Timing register (CBT)

This register is an alternative way to store the CAN bit timing variables described in CTRL1 register. EPRESDIV, EPROPSEG, EPSEG1, EPSEG2, and ERJW are extended versions of PRESDIV, PROPSEG, PSEG1, PSEG2, and RJW fields respectively.

The BTF bit selects the use of the timing variables defined in this register.

The contents of this register are not affected by soft reset.

NOTE

The CAN bit variables in CTRL1 and in CBT are stored in the same register.

NOTE

When the CAN FD feature is enabled (MCR[FDEN] is set), always set CBT[BTF].

NOTE

The user must ensure bit time settings and protocol engine tolerance are in compliance with the CAN Protocol standard (ISO 11898-1).

66.6.2.19.1 Offset

Register	Offset
CBT	50h

66.6.2.19.2 Diagram

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

66.6.2.19.3 Fields

Field	Description
31 BTF	Bit Timing Format Enable Enables the use of extended CAN bit timing fields EPRESDIV, EPROPSEG, EPSEG1, EPSEG2. and ERJW replacing the CAN bit timing variables defined in CTRL1 register. This field can be written in Freeze mode only. 0 - Extended bit time definitions disabled. 1 - Extended bit time definitions enabled.
30-21 EPRESDIV	Extended Prescaler Division Factor This 10-bit field defines the ratio between the PE clock frequency and the serial clock (Sclock) frequency when CBT[BTF] is asserted, otherwise it has no effect. It extends the CTRL1[PRESDIV] value range. The Sclock period defines the time quantum of the CAN protocol. For the reset value, the Sclock frequency is equal to the PE clock frequency (see Protocol timing). This field can be written only in Freeze mode because it is blocked by hardware in other modes. Sclock frequency = PE clock frequency / (EPRESDIV + 1)
20-16 ERJW	Extended Resync Jump Width This 5-bit field defines the maximum number of time quanta that a bit time can be changed by one re-synchronization when CBT[BTF] bit is asserted, otherwise it has no effect. It extends the CTRL1[RJW] value range. One time quantum is equal to the Sclock period. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Resync Jump Width = ERJW + 1.
15-10 EPROPSEG	Extended Propagation Segment This 6-bit field defines the length of the propagation segment in the bit time when CBT[BTF] bit is asserted, otherwise it has no effect. It extends the CTRL1[PROPSEG] value range. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Propagation Segment Time = (EPROPSEG + 1) × Time-Quanta. Time-Quantum = one Sclock period.
9-5 EPSEG1	Extended Phase Segment 1

Table continues on the next page...

Field	Description
	This 5-bit field defines the length of phase segment 1 in the bit time when CBT[BTF] bit is asserted, otherwise it has no effect. It extends the CTRL1[PSEG1] value range. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Phase Buffer Segment 1 = (EPSEG1 + 1) × Time-Quanta. Time-Quantum = one Sclock period.
4-0 EPSEG2	Extended Phase Segment 2 This 5-bit field defines the length of phase segment 2 in the bit time when CBT[BTF] bit is asserted, otherwise it has no effect. It extends the CTRL1[PSEG2] value range. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Phase Buffer Segment 1 = (EPSEG2 + 1) × Time-Quanta. Time-Quantum = one Sclock period.

66.6.2.20 Rx Individual Mask registers (RXIMR0 - RXIMR63)

The RX Individual Mask Registers are used to store the acceptance masks for ID filtering in Rx MBs and the Rx FIFO.

When the Rx FIFO is disabled (MCR[RFEN] bit is negated), an individual mask is provided for each available Rx mailbox on a one-to-one correspondence. When the Rx FIFO is enabled (MCR[RFEN] bit is asserted), an individual mask is provided for each Rx FIFO ID filter table element on a one-to-one correspondence depending on the setting of CTRL2[RFFN] (see Rx FIFO).

RXIMR0 stores the individual mask associated with either MB0 or ID filter table element 0, RXIMR1 stores the individual mask associated with either MB1 or ID filter table element 1, and so on.

RXIMR registers can only be accessed by the CPU when the module is in Freeze mode; otherwise, they are blocked by hardware. These registers are not affected by reset. They are located in RAM and must be explicitly initialized prior to any reception.

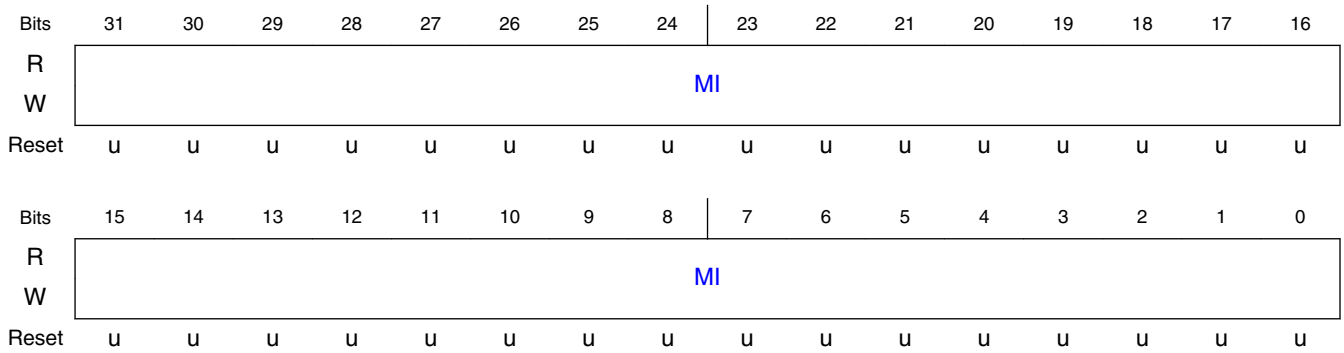
It is possible for the RXIMR memory region to be accessed as general purpose memory. See Bus interface for more information.

66.6.2.20.1 Offset

For n = 0 to 63:

Register	Offset
RXIMRn	880h + (n × 4h)

66.6.2.20.2 Diagram



66.6.2.20.3 Fields

Field	Description
31-0 MI	Individual Mask Bits Each individual mask bit masks the corresponding bit in both the mailbox filter and Rx FIFO ID filter table element in distinct ways. For mailbox filters, see the RXMGMASK register description. For Rx FIFO ID filter table elements, see the RXFGMASK register description. 0b - The corresponding bit in the filter is "don't care." 1b - The corresponding bit in the filter is checked.

66.6.2.21 Glitch Filter Width Register (GFWR)

The Glitch Filter just takes effect when FLEXCAN enters the STOP mode.

66.6.2.21.3 Fields

Field	Description
31-8 —	- Reserved
7-0 GFWR	Glitch Filter Width This bit determines the Glitch Filter width. The width will be divided from Oscillator clock by GFWR values. By default, it is 5.33 µs when the oscillator is 24 MHz. Filter Pulse Width = [(GFWR FIELD + 1) x (1 / Osc. Frequency)]

66.6.2.22 Memory Error Control register (MECR)

This register contains control bits for memory error detection and correction (ECC).

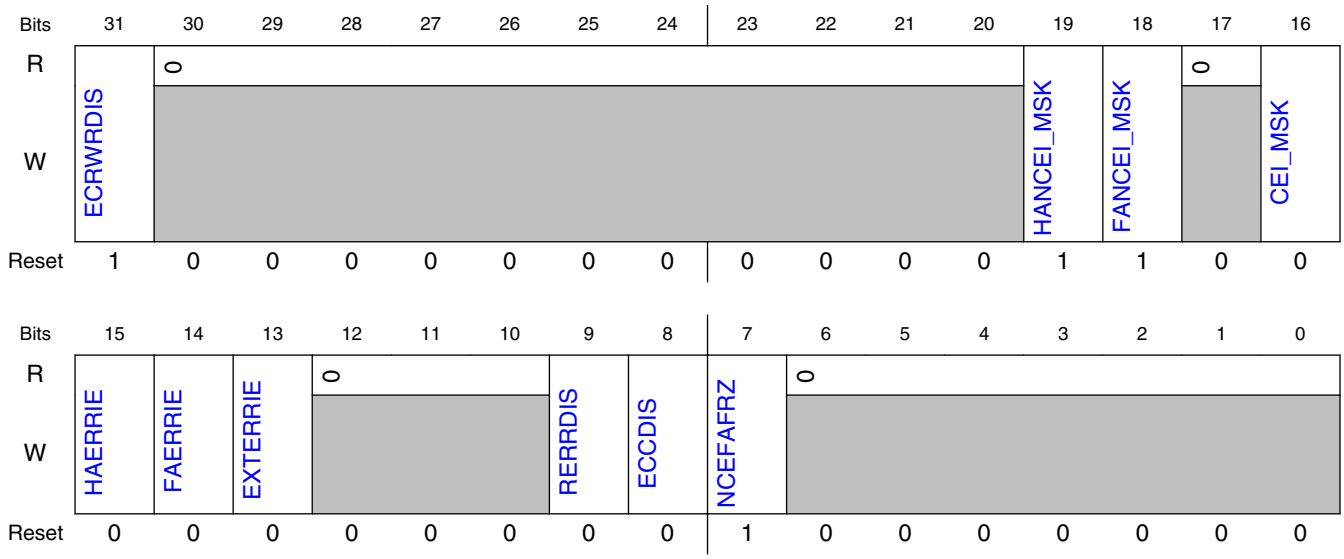
NOTE

When bit CTRL2[ECRWRE] is 0, writes in this register are blocked, except in the ECRWRDIS bit.

66.6.2.22.1 Offset

Register	Offset
MECR	AE0h

66.6.2.22.2 Diagram



66.6.2.22.3 Fields

Field	Description
31 ECRWRDIS	Error Configuration Register Write Disable Disables writes on this register. This bit is automatically set to 1 (disabled) when CTRL2[ECRWRE] is enabled. The protocol described in section Detection and correction of memory errors must be followed. 0 - Write is enabled. 1 - Write is disabled.
30-20 —	Reserved
19 HANCEI_MSK	Host Access With Non-Correctable Errors Interrupt Mask Enables the interrupt in case of non-correctable errors detected in memory reads issued by the host (CPU). 0 - Interrupt is disabled. 1 - Interrupt is enabled.
18 FANCEI_MSK	FlexCAN Access With Non-Correctable Errors Interrupt Mask Enables the interrupt in case of non-correctable errors detected in memory reads issued by the FlexCAN internal processes. 0 - Interrupt is disabled. 1 - Interrupt is enabled.
17 —	Reserved
16	Correctable Errors Interrupt Mask

Table continues on the next page...

Field	Description
CEI_MSK	Enables the interrupt in case of correctable errors detected in memory reads issued by the host or FlexCAN internal processes. 0 - Interrupt is disabled. 1 - Interrupt is enabled.
15 HAERRIE	Host Access Error Injection Enable Enables the injection of errors only in memory reads issued by the host (CPU). 0 - Injection is disabled. 1 - Injection is enabled.
14 FAERRIE	FlexCAN Access Error Injection Enable Enables the injection of errors only in memory reads issued by the FlexCAN internal processes. 0 - Injection is disabled. 1 - Injection is enabled.
13 EXTERRIE	Extended Error Injection Enable Memory accesses performed by internal FlexCAN processes are 64-bit. This bit extends the error injection on 32-bit memory accesses to the complementary 32-bit word using the same 32-bit error injection data and parity words. See Error Injection Data Pattern register (ERRIDPR) and Error Injection Parity Pattern register (ERRIPPR). 0 - Error injection is applied only to the 32-bit word. 1 - Error injection is applied to the 64-bit word.
12-10 —	Reserved
9 RERRDIS	Error Report Disable Disables the update of the error report registers. The update of error-related flags and the generation of bus transfer errors are still active. **NOTE:** When reading the report registers, this bit must be set to assure coherence on the consecutive register reads. 0 - Enable updates of the error report registers. 1 - Disable updates of the error report registers.
8 ECCDIS	Error Correction Disable Disables completely the memory detection and correction mechanism. Besides disabling the error report mechanism, it also stops the update of the error-related flags and generation of bus transfer errors. The parity bits continue being calculated and written into memory on write transactions. 0 - Enable memory error correction. 1 - Disable memory error correction.
7 NCEFAFRZ	Non-Correctable Errors In FlexCAN Access Put Device In Freeze Mode Determines the response when a non-correctable error is detected in a memory read performed by FlexCAN internal processes. In this case, entering Freeze mode prevents corrupted data from being treated as valid by FlexCAN internal processes. 0 - Keep normal operation. 1 - Put FlexCAN in Freeze mode (see section "Freeze mode").
6-0 —	Reserved

66.6.2.23 Error Injection Address register (ERRIAR)

This register holds the address where error is to be injected.

Use the following table to convert from the memory map address to the location in the physical FlexCAN RAM (where pairs of values are provided, the first is the address for MCR[FDEN] negated, the second is for MCR[FDEN] asserted):

RAM contents	Injection address	Memory map
FlexCAN Registers	Not mapped	—
MBs	0000h	0080h
Reserved	—	0480h
RXIMRs	0400h	0880h
Reserved	—	0980h
RXFIR_0	0500h	0A80h
RXFIR_1	0504h	0A84h
RXFIR_2	0508h	0A88h
RXFIR_3	050Ch	0A8Ch
RXFIR_4	0510h	0A90h
RXFIR_5	0514h	0A94h
Reserved	—	0A98h
RXMGMASK	0520h	0AA0h
RXFGMASK	0524h	0AA4h
RX14MASK	0528h	0AA8h
RX15MASK	052Ch	0AACh
Tx_SMB	0530h	0AB0h / 0F28h
Rx_SMB0	0540h / 0578h	0AC0h / 0F70h
Rx_SMB1	0550h / 05C0h	0AD0h / 0FB8h
ECC Registers	Not mapped	0AE0h
Reserved	—	0B00h
CAN FD Registers	Not mapped	0C00h
Reserved	—	0C0Ch

NOTE

For RXFIR addresses, you must inject ECC errors in host access only.

66.6.2.26 Error Report Address register (RERRAR)

Reports the address used for an access in which an error (correctable or non-correctable) was detected, and also reports the identification of the source of that access.

This address is always reported using a 32-bit alignment. Non-aligned accesses (ERRADDR[1:0] non-0) are reported with the address aligned and data is reported in RERRDR accordingly shifted. In case of errors detected in accesses larger than 32-bit (as performed by FlexCAN internal processes), the address of the 32-bit word which the error was detected is reported. In case of errors detected in more than one 32-bit word, only the least significant address is reported.

Table 66-22. Source of memory access

66.6.2.27.3 Fields

Field	Description
31-0 RDATA	Raw data word read from memory with error

66.6.2.28 Error Report Syndrome register (RERRSYNR)

Holds the syndrome detected in a memory read with error. It also reports the bytes which were read in this 32-bit read transaction.

Each SYNDn field indicates the type of error and which bit in byte (n) is affected by the error. (SYND3 corresponds to the most significant byte in the data word read from memory; SYND0 corresponds to the least significant.)

Table 66-23. Syndrome definition

SYNDn (hex)	Type	Bit affected
00	—	none (no error)
01	Code	0
02	Code	1
04	Code	2
07	Data	5
08	Code	3
0E	Data	7
10	Code	4
13	Data	2

Table continues on the next page...

Table 66-23. Syndrome definition (continued)

SYNDn (hex)	Type	Bit affected
15	Data	6
16	Data	1
19	Data	3
1A	Data	4
1C	Data	0
06	—	All-zeros non-correctable error
1F	—	All-ones non-correctable error
All others	—	Non-correctable error

Each BEn field indicates which byte in the 32-bit word reported was effectively read. The syndrome bits are calculated for all bytes, even for the non-read ones. Errors detected in non-read bytes are indicated (see Error indication) and reported (see Error reporting).

Field	Description
31-20 —	Reserved
19 HANCEIF	Host Access With Non-Correctable Error Interrupt Flag Indicates that a non-correctable error was detected in a memory read initiated by host. A bus transfer error is asserted for that access. If MECR[HANCEI_MSK] is set, the interrupt is asserted. 0 - No non-correctable errors were detected in host accesses so far. 1 - A non-correctable error was detected in a host access.
18 FANCEIF	FlexCAN Access With Non-Correctable Error Interrupt Flag Indicates that a non-correctable error was detected in a memory read initiated by FlexCAN internal processes. If MECR[FANCEI_MSK] is set, the interrupt is asserted. 0 - No non-correctable errors were detected in FlexCAN accesses so far. 1 - A non-correctable error was detected in a FlexCAN access.
17 —	Reserved
16 CEIF	Correctable Error Interrupt Flag Indicates that a correctable error was detected in a memory read. If MECR[CEI_MSK] is set, the interrupt is asserted. 0 - No correctable errors were detected so far.

Table continues on the next page...

Field	Description
	1 - A correctable error was detected.
15-4 —	Reserved
3 HANCEIOF	Host Access With Non-Correctable Error Interrupt Overrun Flag Indicates that a non-correctable error was detected in a memory read initiated by host when HANCEIF was set. No interrupt is associated with this flag. See Error indication. 0 - No overrun on non-correctable errors in host access 1 - Overrun on non-correctable errors in host access
2 FANCEIOF	FlexCAN Access With Non-Correctable Error Interrupt Overrun Flag Indicates that a non-correctable error was detected in a memory read initiated by FlexCAN internal processes when FANCEIF was set. No interrupt is associated to this flag. See Error indication. 0 - No overrun on non-correctable errors in FlexCAN access 1 - Overrun on non-correctable errors in FlexCAN access
1 —	Reserved
0 CEIOF	Correctable Error Interrupt Overrun Flag Indicates that a correctable error was detected in a memory read when CEIF was set. No interrupt is associated to this flag. See Error indication. 0 - No overrun on correctable errors 1 - Overrun on correctable errors

66.6.2.30 CAN FD Control register (FDCTRL)

This register contains control bits for the CAN FD operation. It also defines the data size of message buffers allocated in different partitions of RAM (memory blocks) as described in the table below.

When an 8-byte payload is selected:

- Block R0 allocates MB0 to MB31.
- Block R1 allocates MB32 to MB63.

When a payload larger than 8 bytes is selected, the maximum number of MBs in a block is limited as described below:

Table 66-24. Number of message buffers

Payload size	Maximum number of message buffers per RAM block
8 bytes	32
16 bytes	21
32 bytes	12
64 bytes	7

NOTE

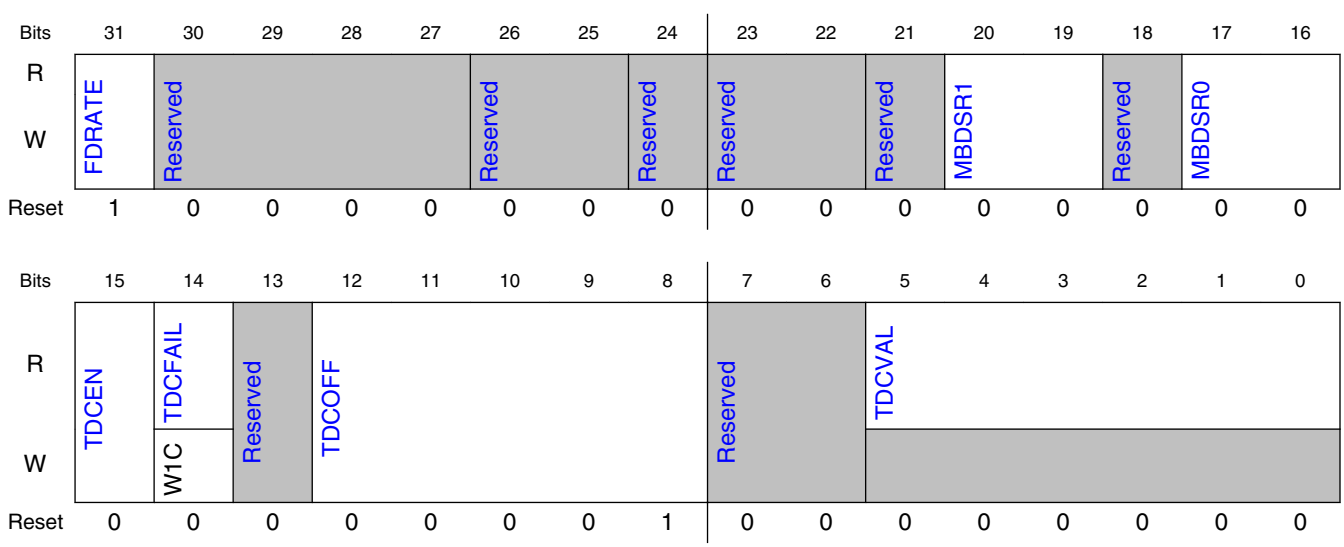
One memory block fits exactly 32 MBs with an 8-byte payload. For other possible payload sizes, empty memory may exist between the last MB in a block and the beginning of the next block. This empty memory corresponds to less than one MB, and must not be used.

The contents of this register are not affected by soft reset.

66.6.2.30.1 Offset

Register	Offset
FDCTRL	C00h

66.6.2.30.2 Diagram



66.6.2.30.3 Fields

Field	Description
31 FDRATE	Bit Rate Switch Enable This bit enables the effect of the Bit Rate Switch (BRS bit) during the data phase of Tx messages. The CPU can write this bit any time. However, its effect turns active only when the CAN bus is in Wait for Bus Idle, Bus Idle, or Bus Off state, or when the current frame under reception or transmission reaches the interframe space. By negating FDCTRL[FDRATE], the CPU can force all bits in CAN FD messages to be transmitted in nominal bit rate, no matter what the value is in the BRS bit of the Tx MBs. 0 - Transmit a frame in nominal rate. The BRS bit in the Tx MB has no effect. 1 - Transmit a frame with bit rate switching if the BRS bit in the Tx MB is recessive.
30-27 —	Reserved
26-25 —	Reserved
24 —	Reserved
23-22 —	Reserved
21 —	Reserved
20-19 MBDSR1	Message Buffer Data Size for Region 1 This two-bit field selects the data size (8, 16, 32, or 64 bytes) for region R1 of message buffers allocated in RAM. It can be written in Freeze mode only. 00 - Selects 8 bytes per message buffer. 01 - Selects 16 bytes per message buffer. 10 - Selects 32 bytes per message buffer. 11 - Selects 64 bytes per message buffer.
18 —	Reserved
17-16 MBDSR0	Message Buffer Data Size for Region 0 This two-bit field selects the data size (8, 16, 32, or 64 bytes) for region R0 of message buffers allocated in RAM. It can be written in Freeze mode only. 00 - Selects 8 bytes per message buffer. 01 - Selects 16 bytes per message buffer. 10 - Selects 32 bytes per message buffer. 11 - Selects 64 bytes per message buffer.
15 TDCEN	Transceiver Delay Compensation Enable This bit can be used to enable and disable the TDC feature. It can be written in Freeze mode only.

Table continues on the next page...

Field	Description
	NOTE: See Transmitter delay compensation in the CAN Protocol standard (ISO 11898-1) for details. **NOTE:** TDC must be disabled when Loop Back mode is enabled (see CTRL1[LPB]). 0 - TDC is disabled 1 - TDC is enabled
14 TDCFAIL	Transceiver Delay Compensation Fail This bit indicates when the Transceiver Delay Compensation (TDC) mechanism is out of range, unable to compensate the transceiver's loop delay and successfully compare the delayed received bits to the transmitted ones (see Transceiver delay compensation). TDCFAIL sets in the first time FlexCAN detects the out of range condition. The CPU needs to write one to clear it. 0 - Measured loop delay is in range. 1 - Measured loop delay is out of range.
13 —	Reserved
12-8 TDCOFF	Transceiver Delay Compensation Offset This bit field contains the offset value to be added to the measured transceiver's loop delay in order to define the position of the delayed comparison point when bit rate switching is active. See Transceiver delay compensation for more details on how the loop delay measurement is performed. TDCOFF can be written in Freeze mode only. Its value can be defined in Protocol Engine (PE) Clock periods (CANCLK, see Protocol timing for more details), and must be selected to be smaller than the CAN bit duration in the data bit rate for proper operation. **NOTE:** It is not recommended to have TDCOFF equal to zero.
7-6 —	Reserved
5-0 TDCVAL	Transceiver Delay Compensation Value This register contains the value of the transceiver loop delay measured from the transmitted EDL to R0 transition edge to the respective received one added to the TDCOFF value specified in the FDCTRL register. This value is an integer multiple of the Protocol Engine (PE) Clock period (CANCLK). See Protocol timing for more details on how the loop delay measurement is performed.

66.6.2.31 CAN FD Bit Timing register (FDCBT)

This register stores the CAN bit timing variables used in the data phase of CAN FD messages when the FDCTRL[FDRATE] is set, compatible with CAN FD specification. FPRESDIV, FPROPSEG, FPSEG1, FPSEG2, and FRJW are used to define the time quantum duration, the number of time quanta per CAN bit, and the sample point position for the data bit rate portion of a CAN FD message with the BRS bit set.

The contents of this register are not affected by soft reset.

NOTE

The sum of the Fast Propagation Segment (FPROPSEG) and Fast Phase Segment 1 (FPSEG1) must be at least two time quanta.

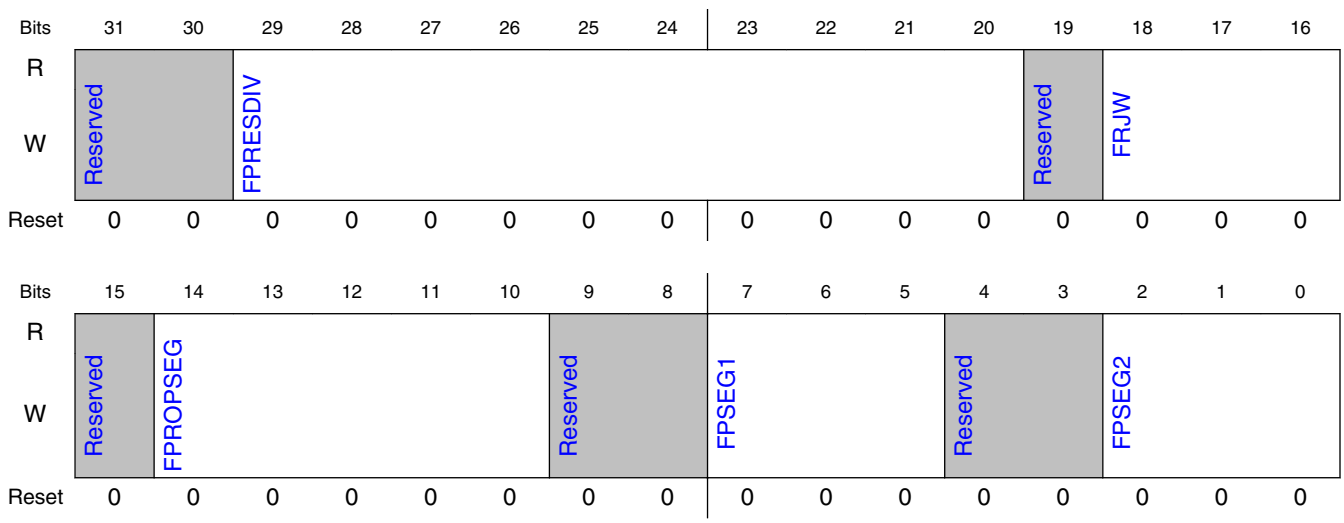
NOTE

The user must ensure bit time settings and protocol engine tolerance are in compliance with the CAN Protocol standard (ISO 11898-1).

66.6.2.31.1 Offset

Register	Offset
FDCBT	C04h

66.6.2.31.2 Diagram



66.6.2.31.3 Fields

Field	Description
31-30 —	Reserved
29-20 FPRESDIV	Fast Prescaler Division Factor This 10-bit field defines the ratio between the PE clock frequency and the serial clock (Sclock) frequency in the data bit rate portion of a CAN FD message with the BRS bit set.

Table continues on the next page...

Field	Description
	The Sclock period defines the time quantum of the CAN FD protocol for the data bit rate. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Sclock frequency = PE clock frequency / (FPRESDIV + 1). **NOTE:** To minimize errors when processing FD frames, use the same value for FPRESDIV and PRESDIV (in CBT or CTRL1). For more details see the first NOTE in section CAN FD frames.
19 —	Reserved
18-16 FRJW	Fast Resync Jump Width This 3-bit field defines the maximum number of time quanta that a bit time can be changed by one resynchronization in the data bit rate portion of a CAN FD message with the BRS bit set. One time quantum is equal to the Sclock period. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Resync Jump Width = FSJW + 1.
15 —	Reserved
14-10 FPROPSEG	Fast Propagation Segment This 5-bit field defines the length of the propagation segment in the bit time in the data bit rate portion of a CAN FD message with the BRS bit set. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Propagation Segment Time = FPROPSEG × Time-Quanta. Time-Quantum = one Sclock period.
9-8 —	Reserved
7-5 FPSEG1	Fast Phase Segment 1 This 3-bit field defines the length of phase segment 1 in the bit time in the data bit rate portion of a CAN FD message with the BRS bit set. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Phase Segment 1 = (FPSEG1 + 1) × Time-Quanta. Time-Quantum = one Sclock period.
4-3 —	Reserved
2-0 FPSEG2	Fast Phase Segment 2 This 3-bit field defines the length of phase segment 2 in the data bit rate portion of a CAN FD message with the BRS bit set. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Phase Segment 2 = (FPSEG2 + 1) × Time-Quanta. Time-Quantum = one Sclock period.

66.6.2.32 CAN FD CRC register (FDCRC)

This register provides information about the CRC of transmitted messages.

FlexCAN uses different CRC polynomials for different frame formats, as shown below.

The CRC_15 polynomial is used for all frames in CAN format. The CRC_17 polynomial is used for frames in CAN FD format with a DATA FIELD up to sixteen bytes. The CRC_21 polynomial is used for frames in CAN FD format with a DATA FIELD longer than sixteen bytes. Each polynomial shown below results in a Hamming distance of 6. This register is updated at the same time the Tx Interrupt flag is asserted.

$$CRC_15 = C599h:\ (x^{15} + x^{14} + x^{10} + x^8 + x^7 + x^4 + x^3 + 1)$$

$$CRC_17 = 3685Bh:\ (x^{17} + x^{16} + x^{14} + x^{13} + x^{11} + x^6 + x^4 + x^3 + x^1 + 1)$$

$$CRC_21 = 302899h:\ (x^{21} + x^{20} + x^{13} + x^{11} + x^7 + x^4 + x^3 + 1)$$

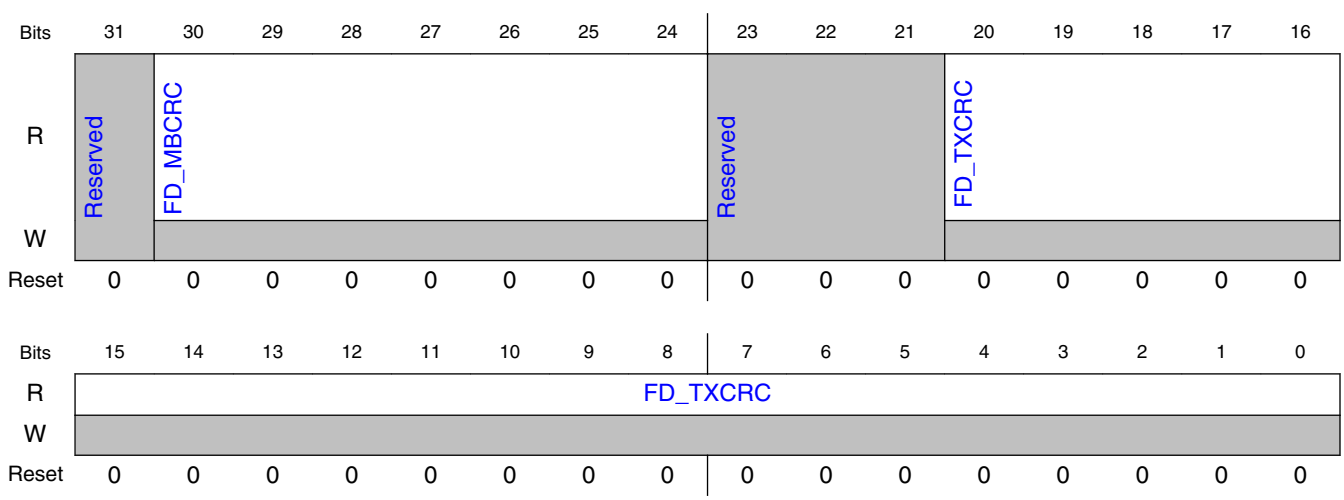
NOTE

See CRC sequence calculation in the CAN Protocol standard (ISO 11898-1) for details.

66.6.2.32.1 Offset

Register	Offset
FDCRC	C08h

66.6.2.32.2 Diagram



66.6.2.32.3 Fields

Field	Description
31 —	Reserved
30-24 FD_MBCRC	CRC Mailbox Number for FD_TXCRC This field indicates the number of the mailbox corresponding to the value in the FD_TXCRC field, for both FD and non-FD frames. It reports the same information as in CRCR[MBCRC].
23-21 —	Reserved
20-0 FD_TXCRC	Extended Transmitted CRC value This 21-bit field contains the CRC value calculated over the most recent transmitted message. Different CRC polynomials are used for different frame formats. A 15-bit polynomial, CRC_15, is used for all frames in CAN format. The second 17-bit polynomial, CRC_17, is used for frames in CAN FD format with a data field up to sixteen bytes long. The third 21-bit polynomial, CRC_21, is used for frames in CAN FD format with a data field longer than sixteen bytes. For CRC_15 and CRC_17, the 6 most significant bits and the 4 most significant bits are reported as zeros, respectively. For CRC_15, this register has the same content as CRC register.

66.6.3 Message buffer structure

The message buffer structure used by the FlexCAN module is represented in the following figure. Both extended (29-bit identifier) and standard (11-bit identifier) frames used in the CAN specification (Version 2.0 Part B) are represented. Each individual MB is formed by 16, 24, 40, or 72 bytes, depending on the quantity of data bytes allocated for the message payload: 8, 16, 32, or 64 data bytes, respectively.

The memory area 80h–47Fh is used by the mailboxes. When CAN FD is enabled, the exact address for each MB depends on the size of its payload. See FlexCAN memory partition for CAN FD for more detailed information.

Table 66-25. Message buffer structure — example with 64-byte payload

	31	30	29	28	27	24	23	22	21	20	19	18	17	16	15	8	7	0

		= Unimplemented or reserved		

EDL — Extended Data Length

This bit distinguishes between CAN format and CAN FD format frames. The EDL bit must not be set for message buffers configured to RANSWER with code field 1010b (see table below).

BRS — Bit Rate Switch

This bit defines whether the bit rate is switched inside a CAN FD format frame.

ESI — Error State Indicator

This bit indicates if the transmitting node is error active or error passive.

CODE — Message Buffer Code

This 4-bit field can be accessed (read or write) by the CPU and by the FlexCAN module itself, as part of the message buffer matching and arbitration process. The encoding is shown in Table 66-26 and Table 66-27. See Functional description for additional information.

Table 66-26. Message buffer code for Rx buffers

CODE description	Rx code BEFORE receive new frame	SRV[1]	Rx code AFTER successful reception[2]	RRS[3]	Comment
0000b: INACTIVE — MB is not active.	INACTIVE	—	—	—	MB does not participate in the matching process.

Table continues on the next page...

Table 66-26. Message buffer code for Rx buffers (continued)

CODE description	Rx code BEFORE receive new frame	SRV[1]	Rx code AFTER successful reception[2]	RRS[3]	Comment
0100b: EMPTY — MB is active and empty.	EMPTY	—	FULL	—	When a frame is received successfully (after the Move-in process), the CODE field is automatically updated to FULL.
0010b: FULL — MB is full.	FULL	Yes	FULL	—	The act of reading the C/S word followed by unlocking the MB (SRV) does not make the code return to EMPTY. It remains FULL. If a new frame is moved to the MB after the MB was serviced, the code still remains FULL. See Matching process for matching details related to FULL code.
		No	OVERRUN	—	If the MB is FULL and a new frame is moved to this MB before the CPU services it, the CODE field is automatically updated to OVERRUN. See Matching process for details about overrun behavior.
0110b: OVERRUN — MB is being overwritten into a full buffer.	OVERRUN	Yes	FULL	—	If the CODE field indicates OVERRUN and CPU has serviced the MB, when a new frame is moved to the MB then the code returns to FULL.
		No	OVERRUN	—	If the CODE field already indicates OVERRUN, and another new frame must be moved, the

Table continues on the next page...

Table 66-26. Message buffer code for Rx buffers (continued)

CODE description	Rx code BEFORE receive new frame	SRV[1]	Rx code AFTER successful reception[2]	RRS[3]	Comment
					MB will be overwritten again, and the code will remain OVERRUN. See Matching process for details about overrun behavior.
1010b: RANSWER[4] — A frame was configured to recognize a Remote Request frame and transmit a Response frame in return.[5]	RANSWER	—	TANSWER(1110b)	0	A Remote Answer was configured to recognize a remote request frame received. After that an MB is set to transmit a response frame. The code is automatically changed to TANSWER (1110b). See Matching process for details. If CTRL2[RRS] is negated, transmit a response frame whenever a remote request frame with the same ID is received.
		—	—	1	This code is ignored during matching and arbitration process. See Matching process for details.
CODE[0]=1: BUSY — FlexCAN is updating the contents of the MB. The CPU must not access the MB.	BUSY[6]	—	FULL	—	Indicates that the MB is being updated. It will be negated automatically and does not interfere with the next CODE.
		—	OVERRUN	—	

1. SRV: Serviced MB. MB was read and unlocked by reading TIMER or other MB.
2. A frame is considered a successful reception after the frame to be moved to MB (move-in process). See Move-in for details.
3. Remote Request Stored bit, see "Control 2 register (CTRL2)" for details.
4. Code 1010b is not considered Tx and an MB with this code should not be aborted.
5. Code 1010b must be used in message buffers configured in CAN FD format, having the EDL bit set.
6. Note that for Tx MBs, the BUSY bit should be ignored upon read, except when AEN bit is set in the MCR register. If this bit is asserted, the corresponding MB does not participate in the matching process.

Table 66-27. Message buffer code for Tx buffers

CODE Description	Tx Code BEFORE tx frame	MB RTR	Tx Code AFTER successful transmission	Comment
1000b: INACTIVE — MB is not active	INACTIVE	—	—	MB does not participate in arbitration process.
1001b: ABORT — MB is aborted	ABORT	—	—	MB does not participate in arbitration process.
1100b: DATA — MB is a Tx data frame (MB RTR must be 0)	DATA	0	INACTIVE	Transmit data frame unconditionally once. After transmission, the MB automatically returns to the INACTIVE state.
1100b: REMOTE — MB is a Tx Remote Request frame (MB RTR must be 1)	REMOTE	1	EMPTY	Transmit remote request frame unconditionally once. After transmission, the MB automatically becomes an Rx Empty MB with the same ID.
1110b: TANSWER — MB is a Tx Response frame from an incoming Remote Request frame	TANSWER	—	RANSWER	This is an intermediate code that is automatically written to the MB by the CHI as a result of a match to a remote request frame. The remote response frame will be transmitted unconditionally once, and then the code will automatically return to RANSWER (1010b). The CPU can also write this code with the same effect. The remote response frame can be either a data frame or another remote request frame depending on the RTR bit value. See Matching process and Arbitration process for details.

SRR — Substitute Remote Request

Fixed recessive bit, used only in extended format. It must be set to one by the user for transmission (Tx Buffers) and will be stored with the value received on the CAN bus for Rx receiving buffers. It can be received as either recessive or dominant. If FlexCAN receives this bit as dominant, then it is interpreted as an arbitration loss.

1 = Recessive value is compulsory for transmission in extended format frames

0 = Dominant is not a valid value for transmission in extended format frames

IDE — ID Extended Bit

This field identifies whether the frame format is standard or extended.

1 = Frame format is extended

0 = Frame format is standard

RTR — Remote Transmission Request

This bit affects the behavior of remote frames and is part of the reception filter. See Table 66-26, Table 66-27, and the description of the RRS field in Control 2 register (CTRL2) for additional details.

If FlexCAN transmits this bit as '1' (recessive) and receives it as '0' (dominant), it is interpreted as an arbitration loss. If this bit is transmitted as '0' (dominant), then if it is received as '1' (recessive), the FlexCAN module treats it as a bit error. If the value received matches the value transmitted, it is considered a successful bit transmission.

1 = Indicates the current MB may have a remote request frame to be transmitted if MB is Tx. If the MB is Rx then incoming remote request frames may be stored.

0 = Indicates the current MB has a data frame to be transmitted. In Rx MB it may be considered in matching processes.

NOTE

When configuring CAN FD frames, the RTR bit must be negated.

DLC — Length of Data in Bytes

This 4-bit field is the length (in bytes) of the Rx or Tx data, which is located in offset 8h–Fh of the MB space (see Table 66-25). In reception, this field is written by the FlexCAN module, copied from the DLC (Data Length Code) field of the received frame. In transmission, this field is written by the CPU and corresponds to the DLC field value of the frame to be transmitted. When RTR = 1, the frame to be transmitted is a remote frame and does not include the data field, regardless of the DLC field (see Table 66-28).

TIME STAMP — Free-Running Counter Time Stamp

This 16-bit field is a copy of the Free-Running Timer, captured for Tx and Rx frames at the time when the beginning of the Identifier field appears on the CAN bus.

PRIO — Local priority

This 3-bit field is used only when MCR[LPRIO_EN] is set, and it only makes sense for Tx mailboxes. These bits are not transmitted. They are appended to the regular ID to define the transmission priority. See Arbitration process.

ID — Frame Identifier

In standard frame format, only the 11 most significant bits (28 to 18) are used for frame identification in both receive and transmit cases. The 18 least significant bits are ignored. In extended frame format, all bits are used for frame identification in both receive and transmit cases.

DATA BYTE 0 to 63 — Data Field

Up to sixty four bytes can be used for a data frame, depending on the size of payload selected for the message buffers.

For Rx frames, the data is stored as it is received from the CAN bus. DATA BYTE (*n*) is valid only if *n* is less than DLC as shown in the table below.

Table 66-28. DATA BYTEs validity

DLC	Valid DATA BYTEs
0	none
1	DATA BYTE 0
2	DATA BYTE 0 to 1
3	DATA BYTE 0 to 2
4	DATA BYTE 0 to 3
5	DATA BYTE 0 to 4
6	DATA BYTE 0 to 5
7	DATA BYTE 0 to 6
8	DATA BYTE 0 to 7
9	DATA BYTE 0 to 11
10	DATA BYTE 0 to 15
11	DATA BYTE 0 to 19
12	DATA BYTE 0 to 23
13	DATA BYTE 0 to 31
14	DATA BYTE 0 to 47
15	DATA BYTE 0 to 63

66.6.4 FlexCAN memory partition for CAN FD

When CAN FD is enabled, the FlexCAN RAM can be partitioned in blocks of 512 bytes. Each block can accommodate a number of message buffers which depends on the configuration provided by FDCTRL[MBDSRn] bit fields as shown in table below.

Table 66-29. RAM partition

RAM block	Number of MBs with 8 bytes (default range)	Size control bit field in FDCTRL register	Number of MBs of different sizes, per block
0	0 to 31	MBDSR0	MBDSR0=00, 32 MBs with 8 bytes payload MBDSR0=01, 21 MBs with 16 bytes payload MBDSR0=10, 12 MBs with 32 bytes payload MBDSR0=11, 7 MBs with 64 bytes payload
1	32 to 63	MBDSR1	MBDSR1=00, 32 MBs with 8 bytes payload MBDSR1=01, 21 MBs with 16 bytes payload MBDSR1=10, 12 MBs with 32 bytes payload MBDSR1=11, 7 MBs with 64 bytes payload

When payload sizes of 16, 32, or 64 bytes are configured in some or all RAM blocks, the total number of MBs and its respective number order may differ from the default configuration of 8 bytes. For example, suppose Block0 is configured to 8 bytes payload, Block1 to 16 bytes, Then the following table indicates how the message buffers will be arranged in RAM.

Table 66-30. RAM partition example

RAM block	Payload size	Number of MBs in the RAM block	Message buffer range
0	FDCTRL[MBDSR0]=00, 8 bytes payload	32	0 to 31
1	FDCTRL[MBDSR1]=01, 16 bytes payload	21	32 to 52

66.6.5 FlexCAN message buffer memory map

The FlexCAN memory buffers are allocated in memory according to the tables below.

66.6.6 Rx FIFO structure

When MCR[RFEN] is set, the memory area 80h–DCh (which is normally occupied by MBs 0–5) is used by the reception FIFO engine.

The region 80h–8Ch contains the output of the FIFO which must be read by the CPU as a message buffer. This output contains the oldest message that has been received but not yet read. The region 90h–DCh is reserved for internal use of the FIFO engine.

An additional memory area, which starts at E0h and may extend up to 2DCh (normally occupied by MBs 6–37) depending on the CTRL2[RFFN] field setting, contains the ID filter table (configurable from 8 to 128 table elements) that specifies filtering criteria for accepting frames into the FIFO.

Out of reset, the ID filter table flexible memory area defaults to E0h and extends only to FCh, which corresponds to MBs 6 to 7 for RFFN = 0, for backward compatibility with previous versions of FlexCAN.

The following shows the Rx FIFO data structure.

Table 66-35. Rx FIFO structure

	31 28 24 23	22	21	20	19 18 17 16	15 8	7 0
80h	IDHIT	SRR	IDE	RTR	DLC	TIME STAMP	
84h		ID standard			ID extended		
88h	Data byte 0	Data byte 1				Data byte 2	Data byte 3
8Ch	Data byte 4	Data byte 5				Data byte 6	Data byte 7
90h–DCh	Reserved						
E0h	ID filter table element 0						
E4h	ID filter table element 1						
E8h–2D4h	ID filter table elements 2 to 125						
2D8h	ID filter table element 126						

Table continues on the next page...

Table 66-35. Rx FIFO structure (continued)

2DCh	ID filter table element 127
	= Unimplemented or reserved

Each ID filter table element occupies an entire 32-bit word and can be compounded by one, two, or four Identifier Acceptance Filters (IDAF) depending on the MCR[IDAM] field setting. The following figures show the IDAF indexation.

The following table shows the three different formats of the ID table elements. Note that all elements of the table must have the same format. See Rx FIFO for more information.

Table 66-36. ID table structure

Format	31	30	29 24	23 16	15	14	13 8	7 1	0
A	RTR	IDE	RXIDA (standard = 29–19, extended = 29–1)						
B	RTR	IDE	RXIDB_0 (standard = 29–19, extended = 29–16)		RTR	IDE	RXIDB_1 (standard = 13–3, extended = 13–0)		
C	RXIDC_0 (std/ext = 31–24)			RXIDC_1 (std/ext = 23–16)	RXIDC_2 (std/ext = 15–8)			RXIDC_3 (std/ext = 7–0)	
	= Unimplemented or Reserved								

RTR — Remote frame

This bit specifies if remote frames are accepted into the FIFO if they match the target ID.

1 = Remote frames can be accepted and data frames are rejected

0 = Remote frames are rejected and data frames can be accepted

IDE — Extended frame

Specifies whether extended or standard frames are accepted into the FIFO if they match the target ID.

1 = Extended frames can be accepted and standard frames are rejected

0 = Extended frames are rejected and standard frames can be accepted

RXIDA — Rx frame identifier (Format A)

Specifies an ID to be used as acceptance criteria for the FIFO. In the standard frame format, only the 11 most significant bits (29 to 19) are used for frame identification. In the extended frame format, all bits are used.

RXIDB_0, RXIDB_1 — Rx frame identifier (Format B)

Specifies an ID to be used as acceptance criteria for the FIFO. In the standard frame format, the 11 most significant bits (a full standard ID) (29 to 19 and 13 to 3) are used for frame identification. In the extended frame format, all 14 bits of the field are compared to the 14 most significant bits of the received ID.

RXIDC_0, RXIDC_1, RXIDC_2, RXIDC_3 — Rx frame identifier (Format C)

Specifies an ID to be used as acceptance criteria for the FIFO. In both standard and extended frame formats, all 8 bits of the field are compared to the 8 most significant bits of the received ID.

IDHIT — Identifier acceptance filter hit indicator

This 9-bit field indicates which identifier acceptance filter was hit by the received message that is in the output of the Rx FIFO. See Rx FIFO for more information.

Chapter 67
Flexible I/O (FlexIO)

67.1 Chip-specific FlexIO information

Table 67-1. Reference links to related information

Topic	Related module(s)	Reference
System memory map	—	System Memory Map
Clocking	CCM	Clock Management Clock Control Module (CCM)
Power management	PMU	Power Management Power Management Unit
Signal multiplexing	IOMUX	External Signals and Pin Multiplexing IOMUX
Trigger mapping	-	

NOTE

For each channel, FlexIO DMA requests have been ORed together at the SoC level. Only one should be enabled at a time.

67.2 Overview

The FlexIO is a highly configurable module providing a wide range of functionality including:

- Emulation of a variety of serial/parallel communication protocols
- Flexible 16-bit timers with support for a variety of trigger, reset, enable and disable conditions
- Programmable logic blocks allowing the implementation of digital logic functions on-chip and configurable interaction of internal and external modules
- Programmable state machine for offloading basic system control functions from CPU

67.2.1 Block Diagram

The Figure 67-1 gives a high-level overview of the configuration of FlexIO timers and shifters.

The FlexIO uses shifters, timers and external triggers to shift data into or out of the FlexIO. The timing of the data shift is controlled by the timers, as shown in the block diagram. The timers can be configured to use generic timer functions, external triggers, or various other conditions to determine this control.

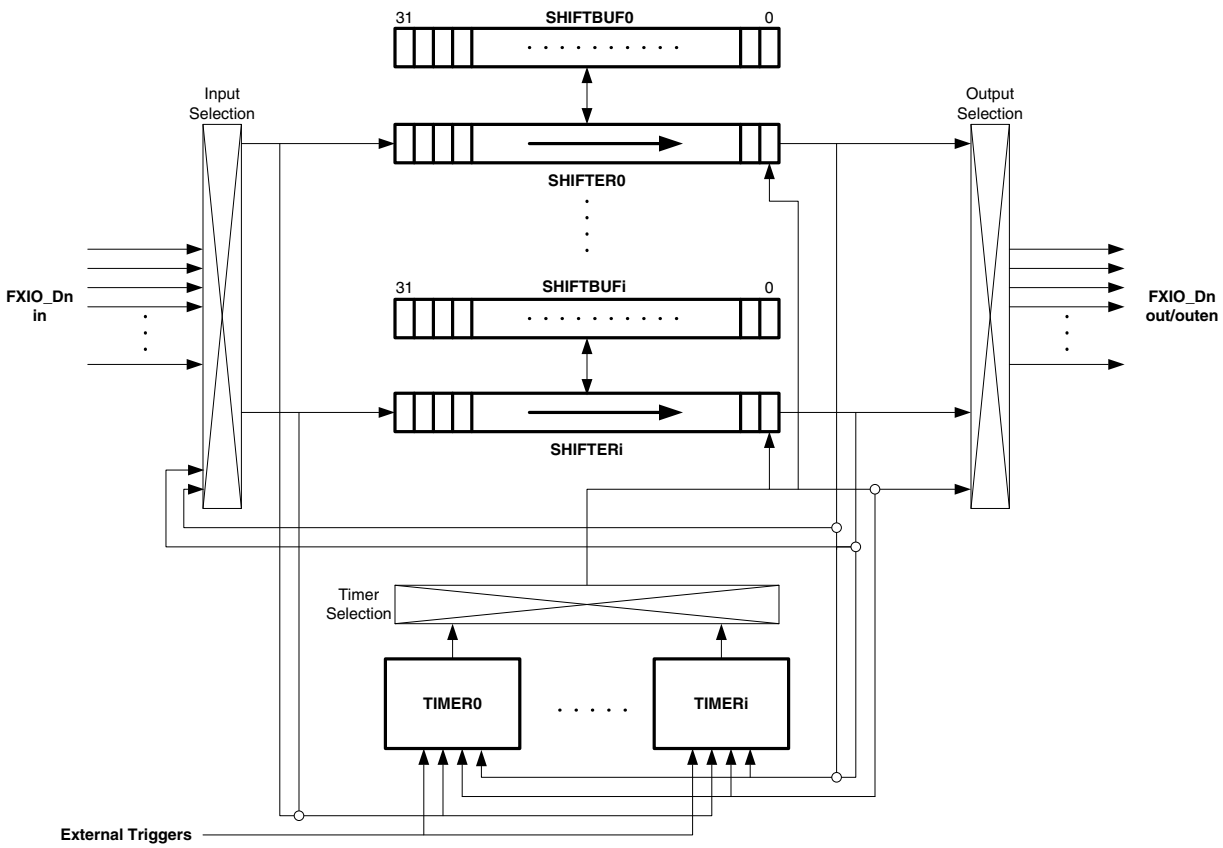

Figure 67-1. FlexIO block diagram

67.2.2 Features

The FlexIO module is capable of supporting a wide range of protocols including, but not limited to:

- UART
- I2C
- SPI

- I2S
- Camera IF
- Motorola 68K/Intel 8080 bus
- PWM/Waveform generation
- Input-capture (pulse edge interval measurement) - Example: SENT

The following key features are provided:

- Array of 32-bit shift registers with transmit, receive, data match, logic mode, and state modes
- Double buffered shifter operation for continuous data transfer
- Shifter concatenation to support large transfer sizes
- Automatic start/stop bit generation
- 1, 2, 4, 8, 16 or 32 multi-bit shift widths for parallel interface support
- Interrupt, DMA or polled transmit/receive operation
- Programmable baud rates independent of bus clock frequency, with support for asynchronous operation during stop modes
- Highly flexible 16-bit timers with support for a variety of internal or external trigger, reset, enable and disable conditions
- Programmable logic mode for integrating external digital logic functions on-chip or combining pin/shifter/timer functions to generate complex outputs
- Programmable state machine for offloading basic system control functions from CPU with support for up to 8 states, 8 outputs and 3 selectable inputs per state

67.3 Functional description

67.3.1 Shifter operation

Shifters are responsible for buffering and shifting data into or out of the FlexIO. The timing of shift, load and store events are controlled by the Timer assigned to the Shifter via the SHIFTCTL[TIMSEL] register. The Shifters are designed to support either DMA, interrupt or polled operation. The following block diagram provides a detailed view of the Shifter microarchitecture.

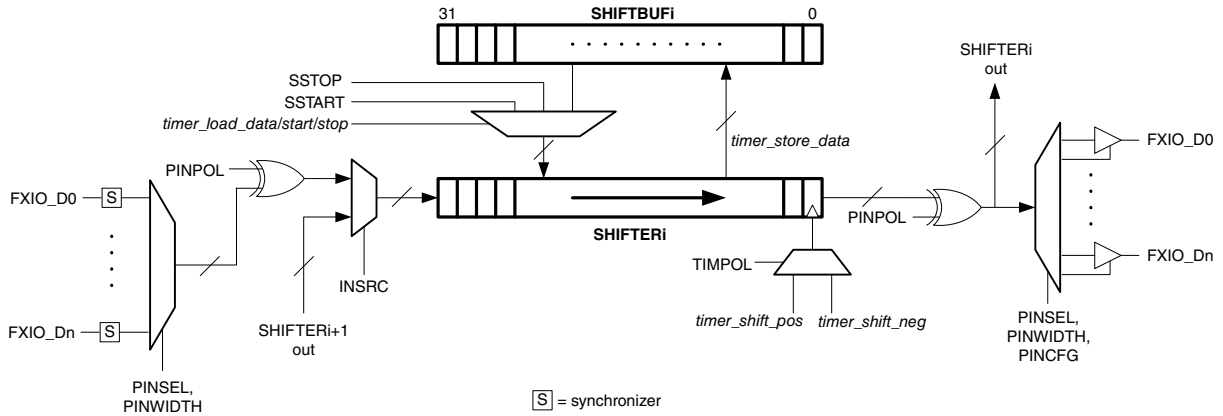

Figure 67-2. Shifter Microarchitecture

67.3.1.1 Transmit Mode

When configured for Transmit mode (SHIFTCTL[SMOD] =Transmit), the shifter loads data from the SHIFTBUF register and shift data out when a load event is signalled by the assigned Timer. An optional start/stop bit can also be automatically loaded before/ afterSHIFTBUF data by configuring the SHIFTCFG[SSTART], TIMCFG[TSTART] or SHIFTCFG[SSTOP], TIMCFG[TSTOP] registers in the Shifter and Timer.

NOTE

The shifter immediately loads a stop bit when the Shifter is initially configured for Transmit mode if a stop bit is enabled.

The Shifter Status Flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set when data has been loaded from the SHIFTBUF register into the Shifter or when the Shifter is initially configured into Transmit mode. The flag clears when new data has been written into the SHIFTBUF register or a logic 1 is written to this flag. In transmit mode, any write of the SHIFTBUF register clears the corresponding Shifter Status Flag. It does not matter what is writing or the state of the DMA/interrupt enables, the flag is cleared. How the flag is set/cleared for each mode is documented in the SSF register description.

The Shifter Error Flag (SHIFTERR[SEF]) and any enabled interrupts are set when an attempt to load data from an empty SHIFTBUF register occurs (buffer underrun). The flag can be cleared by writing it with logic 1.

67.3.1.2 Receive Mode

When configured for Receive mode (SHIFTCTL[SMOD] =Receive), the shifter shifts data in and store data into the SHIFTBUF register when a store event is signalled by the assigned Timer. Checking for a start/stop bit can be enabled before/after shifter data is sampled by configuring the SHIFTCFG[SSTART], TIMCFG[TSTART] or SHIFTCFG[SSTOP], TIMCFG[TSTOP] registers in the Shifter and Timer.

The Shifter Status Flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set when data has been stored into the SHIFTBUF register from the Shifter. The flag clears when the data has been read from theSHIFTBUF register or a logic 1 is written to this flag. Any read of the SHIFTBUF register clears the corresponding Shifter Status Flag when Shifter is configured in Receive mode. It does not matter what is reading or the state of the DMA/interrupt enables, the flag is cleared. How the flag is set/clear for each mode is documented in the SSF register description.

The Shifter Error Flag (SHIFTERR[SEF]) and any enabled interrupts are set when an attempt to store data into a fullSHIFTBUF register occurs (buffer overrun) or when a mismatch occurs on a start/stop bit check. The flag can be cleared by writing it with logic 1.

67.3.1.3 Match Store Mode

When configured for Match Store mode (SHIFTCTL[SMOD] =Match Store), the shifter shifts data in, check for a match result and store matched data into the SHIFTBUF register when a store event is signalled by the assigned Timer. Checking for a start/stop bit can be enabled before/after shifter data is sampled by configuring the SHIFTCFG[SSTART], TIMCFG[TSTART] or SHIFTCFG[SSTOP], TIMCFG[TSTOP] registers in the Shifter and Timer. Up to 16-bits of data can be compared using SHIFTBUF[31:16] to configure the data to be matched and SHIFTBUF[15:0] to mask the match result.

The Shifter Status Flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set when a match occurs and matched data has been stored into the SHIFTBUF register from the Shifter. The flag clears when the matched data has been read from the SHIFTBUF register or a logic 1 is written to this flag. Any read of the SHIFTBUF register clears the corresponding Shifter Status Flag when Shifter is configured in Match Store mode. It does not matter what is reading or the state of the DMA/interrupt enables, the flag is cleared. How the flag is set/clear for each mode is documented in the SSF register description.

The Shifter Error Flag (SHIFTERR[SEF]) and any enabled interrupts are set when an attempt to store matched data into a full SHIFTBUF register occurs (buffer overrun) or when a mismatch occurs on a start/stop bit check. The flag can be cleared by writing it with logic 1.

67.3.1.4 Match Continuous Mode

When configured for Match Continuous mode (SHIFTCTL[SMOD] =Match Continuous), the shifter shifts data in and continuously check for a match result whenever a shift event is signalled by the assigned Timer. Up to 16-bits of data can be compared using SHIFTBUF[31:16] to configure the data to be matched and SHIFTBUF[15:0] to mask the match result.

The Shifter Status Flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set when a match occurs. The flag clears automatically as soon as there is no longer a match between Shifter data and SHIFTBUF register. **The flag cannot be cleared by reading the SHIFTBUF register.**

The Shifter Error Flag (SHIFTERR[SEF]) and any enabled interrupts are set when a match occurs. The flag clears when there is a read from the SHIFTBUF register or it written with logic 1.

67.3.1.5 State Mode

Using State mode enables the user to implement any state machine with up to 8 states, 8 outputs and 3 selectable inputs per state. This feature allows basic control functions to be offloaded from the CPU, which could potentially remain in a low power mode.

When configured for State mode (SHIFTCTL[SMOD] =State), the SHIFTBUF register is used to drive the output and compute next state values when the Shifter has been selected by the current state pointer (SHIFTSTATE[STATE]). The following diagram provides a detailed view of Shifter microarchitecture when configured for State mode.

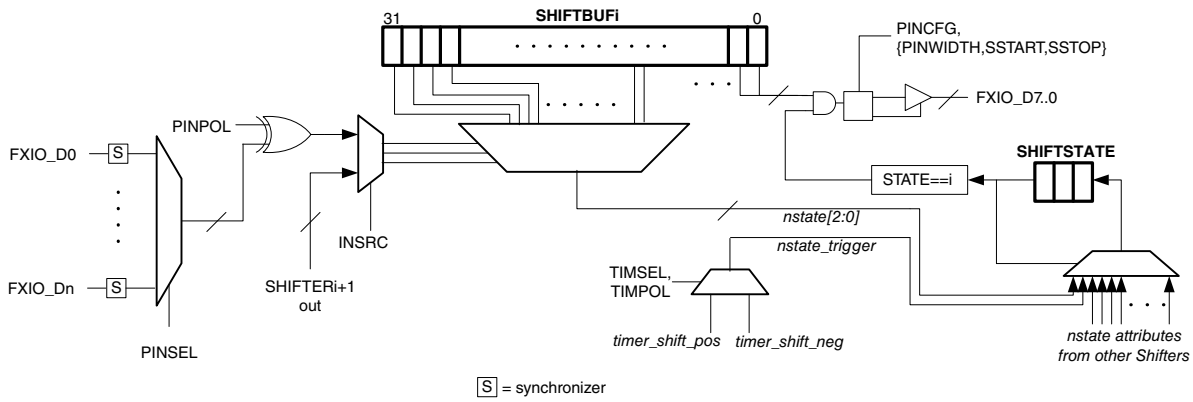

Figure 67-3. State Microarchitecture

When Shifter i has been selected by the current state pointer, output pins FXIO_D[7:0] are driven by SHIFTBUFi[31:24] using the configuration set by SHIFTCTLi[PINCFG]. When set, SHIFTCFGi {PWIDTH[3:0],SSTOP[1:0],SSTART[1:0]} are respectively used to disable the output drive on pins FXIO_D[7:0] for state machine applications which require less than 8 output pins.

The next state value is computed using the 3 input pins selected by SHIFTCTLi[PINSEL] together with SHIFTBUFi[23:0].

NOTE

Each state could potentially use a different set of 3 input pins.

The following table details how the next state value is computed when the current state pointer is pointing to Shifter i.

Table 67-2. Next State computation for SHIFTSTATE[STATE]=i

FXIO_D[PINSEL+2]	FXIO_D[PINSEL+1]	FXIO_D[PINSEL]	Next State Value
0	0	0	SHIFTBUFi[2:0]
0	0	1	SHIFTBUFi[5:3]
0	1	0	SHIFTBUFi[8:6]
0	1	1	SHIFTBUFi[11:9]
...	...	...	...
1	1	1	SHIFTBUFi[23:21]

Note that other shifters/timers could potentially be configured to drive the input pins of a given state, allowing the user to create complex combinations of shifters/timers as desired e.g. the output of a Shifter configured for logic mode could potentially be used to drive a state machine input.

The next state transition is triggered using the Timer output selected by SHIFTCTLi[TIMSEL] with polarity controlled by SHIFTCTLi[TIMPOL]. Note that each state could potentially use a different Timer to trigger each next state transition, allowing a variety of internal/external trigger sources and clocking configurations to be used (see Timer section for more detail).

The current state pointer defaults to Shifter 0 at reset, however it can be written by the user to select a different Shifter for the initial state. If the current state pointer selects a Shifter which is not configured for State mode, then outputs are not driven and a next state transition is never triggered.

The Shifter Status Flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set whenever the Shifter has been selected by the current state pointer. The flag clears when the current state pointer is updated to a different Shifter.

67.3.1.6 Logic Mode

Using logic mode enables the user to implement a small amount of programmable digital logic within a FlexIO Shifter.

When configured for Logic mode (SHIFTCTL[SMOD] =Logic), theSHIFTBUF register is used to implement a 5-input, 32-bit programmable logic look-up table. The following diagram provides a detailed view of Shifter microarchitecture when configured for Logic mode.

The SHIFTBUFi configures the lookup table for the 4 pin inputs and the SHIFTERi can optionally be used to configure a feedback or delayed pin source as the 5th input to the look up table.

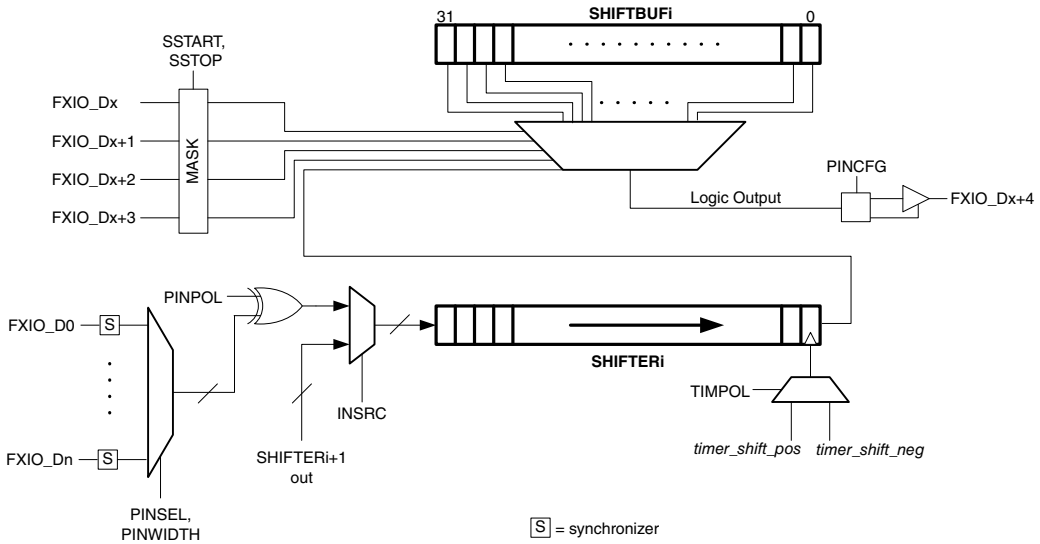

Figure 67-4. Logic Microarchitecture

The look-up table is driven using 4 pin inputs (maskable using SHIFTCFG[SSTOP] and SHIFTCFG[SSTART]) plus 1 input from the internal shifter and can be configured to drive an output pin using the SHIFTCTL[PINCFG] field. Pin inputs and outputs are fixed for each logic look-up table and are not selectable. The following table lists the logic output value selected by the look-up table for Shifter 'i'.

Table 67-3. Logic Look-up table for Shifter 'i'

SHIFTERi[0]	FXIO_D[x+3][1]	FXIO_D[x+2]	FXIO_D[x+1]	FXIO_D[x]	Logic Output to FXIO_D[x+4]
0	0	0	0	0	SHIFTBUFi[0]
0	0	0	0	1	SHIFTBUFi[1]
0	0	0	1	0	SHIFTBUFi[2]
0	0	0	1	1	SHIFTBUFi[3]
...	...	...	...	...	...
1	1	1	1	1	SHIFTBUFi[31]

1. for Shifter i=0...3, x=i

   for Shifter i=4...7, x=i+4

To minimize output glitches, SHIFTCFG[SSTOP] and SHIFTCFG[SSTART] can be used to mask unused input pins. When set, {SSTOP[1:0], SSTART[1:0]} mask FXIO_D[x+3]...FXIO_D[x] inputs respectively, so that any transitions on these pins does not cause the logic output to glitch.

Note that other shifters/timers could potentially be configured to drive the input pins of a given look-up table, allowing the user to concatenate look-up tables or create complex combinations of shifters/timers as desired.

SHIFTCFG[PWIDTH] controls the number of delay stages introduced by the internal shifter input (SHIFTERi[0]). For example, when configured for 1-bit shift (PWIDTH=0), the internal shifter introduces a 32 Shift clock delay before passing its input (selected by SHIFTCTL[PINSEL]) to the look-up table. When configured for 32-bit shift (PWIDTH=16...31), the internal shifter introduces a 1 Shift clock delay to its input.

The Shifter Status Flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set whenever the output pin allocated to the logic look-up table has a value of 1 (after being synchronized to the FlexIO clock). The flag clears when the output pin has a value of 0. This also allows the SSF flag to be used as a trigger to a Timer if desired.

The Shifter Error Flag (SHIFTERR[SEF]) and any enabled interrupts are set when the output pin allocated to the logic look-up table has asserted. The flag can be cleared by writing it with logic 1.

The logic mode input pins (including pins driven by other shifters/timers) are first synchronized to the FlexIO functional clock before they are input to the programmable logic look-up table.

67.3.2 Timer Operation

The FlexIO 16-bit timers control the loading, shifting and storing of the shift registers, the counters load the contents of the compare register and decrement down to zero on the FlexIO clock. They can perform generic timer functions such as generating a clock or select output or a PWM waveform. Timers can be configured to enable in response to a trigger, pin or shifter condition; decrement always or only on a trigger or pin edge; reset in response to a trigger or pin condition; and disable on a trigger or pin condition or on a timer compare. Timers can optionally include a start condition and/or stop condition.

Each timer operates independently, although a timer can be configured to enable or disable at the same time as the previous timer (eg: timer1 can enable or disable at the same time as timer 0) and a timer output can be used to trigger any other timer. The trigger used by each timer is configured independently and can be configured to be a timer output, shifter status flag, pin input or an external trigger input (refer to the chip-specific FlexIO information for details on the external trigger connections). The trigger configuration is separate from the pin configuration, which can be configured for input, output data or output enable.

The Timer Configuration Register (TIMCFGn) should be configured before setting the Timer Mode (TIMOD).

67.3.2.1 Timer 8-bit Baud Counter Mode

In 8-bit Baud Counter Mode, the 16-bit counter is divided into two 8-bit counters. The lower 8-bits are used to configure the baud rate of the shift clock and the upper 8-bits are used to configure the number of shift clock edges in the transfer. When the lower 8-bits decrement to zero, the timer output is toggled and the lower 8-bits reload from the compare register. The upper 8-bits decrement when the lower 8-bits equal zero and decrement.

Note that a timer reset event in 8-bit Baud Counter Mode only resets the lower 8-bit counter, the upper 8-bit counter is not affected and can decrement if the timer reset is configured to update the state of the timer output, and the timer output toggles as a result of the timer reset event.

A timer compare event occurs when the upper 8-bits equal zero and decrements. The timer status flag is set on a timer compare event.

67.3.2.2 Timer 8-bit High PWM Mode

In 8-bit High PWM Mode, the 16-bit counter is divided into two 8-bit counters. The lower 8-bits are used to configure the timer output high period and the upper 8-bits are used to configure the timer output low period. The lower 8-bits decrement when the output is high. When the lower 8-bits equal zero and decrement, the timer output is cleared and the lower 8-bits are reloaded from the compare register. The upper 8-bits decrement when the output is low. When the upper 8-bits equal zero and decrement, the timer output is set and the upper 8-bits are reloaded from the compare register.

A timer compare event occurs when the upper 8-bits equal zero and decrements. The timer status flag is set on a timer compare event.

67.3.2.3 Timer 16-bit Counter Mode

In 16-bit Counter Mode, the 16-bit counter can be used to configure either the baud rate of the shift clock (eg: TIMDEC[1:0] != 10 or 11) or the number of shift clock edges in the transfer (eg: TIMDEC[1:0] = 10 or 11). When the 16-bit counter equals zero and decrements, the timer output toggles and the counter reloads from the compare register.

A timer compare event occurs when the 16-bit counter equals zero and decrements. The timer status flag is set on a timer compare event.

67.3.2.4 Timer 16-bit Counter Disable Mode

In 16-bit Counter Disable Mode, the 16-bit counter can be used to configure either the baud rate of the shift clock (eg: TIMDEC[1:0] != 10 or 11) or the number of shift clock edges in the transfer (eg: TIMDEC[1:0] = 10 or 11). When the 16-bit counter equals zero and decrements, the timer output toggles and the counter reloads from the compare register.

A timer compare event occurs when the 16-bit counter equals zero and decrements. The timer status flag is set on a timer disable event.

67.3.2.5 Timer 8-bit Word Counter Mode

In 8-bit Word Counter Mode, the 16-bit counter is divided into two 8-bit counters. The lower 8-bits are used to configure the number of shift clock edges in each word and the upper 8-bits are used to configure the number number of words in the transfer. When the lower 8-bits decrement to zero, the timer output is toggled and the lower 8-bits reload from the compare register. The upper 8-bits only decrement when the lower 8-bits equal zero and decrement.

A timer compare event occurs when the lower 8-bits equal zero and decrements. The timer status flag is set when the upper 8-bits equal zero and decrements.

67.3.2.6 Timer 8-bit Low PWM Mode

In 8-bit Low PWM Mode, the 16-bit counter is divided into two 8-bit counters. The lower 8-bits are used to configure the timer output low period and the upper 8-bits are used to configure the timer output high period. The lower 8-bits decrement when the output is low. When the lower 8-bits equal zero and decrement, the timer output is set and the lower 8-bits are reloaded from the compare register. The upper 8-bits decrement when the output is high. When the upper 8-bits equal zero and decrement, the timer output is cleared and the upper 8-bits are reloaded from the compare register.

A timer compare event occurs when the upper 8-bits equal zero and decrements. The timer status flag is set on a timer compare event.

67.3.2.7 Timer 16-bit Input Capture Mode

In 16-bit Input Capture Mode, the 16-bit counter uses a fixed initial value of 0xFFFF to load the counter. Whenever a timer counter disable condition is detected (as configured by TIMDIS), the timer status flag is set and the inverted timer counter value is stored in the timer compare register, then the timer counter is immediately restarted from 0xFFFF. The timer output is always output on the FlexIO trigger outputs (which can also be used by other timers as an input trigger) and can also be output to a pin (PINCFG/PINPOL/PINSEL) or a shifter.

If the timer status flag is already set, then the input capture event is missed. When the 16-bit counter equals zero and decrements, the timer output toggles and the counter reloads with 0xFFFF. The timer output can be used to count the number of counter overflows between two input capture events. Input capture mode is not intended to be used to control shift registers, it is to enable software to count the number of bits in a variable length transfer or to monitor the period or frequency of an input.

A timer compare event occurs when the 16-bit counter equals zero and decrements. The timer status flag is set on a timer disable event. Whenever the status flag asserts, the inverted timer counter value is stored in the timer compare register.

67.3.2.8 Timer Enable and Start Bit

When the TIMOD is configured for the desired mode, and the condition configured by timer enable (TIMENA) is detected then the following events occur. When ONETIM is set, then the timer status flag must also be clear to generate a timer enable event, otherwise the timer enable event is blocked. This can be used to enforce software intervention after each timer iteration.

- Timer counter loads the current value of the compare Register and start decrementing as configured by TIMDEC.
- Timer output may update to its initial state depending on the TIMOUT configuration. Shifters that are controlled by this timer do not see this as a rising edge on the timer shift clock.
- Transmit shifters controlled by this timer either output their start bit value, or load the shift register from the shift buffer and output the first bit, as configured by SSTART.

If the Timer start bit is enabled, the timer counter reloads with the compare register on the first rising edge of the shift clock after the timer starts decrementing. If there is no falling edge on the shift clock before the first rising edge (for example, when TIMOUT =1), a shifter that is configured to shift on falling edge and load on the first shift does not load correctly.

67.3.2.9 Timer Decrement and Reset

The Timer then generates the timer output and timer shift clock depending on the TIMOD and TIMDEC fields. The shifter clock is either equal to the timer output (when TIMDEC != 10 or 11) or equal to the decrement clock (when TIMDEC = 10 or 11). When TIMDEC is configured to decrement from a pin or trigger, the timer decrements on both rising and falling edges.

If a Timer is configured to decrement on the FlexIO functional clock divided by 16 or 256 (when TIMDEC = 100 or 101), then a common prescaler that is shared by all Timers is used to generate the two divide ratios. This prescaler is reset when all Timers are either idle or configured to not use the prescaler (TIMDEC != 100 or 101).

When the Timer is configured to reset as configured in the TIMRST field then the Timer counter loads the current value of the compare register again. The timer output and timer shift clock can be configured to update on timer reset, as configured by TIMOUT. This can result in a timer shift clock edge if the timer output toggles as a result of the timer reset. In 8-bit Baud Counter mode this would also decrement the upper 8-bits of the counter.

In general, when the timer counter decrements to zero a timer compare event is triggered. The timer compare event causes the timer counter to load the contents of the timer compare register, the timer output to toggle, any configured transmit shift registers to load, and any configured receive shift registers to store. Depending on the timer mode, the timer status flag may also be set.

67.3.2.10 Timer Disable and Stop Bit

When the is Timer is configured to add a stop bit on each compare, the following additional events occur.

- Transmit shifters controlled by this timer output their stop bit value (if configured by SSTOP).

- Receive shifters controlled by this timer store the contents of the shift register in their shift buffer, as configured by SSTOP.
- On the first rising edge of the shifter clock after the compare, the timer counter reloads the current value of the Compare Register.

Transmit shifters must be configured to load on the first shift when the timer is configured to insert a stop bit on each compare.

When the condition configured by timer disable (TIMDIS) is detected, the following events occur.

- Timer counter reloads the current value of the Compare Register and start decrementing as configured by TIMDEC.
- Timer output clears. Shifters that are controlled by this timer do not see this as a falling edge on the timer shift clock, but can generate a shift event if the timer shift clock would otherwise generate one.
- Transmit shifters controlled by this timer output their stop bit value (if configured by SSTOP).
- Receive shifters controlled by this timer store the contents of the shift register in their shift buffer, as configured by SSTOP.

If the timer stop bit is enabled, the timer counter continues decrementing until the next rising edge of the shift clock is detected, at which point it finishes. Although the timer output is forced low during the stop bit, the timer shift clock can toggle during the stop bit, but does not generate shift events.

A timer enable condition can be detected in the same cycle as a timer disable condition (if timer stop bit is disabled), or on the first rising edge of the shift clock after the disable condition (if stop bit is enabled). When ONETIM is set, the timer status flag must be clear before the next timer enable condition is detected. Receive shift registers with stop bit enabled store the contents of the shift register into the shift buffer and verify the state of the input data on the configured shift edge while the timer is in the stop state condition. If there is no configured edge between the timer disable and the next rising edge of the shift clock then the final store and verify do not occur.

67.3.3 Pin operation

The pin configuration for each timer and shifter can be configured to use any FlexIO pin with either polarity. Each timer and shifter can be configured as an input, output data, output enable or bidirectional output. A pin configured for output enable can be used as an open drain (with inverted polarity, since the output enable assertion would cause logic

zero to be output on the pin) or to control the enable on the bidirectional output. Any timer or shifter could be configured to control the output enable for a pin where the bidirectional output data is driven by another timer or shifter.

67.3.3.1 Parallel Interface

Shifters can be configured to use multiple FlexIO pins in parallel using the SHIFTCFG[PWIDTH] field. PWIDTH is used to configure the following settings of a shifter:

1. Number of bits shifted per Shift clock.
2. Number of pins driven by the shifter per Shift clock (only on shifters supporting parallel transmit i.e. SHIFTER0, SHIFTER4).
3. Number of pins sampled by the shifter per Shift clock (only on Shifter supporting parallel receive i.e. SHIFTER3, SHIFTER7).

When configured for parallel shift, either 4, 8, 16 or 32-bits can be shifted on every Shift clock. If an adjacent shifter is selected as the input source (SHIFTCFG[INSRC] =1), the least significant 4, 8, 16 or 32-bits from the adjacent shifter is sampled on each Shift clock.

For shifters supporting parallel receive (SHIFTER3, SHIFTER7), the shifter can be configured to sample multiple pins (SHIFTCFG[INSRC] =0), with PWIDTH and PINSEL selecting the pins as follows: FXIO_D[PINSEL+PWIDTH]:FXIO_D[PINSEL]. Note that if PWIDTH is less than the number of bits being shifted on each Shift clock, then the most significant bits are masked with 0 e.g. if PINSEL=7 and PWIDTH=6, then SHIFTER[31:24] samples {0,0,FXIO_D[12:7]} on each Shift clock.

For shifters supporting parallel transmit (SHIFTER0, SHIFTER4), the shifter can be configured to drive multiple pins using SHIFTCTL[PINCFG], with PWIDTH and PINSEL selecting the pins as follows: FXIO_D[PINSEL+PWIDTH]:FXIO_D[PINSEL]. Note that if PWIDTH is less than the number of bits being shifted on each Shift clock, then the most significant pins are not driven e.g. if PINSEL=7 and PWIDTH=6, then SHIFTER[5:0] drives only FXIO_D[12:7] on each Shift clock.

67.3.3.2 Pin Synchronization

When configuring a pin as an input (this includes a timer trigger configured as a pin input), the input signal is first synchronized to the FlexIO clock before the signal is used by a timer or shifter. This introduces a small latency of between 0.5 to 1.5 FlexIO clock cycles when using an external pin input to generate an output or control a shifter. This sets the maximum setup time at 1.5 FlexIO clock cycles.

If an input is used by more than one timer or shifter then the synchronization occurs once to ensure any edge is seen on the same cycle by all timers and shifters using that input.

Note that FlexIO pins are also connected internally, configuring a FlexIO shifter or timer to output data on an unused pin makes an internal connection that allows other shifters and timer to use this pin as an input. This allows a shifter output to be used to trigger a timer or a timer output to be shifted into a shifter. This path is also synchronized to the FlexIO clock and therefore incurs a 1 cycle latency.

So when using a Pin input as a Timer Trigger, Timer Clock or Shifter Data Input, the following synchronization delays occur:

1. 0.5 to 1.5 FlexIO clock cycles for external pin
2. 1 FlexIO clock cycle for an internally driven pin

For timing considerations such as output valid time and input setup time for specific applications (SPI Master, SPI Slave, I2C Master, I2S Master, I2S Slave) please refer to the FlexIO Application Information Section.

67.3.4 Low Power Modes

The FlexIO remains functional during low power modes, provided the Doze Enable bit (CTRL[DOZEN]) is clear and the FlexIO functional clock remains enabled.

67.3.5 Debug Mode

The FlexIO remains functional in debug mode provided the Debug Enable bit (CTRL[DBGE]) is set.

67.3.6 Clocks

67.3.6.1 Functional clock

The FlexIO functional clock is asynchronous to the bus clock and can remain enabled in low power modes. The FlexIO functional clock must be enabled before accessing any FlexIO registers. Provided the FlexIO functional clock is at least two times faster than the bus clock, the CTRL[FASTACC] bit can be set to support fast register accesses.

67.3.6.2 Bus clock

The bus clock is only used for bus accesses to the control and configuration registers.

67.3.7 Reset

67.3.7.1 Chip reset

The logic and registers for the FlexIO are reset to their default state on a chip reset.

67.3.7.2 Software reset

The FlexIO implements a software reset bit in its Control Register. The CTRL[SWRST] resets all logic and registers to their default state, except for the CTRL itself.

67.3.8 Interrupts and DMA Requests

The following table illustrates the status flags that can generate the FlexIO interrupt and DMA requests.

Table 67-4. FlexIO Interrupts and DMA Requests

Flag	Description	Interrupt	DMA Request	Low Power Wakeup
SSF	Shifter Status Flag.	Y	Y	Y
SEF	Shifter Error Flag.	Y	N	Y
TSF	Timer Status Flag.	Y	Y	Y

67.3.9 Peripheral Triggers

The connection of the FlexIO peripheral triggers with other peripherals are device specific.

67.3.9.1 Output Triggers

Each FlexIO Timer generates an output trigger equal to the timer output. The output trigger is not affected by the timer pin polarity configuration.

67.3.9.2 Input Trigger

FlexIO supports multiple external trigger inputs that can be used to trigger one or more FlexIO timers. The external triggers are synchronized to the FlexIO functional clock and must assert for at least two cycles of the FlexIO functional clock to be sampled correctly.

67.4 Application Information

This section provides examples for a variety of FlexIO module applications.

67.4.1 UART Transmit

UART transmit can be supported using one Timer, one Shifter and one Pin (two Pins if supporting CTS). The start and stop bit insertion is handled automatically and multiple transfers can be supported using DMA controller. The timer status flag can be used to indicate when the stop bit of each word is transmitted.

Break and idle characters require software intervention, before transmitting a break or idle character the SSTART and SSTOP fields should be altered to transmit the required state and the data to transmit must equal 0xFF or 0x00. Supporting a second stop bit requires the stop bit to be inserted into the data stream using software (and increasing the number of bits to transmit). Note that when performing byte writes to SHIFTBUFn (or SHIFTBUFBIS for transmitting MSB first), the rest of the register remains unaltered allowing an address mark bit or additional stop bit to remain undisturbed.

FlexIO does not support automatic insertion of parity bits.

Table 67-5. UART Transmit Configuration

Register	Value	Comments
SHIFTCFGn	0x0000_0032	Configure start bit of 0 and stop bit of 1.
SHIFTCTLn	0x0003_0002	Configure transmit using Timer 0 on posedge of clock with output data on Pin 0. Can invert output data by setting PINPOL, or can support open drain by setting PINPOL=0x1 and PINCFG =0x1.
TIMCMPn	0x0000_0F01	Configure 8-bit transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:8] = (number of bits x 2) - 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1.

Table continues on the next page...

Table 67-5. UART Transmit Configuration (continued)

Register	Value	Comments
TIMCFGn	0x0000_2222	Configure start bit, stop bit, enable on trigger asserted and disable on compare. Can support CTS by configuring TIMEN=0x3.
TIMCTLn	0x01C0_0001	Configure dual 8-bit counter using Shifter 0 status flag as inverted internal trigger source. Can support CTS by configuring PINSEL=0x1 (for Pin 1) and PINPOL=0x1.
SHIFTBUFn	Data to transmit	Transmit data can be written to SHIFTBUF[7:0] to initiate an 8-bit transfer, use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request. Can support MSB first transfer by writing to SHIFTBUFBBS[7:0] register instead.

An alternative configuration is possible that supports slower baud rates but requires two Timers.

Table 67-6. UART Transmit Configuration for Slow Baud Rate

Register	Value	Comments
SHIFTCFGn	0x0000_0032	Configure start bit of 0 and stop bit of 1.
SHIFTCTLn	0x0003_0002	Configure transmit using Timer 0 on posedge of clock with output data on Pin 0. Can invert output data by setting PINPOL, or can support open drain by setting PINPOL=0x1 and PINCFG =0x1.
TIMCMPn	0x0000_000F	Configure for 8-bit transfer. Set TIMCMP[15:0] = (number of bits x 2) - 1.
TIMCFGn	0x0030_2622	Configure start bit, stop bit, enable on trigger rising edge, decrement on trigger and disable on compare.
TIMCTLn	0x0740_0003	Configure 16-bit counter using Timer 1 output as internal trigger source.
TIMCMP(n+1)	0x0000_0001	Configure baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:0] = (baud rate divider / 2) - 1.
TIMCFG(n+1)	0x0000_1200	Configure enable on trigger asserted and disable on Timer 0 disable. Can support CTS by configuring TIMEN=0x3.
TIMCTL(n+1)	0x01C0_0003	Configure 16-bit counter using Shifter 0 status flag as inverted internal trigger source. Can support CTS by configuring PINSEL =0x1 (for Pin 1) and PINPOL =0x1.

Table continues on the next page...

Table 67-6. UART Transmit Configuration for Slow Baud Rate (continued)

Register	Value	Comments
SHIFTBUFn	Data to transmit	Transmit data can be written to SHIFTBUF[7:0] to initiate an 8-bit transfer, use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request. Can support MSB first transfer by writing to SHIFTBUFBBS[7:0] register instead.

67.4.2 UART Receive

UART receive can be supported using one Timer, one Shifter and one Pin (two Timers and two Pins if supporting RTS). The start and stop bit verification is handled automatically and multiple transfers can be supported using the DMA controller. The timer status flag can be used to indicate when the stop bit of each word is received.

Triple voting of the received data is not supported by FlexIO, data is sampled only once in the middle of each bit. Another timer can be used to implement a glitch filter on the incoming data, another Timer can also be used to detect an idle line of programmable length. Break characters cause the error flag to set and the shifter buffer register returns 0x00.

FlexIO does not support automatic verification of parity bits.

Table 67-7. UART Receiver Configuration

Register	Value	Comments
SHIFTCFGn	0x0000_0032	Configure start bit of 0 and stop bit of 1.
SHIFTCTLn	0x0080_0001	Configure receive using Timer 0 on negedge of clock with input data on Pin 0. Can invert input data by setting PINPOL.
TIMCMPn	0x0000_0F01	Configure 8-bit transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:8] = (number of bits x 2) - 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1.
TIMCFGn	0x0204_2422	Configure start bit, stop bit, enable on pin posedge and disable on compare. Enable resynchronization to received data with TIMOUT=0x2 and TIMRST=0x4.
TIMCTLn	0x0000_0081	Configure dual 8-bit counter using inverted Pin 0 input.

Table continues on the next page...

Table 67-7. UART Receiver Configuration (continued)

Register	Value	Comments
SHIFTBUFn	Data to receive	Received data can be read from SHIFTBUFBYS[7:0], use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request. Can support MSB first transfer by reading from SHIFTBUFBIS[7:0] register instead.

The UART Receiver with RTS configuration uses a 2nd Timer to generate the RTS output. The RTS asserts when the start bit is detected and negate when the data is read from the shifter buffer register. No start bit is detected while the RTS is asserted, the received data is simply ignored.

Table 67-8. UART Receiver with RTS Configuration

Register	Value	Comments
SHIFTCFGn	0x0000_0032	Configure start bit of 0 and stop bit of 1.
SHIFTCTLn	0x0080_0001	Configure receive using Timer 0 on negedge of clock with input data on Pin 0. Can invert input data by setting PINPOL.
TIMCMPn	0x0000_0F01	Configure 8-bit transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:8] = (number of bits x 2) - 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1.
TIMCFGn	0x0204_2522	Configure start bit, stop bit, enable on pin posedge with trigger asserted and disable on compare. Enable resynchronization to received data with TIMOUT=0x2 and TIMRST=0x4.
TIMCTLn	0x02C0_0081	Configure dual 8-bit counter using inverted Pin 0 input. Trigger is internal using inverted Pin 1 input.
TIMCMP(n+1)	0x0000_FFFF	Never compare.
TIMCFG(n+1)	0x0030_6100	Enable on Timer N enable and disable on trigger falling edge. Decrement on trigger to ensure no compare.
TIMCTL(n+1)	0x0143_0003	Configure 16-bit counter and output on Pin 1. Trigger is internal using Shifter 0 flag.
SHIFTBUFn	Data to receive	Received data can be read from SHIFTBUFBYS[7:0], use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request. Can support MSB first transfer by reading from SHIFTBUFBIS[7:0] register instead.

67.4.3 SPI Master

SPI master mode can be supported using two Timers, two Shifters and four Pins. Either CPHA=0 or CPHA=1 can be supported and transfers can be supported using the DMA controller. For CPHA=1, the select can remain asserted for multiple transfers and the timer status flag can be used to indicate the end of the transfer.

The stop bit is used to guarantee a minimum of 1 clock cycle between the slave select negating and before the next transfer. Writing to the transmit buffer by either core or DMA is used to initiate each transfer.

NOTE

Due to synchronization delays, the setup time for the serial input data is 1.5 FlexIO clock cycles, so the maximum baud rate is divide by 4 of the FlexIO clock frequency.

Table 67-9. SPI Master (CPHA=0) Configuration

Register	Value	Comments
SHIFTCFGn	0x0000_0000	Start and stop bit disabled.

67.4.5 I2C Master

I2C master mode can be supported using two Timers, two Shifters and two Pins. One timer is used to generate the SCL output and one timer is used to control the shifters. The two shifters are used to transmit and receive for every word, when receiving the transmitter must transmit 0xFF to tristate the output. FlexIO inserts a stop bit after every word to generate/verify the ACK/NACK. FlexIO waits for the first write to the transmit data buffer before enabling SCL generation. Data transfers can be supported using the DMA controller and the shifter error flag sets on transmit underrun or receive overflow.

The first timer generates the bit clock for the entire packet (START to Repeated START/ STOP), so the compare register needs to be programmed with the total number of clock edges in the packet (minus one). The timer supports clock stretching using the reset counter when pin equal to output (although this increases both the clock high and clock low periods by at least 1 FlexIO clock cycle each). The second timer uses the SCL input pin to control the transmit/receive shift registers, this enforces an SDA data hold time by an extra 2 FlexIO clock cycles.

Both the transmit and receive shifters need to be serviced for each word in the transfer, the transmit shifter must transmit 0xFF when receiving and the receive shifter returns the data actually present on the SDA pin. The transmit shifter loads 1 additional word on the last falling edge of SCL pin, this word should be 0x00 if generating a STOP condition or 0xFF if generating a repeated START condition. During the last word of a master-receiver transfer, the transmit SSTOP bit should be set by software to generate a NACK.

The receive shift register asserts an error interrupt if a NACK is detected, but software is responsible for generating the STOP or repeated START condition. If a NACK is detected during master-transmit, the interrupt routine should immediately write the transmit shifter register with 0x00 (if generating STOP) or 0xFF (if generating repeated START). Software should then wait for the next rising edge on SCL and then disable both timers. The transmit shifter should then be disabled after waiting the setup delay for a repeated START or STOP condition.

NOTE

Due to synchronization delays, the data valid time for the transmit output is 2 FlexIO clock cycles, so the maximum baud rate is divide by 6 of the FlexIO clock frequency.

The I2C master data valid is delayed 2 cycles because the clock output is passed through a synchronizer before clocking the transmit/receive shifter (to guarantee some SDA hold time). Since the SCL output is synchronous with FlexIO clock, the synchronization delay is 1 cycle and then 1 cycle to generate the output.

Table 67-13. I2C Master Configuration

Register	Value	Comments
SHIFTCFGn	0x0000_0032	Start bit enabled (logic 0) and stop bit enabled (logic 1).
SHIFTCTLn	0x0101_0082	Configure transmit using Timer 1 on rising edge of clock with inverted output enable (open drain output) on Pin 0.
SHIFTCFG(n+1)	0x0000_0020	Start bit disabled and stop bit enabled (logic 0) for ACK/NACK detection.
SHIFTCTL(n+1)	0x0180_0001	Configure receive using Timer 1 on falling edge of clock with input data on Pin 0.
TIMCMPn	0x0000_2501	Configure 2 word transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:8] = (number of words x 18) + 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1.
TIMCFGn	0x0102_2222	Configure start bit, stop bit, enable on trigger high, disable on compare, reset if output equals pin. Initial clock state is logic 0 and is not affected by reset.
TIMCTLn	0x01C1_0101	Configure dual 8-bit counter using Pin 1 output enable (SCL open drain), with Shifter 0 flag as the inverted trigger.
TIMCMP(n+1)	0x0000_000F	Configure 8-bit transfer. Set TIMCMP[15:0] = (number of bits x 2) - 1.
TIMCFG(n+1)	0x0020_1112	Enable when Timer 0 is enabled, disable when Timer 0 is disabled, enable start bit and stop bit at end of each word, decrement on pin input.
TIMCTL(n+1)	0x01C0_0183	Configure 16-bit counter using inverted Pin 1 input (SCL).
SHIFTBUFn	Data to transmit	Transmit data can be written to SHIFTBUFBBS[7:0], use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request.
SHIFTBUF(n+1)	Data to receive	Received data can be read from SHIFTBUFBIS[7:0], use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request.

67.4.6 I2S Master

I2S master mode can be supported using two Timers, two Shifters and four Pins. One timer is used to generate the bit clock and control the shifters and one timer is used to generate the frame sync. FlexIO waits for the first write to the transmit data buffer before enabling bit clock and frame sync generation. Data transfers can be supported using the DMA controller and the shifter error flag sets on transmit underrun or receive overflow.

The bit clock frequency is an even integer divide of the FlexIO clock frequency, and the initial frame sync assertion occurs at the same time as the first bit clock edge. The timer uses the start bit to ensure the frame sync is generated one clock cycle before the first output data.

NOTE

Due to synchronization delays, the setup time for the receiver input is 1.5 FlexIO clock cycles, so the maximum baud rate is divide by 4 of the FlexIO clock frequency.

Table 67-14. I2S Master Configuration

Register	Value	Comments
SHIFTCFGn	0x0000_0001	Load transmit data on first shift and stop bit disabled.
SHIFTCTLn	0x0003_0002	Configure transmit using Timer 0 on rising edge of clock with output data on Pin 0.
SHIFTCFG(n+1)	0x0000_0000	Start and stop bit disabled.
SHIFTCTL(n+1)	0x0080_0101	Configure receive using Timer 0 on falling edge of clock with input data on Pin 1.
TIMCMPn	0x0000_3F01	Configure 32-bit transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:8] = (number of bits x 2) - 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1.
TIMCFGn	0x0000_0202	Configure start bit, enable on trigger high and never disable. Initial clock state is logic 1.
TIMCTLn	0x01C3_0281	Configure dual 8-bit counter using inverted Pin 2 output (bit clock), with Shifter 0 flag as the inverted trigger. Clear PINPOL to invert the polarity of the output shift clock.
TIMCMP(n+1)	0x0000_007F	Configure 32-bit transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:0] = (number of bits x baud rate divider) - 1.
TIMCFG(n+1)	0x0000_0100	Enable when Timer 0 is enabled and never disable.
TIMCTL(n+1)	0x0003_0383	Configure 16-bit counter using inverted Pin 3 output (as frame sync). Clear PINPOL to invert the polarity of the output frame sync
SHIFTBUFn	Data to transmit	Transmit data can be written to SHIFTBUFBIS, use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request. Can support LSB first transfer by writing to SHIFTBUF register instead.

Table continues on the next page...

Table 67-14. I2S Master Configuration (continued)

Register	Value	Comments
SHIFTBUF(n+1)	Data to receive	Received data can be read from SHIFTBUFBIS, use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request. Can support LSB first transfer by reading from SHIFTBUF register instead.

67.4.7 I2S Slave

I2S slave mode can be supported using three Timers, two Shifters and four Pins (for single transmit and single receive, other combinations of transmit and receive are possible).

The transmit data must be written to the transmit buffer register before the external frame sync asserts, otherwise the shifter error flag is set.

NOTE

Due to synchronization delays, the output valid time for the serial output data is 2.5 FlexIO clock cycles, so the maximum baud rate is divide by 6 of the FlexIO clock frequency.

The output valid time of I2S slave is max 2.5 cycles because there is a maximum 1.5 cycle delay on the clock synchronization plus 1 cycle to output the data

Timer 2 detects the falling edge of frame sync (start of new frame) and asserts output until rising edge of bit clock (when frame sync is normally sampled). Timer 0 detects rising edge of bit clock with Timer 2 output asserted and asserts output for length of frame. Timer 1 detects falling edge of bit clock with Timer 0 output asserted and controls shift registers for 32-bit transfers.

Table 67-15. I2S Slave Configuration

Register	Value	Comments
SHIFTCFGn	0x0000_0000	Start and stop bit disabled.
SHIFTCTLn	0x0103_0002	Configure transmit using Timer 1 on rising edge of shift clock with output data on Pin 0.
SHIFTCFG(n+1)	0x0000_0000	Start and stop bit disabled.
SHIFTCTL(n+1)	0x0180_0101	Configure receive using Timer 1 on falling edge of shift clock with input data on Pin 1.

Table continues on the next page...

Table 67-15. I2S Slave Configuration (continued)

Register	Value	Comments
TIMCMPn	0x0000_007F	Configure two 32-bit transfers per frame. Set TIMCMP[15:0] = (number of bits x 4) - 1.
TIMCFGn	0x0020_2500	Configure enable on pin rising edge (inverted bit clock) with trigger high (Timer 2) and disable on compare, initial clock state is logic 1 and decrement on pin input (bit clock).
TIMCTLn	0x0B40_0203	Configure 16-bit counter using Pin 2 input (bit clock), with Timer 2 output as the trigger.
TIMCMP(n+1)	0x0000_003F	Configure 32-bit transfers. Set TIMCMP[15:0] = (number of bits x 2) - 1.
TIMCFG(n+1)	0x0020_2500	Configure enable on pin (bit clock) rising edge with trigger (Timer 0) high and disable on compare, initial clock state is logic 1 and decrement on pin input (bit clock).
TIMCTL(n+1)	0x0340_0283	Configure 16-bit counter using inverted Pin 2 input (bit clock), with Timer 0 output as the trigger.
TIMCMP(n+2)	0x0000_0000	Compare on zero (first edge).
TIMCFG(n+2)	0x0020_6400	Configure enable on inverted pin (frame sync) rising edge and disable on trigger falling edge (bit clock), initial clock state is logic 1 and decrement on inverted pin input (frame sync).
TIMCTL(n+2)	0x04C0_0383	Configure 16-bit counter using inverted Pin 3 input (frame sync), with Pin 2 inverted input (bit clock) as the trigger.
SHIFTBUFn	Data to transmit	Transmit data can be written to SHIFTBUFBIS, use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request. Can support LSB first transfer by writing to SHIFTBUF register instead.
SHIFTBUF(n+1)	Data to receive	Received data can be read from SHIFTBUFBIS, use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request. Can support LSB first transfer by reading from SHIFTBUF register instead.

67.4.8 SENT Receiver

SENT receiver can be supported by using one Timer and one Pin. The Timer is configured as Input-Capture mode, and captures the conter value at falling edge of the Pin input. Once the counter value is captured, the counter is automatically restarted from counter value 0. Therefore, the captured value is always indicating the period between previous falling edge and current falling edge. CPU interrupt or DMA trigger can be configured at each capture of the counter, and the entire SENT frame decoding with the latest tick width adustment is performed by CPU software.

Table 67-16. SENT Receiver Configuration

Register	Value	Comments
TIMCMPn	-	Counter value at the falling edge of the Pin is stored in this register.
TIMCFGn	0x0000_6000	Timer always enabled, Timer disabled on Trigger falling edge, Decrement counter on FlexIO clock.
TIMCTLn	0xnn40_0007	Single 16-bit input capture mode, Timer pin input and output are selected by PINSEL, Timer pin output disabled, Internal trigger selected, Select Pin nn as Trigger.

67.4.9 Camera Interface

Camera Interface can be supported using one Timer, one or more Shifters and multiple Pins. Multiple transfers can be supported using DMA controller.

The example below describes FlexIO configuration for interfacing to an 8-bit CMOS sensor with PCLK, VSYNC, HREF and D[7:0] outputs. The example uses a 128-bit buffer to capture 16-pixels of image data before interrupt or DMA transfer, however a bigger or smaller buffer may be used depending on system DMA performance and FlexIO resource usage by other applications. Note that additional timers may be used to track number of pixels per row and number of rows per frame or HREF/VSYNC may be assigned as GPIO interrupts for software tracking.

Table 67-17. Camera Interface Configuration for 8-bit CMOS sensor

Register	Value	Comments
SHIFTCFGn...n+2[1]	0x0007_0100	Configure 8-bit parallel shift in from adjacent shifter.
SHIFTCFGn+3	0x0007_0000	Configure 8-bit parallel shift in from pins FXIO_D[7:0] (D[7:0]).

1. n=0 or 4

67.4.10 Motorola 68K/Intel 8080 Bus Interface

The Motorola 68K and Intel 8080 bus are two parallel interfaces commonly used by Smart/Asynchronous LCD controllers. In conjunction with GPIO, FlexIO is able to drive these interfaces using one Timer and one Shifter, although additional Shifters could be used to support large transfers via the DMA controller.

The configuration below provides an example of how to drive a 16-bit 68K or 8080 bus. For a 8080 bus, two GPIO are used to drive the nCS and RS pins. For a 68K bus, an additional GPIO is required to drive the RDWR pin.

Table 67-18. Motorola 68K/Intel 8080 Write Configuration

Register	Value	Comments
SHIFTCFG0...7	0x000F_0100	Configure 16-bit parallel shift in from adjacent shifter.
SHIFTCTL0	0x0003_0002	Configure transmit using Timer 0 on posedge of clock with data output to FXIO_D[15:0].
SHIFTCTL1...7	0x0000_0002	Configure transmit using Timer 0 on posedge of clock.
TIMCMP0	0x0000_0101 (1-beat) 0x0000_1F01 (16-beats)	Configure 1 or 16-beat transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:8] = (number of beats x 2) - 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1.

Table continues on the next page...

Register	Value	Comments
TIMCFG0	0x0000_2200	Configure enable on trigger high and disable on compare. Timer output high on enable.
TIMCTL0	0x01C3_1001 (Motorola 68K, 1-beat) 0x1DC3_1001 (Motorola 68K, 16-beats) 0x01C3_1081 (Intel 8080, 1-beat) 0x1DC3_1081 (Intel 8080, 16-beats)	Configure dual 8-bit counter using FXIO_D[16] output (EN pin for 68K, nWR pin for 8080), with Shifter 0 (1-beat) or Shifter 7 (16-beats) flag as the inverted trigger.
SHIFTBUF0...7	Data to transmit	Transmit data can be written to SHIFTBUF0 (1-beat) or SHIFTBUF0...7 (16-beats) to initiate a transfer, use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request.

Table 67-19. Motorola 68K/Intel 8080 Read Configuration

Register	Value	Comments
SHIFTCFG0...6	0x000F_0100	Configure 16-bit parallel shift in from adjacent shifter.
SHIFTCFG7	0x000F_0000	Configure 16-bit parallel shift in from pin.
SHIFTCTL0...7	0x0080_0001	Configure receive using Timer 0 on negedge of clock with data input from FXIO_D[15:0].
TIMCMP0	0x0000_0101 (1-beat) 0x0000_1F01 (16-beats)	Configure 1 or 16-beat transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:8] = (number of beats x 2) - 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1.
TIMCFG0	0x0000_2220	Configure stop_bit, enable on trigger high and disable on compare. Timer output high on enable.
TIMCTL0	0x1DC3_1001 (Motorola 68K, 1 beat) 0x01C3_1001 (Motorola 68K, 16 beats) 0x1DC3_1181 (Intel 8080, 1 beat) 0x01C3_1181 (Intel 8080, 16 beats)	Configure dual 8-bit counter using either FXIO_D[16] output (EN pin for 68K) or FXIO_D[17] output (nRD pin for 8080), with Shifter 7 flag (1-beat) or Shifter 0 flag (16-beats) as the inverted trigger.
SHIFTBUF0...7	Data received	Received data can be read from SHIFTBUF0 (1-beat) or SHIFTBUF0...7 (16-beats), use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request.

In general, any operation to a 68K/8080 bus slave begins with a register write cycle followed by one or more data read or write cycles. To accomplish this, the following program flow should be used:

1. Configure FlexIO with 1-beat write configuration
2. Configure GPIO to assert nCS, RS pins (and deassert RDWR pin for 68K)
3. Write register index data to SHIFTBUF0[15:0]
4. Configure GPIO to deassert RS pin (and assert RDWR pin for 68K data read)
5. Configure FlexIO with desired read or write configuration (e.g. 1 or 16-beats)
6. Use the Shifter Status Flag to trigger interrupt or DMA driven data transfers to/from SHIFTBUF registers
7. Configure GPIO to deassert nCS pin

67.4.11 Low Power State Machine

The configuration below details a hypothetical state machine example to illustrate the flexibility allowed when using Shifter state mode.

In this example, FlexIO waits for the FXIO_D[2] pin to assert and then drives a complementary square wave output at a frequency of FLEXIO_CLK/131072 on the FXIO_D[1:0] pins while the comparator output is asserted (This assumes comparator is connected to external trigger 15. See the chip-specific FlexIO information for actual FlexIO trigger mappings). Throughout this operation, the CPU can be kept in a STOP/ VLPS mode by clearing the CTRL[DOZEN] bit and ensuring the FLEXIO_CLK is enabled. The state diagram below shows the states and transitions implemented by this example.

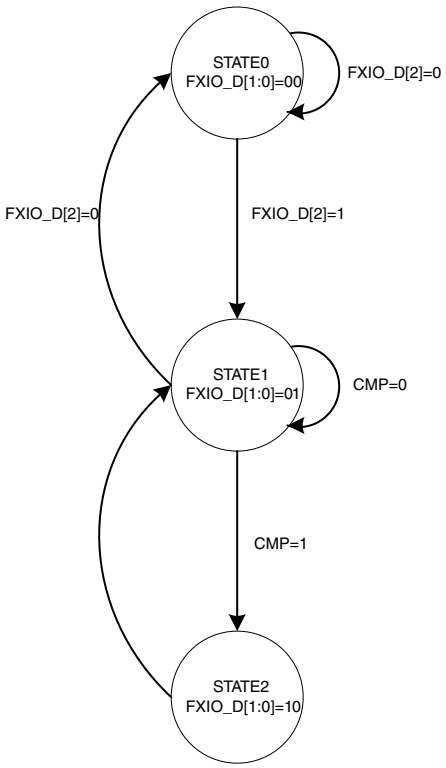

Figure 67-5. State Diagram

Table 67-20. State Machine Configuration

Register	Value	Comments
SHIFTCFG0...2	0x0000_0003	Enable FXIO_D[1:0] as outputs.
SHIFTCTL0	0x0080_0206	Configure for State mode using FXIO_D[4:2] as inputs to select next state and Timer0 output low to trigger next state.
SHIFTBUF0	0x0020_8208	State0: Drive FXIO_D[1:0]=00, transition to State0 if FXIO_D[2]=0, State1 if FXIO_D[2]=1.
SHIFTCTL1	0x0000_0206	Configure for State mode using FXIO_D[4:2] as inputs to select next state and Timer0 output high to trigger next state.
SHIFTBUF1	0x0140_8408	State1: Drive FXIO_D[1:0]=01, transition to State0 if FXIO_D[2]=0, State1 if CMP=0, State2 if CMP=1 (FXIO_D[3]=1)
SHIFTCTL2	0x0080_0206	Configure for State mode using FXIO_D[4:2] as inputs to select next state and Timer0 output low to trigger next state.
SHIFTBUF2	0x0224_9249	State2: Drive FXIO_D[1:0]=10, transition to State1 when Timer0 output low

Table continues on the next page...

Table 67-20. State Machine Configuration (continued)

Register	Value	Comments
TIMCMP0	0x0000_FFFF	Configure baud rate of divide by 131072 of the FlexIO clock. Set TIMCMP[7:0] = (baud rate divider / 2) - 1.
TIMCFG0	0x0000_0000	Configure timer always enabled.
TIMCTL0	0x0000_0003	Configure single 16-bit counter.
TIMCFG1	0x0010_7600	Configure timer enabled on trigger rising edge, disabled on trigger falling edge, decrement on trigger edge.
TIMCTL1	0x0F03_0303	Configure timer output enabled on FXIO_D[3], external trigger 15 (comparator output) selected.

67.4.12 Keypad Interface

The Keypad Interface can support a 3x4 keypad matrix using 3 timers and 3 shifters, although a larger matrix could be supported using additional shifters. The configuration is designed for 4 columns which are configured as active low open drain pins, and 3 rows which are configured as input pins with pullup resistors enabled.

One shifter is configured in logic mode and is configured to assert its output when any of the row inputs are low, indicating a key is pressed. A timer is used to filter the shifter output to ensure the key is pressed for a minimum amount of time before performing the column scan.

Another shifter is configured for parallel transmit, this shifter is used to scan each column when a key press is detected. Whenever not scanning, the shifter output is configured to assert all active low open drain column outputs to detect any keypress. A dedicated timer is used to control the transmit shifter.

The last shifter is configured for parallel receive, this shifter is used to capture the result of the column scanning for software to decode which key or keys was pressed. This configuration captures the state of both row and colum pins for each scan, although the row state could also be deduced by the shift order. A dedicated timer is used to control the receive shifter, it shifts at half the frequency of the transmit shifter.

Once the result of the key scan is available in the receive shifter register, FlexIO continues to monitor the row inputs and can trigger multiple scans from the one key press. To support deboucing, software can decide how many consecutive scans should be considered a single key press.

Since the pins used in logic mode are fixed per shifter, and the shifters that support parallel shifts are limited, this configuration is restricted in what pins and shifters it can use. Increasing the matrix beyond 4 row inputs requires multiple shifters in logic mode and increasing beyond 4 column outputs requires concatenating transmit shifters to create a larger shift register.

Table 67-21. Keypad Interface Configuration

Register	Value	Comments
SHIFTCFG0	0x0003_0032	Start bit enabled (logic 0) and stop bit enabled (logic 1), configired for 4-bit shift.
SHIFTCTL0	0x0101_0402	Configure transmit using Timer 1 on rising edge of clock generating open drain output on Pins [7:4] (column outputs).
SHIFTBUF0	0x0804_0201	Static data containing the column scan pattern, each column is scanned one-hot with deadtime inbetween.
SHIFTCFG1	0x0000_0020	In logic mode, mask input 3.
SHIFTCTL1	0x0000_0007	Configure logic mode.
SHIFTBUF1	0x07ff_07ff	Static data configuring logic mode LUT. Output asserts if pins [3:1] are logic 0.
SHIFTCFG3	0x0007_0000	Configured for 8-bit shift.
SHIFTCTL3	0x0280_0001	Configure receive using Timer 2 on falling edge of clock with input data on Pins [7:0] (both rows and columns, pin 0 is don't care).
TIMCMP0	0x0000_00ff	Configures pre-scanning glitch filter to 256 FlexIO clock cycles. For different filter cycles, set TIMCMP[15:0] = (filter cycles) - 1.
TIMCFG0	0x0103_6600	Configure enable on trigger rising edge and disable on trigger falling edge. Initial clock state is logic 0 and is not affected by reset.
TIMCTL0	0x0540_0003	Configure 16-bit counter using Shifter 1 flag (logic state) as trigger.
TIMCMP1	0x0000_0f3f	Configure 8 shifts (twice for each column) at column scan rate of divide by 128. For different scan frequency, set TIMCMP[7:0] = (scan divider / 2) - 1.
TIMCFG1	0x0020_2622	Enable on trigger rising edge, disable on compare, start and stop bits are enabled.
TIMCTL1	0x0340_0001	Configure dual 8-bit counter using Timer 0 output as the trigger.
TIMCMP2	0x0000_0801	Configure 4 shifts at half the frequency of Timer 1 trigger.

Table continues on the next page...

Table 67-21. Keypad Interface Configuration (continued)

Register	Value	Comments
TIMCFG2	0x0110_2100	Enable on Timer 1 enable, disable on compare, decrement on trigger input with output initially negated and not affected by reset
TIMCTL2	0x0740_0001	Configure dual 8-bit counter using Timer 1 output as the trigger.
SHIFTBUF3	Keypad Scan Result	Keypad scan result can be read from SHIFTBUF3, each byte is the result of one scan with both row and column pin state from the scan (note that pin 0 is not used). Use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request.

67.5 FlexIO Signal Descriptions

Signal	Description	I/O
FXIO_Dn (n=0...31)	Bidirectional FlexIO Shifter and Timer pin inputs/outputs	I/O

67.6.1.6.3 Fields

Field	Description
31-8 —	Reserved
7-0 SSF	Shifter Status Flag The shifter status flag is updated when one of the following events occurs: For SMOD =Receive, the status flag is set when SHIFTBUF has been loaded with data from Shifter (SHIFTBUF is full), and the status flag is cleared when SHIFTBUF register is read. For SMOD =Transmit, the status flag is set when SHIFTBUF data has been transferred to the Shifter (SHIFTBUF is empty) or when initially configured for SMOD=Transmit, and the status flag is cleared when the SHIFTBUF register is written. For SMOD =Match Store, the status flag is set when a match has occured between SHIFTBUF and Shifter, and the status flag is cleared when the SHIFTBUF register is read. For SMOD =Match Continuous, returns the current match result between the SHIFTBUF and Shifter. The status flag cannot be cleared by reading SHIFTBUF. For SMOD =State, the status flag for a shifter sets when it is selected by the current state pointer. For SMOD =Logic, returns the current value of the programmable logic block output. The status flag can also be cleared by writing a logic one to the flag for all modes except Match Continuous/State/Logic. 0b - Status flag is clear. 1b - Status flag is set.

67.6.1.7.3 Fields

Field	Description
31-8 —	Reserved
7-0 SEF	Shifter Error Flags The shifter error flag is set when one of the following events occurs: For SMOD =Receive, indicates Shifter was ready to store new data into SHIFTBUF before the previous data was read from SHIFTBUF (SHIFTBUF Overrun), or indicates that the received start or stop bit does not match the expected value. For SMOD =Transmit, indicates Shifter was ready to load new data from SHIFTBUF before new data had been written into SHIFTBUF (SHIFTBUF Underrun). For SMOD =Match Store, indicates a match event occured before the previous match data was read from SHIFTBUF (SHIFTBUF Overrun). For SMOD =Match Continuous, the error flag is set when a match has occured between SHIFTBUF and Shifter. For SMOD =Logic, the error flag is set when the output of the programmable logic block has asserted. Can be cleared by writing logic one to the flag. For SMOD=Match Continuous, can also be cleared when the SHIFTBUF register is read. 0b - Shifter Error Flag is clear. 1b - Shifter Error Flag is set.

Field	Description
31-8 —	Reserved
7-0 TSF	Timer Status Flags The timer status flag sets depending on the timer mode, and can be cleared by writing logic one to the flag. In 8-bit baud counter mode, the timer status flag is set when the upper 8-bit counter equals zero and decrements. In 8-bit high PWM mode, the timer status flag is set when the upper 8-bit counter equals zero and decrements. In 16-bit counter mode, the timer status flag is set when the 16-bit counter equals zero and decrements. In 16-bit counter disable mode, the timer status flag is set when a timer disable event is detected. In 8-bit word counter mode, the timer status flag is set when the upper 8-bit counter equals zero and decrements. In 8-bit low PWM mode, the timer status flag is set when the upper 8-bit counter equals zero and decrements.

Field	Description
	In 16-bit input capture mode, the timer status flag is set when a timer disable event is detected and the timer status flag is clear. In this mode, the timer compare register should only be read when the timer status flag is set. 0b - Timer Status Flag is clear. 1b - Timer Status Flag is set.

7 PINPOL	Shifter Pin Polarity For pins configured as an output (PINCFG=11), this field takes effect when the register is written. 0 - Pin is active high

Table continues on the next page...

Field	Description
	1 - Pin is active low
6-3 —	Reserved
2-0 SMOD	Shifter Mode Configures the mode of the Shifter. 000 - Disabled. 001 - Receive mode. Captures the current Shifter content into the SHIFTBUF on expiration of the Timer. 010 - Transmit mode. Load SHIFTBUF contents into the Shifter on expiration of the Timer. 011 - Reserved. 100 - Match Store mode. Shifter data is compared to SHIFTBUF content on expiration of the Timer. 101 - Match Continuous mode. Shifter data is continuously compared to SHIFTBUF contents. 110 - State mode. SHIFTBUF contents are used for storing programmable state attributes. 111 - Logic mode. SHIFTBUF contents are used for implementing programmable logic look up table.

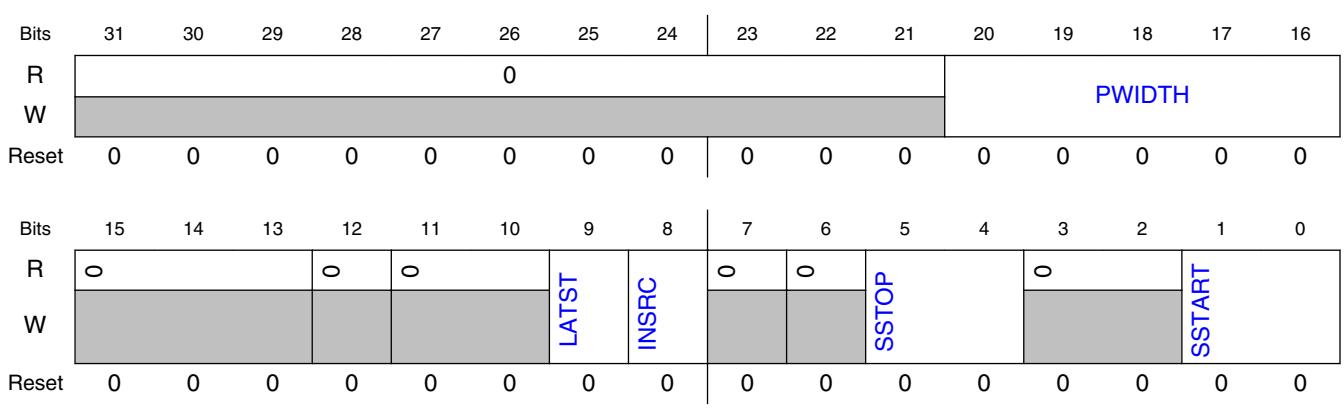
67.6.1.16 Shifter Configuration N Register (SHIFTCFG0 - SHIFTCFG7)

67.6.1.16.1 Offset

For a = 0 to 7:

Register	Offset
SHIFTCFGa	100h + (a × 4h)

67.6.1.16.2 Diagram



67.6.1.16.3 Fields

Field	Description
31-21 —	Reserved
20-16 PWIDTH	Parallel Width For all Shifters, this register field configures the number of bits to be shifted on each Shift clock as follows: 1-bit shift for PWIDTH=0 2-bit shift for PWIDTH=1 4-bit shift for PWIDTH=2...3 8-bit shift for PWIDTH=4...7 16-bit shift for PWIDTH=8...15 32-bit shift for PWIDTH=16...31 For Shifters which support parallel transmit (SHIFTER0, SHIFTER4, ...) or parallel receive (SHIFTER3, SHIFTER7, ...), this register field, together with SHIFTCTL[PINSEL], also selects the pins to be driven or sampled on each Shift clock as follows: • FXIO_D[PINSEL+PWIDTH]:FXIO_D[PINSEL] Shifters which do not support parallel transmit or parallel receive only support parallel shift when INSRC =1. For SMOD =State, this field is used to disable state outputs. See State Mode section for more detail.
15-13 —	Reserved
12 —	Reserved
11-10 —	Reserved
9 LATST	Late Store Configures what happens when a receive or match shift register is configured to both shift and store on the same cycle. 0 - Shift register stores the pre-shift register state. 1 - Shift register stores the post-shift register state.
8 INSRC	Input Source Selects the input source for the shifter. Configuring INSRC=1 is not supported for the last shifter. 0 - Pin 1 - Shifter N+1 Output
7 —	Reserved
6 —	Reserved
5-4	Shifter Stop bit

Table continues on the next page...

Field	Description
SSTOP	For SMOD =Transmit, this field allows automatic stop bit insertion if the selected timer has also enabled a stop bit. For SMOD =Receive or Match Store, this field allows automatic stop bit checking if the selected timer has also enabled a stop bit. For SMOD =State, this field is used to disable state outputs. See 'State Mode' section for more detail. For SMOD =Logic, this field is used to mask logic pin inputs. See 'Logic Mode' section for more detail. 00 - Stop bit disabled for transmitter/receiver/match store 01 - Reserved for transmitter/receiver/match store 10 - Transmitter outputs stop bit value 0 on store, receiver/match store sets error flag if stop bit is not 0 11 - Transmitter outputs stop bit value 1 on store, receiver/match store sets error flag if stop bit is not 1
3-2 —	Reserved
1-0 SSTART	Shifter Start bit For SMOD =Transmit, this field allows automatic start bit insertion if the selected timer has also enabled a start bit. For SMOD =Receive or Match Store, this field allows automatic start bit checking if the selected timer has also enabled a start bit. For SMOD =State, this field is used to disable state outputs. See 'State Mode' section for more detail. For SMOD =Logic, this field is used to mask logic pin inputs. See 'Logic Mode' section for more detail. 00 - Start bit disabled for transmitter/receiver/match store, transmitter loads data on enable 01 - Start bit disabled for transmitter/receiver/match store, transmitter loads data on first shift 10 - Transmitter outputs start bit value 0 before loading data on first shift, receiver/match store sets error flag if start bit is not 0 11 - Transmitter outputs start bit value 1 before loading data on first shift, receiver/match store sets error flag if start bit is not 1

67.6.1.17 Shifter Buffer N Register (SHIFTBUF0 - SHIFTBUF7)

67.6.1.17.1 Offset

67.6.1.17.3 Fields

Field	Description
31-0 SHIFTBUF	Shift Buffer Shift buffer data is used for a variety of functions depending on the SMOD setting: For SMOD=Receive, Shifter data is transferred into SHIFTBUF at the expiration of Timer. The SHIFTBUF register should only be read when the corresponding shifter status flag is set, indicating new Shifter data is available. For SMOD=Transmit, SHIFTBUF data is transferred into the Shifter before the Timer begins. For SMOD=Match Store, SHIFTBUF[31:16] contains the data to be matched with the Shifter contents and SHIFTBUF[15:0] can be used to mask the match result (1=mask, 0=no mask). The Match is checked when the Timer expires and Shifter data [31:16] is written to SHIFTBUF[31:16] whenever a match event occurs. The SHIFTBUF register should only be read when the corresponding shifter status flag is set, indicating new Shifter data is available. For SMOD=Match Continuous, SHIFTBUF[31:16] contains the data to be matched with the Shifter contents and SHIFTBUF[15:0] can be used to mask the match result (1=mask, 0=no mask). For SMOD=Logic, SHIFTBUF[31:0] is used to implement a 5-input, 32-bit programmable logic look-up table. See Logic Mode section for more detail. For SMOD=State, SHIFTBUF[31:24] is used to drive the output value when this shifter is selected by the current state pointer and SHIFTBUF[23:0] is used to configure the value of the next state transition. See State Mode section for more detail.

67.6.1.18 Shifter Buffer N Bit Swapped Register (SHIFTBUFBIS0 - SHIFTBUFBIS7)

67.6.1.18.1 Offset

67.6.1.20.3 Fields

Field	Description
31-0 SHIFTBUFBBS	Shift Buffer Alias to SHIFTBUF register, except reads/writes to this register are bit swapped within each byte. Reads return { SHIFTBUF[24:31], SHIFTBUF[16:23], SHIFTBUF[8:15], SHIFTBUF[0:7] }.

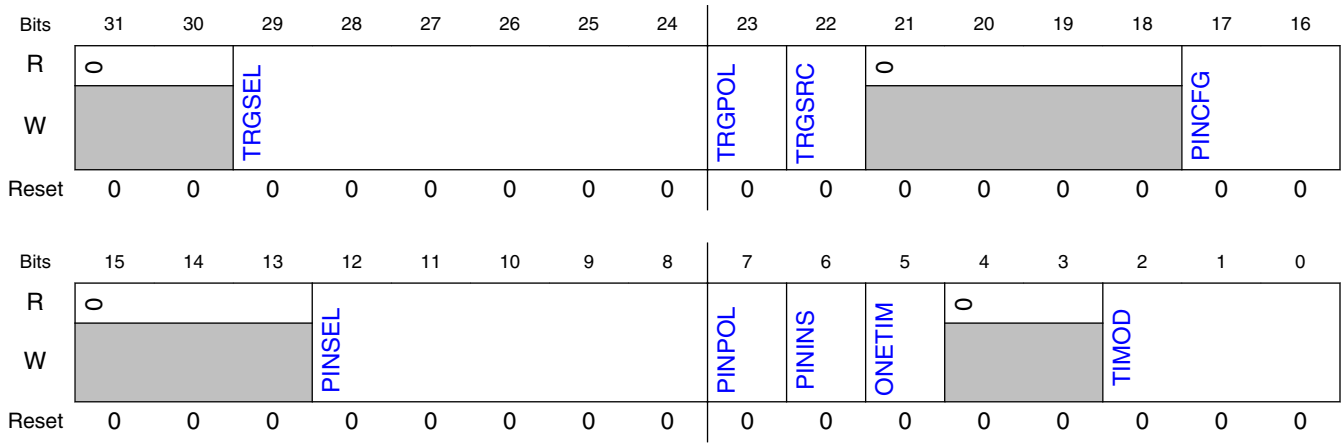
67.6.1.21 Timer Control N Register (TIMCTL0 - TIMCTL7)

67.6.1.21.1 Offset

For a = 0 to 7:

Register	Offset
TIMCTLa	400h + (a × 4h)

67.6.1.21.2 Diagram



67.6.1.21.3 Fields

Field	Description
31-30 —	Reserved
29-24 TRGSEL	Trigger Select The valid values for TRGSEL depends on the FLEXIO_PARAM register. • When TRGSRC = 1, the valid values for N depends on PIN, TIMER, SHIFTER fields in the FLEXIO_PARAM register. • When TRGSRC = 0, the valid values for N depends on TRIGGER field in FLEXIO_PARAM register. Refer to the chip-specific FlexIO information for external trigger selection. **NOTE:** For a pin, N=0 to 31. For a Shifter, N=0 to 7. For a Timer, N=0 to 7. When TRGSRC = 0 the trigger selection is configured as follows: • N - External trigger N input When TRGSRC = 1 the internal trigger can be configured to select an input pin as follows: • 2*N - Pin N input When TRGSRC = 1 the internal trigger can be configured to select a shifter/timer signal as follows: • 4*N+1 - Shifter N status flag • 4*N+3 - Timer N trigger output In other words, the expanded internal trigger selection (TRGSRC = 1) is as follows: • 0000 = Pin 0 • 0001 = Shifter 0 Flag • 0010 = Pin 1 • 0011 = Timer 0 Trigger • 0100 = Pin 2 • 0101 = Shifter 1 Flag • 0110 = Pin 3 • 0111 = Timer 1 Trigger • ... • This continues up to the Pin 31, Shifter 7 and Timer 7.

Table continues on the next page...

Field	Description
23 TRGPOL	Trigger Polarity 0 - Trigger active high 1 - Trigger active low
22 TRGSRC	Trigger Source 0 - External trigger selected 1 - Internal trigger selected
21-18 —	Reserved
17-16 PINCFG	Timer Pin Configuration Configures the direction of the Timer pin. For pins configured as an output (PINCFG=11), this field takes effect when the register is written. 00 - Timer pin output disabled 01 - Timer pin open drain or bidirectional output enable 10 - Timer pin bidirectional output data 11 - Timer pin output
15-13 —	Reserved
12-8 PINSEL	Timer Pin Select Selects which pin is used by the Timer input or output. PINSEL=i selects the FXIO_Di pin. For pins configured as an output (PINCFG=11), this field takes effect when the register is written.
7 PINPOL	Timer Pin Polarity For pins configured as an output (PINCFG=11), this field takes effect when the register is written. 0 - Pin is active high 1 - Pin is active low
6 PININS	Timer Pin Input Select When set, the timer input pin is a different pin from the timer output pin. PINSEL must select an even numbered pin when this bit is set, so the output pin is even numbered and input pin is odd numbered. 0 - Timer pin input and output are selected by PINSEL. 1 - Timer pin input is selected by PINSEL+1, timer pin output remains selected by PINSEL.
5 ONETIM	Timer One Time Operation When set, configures the timer to perform a single enable/disable iteration, after which software must clear the timer status flag for the timer to be enabled again. 0 - The timer enable event is generated as normal. 1 - The timer enable event is blocked unless timer status flag is clear.
4-3 —	Reserved
2-0 TIMOD	Timer Mode In 8-bit baud counter mode, the lower 8-bits of the counter and compare register are used to configure the baud rate of the timer shift clock, and the upper 8-bits are used to configure the shifter bit count.

Field	Description
	In 8-bit PWM high mode, the lower 8-bits of the counter and compare register are used to configure the high period of the timer shift clock, and the upper 8-bits are used to configure the low period of the timer shift clock. The shifter bit count is configured using another timer or external signal. In 16-bit counter mode, the full 16-bits of the counter and compare register are used to configure either the baud rate of the shift clock or the shifter bit count. In 16-bit counter disable mode, the full 16-bits of the counter and compare register are used to configure either the baud rate of the shift clock or the shifter bit count. In 8-bit word counter mode, the lower 8-bits of the counter and compare register are used to configure the shifter bit count, and the upper 8-bits are used to configure the shifter word count. In 8-bit PWM low mode, the lower 8-bits of the counter and compare register are used to configure the low period of the timer shift clock and the upper 8-bits are used to configure the high period of the timer shift clock. The shifter bit count is configured using another timer or external signal. In 16-bit input capture mode, the inverted value of 16-bit counter is latched into the compare register when a timer counter disable condition is detected (as configured by TIMDIS). This also sets the timer status flag. The timer counter is immediately restarted from 0xFFFF 000 - Timer Disabled. 001 - Dual 8-bit counters baud mode. 010 - Dual 8-bit counters PWM high mode. 011 - Single 16-bit counter mode. 100 - Single 16-bit counter disable mode. 101 - Dual 8-bit counters word mode. 110 - Dual 8-bit counters PWM low mode. 111 - Single 16-bit input capture mode.

67.6.1.22 Timer Configuration N Register (TIMCFG0 - TIMCFG7)

The options to enable or disable the timer using the Timer N-1 enable or disable are reserved when N is evenly divisible by 4 (eg: Timer 0).

NOTE

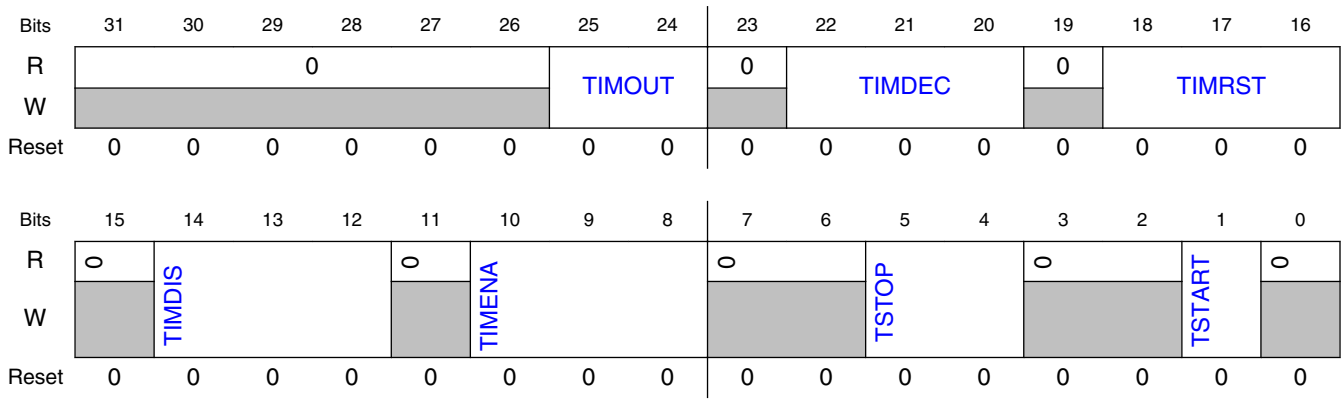
The pin and trigger level/edges specified below refer to the signal state after being modified by the PINPOL or TRGPOL setting in the TIMCTL register. For example, "Trigger low" means a trigger is actually at logic level 1 if the TRGPOL is set to 1 (active low).

67.6.1.22.1 Offset

For a = 0 to 7:

Register	Offset
TIMCFGa	480h + (a × 4h)

67.6.1.22.2 Diagram



67.6.1.22.3 Fields

Field	Description
31-26 —	Reserved
25-24 TIMOUT	Timer Output Configures the initial state of the Timer Output and whether it is affected by the Timer reset. 00 - Timer output is logic one when enabled and is not affected by timer reset 01 - Timer output is logic zero when enabled and is not affected by timer reset 10 - Timer output is logic one when enabled and on timer reset 11 - Timer output is logic zero when enabled and on timer reset
23 —	Reserved
22-20 TIMDEC	Timer Decrement Configures the source of the Timer decrement and the source of the Shift clock. 000 - Decrement counter on FlexIO clock, Shift clock equals Timer output. 001 - Decrement counter on Trigger input (both edges), Shift clock equals Timer output. 010 - Decrement counter on Pin input (both edges), Shift clock equals Pin input. 011 - Decrement counter on Trigger input (both edges), Shift clock equals Trigger input. 100 - Decrement counter on FlexIO clock divided by 16, Shift clock equals Timer output. 101 - Decrement counter on FlexIO clock divided by 256, Shift clock equals Timer output. 110 - Decrement counter on Pin input (rising edge), Shift clock equals Pin input.

Table continues on the next page...

Field	Description
	111 - Decrement counter on Trigger input (rising edge), Shift clock equals Trigger input.
19 —	Reserved
18-16 TIMRST	Timer Reset Configures the condition that causes the timer counter (and optionally the timer output) to be reset. In 8-bit counter mode, the timer reset only resets the lower 8-bits that configure the baud rate. In all other modes, the timer reset resets the full 16-bits of the counter. 000 - Timer never reset 001 - Timer reset on Timer Output high. 010 - Timer reset on Timer Pin equal to Timer Output 011 - Timer reset on Timer Trigger equal to Timer Output 100 - Timer reset on Timer Pin rising edge 101 - Reserved 110 - Timer reset on Trigger rising edge 111 - Timer reset on Trigger rising or falling edge
15 —	Reserved
14-12 TIMDIS	Timer Disable Configures the condition that causes the Timer to be disabled and stop decrementing. 000 - Timer never disabled 001 - Timer disabled on Timer N-1 disable 010 - Timer disabled on Timer compare (upper 8-bits match and decrement) 011 - Timer disabled on Timer compare (upper 8-bits match and decrement) and Trigger Low 100 - Timer disabled on Pin rising or falling edge 101 - Timer disabled on Pin rising or falling edge provided Trigger is high 110 - Timer disabled on Trigger falling edge 111 - Reserved
11 —	Reserved
10-8 TIMENA	Timer Enable Configures the condition that causes the Timer to be enabled and start decrementing. 000 - Timer always enabled 001 - Timer enabled on Timer N-1 enable 010 - Timer enabled on Trigger high 011 - Timer enabled on Trigger high and Pin high 100 - Timer enabled on Pin rising edge 101 - Timer enabled on Pin rising edge and Trigger high 110 - Timer enabled on Trigger rising edge 111 - Timer enabled on Trigger rising or falling edge
7-6	Reserved

Table continues on the next page...

Field	Description
—	
5-4 TSTOP	Timer Stop Bit The stop bit can be added on a timer compare (between each word) or on a timer disable. When stop bit is enabled, configured shifters output the contents of the stop bit when the timer is disabled. When stop bit is enabled on timer disable, the timer remains disabled until the next rising edge of the shift clock. If configured for both timer compare and timer disable, only one stop bit is inserted on timer disable. 00 - Stop bit disabled 01 - Stop bit is enabled on timer compare 10 - Stop bit is enabled on timer disable 11 - Stop bit is enabled on timer compare and timer disable
3-2 —	Reserved
1 TSTART	Timer Start Bit When start bit is enabled, configured shifters outputs the contents of the start bit when the timer is enabled and the timer counter reloads from the compare register on the first rising edge of the shift clock. 0 - Start bit disabled 1 - Start bit enabled
0 —	Reserved

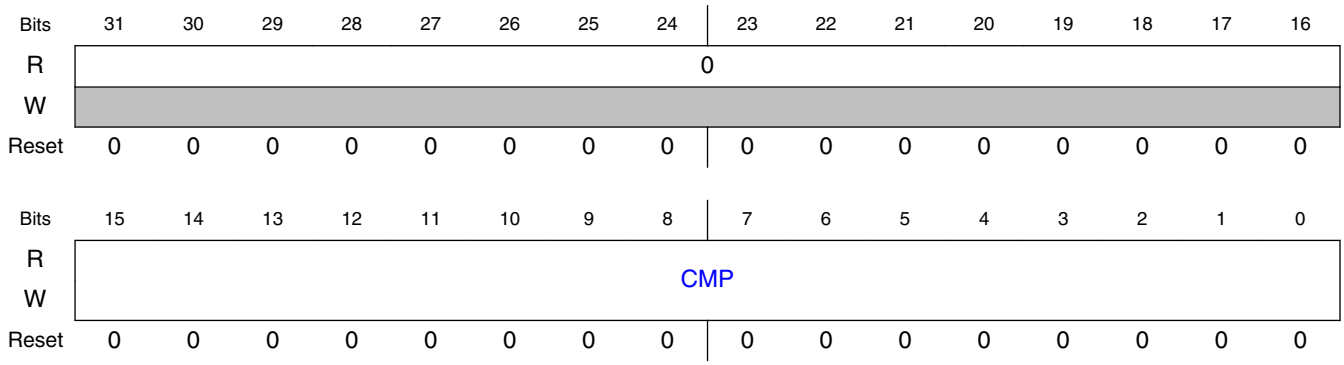
67.6.1.23 Timer Compare N Register (TIMCMP0 - TIMCMP7)

67.6.1.23.1 Offset

For a = 0 to 7:

Register	Offset
TIMCMPa	500h + (a × 4h)

67.6.1.23.2 Diagram



67.6.1.23.3 Fields

Field	Description
31-16 —	Reserved
15-0 CMP	Timer Compare Value The timer compare value is loaded into the timer counter when the timer is first enabled, when the timer is reset and when the timer decrements down to zero. In 8-bit baud counter mode, the lower 8-bits configure the baud rate divider equal to (CMP[7:0] + 1) * 2. The upper 8-bits configure the number of bits in each word equal to (CMP[15:8] + 1) / 2. In 8-bit PWM high mode, the lower 8-bits configure the high period of the output to (CMP[7:0] + 1) and the upper 8-bits configure the low period of the output to (CMP[15:8] + 1). In 16-bit counter mode, the compare value can be used to generate the baud rate divider (if shift clock source is timer output) to equal (CMP[15:0] + 1) * 2. When the shift clock source is a pin or trigger input, the compare register is used to set the number of bits in each word equal to (CMP[15:0] + 1) / 2. In 16-bit counter disable mode, the compare value can be used to generate the baud rate divider (if shift clock source is timer output) to equal (CMP[15:0] + 1) * 2. When the shift clock source is a pin or trigger input, the compare register is used to set the number of bits in each word equal to (CMP[15:0] + 1) / 2. In 8-bit word counter mode, the lower 8-bits configure the number of bits in each word equal to (CMP[7:0] + 1) / 2. The upper 8-bits configure the number of words to transfer equal to (CMP[15:8] + 1) / 2. In 8-bit PWM low mode, the lower 8-bits configure the low period of the output to (CMP[7:0] + 1) and the upper 8-bits configure the high period of the output to (CMP[15:8] + 1). In 16-bit input capture mode, the compare register is updated with the inverse of the timer counter value whenever the timer status flag is set. The timer compare register should only be read when the timer status flag is set.

68.2 Overview

The Keypad Port (KPP) is a 16-bit peripheral that can be used as a keypad matrix interface or as general purpose input/output (I/O). The figure below shows the KPP block diagram. The KPP provides interface for the keypad matrix with 2-point contact or 3-point contact keys. The KPP is designed to simplify the software task of scanning a keypad matrix. With appropriate software support, the KPP is capable of detecting, debouncing, and decoding one or multiple keys pressed simultaneously on the keypad.

68.2.1 Block diagram

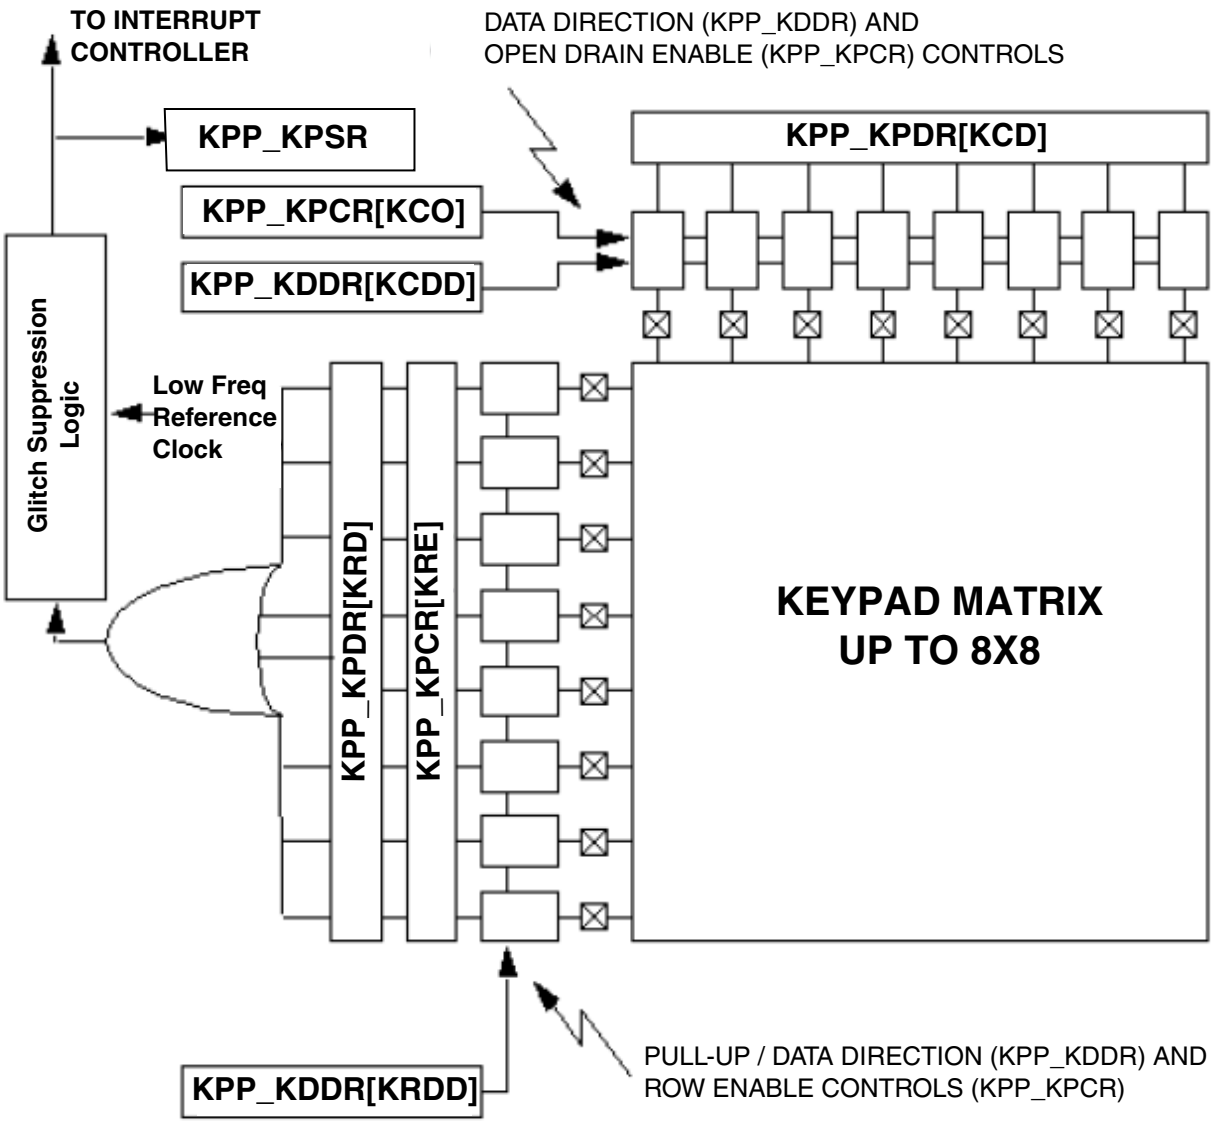

Figure 68-1. KPP Peripheral Block Diagram

68.2.2 Features

The KPP includes these distinctive features:

- Supports up to an 8 x 8 external key pad matrix
- Port pins can be used as general purpose I/O
- Open drain design
- Glitch suppression circuit design
- Multiple-key detection

- Long key-press detection
- Standby key-press detection
- Synchronizer chain clear
- Supports a 2-point and 3-point contact key matrix

68.3 Functional Description

The Keypad Port (KPP) is designed to simplify the software task of scanning a keypad matrix. With appropriate software support and matrix organization, the KPP is capable of detecting, debouncing, and decoding one or more keys pressed simultaneously on the keypad.

Logic in the KPP is capable of detecting a key press even while the processor is in one of the low power standby modes provided that a low frequency reference clock (ipg_clk_32k) is on. The KPP may generate an ARM platform interrupt any time a key press or key release is detected. This interrupt is capable of forcing the processor out of a low power mode.

68.3.1 Modes and Operations

This block supports the following modes:

- Run Mode-This is the normal functional mode in which the KPP can detect any key press event.
- Low Power Mode-The keypad can detect any key press even in low power modes (when there is no MCU clock).

68.3.2 Keypad Matrix Construction

The KPP is designed to interface to a keypad matrix, which shorts the intersecting row and column lines together whenever a key is depressed. The interface is not optimized for any other switch configuration.

68.3.3 Keypad Port Configuration

The software must initialize the KPP for the size of the keypad matrix. Pins connected to the keypad columns should be configured as open-drain outputs. Pins connected to the keypad rows should be configured as inputs. On-chip, pull-up resistors should be implemented for active keypad rows.

In addition to enabled row inputs in the Keypad Control register, corresponding interrupt (depress or/and release) must also be enabled to generate an interrupt.

Discrete switches that are not part of the matrix may be connected to any unused row inputs. The second terminal of the discrete switch is connected to ground. The hardware detects closures of these switches without the need for software polling.

68.3.4 Keypad Matrix Scanning

Keypad scanning is performed by a software loop that walks a zero across each of the keypad columns, reading the value on the rows at each step. The process is repeated several times in succession, with the results of each pass optionally compared to those from the previous pass. When several consecutive scans yield the same key closures, a valid key press has been detected. Software then can decode exactly which switch was depressed and pass the value up to the next software layer.

The KPP may be used to control the debounce period, but it must be defined in software by the user's application. The basic period is the period between the scan of two consecutive columns, so the debouncing time between two consecutive scans of the whole matrix shall be the number of columns multiplied by the basic period.

68.3.5 Keypad Standby

There is no need for the ARM platform to continually scan the keypad. Between key presses, the keypad can be left in a state that requires no software intervention until the next key press is detected. To place the keypad in a standby state, software should write all column outputs low. Row inputs are left enabled. At this point, the ARM platform can attend to other tasks or revert to a low power standby mode. The KPP can interrupt the ARM platform if any key is pressed.

Upon receiving a keypad interrupt, the ARM platform should set all the column strobes high, and begin a normal keypad scanning routine to determine which key was pressed. It is important that open-drain drivers be used when scanning to prevent a possible DC path between power and ground through two or more switches.

68.3.6 Glitch Suppression on Keypad Inputs

A glitch suppression circuit qualifies the keypad inputs to prevent noise from inadvertently interrupting the ARM platform. The circuit is a 4-state synchronizer clocked from a low frequency reference clock (ipg_clk_32k) source. This clock must continue to run in any low power mode where the keypad is a wake-up source, as the ARM platform interrupt is generated from the synchronized input. An interrupt is not generated until all four synchronizer stages have latched a valid key assertion. This guarantees the filtering out of any noise less than three clock periods in duration of a low frequency reference clock. Noise filtering of the duration between three to four clock periods cannot be guaranteed. The interrupt output is latched in an S-R latch and remains asserted until cleared by the software. The Set input of the latch is rising-edge clocked. See the figure below.

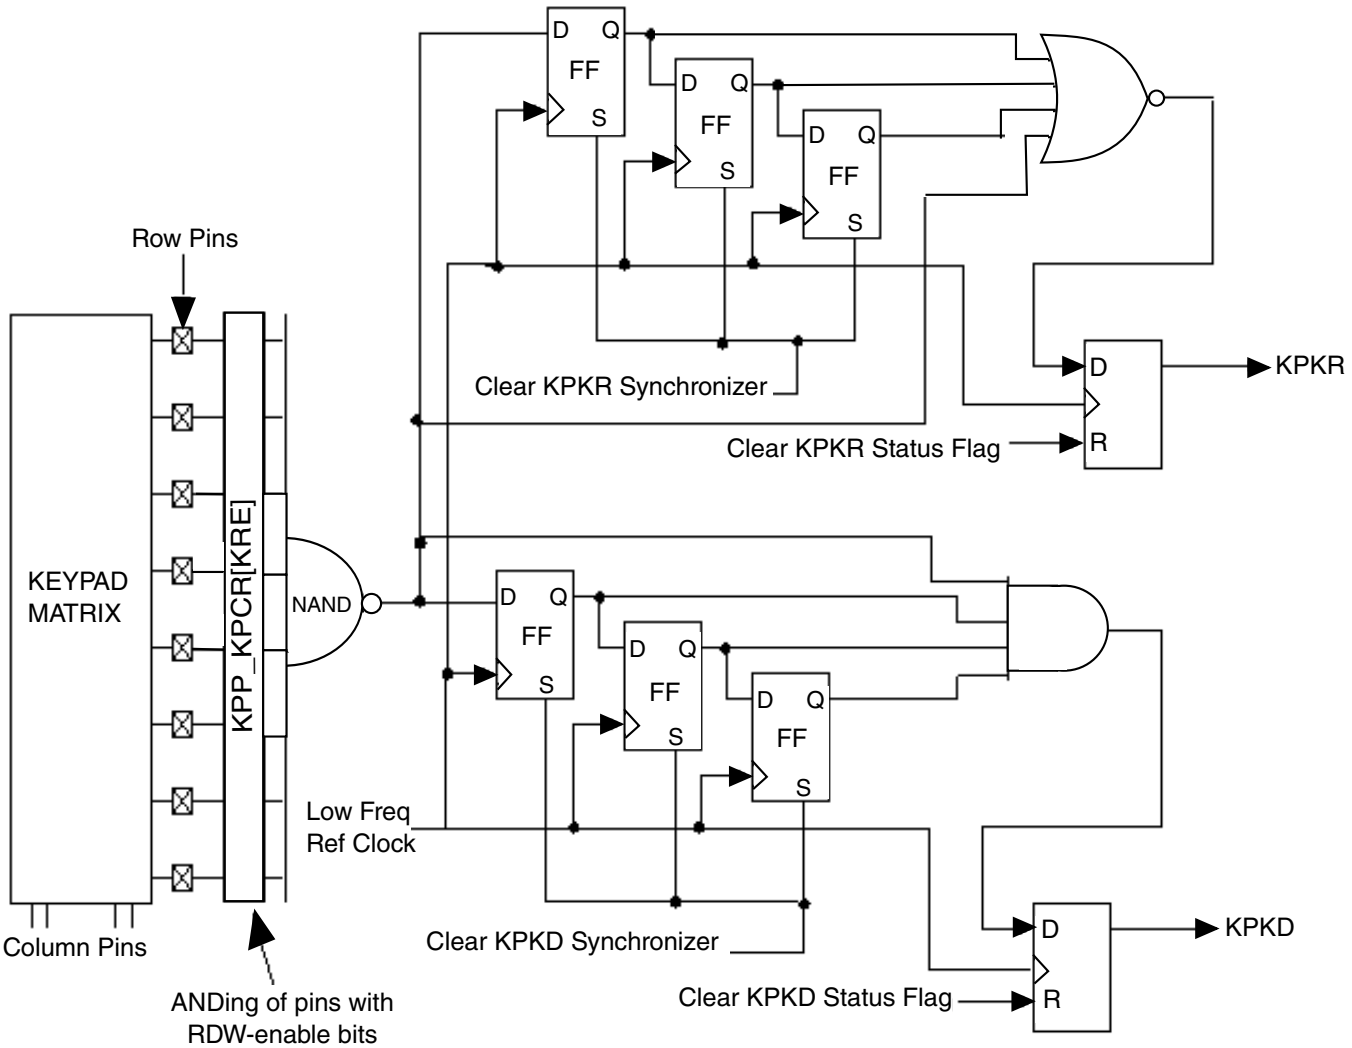

Figure 68-2. Keypad Synchronizer Functional Diagram

68.3.7 Multiple Key Closures

Using the key press and key release interrupts, the software can detect multiple keys or achieve n key rollover. The key scanning routine can be programmed accordingly (See Initialization/Application Information for more information).

The following figures illustrate the interface of a 2-contact keypad matrix with the KPP controller. With proper enabling of row lines and the performing scan-routine, multiple key presses can be detected. When keys present on the same row are pressed, corresponding row lines (multiple lines) become low when the column is driven low during a scan-routine. By reading the data-register, pressed keys can be detected.

Similarly, when keys present on same column line are pressed, the corresponding row line (only one line) becomes low when logic "0" is driven on the column line during a scan-routine.

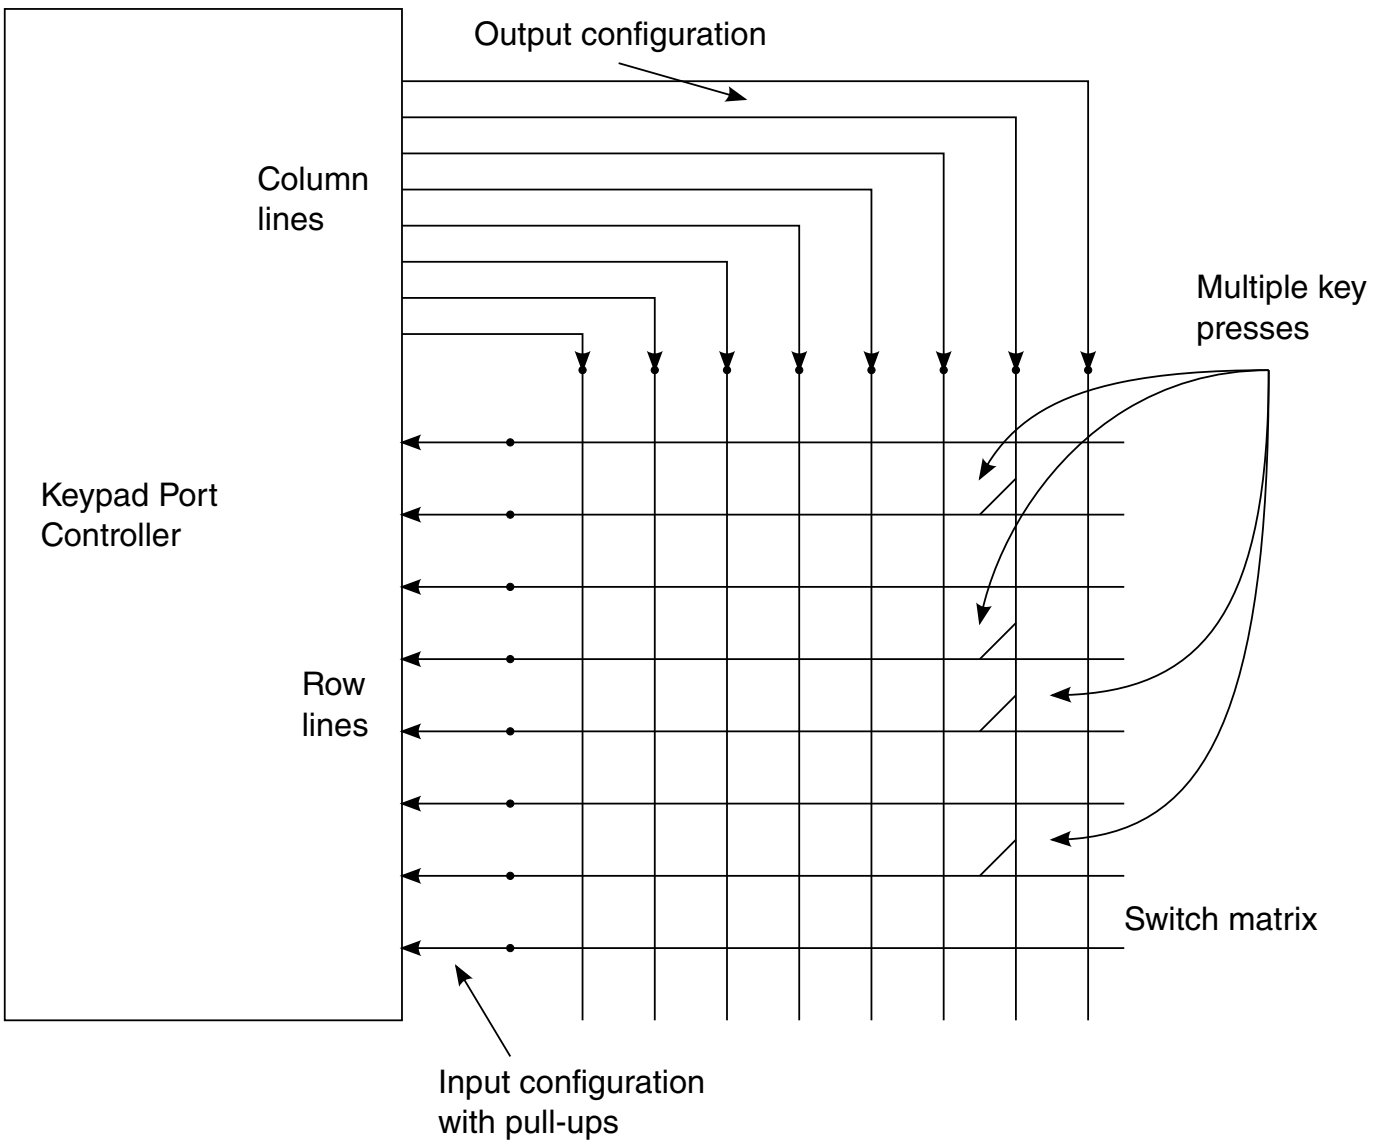

Figure 68-3. Multiple Key Presses on Same Column Line (Simplified View)

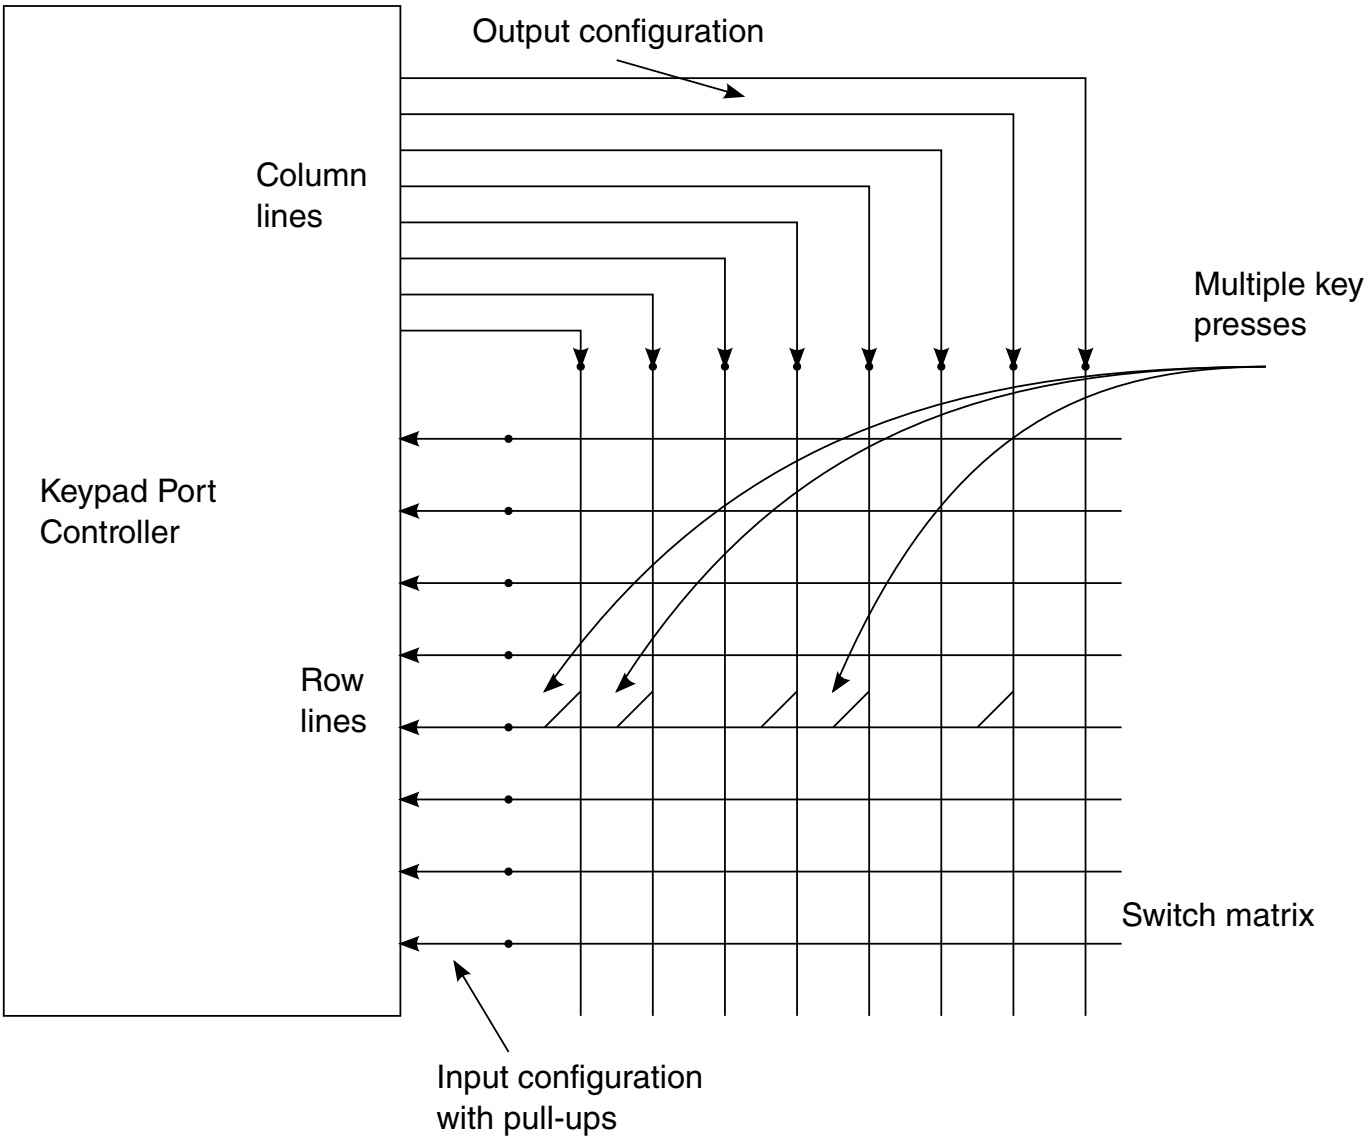

Figure 68-4. Multiple Key Presses on Same Row Line (Simplified View)

NOTE

An n key rollover is a technique with which the system can recognize the order in which keys are pressed.

68.3.7.1 Ghost Key Problem and Correction

The KPP detects if one or multiple keys are pressed or released. In the case where a simple keypad matrix with two-contact switches is used, there is a chance of "ghost" key detection when three or more keys are pressed. This is a limitation imposed by such a keypad matrix.

As seen in Figure 68-5, three keys pressed simultaneously can cause a short between the column currently "scanned" by the software and another column. Depending on the location of the third key pressed, a "ghost" key press may be detected.

However, this can be corrected by using a keypad matrix that provides "ghost" key protection. Such a matrix implements a one-way "diode" at all keypad points between rows and columns. This way, the multiple pressing of three keys will not cause a short at a fourth key (see Figure 68-6).

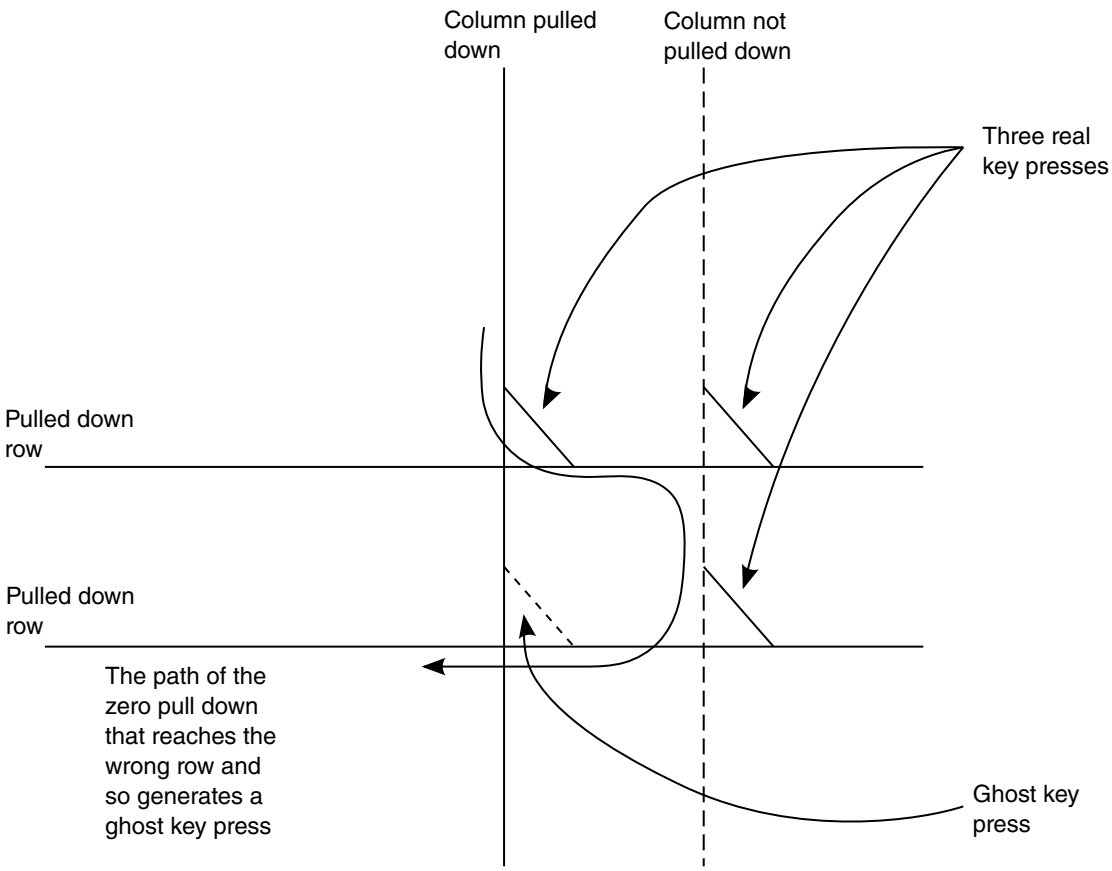

Figure 68-5. Decoding Wrong Three- Key-Presses

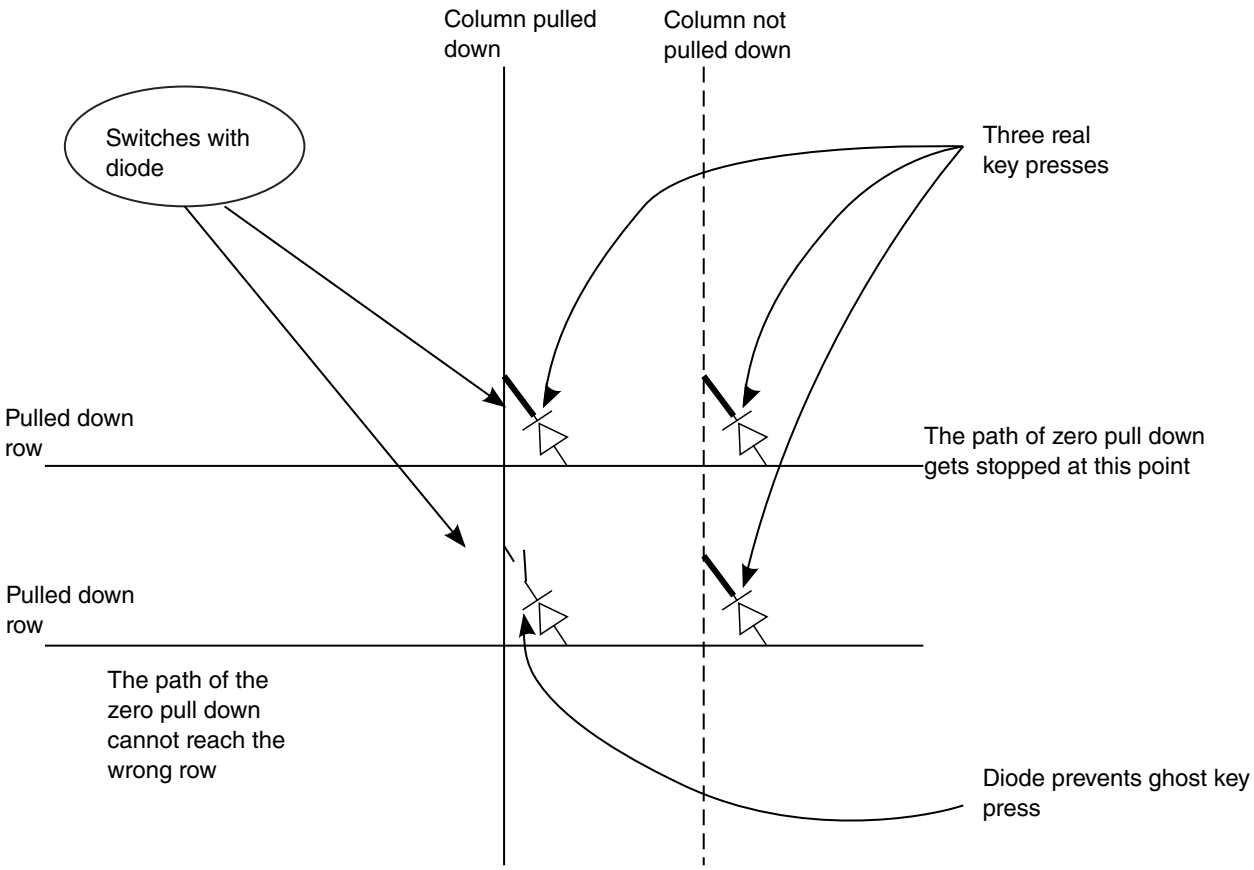

Figure 68-6. Matrix with "Ghost" Key Protections

68.3.8 3-Point Contact Keys Support

The KPP supports interfacing to a matrix consisting of 3-point contact keys. As shown in Figure 68-7, two points of such a key are connected to keypad lines, while a third point is connected to ground (low logic).

The keypad lines should be configured as input and a pull-up should to be present on these lines. When such a key is pressed, corresponding keypad lines go low and an interrupt is generated. There is no need to perform a scanning routine for identification of pressed key as it can be done by reading the keypad data-register. A limitation with such a matrix is that for every key at least one keypad row line should be used.

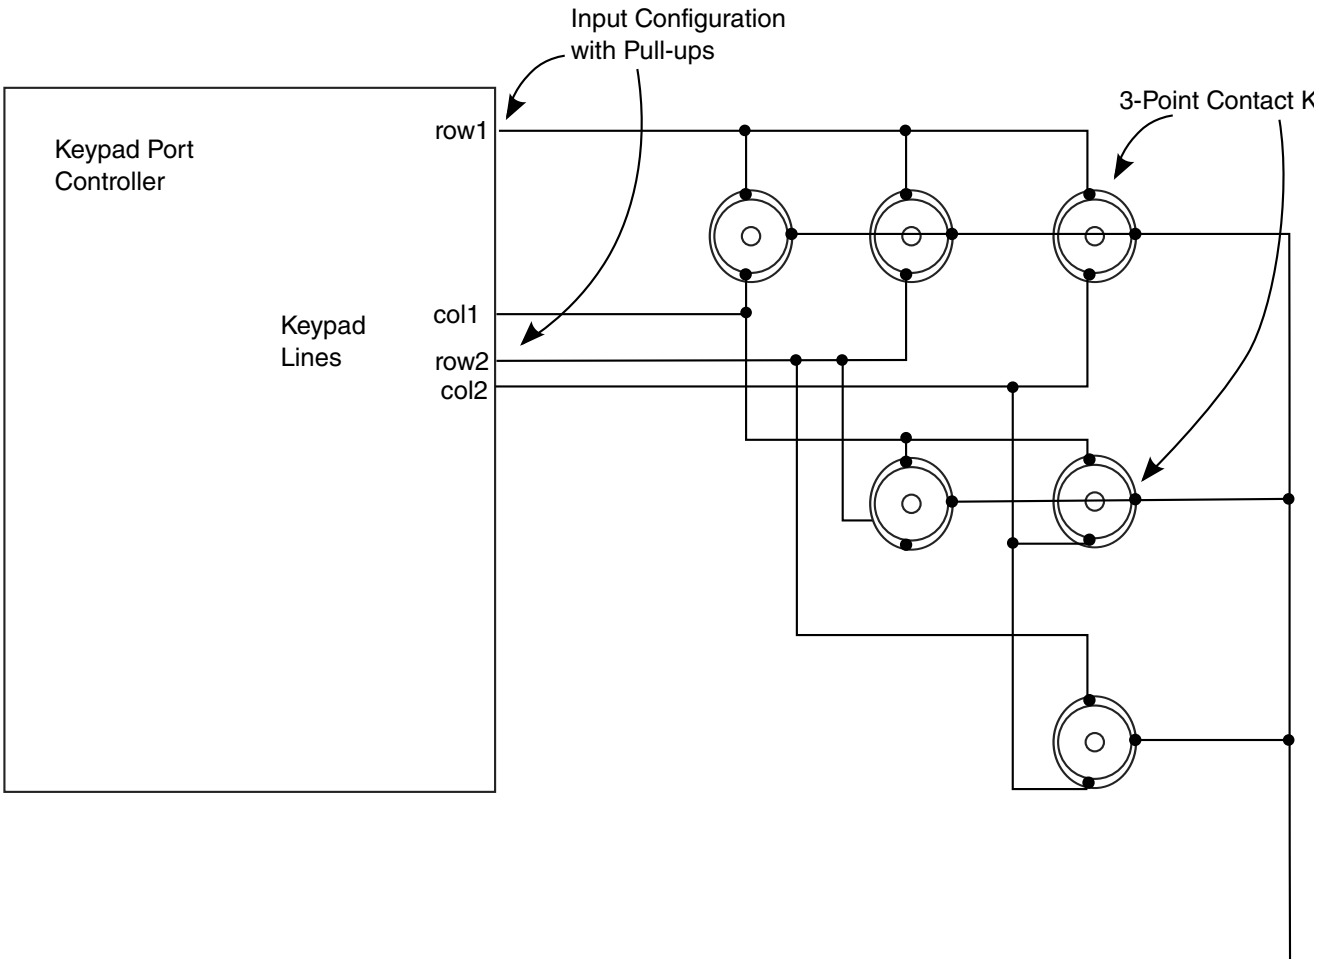

Figure 68-7. KPP Interface with 3-point Contact Key Matrix (Simplified View)

68.3.9 Clocks

The table found here describes the clock sources for KPP. Please see clock control block for clock setting, configuration and gating information.

Table 68-2. KPP Clocks

Clock name	Description
ipg_clk_32k	Low-frequency reference clock (32 kHz)
ipg_clk_s	Peripheral access clock

68.4 External Signals

There are several pins dedicated to the KPP. Keypads of any configuration up to eight rows and eight columns are supported through the software configuration of the peripheral pins. Any pins not used for the keypad are available as general purpose I/O. The registers are configured such that the pins can be treated as an I/O port up to 16 bits wide. Please see IOMUX Controller for KPP pin mux assignments.

See the table below for the list of external signals.

Table 68-3. KPP External Signals

Name	Direction	Function	Reset State	Pull-Up
KEY_COL[7:0]	IO	Column input or output pin, from chip	0	Active[1]
KEY_ROW[7:0]	IO	Row input or output pin, from chip	1	Active[1]

1. The corresponding pads are required to be pull-up enabled.

68.4.1 Input Pins

Any of the 16 pins associated with the KPP can be configured as inputs by writing a "0" to the appropriate bits in the KPP_KDDR. Additionally, the least significant 8 bits (ROW inputs) corresponding to KPP_KDDR[KRDD] have internal pull-ups, which are enabled when the pin is used as an input.

68.4.2 Output Pins

Any of the 16 pins associated with the KPP can be configured as outputs by writing the appropriate bits in the KPP_KDDR to a "1". Additionally, the 8 most significant bits (15-8) can be designated as open drain outputs by writing a "1" to the appropriate bits in the KPP_KPCR. The lower 8 bits (7-0) are always in "totem pole" style, driven when configured as outputs.

See the table below.

Table 68-4. Keypad Port Column Modes

KPP_KDDR (15:8)	KPP_KPCR (15:8)	Pin Function
0	x	Input
1	0	Totem-Pole Output
1	1	Open-Drain Output

NOTE

Totem pole configuration helps for a faster discharge of keypad capacitance when all columns need to be quickly brought to a "1" during the scan routine. With this configuration, delay between the scanning of two subsequent columns is reduced. Totem pole mode is to be used temporarily on the column pins to discharge the lines only, but should be switched to open-drain mode for normal operation.

68.4.3 Generation of Transfer Error Signal on Peripheral Bus

If there is an access to an address which is not implemented, then the KPP asserts a transfer error signal on Peripheral Bus.

68.5 Initialization/Application Information

68.5.1 Typical Keypad Configuration and Scanning Sequence

Perform the following steps to configure the keypad:

1. Enable the number of rows in the keypad (KPP_KPCR[KRE]).
2. Write 0s to KPP_KPDR[KCD].
3. Configure the keypad columns as open-drain (KPP_KPCR[KCO]).
4. Configure columns as output (KPP_KDDR[KCDD]) and rows as input (KPP_KDDR[KRDD]).
5. Clear the KPKD Status Flag and Synchronizer chain.
6. Set the KDIE control bit, and clear the KRIE control bit (avoid false release events).
7. (The system is now in standby mode, and awaiting a key press.)

68.5.2 Key Press Interrupt Scanning Sequence

Perform the following steps to perform a keypad scanning routine:

1. Disable both (depress and release) keypad interrupts.
2. Write 1s to KPP_KPDR[KCD], setting column data to 1s.
3. Configure columns as totem pole outputs (for quick discharging of keypad capacitance).

4. Configure columns as open-drain.
5. Write a single column to 0, and other columns to 1.
6. Sample row inputs and save data. Multiple key presses can be detected on a single column.
7. Repeat Steps 2-6 for remaining columns.
8. Return all columns to 0 in preparation for standby mode.
9. Clear KPKD and KPKR status bit(s) by writing to a "1"; set the KPKR synchronizer chain by writing a "1" to the KPP_KRSS register; and clear the KPKD synchronizer chain by writing a "1" to the KDSC register.
10. Re-enable the appropriate keypad interrupt(s) so that the KDIE detects a key hold condition, or the KRIE detects a key-release event.

68.5.3 Additional Comments

The order of key press detection can be done in software only. Therefore, the software may need to run the scan routines at very short intervals of time per the application's demands. The reason that such functionality cannot be put in the KPP is that the block is limited by the number of external pins.

For the keys that require a very precise order (such as game keys), individual GPIO pins may be more useful.

68.6 Memory Map and Register Definition

68.6.1 KPP register descriptions

The KPP contains four registers.

68.6.1.1 KPP memory map

KPP base address: 400E_0000h

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)
0	Keypad Control Register (KPCR)	16	RW	0000
2	Keypad Status Register (KPSR)	16	RW	0400
4	Keypad Data Direction Register (KDDR)	16	RW	0000
6	Keypad Data Register (KPDR)	16	RW	0000

68.6.1.2 Keypad Control Register (KPCR)

The Keypad Control Register determines which of the eight possible column strobes are to be open drain when configured as outputs, and which of the eight row sense lines are considered in generating an interrupt to the core.

It is up to the programmer to ensure that pins being used for functions other than the keypad are properly disabled. The KPP_KPCR register is byte- or half-word-addressable.

68.6.1.2.1 Offset

Register	Offset
KPCR	0h

68.6.1.2.2 Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

68.6.1.2.3 Fields

Field	Description
15-8 KCO	KCO Keypad Column Strobe Open-Drain Enable. Setting a column open-drain enable bit (KCO7-KCO0) disables the pull-up driver on that pin. Clearing the bit allows the pin to drive to the high state. This bit has no effect when the pin is configured as an input. **NOTE:** Configuration of external port control logic (for example, IOMUX) should be done properly so that the KPP controls an open-drain enable of the pin.

Table continues on the next page...

Field	Description
	00000000 - Column strobe output is totem pole drive. 00000001 - Column strobe output is open drain.
7-0 KRE	KRE Keypad Row Enable. Setting a row enable control bit in this register enables the corresponding row line to participate in interrupt generation. Likewise, clearing a bit disables that row from being used to generate an interrupt. This register is cleared by a reset, disabling all rows. The row-enable logic is independent of the programmed direction of the pin. Writing a "0" to the data register of the pins configured as outputs will cause a keypad interrupt to be generated if the row enable associated with that bit is set. 00000000 - Row is not included in the keypad key press detect. 00000001 - Row is included in the keypad key press detect.

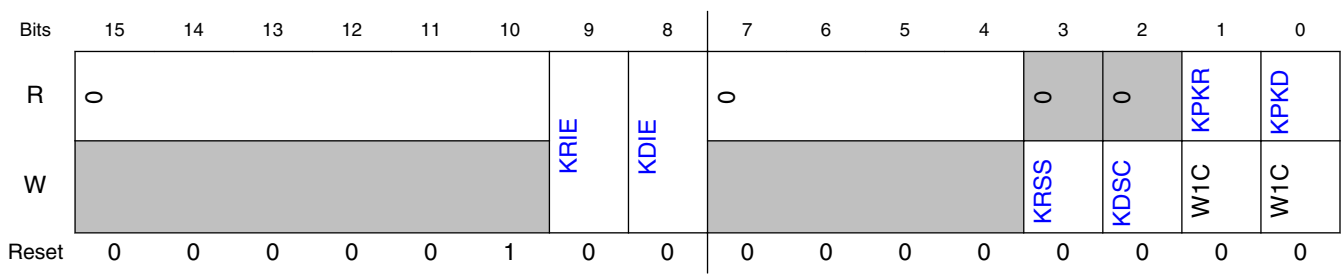
68.6.1.3 Keypad Status Register (KPSR)

The Keypad Status Register reflects the state of the key press detect circuit. The KPP_KPSR register is byte- or half-word-addressable.

68.6.1.3.1 Offset

Register	Offset
KPSR	2h

68.6.1.3.2 Diagram



68.6.1.3.3 Fields

Field	Description
15-10	-

Table continues on the next page...

Field	Description
—	Reserved
9 KRIE	KRIE Keypad Release Interrupt Enable. The software should ensure that the interrupt for a Key Release event is masked until it has entered the key pressed state, and vice versa, unless this activity is desired (as might be the case when a repeated interrupt is to be generated). The synchronizer chains are capable of being initialized to detect repeated key presses or releases. If they are not initialized when the corresponding event flag is cleared, false interrupts may be generated for depress (or release) events shorter than the length of the corresponding chain. 0 - No interrupt request is generated when KPKR is set. 1 - An interrupt request is generated when KPKR is set.
8 KDIE	KDIE Keypad Key Depress Interrupt Enable. Software should ensure that the interrupt for a Key Release event is masked until it has entered the key pressed state, and vice-versa, unless this activity is desired (as might be the case when a repeated interrupt is to be generated). The synchronizer chains are capable of being initialized to detect repeated key presses or releases. If they are not initialized when the corresponding event flag is cleared, false interrupts may be generated for depress (or release) events shorter than the length of the corresponding chain. 0 - No interrupt request is generated when KPKD is set. 1 - An interrupt request is generated when KPKD is set.
7-4 —	- Reserved, should be cleared
3 KRSS	KRSS Key Release Synchronizer Set. Self-clear bit. The Key release synchronizer is set by writing a logic one into this bit. Reads return a value of "0". 0 - No effect 1 - Set bits which sets keypad release synchronizer chain
2 KDSC	KDSC Key Depress Synchronizer Clear. Self-clear bit. The Key depress synchronizer is cleared by writing a logic "1" into this bit. Reads return a value of "0". 0 - No effect 1 - Set bits that clear the keypad depress synchronizer chain
1 KPKR	KPKR Keypad Key Release. The keypad key release (KPKR) status bit is set when all enabled rows are detected high after synchronization (the KPKR status bit will be set when cleared by a reset). The KPKR bit may be used to generate a maskable key release interrupt. The key release synchronizer may be set high by software after scanning the keypad to ensure a known state. Due to the logic function of the release and depress synchronizer chains, it is possible to see the re-assertion of a status flag (KPKD or KPKR) if it is cleared by software prior to the system exiting the state it represents. Reset value of register is "0" as long as reset is asserted. However when reset is de-asserted, the value of the register depends upon the external row pins and can become "1". 0 - No key release detected 1 - All keys have been released
0	KPKD

Field	Description
KPKD	Keypad Key Depress. The keypad key depress (KPKD) status bit is set when one or more enabled rows are detected low after synchronization. The KPKD status bit remains set until cleared by the software. The KPKD bit may be used to generate a maskable key depress interrupt. If desired, the software may clear the key press synchronizer chain to allow a repeated interrupt to be generated while a key remains pressed. In this case, a new interrupt will be generated after the synchronizer delay (4 cycles of the low frequency reference clock (ipg_clk_32k) elapses if a key remains pressed. This functionality can be used to detect a long key press. This allows detection of additional key presses of the same key or other keys. Due to the logic function of the release and depress synchronizer chains, it is possible to see the re-assertion of a status flag (KPKD or KPKR) if it is cleared by the software prior to the system exiting the state it represents. 0 - No key presses detected 1 - A key has been depressed

68.6.1.4 Keypad Data Direction Register (KDDR)

The bits in the KPP_KDDR control the direction of the keypad port pins. The upper eight bits in the register affect the pins designated as column strobes, while the lower eight bits affect the row sense pins. Setting any bit in this register configures the corresponding pin as an output. Clearing any bit in this register configures the corresponding port pin as an input. For the Keypad Row DDR, an internal pull-up is enabled if the corresponding bit is clear. This register is cleared by a reset, configuring all pins as inputs. The KPP_KDDR register is byte- or half-word addressable.

NOTE

When a pin is used as row pin for keypad purposes, all corresponding pull-ups should be enabled at the upper level (for example, IOMUX) when the bit in KRDD is cleared.

68.6.1.4.1 Offset

Register	Offset
KDDR	4h

68.6.1.4.2 Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

68.6.1.4.3 Fields

Field	Description
15-8 KCDD	KCDD Keypad Column Data Direction Register. Setting a bit configures the corresponding COL*n* pin as an output (where *n* = 7 through 0). 00000000 - COLn pin is configured as an input. 00000001 - COLn pin is configured as an output.
7-0 KRDD	KRDD Keypad Row Data Direction. Setting a bit configures the corresponding ROW*n* pin as an output (where *n* = 7 through 0). 00000000 - ROWn pin configured as an input. 00000001 - ROWn pin configured as an output.

68.6.1.5 Keypad Data Register (KPDR)

This 16-bit register is used to access the column and row data. Data written to this register is stored in an internal latch, and for each pin configured as an output, the stored data is driven onto the pin. A read of this register returns the value on the pin for those bits configured as inputs. Otherwise, the value read is the value stored in the register.

The KPP_KPDR register is byte- or half-word addressable. This register is not initialized by a reset. Valid data should be written to this register before any bits are configured as outputs.

68.6.1.5.1 Offset

Register	Offset
KPDR	6h

Chapter 69
Low Power Inter-Integrated Circuit (LPI2C)

69.1 Chip-specific LPI2C information

Table 69-1. Reference links to related information

Topic	Related module(s)	Reference
System memory map	-	System Memory Map
Clocking	CCM	Clock Management Clock Control Module (CCM)
Power management	PMU	Power Management Power Management Unit
Signal multiplexing	IOMUX	External Signals and Pin Multiplexing IOMUX
Interrupts, DMA Events and XBAR Assignments	-	Interrupts, DMA Events and XBAR Assignments

NOTE

For LPI2C on this device, only LPI2C1 fully supports the 5 wires, while other instances (LPI2C2, ...) have only 2 wires.

69.2 Overview

The LPI2C is a low power Inter-Integrated Circuit (I2C) module that supports an efficient interface to an I^2C bus as a master and/or as a slave.

- Implements logic support for standard-mode, fast-mode, fast-mode plus and ultra-fast modes of operation.
- Uses little CPU overhead, with DMA offloading of FIFO register accesses.
- Continues operating in stop modes if an appropriate clock is available.

The LPI2C module also complies with the System Management Bus (SMBus) Specification, version 3. The SMBus is a single-ended simple two-wire bus, which is typically used for low bandwidth communications.

NOTE

The I^2C (Inter-Integrated Circuit) serial bus is multi-master, multi-slave, packet-switched, and single-ended, and is often used to attach microcontroller ICs to lower-speed peripheral ICs.

69.2.1 Block diagram

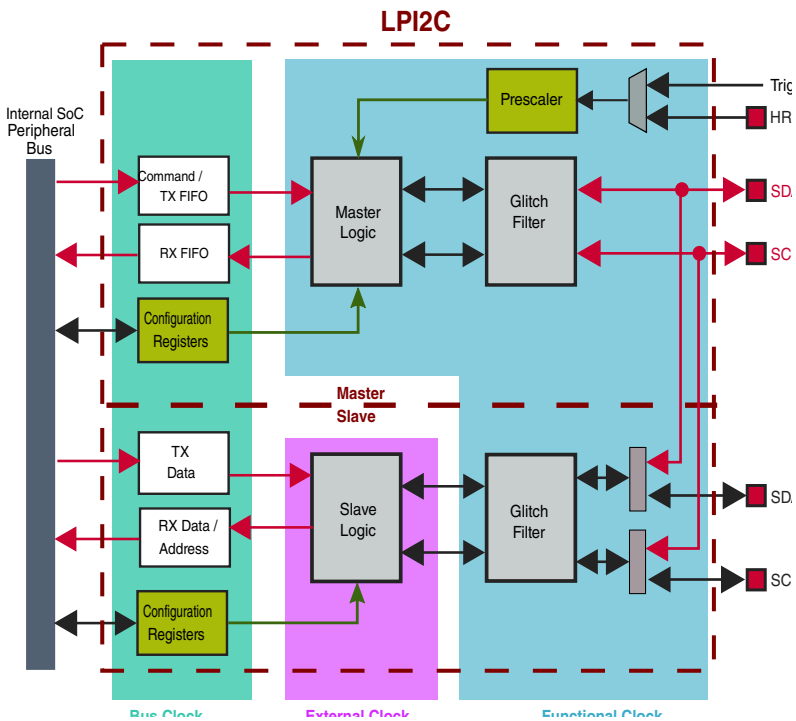

Figure 69-1. LPI2C block diagram

69.2.2 Features

The LPI2C supports:

- Standard, Fast, Fast+ and Ultra Fast modes are supported
- High speed mode (HS) in slave mode
- Multi-master support, including synchronization and arbitration. Multi-master means any number of master nodes can be present. Additionally, master and slave roles may be changed between messages (after a STOP is sent).

- Clock stretching: Sometimes multiple I2C nodes may be driving the lines at the same time. If any I2C node is driving a line low, then that line will be low. I2C nodes that are starting to transmit a logical one (by letting the line float high) can detect that the line is low, and thereby know that another I2C node is active at the same time.
  - When node detection is used on the SCL line, it is called *clock stretching*, and clock stretching is used as a I2C flow control mechanism for multiple slaves.
  - When node detection is used on the SDA line, it is called *arbitration*, and arbitration ensures that there is only one I2C node transmitter at a time.
- General call, 7-bit and 10-bit addressing
- Software reset, START byte and Device ID (also require software support)

The LPI2C master supports:

- Command/transmit FIFO of 4words (8-bit transmit data + 3-bit command).
- Receive FIFO of 4words (8-bit receive data).
- Command FIFO will wait for idle I2C bus before initiating transfer
- Command FIFO can initiate (repeated) START and STOP conditions and one or more master-receiver transfers
- STOP condition can be generated from command FIFO, or generated automatically when the transmit FIFO is empty
- Host request input to control the start time of an I2C bus transfer
- Flexible receive data match can generate interrupt on data match and/or discard unwanted data
- Flag and optional interrupt to signal Repeated START condition, STOP condition, loss of arbitration, unexpected NACK, and command word errors
- Supports configurable bus idle timeout and pin-stuck-low timeout

The LPI2C slave supports:

- Separate I2C slave registers to minimize software overhead because of master/slave switching
- Support for 7-bit or 10-bit addressing, address range, SMBus alert and general call address
- Transmit data register that supports interrupt or DMA requests
- Receive data register that supports interrupt or DMA requests
- Software-controllable ACK or NACK, with optional clock stretching on ACK/NACK bit
- Configurable clock stretching, to avoid transmit FIFO underrun and receive FIFO overrun errors
- Flag and optional interrupt at end of packet, STOP condition, or bit error detection

69.3 Functional description

69.3.1 Master Mode

The LPI2C master logic operates independently from the slave logic to perform all master mode transfers on the I2C bus.

69.3.1.1 Transmit and Command FIFO commands

The transmit FIFO stores command data to initiate the various I2C operations. The following operations can be initiated through commands in the transmit FIFO:

- START or Repeated START condition with address byte and expecting ACK or NACK.
- Transmit data (this is the default for zero extended byte writes to the transmit FIFO).
- Receive 1-256 bytes of data (can also be configured to discard receive data and not store in receive FIFO).
- STOP condition (can also be configured to send STOP condition when transmit FIFO is empty).

Multiple transmit and receive commands can be inserted between the START condition and STOP conditon; transmit and receive commands must not be interleaved (to comply with the I2C specification). The receive data command and the receive data and discard commands can be interleaved, to ensure that only the desired received data is stored in the receive FIFO (or compared with the data match logic).

The LPI2C master automatically transmits a NACK on the last byte of a receive data command unless the next command in the FIFO is also a receive data command. A NACK is also automatically transmitted if the transmit FIFO is empty when a receive data command completes.

The LPI2C master supports 10-bit addressing through a (repeated) START condition, followed by a transmit data byte containing the second address byte, followed by any number of data bytes with the master-transmit data.

A START or Repeated START condition that is expecting a NACK (for example,HS-mode master code) must be followed by a STOP or (repeated) START condition.

69.3.1.2 Master operations

Whenever the LPI2C is enabled, it monitors the I2C bus to detect when the I2C bus is idle (MSR[BBF]). The I2C bus is no longer considered idle if either SCL or SDA are low, and the I2C bus becomes idle if a STOP condition is detected or if a bus idle timeout is detected (as configured by MCFGR2[BUSIDLE]). After the I2C bus is idle, the transmit FIFO is not empty, and the host request is either asserted or disabled, then the LPI2C master initiates a transfer on the I2C bus. This involves the following steps:

- Wait the bus idle time equal to (MCCR0[CLKLO] + 1) multiplied by the prescaler (MCFGR1[PRESCALE]).
- Transmit a START condition and address byte using the timing configuration in Master Clock Configuration 0 (MCCR0); if a high speed mode transfer is configured, then the timing configuration from Master Clock Configuration 1 (MCCR1) is used instead.
- Perform master-transmit or master-receive transfers, as configured by the transmit FIFO.
- Transmit NACK on the last byte of a master-receive transfer, unless the next command in the transmit FIFO is also a receive data command and the transmit FIFO is not empty.
- Transmit a Repeated START or STOP condition as configured by the transmit FIFO and/or MCFGR1[AUTOSTOP]. A repeated START can change which timing configuration register is used.

When the LPI2C master is disabled (either due to MCR[MEN] being clear or automatically due to mode entry), the LPI2C continues to empty the transmit FIFO until a STOP condition is transmitted. However, the LPI2C will no longer stall the I2C bus waiting for the transmit or receive FIFO, and after the transmit FIFO is empty, the LPI2C generates a STOP condition automatically.

The LPI2C master can stall the I2C bus under certain conditions; this results in SCL pulled low continuously on the first bit of a byte, until the condition is removed:

- LPI2C master is enabled and busy, the transmit FIFO is empty, and MCFGR1[AUTOSTOP] is clear.
- LPI2C master is enabled and receiving data, receive data is not being discarded (due to command or receive data match), and the receive FIFO is full.

69.3.1.3 Receive FIFO and Data Matching

The receive FIFO is used to store receive data during master-receiver transfers. Receive data can also be configured to discard receive data instead of storing in the receive FIFO; this is configured by the command word in the transmit FIFO.

Receive data supports a receive data match function that can match received data against one of two bytes or against a masked data byte. The data match function can also be configured to compare only the first one or two received data words since the last (repeated) START condition. Receive data that is already discarded due to the command word cannot cause the data match to set, and delaya the match on the first received data word until after the discarded data is received. The receiver match function can also be configured to discard all receive data until a data match is detected, using the MCFGR0[RDMO] control bit. When clearing the MCFGR0[RDMO] control bit following a data match, clear MCFGR0[RDMO] before clearing MSR[DMF], to allow all subsequent data to be received.

69.3.1.4 Timing Parameters

The following timing parameters can be configured by the LPI2C master. Parameters are configured separately for high speed mode (Master Clock Configuration 1 (MCCR1)) and other modes (Master Clock Configuration 0 (MCCR0)). This allows the high speed mode master code to be sent using the regular timing parameters, and then switch to the high speed mode timing (following a repeated START) until the next STOP condition.

The LPI2C master timing parameters in LPI2C functional clock cycles are configured as follows. They must be configured to meet the I2C timing specification for the required mode.

Table 69-2. Timing Parameters

I2C Specification Timing Parameter	I2C Specification Timing Symbol	LPI2C Timing Parameter (LPI2C functional clock cycles)
SCL clock period	tSCL	(CLKHI + CLKLO + 2 + SCL_LATENCY) x (2 ^ PRESCALE)
hold time (repeated) START condition	tHD:STA	(SETHOLD +1) x (2 ^ PRESCALE)
LOW period of the SCL clock	tLOW	(CLKLO + 1) x (2 ^ PRESCALE)
HIGH period of the SCL clock	tHIGH	(CLKHI + 1 + SCL_LATENCY) x (2 ^ PRESCALE)
setup time for a repeated START condition or STOP condition	tSU:STA, tSU:STO	(SETHOLD + 1 + SCL_LATENCY) x (2 ^ PRESCALE)
data hold time	tHD:DAT	(DATAVD + 1) x (2 ^ PRESCALE)
data setup time	tSU:DAT	(SDA_LATENCY + 1) x (2 ^ PRESCALE)

Table continues on the next page...

Table 69-2. Timing Parameters (continued)

I2C Specification Timing Parameter	I2C Specification Timing Symbol	LPI2C Timing Parameter (LPI2C functional clock cycles)
bus free time between a STOP and START condition	tBUF	(CLKLO + 1 + SDA_LATENCY) x (2 ^ PRESCALE)
data valid time, data valid acknowledge time	tVD:DAT, tVD:ACK	(DATAVD + 1) x (2 ^ PRESCALE)

The latency parameters are defined in the following table, these parameters assume the risetime is less than one LPI2C functional clock cycle. The risetime depends on a number of factors, including the I/O propagation delay, the I2C bus loading and the external pull-up resistor sizing. A larger rise time increasea the number of cycles that the signal takes to propagate through the synchronizer (and glitch filter), which increases the latency.

Table 69-3. Synchronization Latency

Timing Parameter	Timing Definition
SCL_LATENCY	ROUNDDOWN ((2 + FILTSCL + SCL_RISETIME) / (2 ^ PRESCALE))
SDA_LATENCY	ROUNDDOWN ((2 + FILTSDA + SDA_RISETIME) / (2 ^ PRESCALE))

The following timing restrictions must be enforced to avoid unexpected START or STOP conditions on the I2C bus, or to avoid unexpected START or STOP conditions detected by the LPI2C master. The timing restrictions can be summarized as **SDA cannot change when SCL is high outside of a transmitted (repeated) START or STOP condition**.

Table 69-4. LPI2C Timing Parameter Restrictions

Timing Parameter	Minimum	Maximum	Comment
CLKLO	0x03	-	Also: CLKLO x (2 ^ PRESCALE) > SCL_LATENCY
CLKHI	0x01	-	Configure CLKHI to meet the duty cycle requirements in the I2C specification
SETHOLD	0x02	-	Also: SETHOLD x (2 ^ PRESCALE) > SDA_LATENCY
DATAVD	0x01	CLKLO - SDA_LATENCY - 1	Configure DATAVD to meet the data hold requirement in the I2C specification
FILTSCL	0x00	[CLKLO x (2 ^ PRESCALE)] - 3	FILTSCL and FILTSDA are the only parameters not multiplied by (2 ^ PRESCALE)
FILTSDA	FILTSCL	[CLKLO x (2 ^ PRESCALE)] - 3	Configuring FILTSDA greater than FILTSCL can delay the SDA input to compensate for board level skew
BUSIDLE	(CLKLO+SETHOLD+2) x 2	-	Must also be greater than (CLKHI+1)

The timing parameters must be configured to meet the requirements of the I2C specification; this depends on the mode being supported and the LPI2C functional clock frequency. When switching between two modes using the different clock configuration registers (for example, Fast and HS-mode), the PRESCALE factor must remain constant between the modes. Some example timing configurations are provided below.

Table 69-5. LPI2C Example Timing Configurations

I2C Mode	Clock Frequency	Baud Rate	PRESCALE	FILTSCL / FILTSDA	SETHOLD	CLKLO	CLKHI	DATAVD
Fast	8 MHz	400 kbps	0x0	0x0/0x0	0x04	0x0B	0x05	0x02
Fast+	8 MHz	1 Mbps	0x0	0x0/0x0	0x02	0x03	0x01	0x01
Fast	48 MHz	400 kbps	0x0	0x1/0x1	0x1D	0x3E	0x35	0x0F
Fast	48 MHz	400 kbps	0x2	0x1/0x1	0x07	0x11	0x0B	0x03
Fast+	48 MHz	1 Mbps	0x2	0x1/0x1	0x03	0x06	0x04	0x04
HS-mode	48 MHz	3.2 Mbps	0x0	0x0/0x0	0x07	0x08	0x03	0x01
Fast	60 MHz	400 kbps	0x1	0x2/0x2	0x11	0x28	0x1F	0x08
Fast+	60 MHz	1 Mbps	0x1	0x2/0x2	0x07	0x0F	0x0B	0x01
HS-mode	60 MHz	3.33 Mbps	0x1	0x0/0x0	0x04	0x04	0x02	0x01

69.3.1.5 Error Conditions

The LPI2C master monitors for errors while it is active, the following conditions generates an error flag and block a new START condition from being sent, until the flag is cleared by software:

- A START or STOP condition is detected and is not generated by the LPI2C master (sets MSR[ALF]).
- Transmitting data on SDA and different values are being received (sets MSR[ALF]).
- NACK is detected when transmitting data, and MCFGR1[IGNACK] is clear (sets MSR[NDF]).
- NACK is detected and is expecting ACK for the address byte, and MCFGR1[IGNACK] is clear (sets MSR[NDF]).
- ACK is detected and is expecting NACK for the address byte, and MCFGR1[IGNACK] is clear (sets MSR[NDF]).
- Transmit FIFO is requesting to transmit or receive data without a START condition (sets MSR[FEF]).
- SCL (or SDA if MCFGR1[TIMECFG] is set) is low for (MCFGR2[TIMELOW] * 256) prescaler cycles without a pin transition (sets MSR[PLTF]).

Software must respond to the MSR[PLTF] flag to terminate the existing command either cleanly (by clearing MCR[MEN]), or abruptly (by setting MCR[RST]).

The MCFGR2[BUSIDLE] field can be used to force the I2C bus to be considered idle when SCL and SDA remain high for (BUSIDLE+1) prescaler cycles. The I2C bus is normally considered idle when the LPI2C master is first enabled, but when BUSIDLE is configured greater than zero then SCL and/or SDA must be high for (BUSIDLE+1) prescaler cycles before the I2C bus is first considered idle.

69.3.1.6 Pin Configuration

- **Open-drain support:** The LPI2C master defaults to open-drain configuration of the SDA and SCL pins. Support for true open drain depends on the specific device, and requires the pins where LPI2C pins are muxed to support true open drain.
- **High Speed mode support:** Support for high speed mode also depends on the specific device, and requires the SCL pin to support the current source pull-up required in the I2C specification.
- **Ultra-Fast mode support:** The LPI2C master also supports the output-only push-pull function required for I2C ultra-fast mode using the SDA and SCL pins. Support for ultra-fast mode also requires the MCFGR1[IGNACK] bit to be set.
- **Push-pull 2-wire support:** A push-pull 2-wire configuration is also available to the LPI2C master that may support a partial high speed mode, if the LPI2C is the only master and all I2C pins on the bus are at the same voltage. This configures the SCL pin as push-pull for every clock except the 9th clock pulse, to allow high speed mode compatible slaves to perform clock stretching. In this mode, the SDA pin is tristated for master-receive data bits and master-transmit ACK/NACK bits, and is configured as push-pull at other times. To avoid the risk of contention when SDA is push-pull, the pin can be configured for open-drain operation, as part of the device-specific configuration.
- **Push-pull 4-wire support:** The push-pull 4-wire configuration separates the SCL input data and output data into separate pins, and separates the SDA input data and output data into separate pins. The SCL/SDA pins are used for input data; the SCLS/SDAS pins are used for output data, with configurable polarity. This simplifies external connections when connecting the LPI2C to the I2C bus through external level shifters or discrete components. When using this 4-wire configuration, the LPI2C master logic and LPI2C slave logic are not able to connect to separate I2C buses.

69.3.2 Slave Mode

To perform all slave mode transfers on the I2C bus, the LPI2C slave logic operates independently from the LPI2C master logic.

69.3.2.1 Address Matching

The LPI2C slave can be configured:

- To match one of two addresses, using either 7-bit or 10-bit addressing modes for each address
- To match a range of addresses in either 7-bit or 10-bit addressing modes
- To match the General Call Address, and generate appropriate flags
- To match the SMBus Alert Address, and generate appropriate flags
- To detect the high speed mode master code, and to disable the digital filters and output valid delay time until the next STOP condition is detected

After a valid address is matched, the LPI2C slave automatically performs slave-transmit or slave-receive transfers until:

- A NACK is detected (unless MCFGR1[IGNACK] is set)
- A bit error is detected (the LPI2C slave is driving SDA, but a different value is sampled)
- A (repeated) START or STOP condition is detected

69.3.2.2 Transmit and Receive Data

- The Transmit and Receive Data registers are double-buffered and only update during a slave-transmit and slave-receive transfer, respectively.
- The slave address *that was received* can be configured to be read from either the Receive Data register (for example, when using DMA to transfer data), or from the Address Status register.
- The Transmit Data register can be configured to only request data after a slave-transmit transfer is detected, or to request new data whenever the Transmit Data register is empty.
- The Transmit Data register should only be written when the Transmit Data flag is set.
- The Receive Data register should only be read when the Received Data flag is set (or the Address Valid flag is set and SCFGR1[RXCFG] = 1).
- The Address Status register should only be read when the Address Valid flag is set.

69.3.2.3 Clock Stretching

The LPI2C slave supports many configurable options for when clock stretching is performed. The following conditions can be configured to perform clock stretching:

- During the 9th clock pulse of the address byte and the Address Valid flag is set.

- During the 9th clock pulse of a slave-transmit transfer and the Transmit Data flag is set.
- During the 9th clock pulse of a slave-receive transfer and the Receive Data flag is set.
- During the 8th clock pulse of an address byte or a slave-receive transfer and the Transmit ACK flag is set. In high speed mode, this is disabled.
- Clock stretching can also be extended for CLKHOLD cycles, to allow additional setup time to sample the SDA pin externally. In high speed mode, this is disabled.

Unless extended by the CLKHOLD configuration, clock stretching extends for one peripheral bus clock cycle after SDA updates when clock stretching is enabled.

69.3.2.4 Timing Parameters

The LPI2C slave can configure the following timing parameters. These parameters are disabled when SCR[FILTEN] is clear, when SCR[FILTDZ] is set in Doze mode, and when LPI2C slave detects high speed mode. When disabled, the LPI2C slave is clocked directly from the I2C bus, and may not satisfy all timing requirements of the I2C specification (such as SDA minimum hold time in Standard/Fast mode).

- SDA data valid time from SCL negation to SDA update
- SCL hold time when clock stretching is enabled to increase setup time when sampling SDA externally
- SCL glitch filter time
- SDA glitch filter time

The LPI2C slave imposes the following restrictions on the timing parameters.

- FILTSDA must be configured to greater than or equal to FILTSCL (unless compensating for board level skew between SDA and SCL).
- DATAVD must be configured less than the minimum SCL low period.

69.3.2.5 Error Conditions

The LPI2C slave can detect the following error conditions:

- Bit error flag sets when the LPI2C slave is driving SDA, but samples a different value than what is expected.

- FIFO error flag sets due to a transmit data underrun or a receive data overrun. To eliminate the possibility of underrun and overrun occurring, enable clock stretching.
- FIFO error flag also sets due to an address overrun when SCFGR1[RXCFG] is set, otherwise an address overrun is not flagged. To eliminate the possibility of overrun occurring, enable clock stretching.

The LPI2C slave does not implement a timeout due to SCL and/or SDA being stuck low. If this detection is required, then the LPI2C master logic should be used and so software can reset the LPI2C slave when this condition is detected.

69.3.3 Modes of operation

Table 69-6. Chip modes supported by the LPI2C module

Chip mode	LPI2C Operation
Run	Normal operations
Stop	Can continue operating in stop mode if the Doze Enable bit (MCR[DOZEN]) is clear and the LPI2C is using an external or internal clock source that remains operating during stop mode.
Low Power Stop (also called Low Leakage Stop or LLS)	Before entering low power stop mode, the LPI2C will wait for the current transfer to finish any pending operation, while temporarily ignoring The Doze Enable (MCR[DOZEN]) bit.
Debug	Can continue operating in debug mode if the Debug Enable bit (MCR[DBGE]) is set.

69.3.4 Interrupts and DMA Requests

Depending on the specific device, interrupts and DMA requests can be combined in some ways:

- The LPI2C master and slave interrupts may be combined
- The LPI2C master and slave transmit DMA requests may be combined
- The LPI2C master and slave receive DMA requests may be combined

69.3.4.1 Master mode

The next table lists the master mode sources that can generate LPI2C master interrupts and LPI2C master transmit/receive DMA requests.

Table 69-7. Master Interrupts and DMA Requests

Master Status Register (MSR)		Description	Can generate		
Flag	Name		Interrupt?	DMA Request?	Low Power Wakeup?
TDF	Transmit Data Flag	Data can be written to Transmit FIFO, as configured by the Transmit FIFO Watermark MFCR[TXWATER]	Y	TX	Y
RDF	Receive Data Flag	Data can be read from the Receive FIFO, as configured by the Receive FIFO Watermark MFCR[RXWATER]	Y	RX	Y
EPF	End Packet Flag	Master has transmitted a Repeated START or STOP condition	Y	N	Y
SDF	STOP Detect Flag	Master has transmitted a STOP condition	Y	N	Y
NDF	NACK Detect Flag	• During an address byte, the master expected an ACK but detected a NACK • During an address byte, the master expected a NACK but detected an ACK • During a master-transmitter data byte, the master detected a NACK	Y	N	Y
ALF	Arbitration Lost Flag	• The master lost arbitration due to a START/STOP condition detected at the wrong time • Or the master was transmitting data but received different data than the data that was transmitted	Y	N	Y
FEF	FIFO Error Flag	The master is expecting a START condition in the Command FIFO, but the next entry in the Command FIFO is not a START condition	Y	N	Y
PLTF	Pin Low Timeout Flag	Pin low timeout is enabled and SCL (or SDA if configured) is low for longer than the configured timeout	Y	N	Y
DMF	Data Match Flag	The received data matches the configured data match, but the received data is not discarded due to a command FIFO entry	Y	N	Y
MBF	Master Busy Flag	LPI2C master is busy transmitting/receiving data	N	N	N
BBF	Bus Busy Flag	LPI2C master is enabled and activity is detected on I2C bus, but a STOP condition has not been detected and a bus idle timeout (if enabled) has not occurred.	N	N	N

69.3.4.2 Slave mode

The next table lists the slave mode sources that can generate LPI2C slave interrupts and the LPI2C slave transmit/receive DMA requests.

Table 69-8. Slave Interrupts and DMA Requests

Slave Status Register (SSR)		Description	Can generate		
Flag	Name		Interrupt?	DMA Request?	Low Power Wakeup?
TDF	Transmit Data Flag	Data can be written to the Slave Transmit Data Register (STDR)	Y	TX	Y
RDF	Receive Data Flag	Data can be read from the Slave Receive Data Register (SRDR)	Y	RX	Y
AVF	Address Valid Flag	Address can be read from the Slave Address Status Register (SASR)	Y	RX	Y
TAF	Transmit ACK Flag	ACK/NACK can be written to the Slave Transmit ACK Register (STAR)	Y	N	Y
RSF	Repeated Start Flag	Slave has detected an address match followed by a Repeated START condition	Y	N	Y
SDF	STOP Detect Flag	Slave has detected an address match followed by a STOP condition	Y	N	Y
BEF	Bit Error Flag	Slave was transmitting data, but received different data than what was transmitted	Y	N	Y
FEF	FIFO Error Flag	• Transmit data underrun • Receive data overrun • Address status overrun (when Receive Data Configuration SCFGR1[RXCFG] = 1,) FEF flag can only set when clock stretching is disabled.	Y	N	Y
AM0F	Address Match 0 Flag	Slave detected an address match with SAMR[ADDR0] field	Y	N	N
AM1F	Address Match 1 Flag	Slave detected an address match with SAMR[ADDR1] field or using an address range	Y	N	N
GCF	General Call Flag	Slave detected an address match with the General Call address	Y	N	N
SARF	SMBus Alert Response Flag	Slave detected an address match with the SMBus Alert address	Y	N	N
SBF	Slave Busy Flag	LPI2C slave is busy receiving an address byte or is transmitting/receiving data	N	N	N
BBF	Bus Busy Flag	LPI2C slave is enabled and a START condition is detected on I2C bus, but a STOP condition has not been detected	N	N	N

69.3.5 Clocking and Resets

For device-specific clocking information, refer to the Clocking chapter.

Table 69-9. Clocks

LPI2C Functional clock	The LPI2C functional clock is asynchronous to the bus clock and can remain enabled in low power modes to support I2C bus transfers by the LPI2C master. The functional clock is also used by the LPI2C slave to support digital filter and data hold time configurations. The LPI2C master divides the functional clock by a prescaler and the resulting frequency must be at least 8 times faster than the I2C bus bandwidth.
External clock	The LPI2C slave logic is clocked directly from the external pins SCL and SDA (or SCLS and SDAS if master and slave are implemented on separate pins). This allows the LPI2C slave to remain operational, even when the LPI2C functional clock is disabled. **NOTE:** The LPI2C slave digital filter must be disabled if the LPI2C functional clock is disabled, and this can affect compliance with some of the timing parameters of the I2C specification, such as the data hold time.
Bus clock	The bus clock is only used for bus accesses to the control and configuration registers. The bus clock frequency must be sufficient to support the data bandwidth requirements of the LPI2C master and slave registers.

Table 69-10. Resets

Chip reset	The logic and registers for the LPI2C master and slave are reset to their default state on a chip reset.
Software reset	• The LPI2C master implements a software reset bit in its Control Register. The MCR[RST] will reset all master logic and registers to their default state, except for the MCR itself. • The LPI2C slave implements a software reset bit in its Control Register. The SCR[RST] will reset all slave logic and registers to their default state, except for the SCR itself.
FIFO reset	• The LPI2C master implements write-only control bits that reset the transmit FIFO (MCR[RTF]) and receive FIFO (MCR[RRF]). After a FIFO is reset, that FIFO is empty. • The LPI2C slave implements write-only control bits that reset the transmit data register (SCR[RTF] and receive data register (SCR[RRF]). After a data register is reset, that data register is empty.

69.3.6 Peripheral Triggers

The connection of the LPI2C peripheral triggers to other peripherals depend upon the specific device being used.

Table 69-11. LPI2C Triggers

Trigger	Description
Master Output Trigger	The LPI2C master generates an output trigger that can be connected to other peripherals on the device. The master output trigger asserts on both a Repeated START or STOP condition, and the master output trigger remains asserted for one cycle of the LPI2C functional clock divided by the prescaler.
Slave Output Trigger	The LPI2C slave generates an output trigger that can be connected to other peripherals on the device. The slave output trigger asserts on both a Repeated START or STOP condition that occurs after a slave address match, and the slave output trigger remains asserted until the next slave SCL pin negation.

Table continues on the next page...

Table 69-11. LPI2C Triggers (continued)

Trigger	Description
Input Trigger	To control the start of a LPI2C bus transfer, the LPI2C input trigger can be selected instead of the HREQ input. The input trigger is synchronized and to be detected, the input trigger must assert for at least 2 cycles of the LPI2C functional clock divided by the PRESCALE configuration. When the LPI2C is busy, the HREQ input (and therefore the input trigger) is ignored.

69.4 Signal descriptions

Table 69-12. Signals

Signal	Name	2-Wire Scheme	4-Wire Scheme	I/O
SCL	LPI2C clock line	SCL	In 4-wire mode, this is the SCL input pin.	I/O
SDA	LPI2C data line	SDA	In 4-wire mode, this is the SDA input pin.	I/O
SCLS	Secondary I2C clock line	Not used	In 4-wire mode, this is the SCLS output pin. If LPI2C master/slave are configured to use separate pins, then this is the LPI2C slave SCL pin.	I/O
SDAS	Secondary I2C data line	Not used	In 4-wire mode, this is the SDAS output pin. If LPI2C master/slave are configured to use separate pins, then this is the LPI2C slave SDA pin.	I/O
HREQ	Host request	If host request is asserted and the I2C bus is idle, then it initiates an LPI2C master transfer. HREQ is an additional pin separate from the 2-wire or 4-wire scheme.		I

The I^2C 2-wire serial bus diagram shows the 2 signal connection.

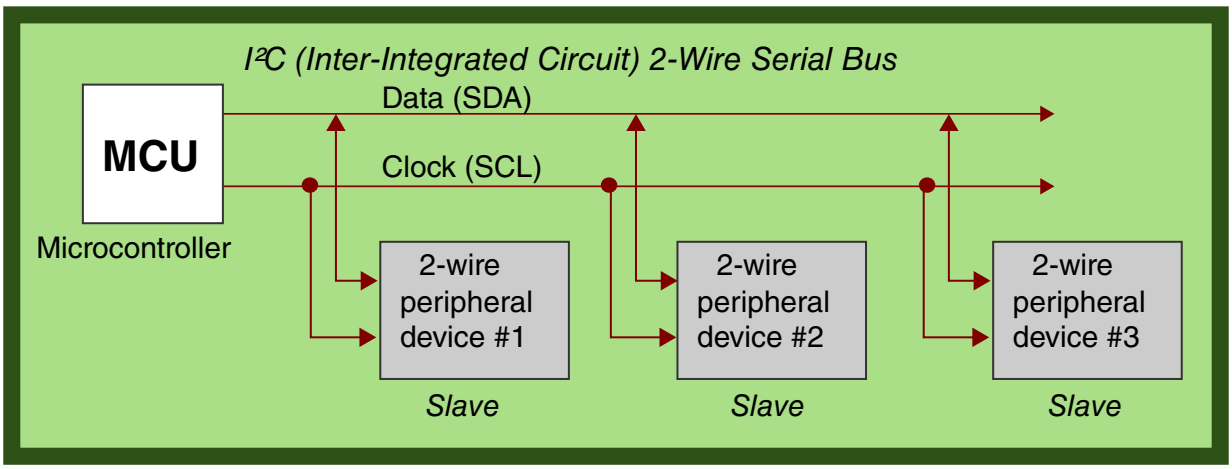

Figure 69-2. I²C 2-wire serial bus

The I²C 4-wire serial bus diagram shows a possible 4 signal connection.

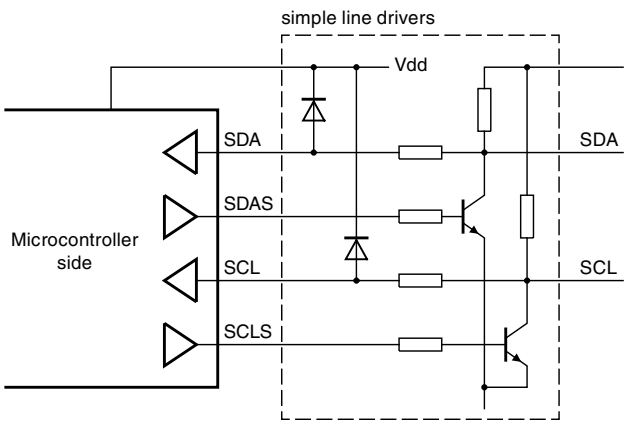

Figure 69-3. I²C 4-wire serial bus

69.5 Memory Map and Registers

NOTE

Writing a Read-Only (RO) register or reading a Write-Only (WO) register can cause bus errors. This module will not check if programmed values in the registers are correct; the application software must ensure that valid programmed values are being written.

69.5.1.3.3 Fields

Field	Description
31-16 —	Reserved
15-12 —	Reserved
11-8	Master Receive FIFO Size

Table continues on the next page...

Field	Description
MRXFIFO	Configures the number of words in the master receive FIFO to $2^{MRXFIFO}$
7-4 —	Reserved
3-0 MTXFIFO	Master Transmit FIFO Size Configures the number of words in the master transmit FIFO to $2^{MTXFIFO}$

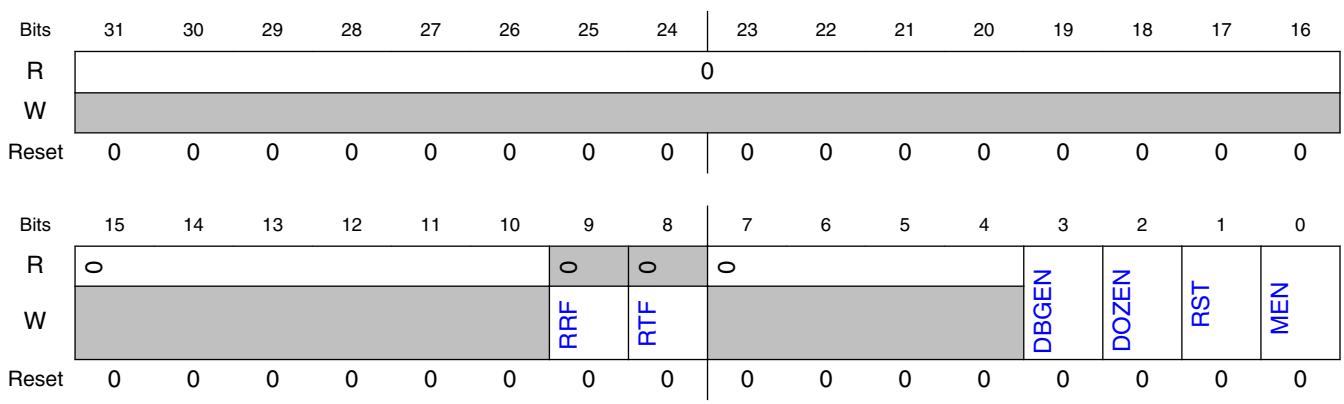
69.5.1.4 Master Control (MCR)

The MCR register contains resets, debug enable, and other master control settings.

69.5.1.4.1 Offset

Register	Offset
MCR	10h

69.5.1.4.2 Diagram



69.5.1.4.3 Fields

Field	Description
31-10 —	Reserved
9 RRF	Reset Receive FIFO Resets the Receive FIFO. 0 - No effect

Table continues on the next page...

Field	Description
	1 - Receive FIFO is reset
8 RTF	Reset Transmit FIFO Resets the Transmit FIFO. 0 - No effect 1 - Transmit FIFO is reset
7-4 —	Reserved
3 DBGEN	Debug Enable Enables the Master in Debug mode. 0 - Master is disabled in debug mode 1 - Master is enabled in debug mode
2 DOZEN	Doze mode enable Enables or disables the master in Doze mode. 0 - Master is enabled in Doze mode 1 - Master is disabled in Doze mode
1 RST	Software Reset Resets all internal master logic and registers, except the Master Control (MCR) register. RST remains set until cleared by software. The reset takes effect immediately and remains asserted until negated by software. There is no minimum delay required before clearing the software reset. 0 - Master logic is not reset 1 - Master logic is reset
0 MEN	Master Enable Enables the Master logic. 0 - Master logic is disabled 1 - Master logic is enabled

69.5.1.5 Master Status (MSR)

MSR contains status flags for transmit and receive data; Start and Stop conditions; and bus and master busy or idle status.

69.5.1.5.1 Offset

Register	Offset
MSR	14h

69.5.1.5.2 Diagram

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

69.5.1.5.3 Fields

Field	Description
31-26 —	Reserved
25 BBF	Bus Busy Flag Indicates that the I2C bus is busy. 0 - I2C Bus is idle 1 - I2C Bus is busy
24 MBF	Master Busy Flag Indicates that the I2C Master is busy. 0 - I2C Master is idle 1 - I2C Master is busy
23-16 —	Reserved
15 —	Reserved
14 DMF	Data Match Flag Indicates that the received data has matched the MDMR[MATCH0] and/or MDMR[MATCH1] fields (as configured by MCFGR1[MATCFG]. Received data *that is discarded due to CMD field* does not cause DMF to set. 0 - Have not received matching data 1 - Have received matching data
13 PLTF	Pin Low Timeout Flag Sets when the SCL and/or SDA input is low for more than PINLOW cycles (Pin Low Timeout, MCFGR3[PINLOW]), even when the LPI2C master is idle. • Software is responsible for resolving the pin low condition.

Table continues on the next page...

Field	Description
	• PLTF cannot be cleared as long as the pin low timeout continues. • Before the LPI2C can initiate a START condition, the PLTF must be cleared. 0 - Pin low timeout has not occurred or is disabled 1 - Pin low timeout has occurred
12 FEF	FIFO Error Flag Detects an attempt to send or receive data without first generating a (repeated) START condition. This can occur if the transmit FIFO underflows when MCFGR1[AUTOSTOP] = 1. When FEF is set, the LPI2C master sends a STOP condition (if busy), and does not initiate a new START condition until FEF has been cleared. 0 - No error 1 - Master sending or receiving data without a START condition
11 ALF	Arbitration Lost Flag Set if either of these conditions exist: • The LPI2C master transmits a logic one and detects a logic zero on the I2C bus • The LPI2C master detects a START or STOP condition while the LPI2C master is transmitting data When ALF sets, the LPI2C master releases the I2C bus (goes idle), and the LPI2C master does not initiate a new START condition until the ALF has been cleared. 0 - Master has not lost arbitration 1 - Master has lost arbitration
10 NDF	NACK Detect Flag Set if the LPI2C master detects a NACK it was not expecting when transmitting an address or data. When set, the master does not initiate a new START condition until NDF has been cleared. If a NACK is expected for a given address (as configured by the command word), then the NDF sets if a NACK is not generated. When NDF is set, the LPI2C master automatically transmits a STOP condition if MCFGR1[AUTOSTOP] = 1, or the transmit FIFO is not empty. 0 - Unexpected NACK was not detected 1 - Unexpected NACK was detected
9 SDF	STOP Detect Flag Set when the LPI2C master generates a STOP condition. 0 - Master has not generated a STOP condition 1 - Master has generated a STOP condition
8 EPF	End Packet Flag Set when the LPI2C master generates either a repeated START condition or a STOP condition. Does not set when the master first generates a START condition. 0 - Master has not generated a STOP or Repeated START condition 1 - Master has generated a STOP or Repeated START condition
7-2 —	Reserved
1 RDF	Receive Data Flag RDF sets whenever the number of words in the receive FIFO is greater than MFCR[RXWATER]. 0 - Receive Data is not ready

Table continues on the next page...

Field	Description
	1 - Receive data is ready
0 TDF	Transmit Data Flag TDF sets whenever the number of words in the transmit FIFO is equal or less than MFCR[TXWATER]. 0 - Transmit data is not requested 1 - Transmit data is requested

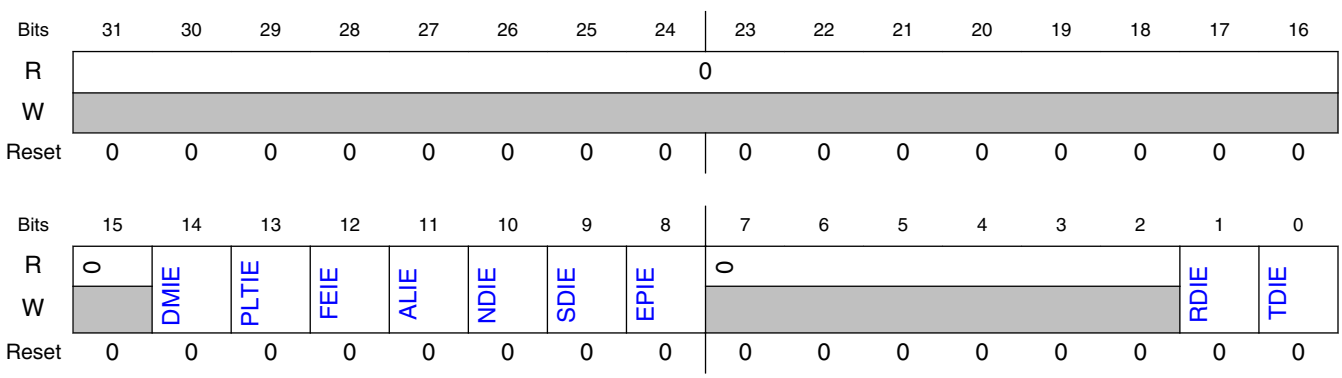
69.5.1.6 Master Interrupt Enable (MIER)

MIER contains transmit and receive data interrupt enables; Start, Stop, and Nack detect interrupt enables; and DMA interrupt enables.

69.5.1.6.1 Offset

Register	Offset
MIER	18h

69.5.1.6.2 Diagram



69.5.1.6.3 Fields

Field	Description
31-16 —	Reserved
15 —	Reserved

Table continues on the next page...

Field	Description
14 DMIE	Data Match Interrupt Enable Enables interrupt for data match. 0 - Disabled 1 - Enabled
13 PLTIE	Pin Low Timeout Interrupt Enable Enables interrupt for pin low timeout. 0 - Disabled 1 - Enabled
12 FEIE	FIFO Error Interrupt Enable Enables interrupt for FIFO error. 0 - Enabled 1 - Disabled
11 ALIE	Arbitration Lost Interrupt Enable Enables interrupt for arbitration lost. 0 - Disabled 1 - Enabled
10 NDIE	NACK Detect Interrupt Enable Enables interrupt for NACK detect. 0 - Disabled 1 - Enabled
9 SDIE	STOP Detect Interrupt Enable Enables interrupt for STOP detect. 0 - Disabled 1 - Enabled
8 EPIE	End Packet Interrupt Enable Enables interrupt for end packet. 0 - Disabled 1 - Enabled
7-2 —	Reserved
1 RDIE	Receive Data Interrupt Enable Enables interrupt for receive data. 0 - Disabled 1 - Enabled
0 TDIE	Transmit Data Interrupt Enable Enables interrupt for transmit data. 0 - Disabled 1 - Enabled

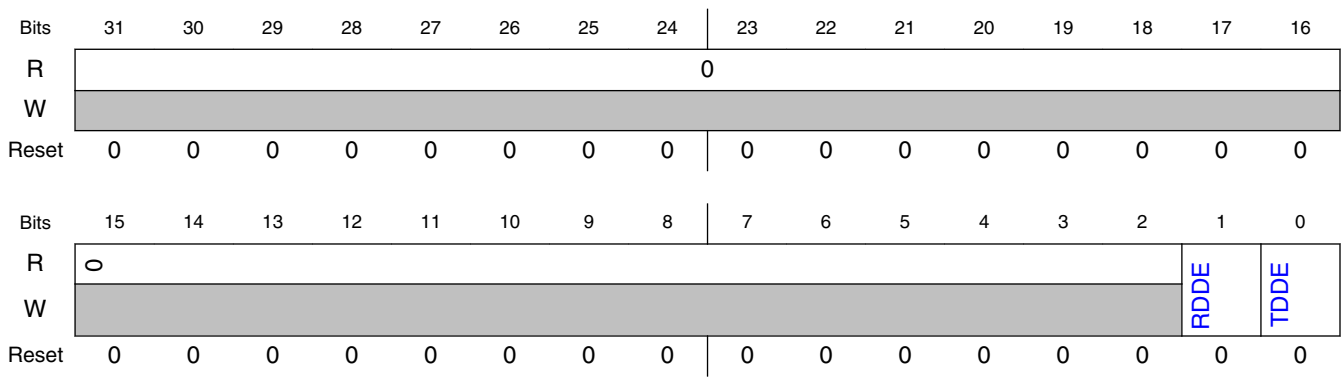
69.5.1.7 Master DMA Enable (MDER)

MDER contains DMA transmit, request, and receive enables.

69.5.1.7.1 Offset

Register	Offset
MDER	1Ch

69.5.1.7.2 Diagram



69.5.1.7.3 Fields

Field	Description
31-2 —	Reserved
1 RDDE	Receive Data DMA Enable Enables DMA receive data. 0 - DMA request is disabled 1 - DMA request is enabled
0 TDDE	Transmit Data DMA Enable Enables DMA transmit data. 0 - DMA request is disabled 1 - DMA request is enabled

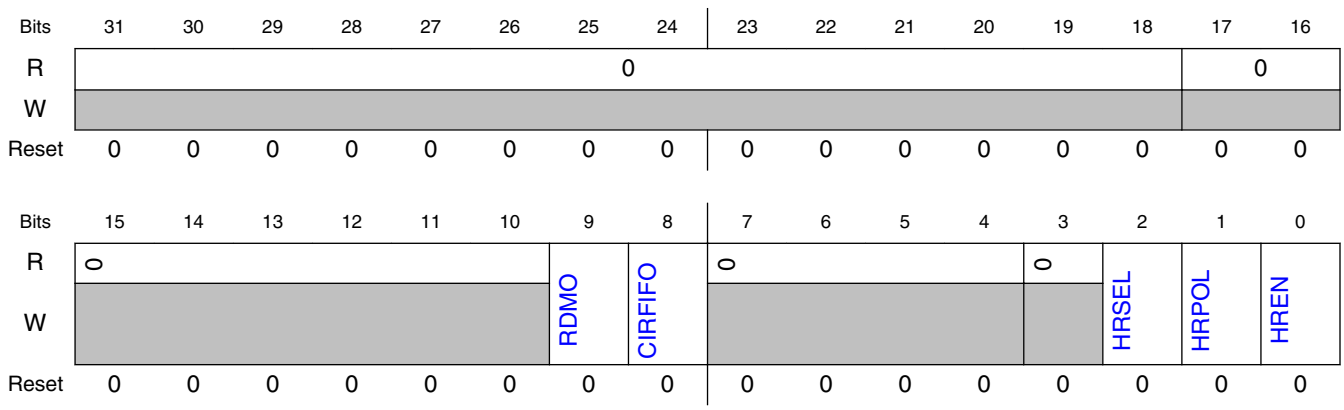
69.5.1.8 Master Configuration 0 (MCFGR0)

MCFGR0 contains host settings and other receive and transfer settings.

69.5.1.8.1 Offset

Register	Offset
MCFGR0	20h

69.5.1.8.2 Diagram



69.5.1.8.3 Fields

Field	Description
31-18 —	Reserved
17-16 —	Reserved
15-10 —	Reserved
9 RDMO	Receive Data Match Only When enabled, all received data that does not cause the Data Match Flag (MSR[DMF]) to set is discarded. After MSR[DMF] is set, the RDMO configuration is ignored. When disabling RDMO, clear RDMO before clearing MSR[DMF], to ensure that no receive data is lost. 0 - Received data is stored in the receive FIFO 1 - Received data is discarded unless the the Data Match Flag (MSR[DMF]) is set
8 CIRFIFO	Circular FIFO Enable When enabled, the transmit FIFO read pointer is saved to a temporary register. The transmit FIFO empties as normal, but after the LPI2C master is idle and the transmit FIFO is empty, then the read

Table continues on the next page...

Field	Description
	pointer value will be restored from the temporary register. This causes the contents of the transmit FIFO to be cycled through repeatedly. If MCFGR1[AUTOSTOP] is set, then a STOP condition is sent whenever the transmit FIFO is empty and the read pointer is restored. 0 - Circular FIFO is disabled 1 - Circular FIFO is enabled
7-4 —	Reserved
3 —	Reserved
2 HRSEL	Host Request Select Selects the source of the host request input. When host request is enabled, HRSEL should remain static (the Host Request Select should not change). 0 - Host request input is pin HREQ 1 - Host request input is input trigger
1 HRPOL	Host Request Polarity Configures the polarity of the host request pin. When host request is enabled, HRPOL should remain static (Host Request Polarity should not change). 0 - Active low 1 - Active high
0 HREN	Host Request Enable When enabled, the LPI2C master only initiates a START condition if the host request input is asserted and the bus is idle. A repeated START is not affected by the host request. 0 - Host request input is disabled 1 - Host request input is enabled

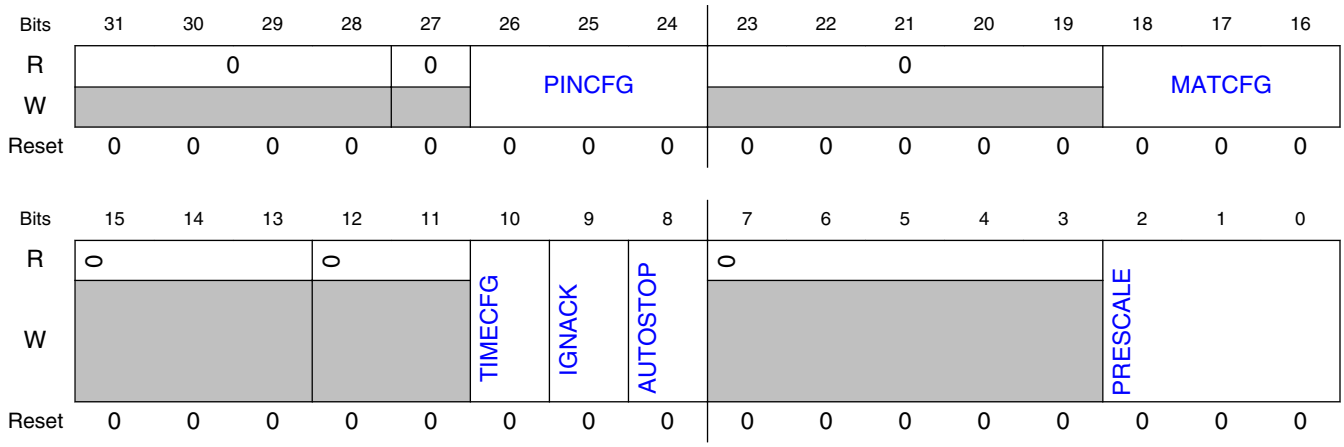
69.5.1.9 Master Configuration 1 (MCFGR1)

The MCFGR1 should only be written when the I2C Master is disabled.

69.5.1.9.1 Offset

Register	Offset
MCFGR1	24h

69.5.1.9.2 Diagram



69.5.1.9.3 Fields

Field	Description
31-28 —	Reserved
27 —	Reserved
26-24 PINCFG	Pin Configuration Configures the pin mode for LPI2C. **Table 69-13. 2-pin / 4-pin pin configurations for masters and slaves** 000 - 2-pin open drain mode 001 - 2-pin output only mode (ultra-fast mode) 010 - 2-pin push-pull mode

PINCFG	SCL / SDA pins	SCLS / SDAS pins
000	Bi-directional open drain for master and slave	Not used
001	Output-only (ultra-fast mode) open drain for master and slave	Not used
010	Bi-directional push-pull for master and slave	Not used
011	Input only for master and slave	Output-only push-pull for master and slave
100	Bi-directional open drain for master	Bi-directional open drain for slave
101	Output-only (ultra-fast mode) open drain for master	Output-only open drain for slave
110	Bi-directional push-pull for master	Bi-directional push-pull for slave
111	Input only for master and slave	Inverted output-only push-pull for master and slave

Table continues on the next page...

Field	Description
	011 - 4-pin push-pull mode 100 - 2-pin open drain mode with separate LPI2C slave 101 - 2-pin output only mode (ultra-fast mode) with separate LPI2C slave 110 - 2-pin push-pull mode with separate LPI2C slave 111 - 4-pin push-pull mode (inverted outputs)
23-19 —	Reserved
18-16 MATCFG	Match Configuration Configures the condition that causes MSR[DMF] to set. See Master Data Match (MDMR). 000 - Match is disabled 001 - Reserved 010 - Match is enabled (1st data word equals MDMR[MATCH0] OR MDMR[MATCH1]) 011 - Match is enabled (any data word equals MDMR[MATCH0] OR MDMR[MATCH1]) 100 - Match is enabled (1st data word equals MDMR[MATCH0] AND 2nd data word equals MDMR[MATCH1) 101 - Match is enabled (any data word equals MDMR[MATCH0] AND next data word equals MDMR[MATCH1) 110 - Match is enabled (1st data word AND MDMR[MATCH1] equals MDMR[MATCH0] AND MDMR[MATCH1]) 111 - Match is enabled (any data word AND MDMR[MATCH1] equals MDMR[MATCH0] AND MDMR[MATCH1])
15-13 —	Reserved
12-11 —	Reserved
10 TIMECFG	Timeout Configuration TIMECFG configures the timeout settings for the Pin Low Timeout Flag field (MSR[PLTF]). 0 - MSR[PLTF] sets if SCL is low for longer than the configured timeout 1 - MSR[PLTF] sets if either SCL or SDA is low for longer than the configured timeout
9 IGNACK	IGNACK When set, the received NACK field is ignored and assumed to be ACK. IGNACK bit is required to be set in Ultra-Fast Mode. 0 - LPI2C Master receives ACK and NACK normally 1 - LPI2C Master treats a received NACK as if it (NACK) was an ACK
8 AUTOSTOP	Automatic STOP Generation When enabled, a STOP condition is generated whenever the LPI2C master is busy and the transmit FIFO is empty. The STOP condition can also be generated using a transmit FIFO command. 0 - No effect 1 - STOP condition is automatically generated whenever the transmit FIFO is empty and the LPI2C master is busy
7-3	Reserved

Table continues on the next page...

Field	Description
—	
2-0 PRESCALE	Prescaler Configures the clock prescaler used for all LPI2C master logic, except for the digital glitch filters. 000 - Divide by 1 001 - Divide by 2 010 - Divide by 4 011 - Divide by 8 100 - Divide by 16 101 - Divide by 32 110 - Divide by 64 111 - Divide by 128

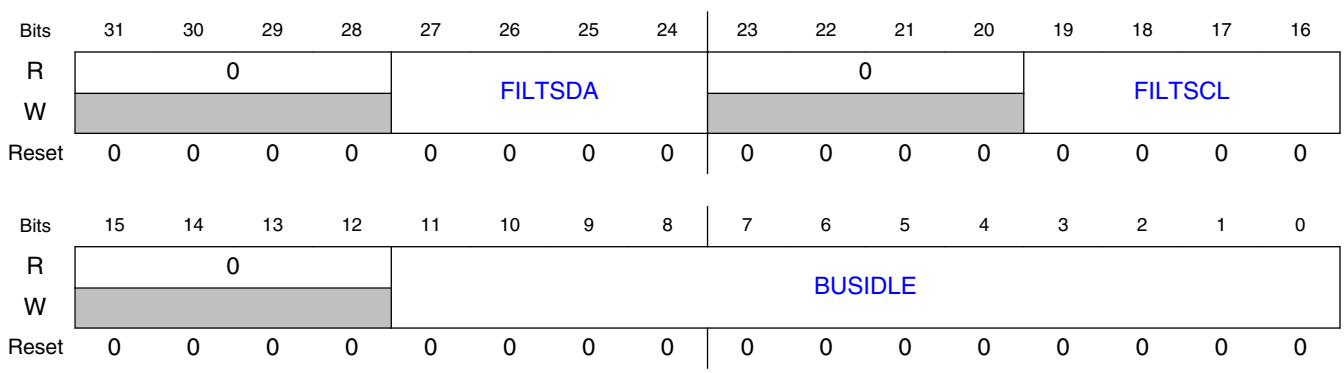
69.5.1.10 Master Configuration 2 (MCFGR2)

The Master Configuration Register 2 should only be written when the I2C Master is disabled.

69.5.1.10.1 Offset

Register	Offset
MCFGR2	28h

69.5.1.10.2 Diagram



69.5.1.10.3 Fields

Field	Description
31-28 —	Reserved
27-24 FILTSDA	Glitch Filter SDA Configures the I2C master digital glitch filters for SDA input. • A configuration of 0 disables the glitch filter • Glitches equal to or less than FILTSDA cycles long are filtered out and ignored • The latency through the glitch filter is equal to FILTSDA cycles, and must be configured to be less than the minimum SCL low or high period • The glitch filter cycle count is not affected by the PRESCALE configuration, and the glitch filter cycle count is automatically bypassed in High Speed mode
23-20 —	Reserved
19-16 FILTSCL	Glitch Filter SCL Configures the I2C master digital glitch filters for SCL input. • A configuration of 0 disables the glitch filter • Glitches equal to or less than FILTSCL cycles long are filtered out and ignored.The FILTSCL cycles are based on the functional clock. • The latency through the glitch filter is equal to FILTSCL cycles, and must be configured to be less than the minimum SCL low or high period • The glitch filter cycle count is not affected by the PRESCALE configuration, and the glitch filter cycle count is automatically bypassed in High Speed mode
15-12 —	Reserved
11-0 BUSIDLE	Bus Idle Timeout Configures the bus idle timeout period in clock cycles. • If both SCL and SDA are high for longer than BUSIDLE cycles, then the I2C bus is assumed to be idle and the master can generate a START condition • When Bus Idle Timeout is set to zero, the Bus Idle Timeout is disabled

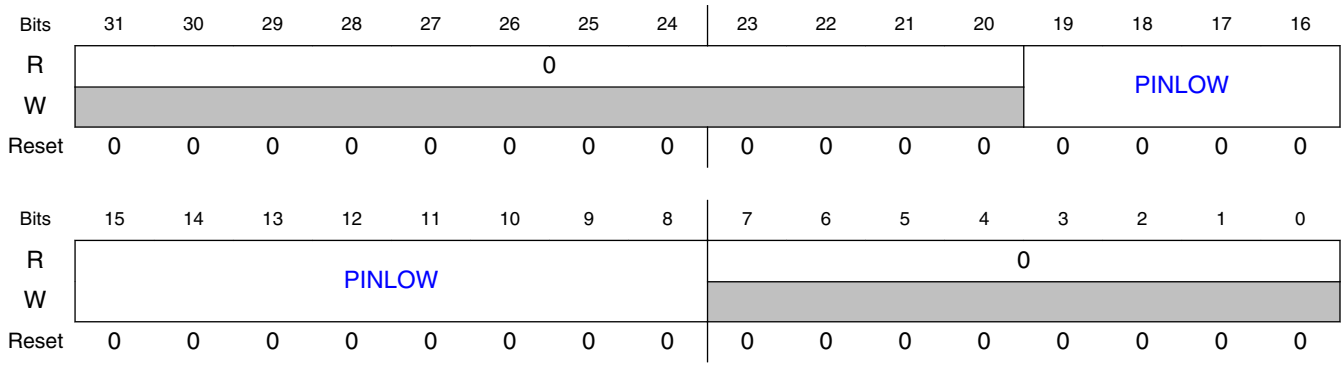
69.5.1.11 Master Configuration 3 (MCFGR3)

The MCFGR3 should only be written when the I2C Master is disabled.

69.5.1.11.1 Offset

Register	Offset
MCFGR3	2Ch

69.5.1.11.2 Diagram



69.5.1.11.3 Fields

Field	Description
31-20 —	Reserved
19-8 PINLOW	Pin Low Timeout Configures the pin low timeout flag in clock cycles. • If SCL or, either SCL or SDA, is low for longer than (PINLOW * 256) cycles, then MSR[PLTF] is set. • When Pin Low Timeout is set to zero, the Pin Low Timeout feature is disabled
7-0 —	Reserved

69.5.1.12 Master Data Match (MDMR)

The MDMR should only be written when the I2C Master is disabled or idle.

69.5.1.12.1 Offset

Register	Offset
MDMR	40h

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

69.5.1.13.3 Fields

Field	Description
31-30 —	Reserved
29-24 DATAVD	Data Valid Delay Minimum number of cycles (minus one) that is used as the data hold time for SDA. Must be configured less than the minimum SCL low period.
23-22 —	Reserved
21-16 SETHOLD	Setup Hold Delay Minimum number of cycles (minus one) that is used by the master for these conditions: • Hold time for a START • Setup and hold time for a repeated START • Setup time for a STOP The setup time is extended by the time it takes to detect a rising edge on the external SCL pin. Ignoring any additional board delay due to external loading, this time is equal to (2 + FILTSCL) / 2^PRESCALE cycles.
15-14 —	Reserved
13-8 CLKHI	Clock High Period Minimum number of cycles (minus one) that the SCL clock is driven high by the master. The SCL high time is extended by the time it takes to detect a rising edge on the external SCL pin. Ignoring any additional board delay due to external loading, this time is equal to (2 + FILTSCL) / 2^PRESCALE cycles.
7-6 —	Reserved
5-0 CLKLO	Clock Low Period Minimum number of cycles (minus one) that the SCL clock is driven low by the master. The Clock Low Period value is also used for the minimum bus free time between a STOP and a START condition; this is extended by the time it takes to detect a rising edge on the external SCL pin. Ignoring any additional board delay due to external loading, this time is equal to (2 + FILTSCL) / 2^PRESCALE cycles.

69.5.1.14 Master Clock Configuration 1 (MCCR1)

The MCCR1 cannot be changed when the I2C master is enabled and is used for high speed mode transfers. The separate clock configuration for high speed mode allows arbitration to take place in Fast mode (with timing configured by Master Clock Configuration 0 (MCCR0)), before switching to high speed mode (with timing configured by MCCR1).

Field	Description
31-26 —	Reserved
25 BBF	Bus Busy Flag Indicates if an I2C bus is idle or busy. 0 - I2C Bus is idle 1 - I2C Bus is busy
24 SBF	Slave Busy Flag Indicates if an I2C slave is idle or busy. 0 - I2C Slave is idle 1 - I2C Slave is busy
23-16 —	Reserved
15 SARF	SMBus Alert Response Flag • SARF is cleared by reading the Slave Address Status (SASR) register • SARF cannot generate an asynchronous wakeup 0 - SMBus Alert Response is disabled or not detected 1 - SMBus Alert Response is enabled and detected
14 GCF	General Call Flag Indicates whether a slave has detected the General Call Address. • General Call Flag is cleared by reading the Slave Address Status (SASR) register • General Call Flag cannot generate an asynchronous wakeup 0 - Slave has not detected the General Call Address or the General Call Address is disabled 1 - Slave has detected the General Call Address
13 AM1F	Address Match 1 Flag Indicates that the received address has matched the ADDR1 field or ADDR0 to ADDR1 range as configured by SCFGR1[ADDRCFG]. • Address Match 1 Flag is cleared by reading the Slave Address Status (SASR) register • Address Match 1 Flag cannot generate an asynchronous wakeup 0 - Have not received an ADDR1 or ADDR0/ADDR1 range matching address 1 - Have received an ADDR1 or ADDR0/ADDR1 range matching address
12 AM0F	Address Match 0 Flag Indicates that the received address has matched the ADDR0 field as configured by SCFGR1[ADDRCFG]. • AM0F is cleared by reading the Slave Address Status (SASR) register • AM0F cannot generate an asynchronous wakeup 0 - Have not received an ADDR0 matching address 1 - Have received an ADDR0 matching address
11	FIFO Error Flag

Table continues on the next page...

Field	Description
FEF	FEF can only be set when clock stretching is disabled. 0 - FIFO underflow or overflow was not detected 1 - FIFO underflow or overflow was detected
10 BEF	Bit Error Flag BEF sets if the LPI2C slave transmits a logic one and detects a logic zero on the I2C bus. The slave ignores the rest of the transfer until the next (repeated) START condition. 0 - Slave has not detected a bit error 1 - Slave has detected a bit error
9 SDF	STOP Detect Flag SDF sets when the LPI2C slave detects a STOP condition and if the LPI2C slave matched the last address byte. 0 - Slave has not detected a STOP condition 1 - Slave has detected a STOP condition
8 RSF	Repeated Start Flag RSF sets when the LPI2C slave detects a repeated START condition and if the LPI2C slave matched the last address byte. The RSF does not set when the slave first detects a START condition. 0 - Slave has not detected a Repeated START condition 1 - Slave has detected a Repeated START condition
7-4 —	Reserved
3 TAF	Transmit ACK Flag TAF is cleared by writing to the Slave Transmit ACK (STAR) register. 0 - Transmit ACK/NACK is not required 1 - Transmit ACK/NACK is required
2 AVF	Address Valid Flag AVF is cleared by reading the Slave Address Status (SASR) register. When SCFGR1[RXCFG] = 1, SSR[AVF] is also cleared by reading the Slave Receive Data (SRDR) register. 0 - Address Status Register is not valid 1 - Address Status Register is valid
1 RDF	Receive Data Flag RDF is cleared by reading the Slave Receive Data (SRDR) register. When SCFGR1[RXCFG] = 1, RDF is not cleared when reading the Slave Receive Data (SRDR) register and if SSR[AVF] is set. 0 - Receive data is not ready 1 - Receive data is ready
0 TDF	Transmit Data Flag TDF is cleared by writing the to the Slave Transmit Data (STDR) register. When SCFGR1[TXCFG] = 0 and if a NACK or a Repeated START or STOP condition is detected, then TDF is also cleared. 0 - Transmit data not requested 1 - Transmit data is requested

69.5.1.21 Slave Interrupt Enable (SIER)

SIER contains transmit and receive data interrupt enables; Start and Stop detect interrupt enables; and other slave interrupt enables.

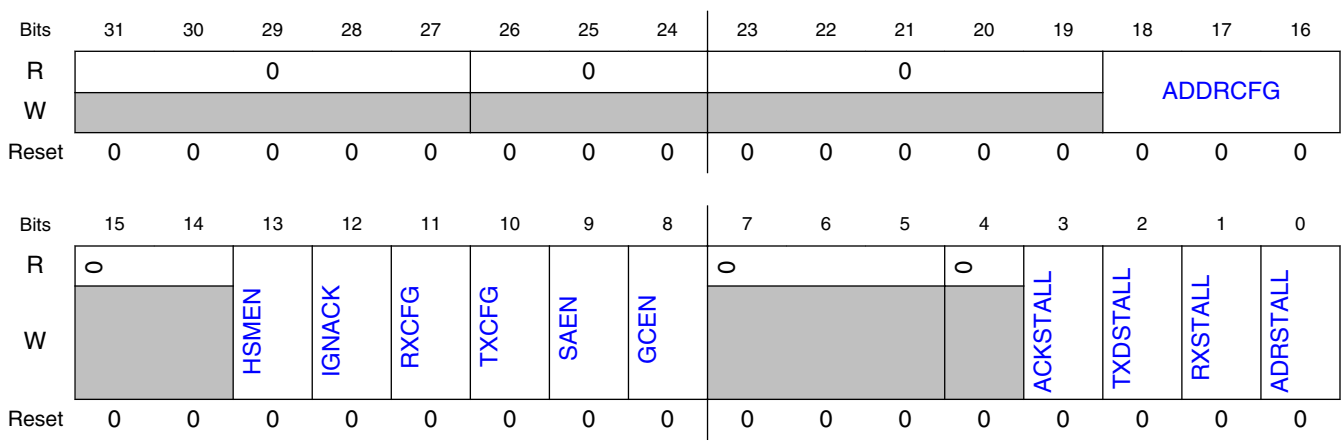
69.5.1.23.2 Diagram



69.5.1.23.3 Fields

Field	Description
31-27 —	Reserved

Table continues on the next page...

Field	Description
26-24 —	Reserved
23-19 —	Reserved
18-16 ADDRCFG	Address Configuration Configures the condition that causes an address to match. 000 - Address match 0 (7-bit) 001 - Address match 0 (10-bit) 010 - Address match 0 (7-bit) or Address match 1 (7-bit) 011 - Address match 0 (10-bit) or Address match 1 (10-bit) 100 - Address match 0 (7-bit) or Address match 1 (10-bit) 101 - Address match 0 (10-bit) or Address match 1 (7-bit) 110 - From Address match 0 (7-bit) to Address match 1 (7-bit) 111 - From Address match 0 (10-bit) to Address match 1 (10-bit)
15-14 —	Reserved
13 HSMEN	High Speed Mode Enable Enables detection of the High-Speed Mode master code of slave address 0000_1XX, but does not cause an address match on this code. When set and any HS-mode master code is detected, SCR[FILTEN] and SCFGR1[ACKSTALL] bits are ignored until the next STOP condition is detected. 0 - Disables detection of HS-mode master code 1 - Enables detection of HS-mode master code
12 IGNACK	Ignore NACK When Ignore NACK is set, the LPI2C slave continues transfers after a NACK is detected. Ignore NACK bit is required to be set in Ultra-Fast mode. 0 - Slave ends transfer when NACK is detected 1 - Slave does not end transfer when NACK detected
11 RXCFG	Receive Data Configuration 0 - Reading the Receive Data register returns received data and clears the Receive Data flag (MSR[RDF]). 1 - Reading the Receive Data register when the Address Valid flag (SSR[AVF])is set, returns the Address Status register and clear the Address Valid flag. Reading the Receive Data register when the Address Valid flag is clear, returns received data and clears the Receive Data flag (MSR[RDF]).
10 TXCFG	Transmit Flag Configuration The transmit data flag always asserts before a NACK is detected at the end of a slave-transmit transfer. This can cause an extra word to be written to the transmit data FIFO. • When TXCFG = 0, the Transmit Data register is automatically emptied when a slave-transmit transfer is detected. This causes the transmit data flag to assert whenever a slave-transmit transfer is detected, and causes the transmit data flag to negate at the end of the slave-transmit transfer. • When TXCFG = 1, the Transmit Data flag asserts whenever the Transmit Data register is empty, and the Transmit Data flag negates when the Transmit Data register is full. This allows the Transmit Data register to be filled before a slave-transmit transfer is detected, but can cause the Transmit Data register to be written before a NACK is detected on the last byte of a slave transmit transfer.

Table continues on the next page...

Field	Description
	0 - Transmit Data Flag only asserts during a slave-transmit transfer when the Transmit Data register is empty 1 - Transmit Data Flag asserts whenever the Transmit Data register is empty
9 SAEN	SMBus Alert Enable Enables a match on an SMBus alert. 0 - Disables match on SMBus Alert 1 - Enables match on SMBus Alert
8 GCEN	General Call Enable Enables a general call address. 0 - General Call address is disabled 1 - General Call address is enabled
7-5 —	Reserved
4 —	Reserved
3 ACKSTALL	ACK SCL Stall Enables SCL clock stretching during slave-transmit address byte(s) and slave-receiver address and data byte(s), to allow software to write the Slave Transmit ACK (STAR) register before the ACK or NACK is transmitted. Clock stretching occurs when transmitting the 9th bit, and is therefore not compatible with high speed mode. When ACKSTALL is enabled, there is no need to set either RX SCL Stall (SCFGR1[RXSTALL]) or Address SCL Stall (SCFGR1[ADRSTALL]). 0 - Clock stretching is disabled 1 - Clock stretching is enabled
2 TXDSTALL	TX Data SCL Stall Enables SCL clock stretching when the SSR[TDF] = 1 during a slave-transmit transfer. Clock stretching occurs following the 9th bit, and is therefore compatible with high speed mode. 0 - Clock stretching is disabled 1 - Clock stretching is enabled
1 RXSTALL	RX SCL Stall Enables SCL clock stretching when SSR[RDF] = 1 during a slave-receive transfer. Clock stretching occurs following the 9th bit, and is therefore compatible with high speed mode. 0 - Clock stretching is disabled 1 - Clock stretching is enabled
0 ADRSTALL	Address SCL Stall Enables SCL clock stretching when SSR[AVF] = 1. Clock stretching only occurs following the 9th bit, and is therefore compatible with high speed mode. 0 - Clock stretching is disabled 1 - Clock stretching is enabled

69.5.1.24 Slave Configuration 2 (SCFGR2)

The Slave Configuration Register 2 should only be written when the I2C Slave is disabled.

69.5.1.25.3 Fields

Field	Description
31-27 —	Reserved
26-17 ADDR1	Address 1 Value Compared against the received address to detect the Slave Address. • In 10-bit mode, the first address byte is compared to { 11110, ADDR1[26:25] } and the second address byte is compared to ADDR1[24:17] • In 7-bit mode, the address is compared to ADDR1[23:17]
16-11 —	Reserved
10-1 ADDR0	Address 0 Value Compared against the received address to detect the Slave Address. • In 10-bit mode, the first address byte is compared to { 11110, ADDR0[10:9] } and the second address byte is compared to ADDR0[8:1] • In 7-bit mode, the address is compared to ADDR0[7:1] •
0 —	Reserved

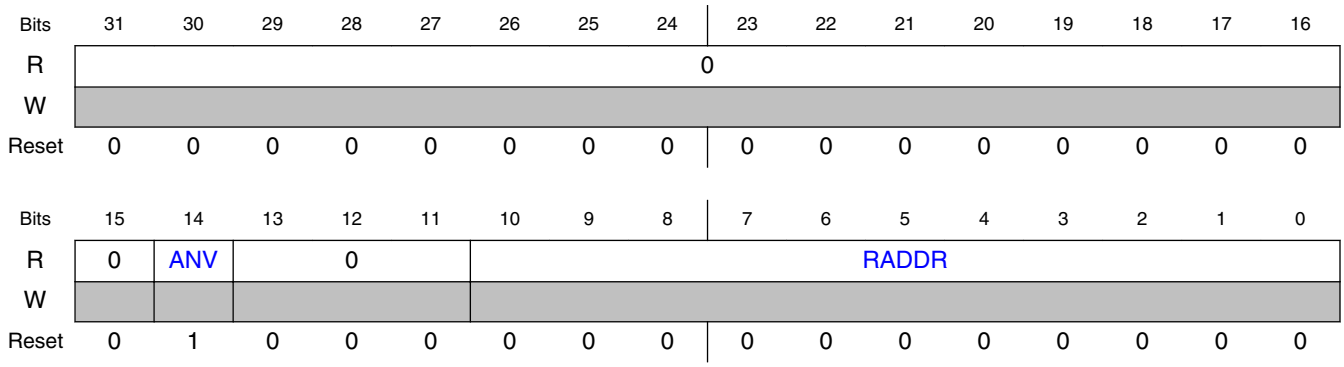
69.5.1.26 Slave Address Status (SASR)

SASR contains the read-only RADDR and ANV fields.

69.5.1.26.1 Offset

Register	Offset
SASR	150h

69.5.1.26.2 Diagram



69.5.1.26.3 Fields

Field	Description
31-15 —	Reserved
14 ANV	Address Not Valid 0 - Received Address (RADDR) is valid 1 - Received Address (RADDR) is not valid
13-11 —	Reserved
10-0 RADDR	Received Address The Received Address updates whenever the AMF is set; the AMF is cleared by reading the Slave Address Status register. • In 7-bit mode, the address byte is stored in RADDR[7:0] • In 10-bit mode, the first address byte is { 11110, RADDR[10:9], RADDR[0] } and the second address byte is RADDR[8:1]. The R/W bit is therefore always stored in RADDR[0]

69.5.1.27 Slave Transmit ACK (STAR)

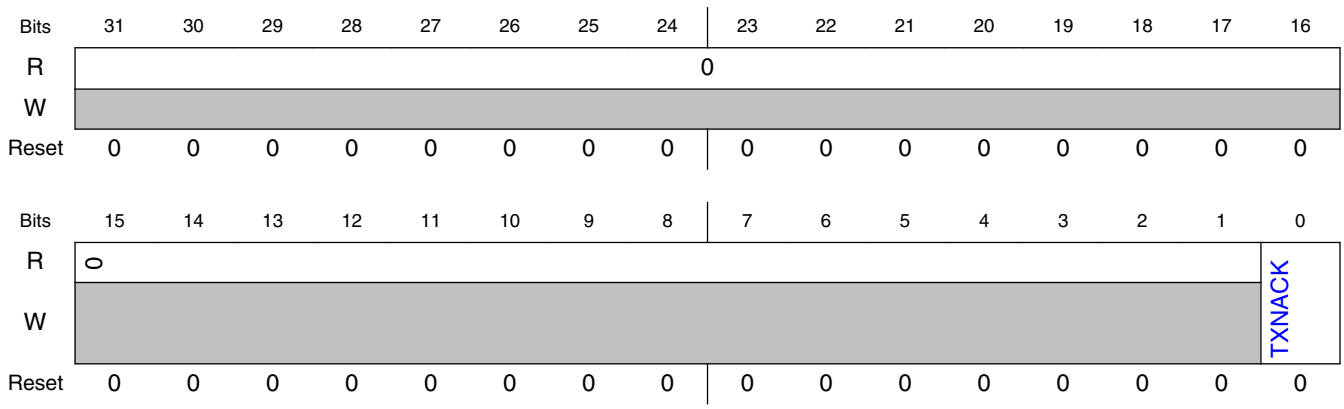
STAR can only be written when the ACK SCL Stall bit is set (SCFGR1[ACKSTALL]).

- The SCFGR1[ACKSTALL] bit enables clock stretching during the ACK/NACK bit slot, and during this time, the STAR register can be written by software.
- The logic ensures that the clock stretching continues for at least 1 bus clock cycle after the STAR register is updated.
- This clock stretching time can be extended more using the Clock Hold Time field (SCFGR2[CLKHOLD]).

69.5.1.27.1 Offset

Register	Offset
STAR	154h

69.5.1.27.2 Diagram



69.5.1.27.3 Fields

Field	Description
31-1 —	Reserved
0 TXNACK	Transmit NACK After receiving each word, software can transmit either an ACK (logic 0) or a NACK (logic 1); Transmit NACK selects which to use: ACK or NACK. • When SCFGR1[ACKSTALL] is set, a Transmit NACK must be written once for each matching address byte and each received word. ACKSTALL must be set, because that stalls the data transfer until software reads the received word (and decides whether to respond with an ACK or NACK). • To configure the default ACK/NACK, Transmit NACK can also be written when LPI2C Slave is disabled or idle. 0 - Write a Transmit ACK for each received word 1 - Write a Transmit NACK for each received word

69.5.1.28 Slave Transmit Data (STDR)

Clock stretching (enabled or disabled) affects when the transmit data is transferred. The SCFGR1[TXDSTALL] bit enables clock stretching during the 1st data bit of a slave-transmit transfer.

- **If clock stretching is enabled (SCFGR1[TXDSTALL] = 1)**, then the transmit data transfer is stalled until the STDR is updated. Clock stretching is extended by at least 1 bus clock cycle after STDR is updated, and clock stretching can be delayed even more using the Clock Hold Time field (SCFGR2[CLKHOLD].
- **If clock stretching is disabled (SCFGR1[TXDSTALL] = 0)**, then the transmit data should be written before the start of the slave-transmit transfer; otherwise (that is, if the transmit data is not written before the start of the slave-transmit transfer), the FIFO Error Flag (SSR[FEF]) sets.

Chapter 70
Low Power Serial Peripheral Interface (LPSPI)

70.1 Chip-specific LPSPI information

Table 70-1. Reference links to related information

Topic	Related module(s)	Reference
System memory map	-	System Memory Map
Clocking	CCM	Clock Management Clock Control Module (CCM)
Power management	PMU	Power Management Power Management Unit
Signal multiplexing	IOMUX	External Signals and Pin Multiplexing IOMUX

NOTE

The output trigger in "Peripheral Triggers" section is not applicable for this device.

70.2 Overview

LPSPI provides an efficient interface to a SPI bus, either as a master or slave. A SPI bus is a synchronous serial communication interface used in embedded systems. It is typically used to perform short distance communications between microcontrollers and peripheral devices, on printed circuit boards. Typical applications include interfacing to Secure Digital cards and LCD displays.

70.2.1 Block diagram

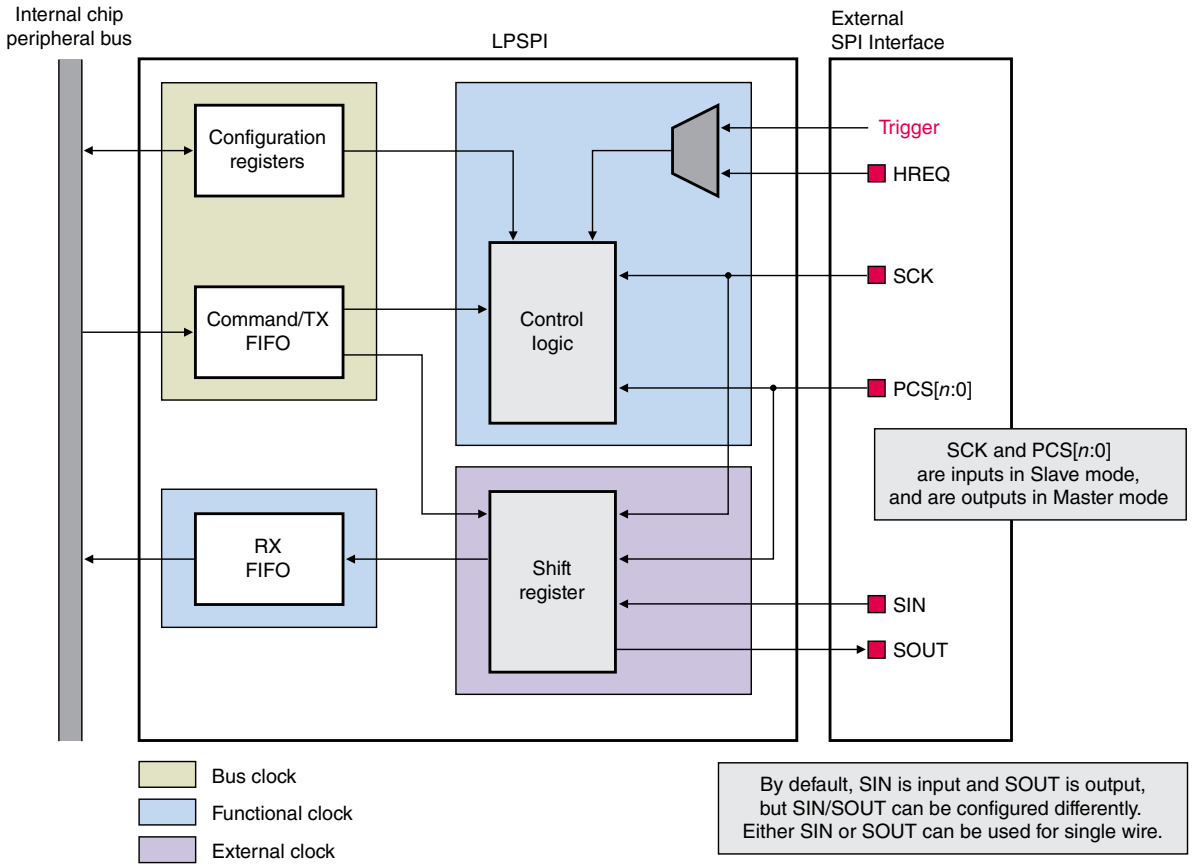

Figure 70-1. Block diagram

70.2.2 Features

- Requires minimal CPU overhead, with FIFO register access supported by DMA transmit and receive requests.
- Continues operating in Stop mode, if configured to do so and an appropriate clock is available
- 32-bit word size
- Configurable clock polarity and phase
- Master mode—supports 4 peripheral chip selects
- Slave mode
- 16-word transmit and command FIFO
- 16-word receive FIFO
- Flexible timing parameters in Master mode, including SCK frequency and delays between PCS and SCK edges
- Full-duplex transfers support 1-bit transmit and receive on each clock edge
- Half-duplex transfers support:

  - 1-bit transmit or receive on each clock edge
  - 2-bit transmit or receive on each clock edge (Master mode only)
  - 4-bit transmit or receive on each clock edge (Master mode only)
- Can use host request to control the start of a SPI bus transfer (Master mode only)
- Receive data match logic supports discard of non-matching data and interrupt on data match

70.3 Functional description

70.3.1 Master mode

70.3.1.1 Transmit and command FIFO commands

The transmit and command FIFO is a combined FIFO that includes both transmit data words and command words.

- You store transmit data words to the transmit and command FIFO, by writing to Transmit Data (TDR).
- You store command words to the transmit and command FIFO, by writing to Transmit Command (TCR).

When a command word is at the top of the transmit and command FIFO, the actions that can occur depend upon whether the LPSPI module is busy or between frames. See TCR[CONT] and TCR[CONTC].

Table 70-2. Possible actions when a command word is at the top of the transmit and command FIFO

Condition	Action
LPSPI is enabled and idle	The command word is pulled from the FIFO, and that command word controls all subsequent transfers.
LPSPI is busy and the Continuing Command field (TCR[CONTC]) is 0	The SPI frame completes at the end of the existing word, ignoring TCR[FRAMESZ]. The command word is then pulled from the FIFO and that command word controls all subsequent transfers (or until the next update to the command word). Note that a command word with TCR[CONTC] = 0 always terminates the existing transfer regardless of the previous TCR[CONT] value.
LPSPI is busy, the existing TCR[CONT] value is 1 and the new TCR[CONTC] value is 1	The command word must be updated at the frame boundary. The command word is pulled from the FIFO during the last SCK pulse of the existing frame (based on the FRAMESZ value), and the frame continues using the new command value for the rest of the frame (or until the next update to the command word). When TCR[CONTC] = 1, only the lower 24-bits of the command word are updated. If the command word is updated at a word boundary, then the transfer halts (stops) after that word. TCR[CONTC] is ignored when not at a frame boundary, so the frame ends prematurely.

About TCR[CONT] and TCR[CONTC] :

- TCR[CONT] = 1 keeps PCS asserted at end of frame, allowing the transfer to continue.
- TCR[CONTC] = 1 specifies that this command word should not terminate the existing frame, and the transfer can continue using the new command word.

TCR[CONTC] = 1 is restricted in the sense that the new command must load on a frame boundary, and the only way for a transfer to continue from a frame boundary is when the previous command has TCR[CONT] = 1.

You can read the current state of the existing command word from Transmit Command (TCR). It requires at least 3 LPSPI functional clock cycles for TCR to update after TCR is written (assuming an empty FIFO), and LPSPI must be enabled (CR[MEN] = 1).

Writing the TCR does not initiate a SPI bus transfer, unless the TCR[TXMSK] = 1. When the TCR[TXMSK] = 1, a new command word is not loaded until the end of the existing frame (based on the TCR[FRAMESZ] value); at the end of the transfer, TCR[TXMSK] transitions to 0.

In Master mode, the LPSPI command word in TCR controls SPI attributes based on selections in register fields.

Table 70-3. Command word in Master mode

Transmit Command (TCR)		Description	Can this field be modified during a data transfer?
Field	Name		
CPOL	Clock polarity	Specifies the polarity of the SCK pin. Any change of CPOL value causes a transition on the SCK pin.	N
CPHA	Clock phase	Specifies the clock phase of the transfer.	N
PRESCALE	Prescaler value	Specifies a prescaler used to divide the LPSPI functional clock, to generate the timing parameters of the SPI bus transfer. Changing PRESCALE in conjunction with PCS enables the LPSPI module to connect to different slave devices at different frequencies.	N
PCS	Peripheral chip select	Specifies which PCS pin asserts for the transfer; the polarity of PCS is static and specified by CFGR1[PCSPOL]. If CFGR1[PCSCFG] = 1, do not select PCS[3:2].	N
LSBF	LSB first	Specifies whether LSB (bit 0) or MSB (bit 31 for a 32-bit word) is transmitted or received first.	Y
BYSW	Byte swap	Enables byte swap on each 32-bit word when transmitting and receiving data. Byte swapping can be useful when interfacing to devices that organize data as big-endian.	Y
CONT	Continuous transfer	Configures LPSPI for a continuous transfer that keeps PCS asserted between frames (as specified by FRAMESZ). You must write a new	Y

Table continues on the next page...

Table 70-3. Command word in Master mode (continued)

Transmit Command (TCR)		Description	Can this field be modified during a data transfer?
Field	Name		
		command word to cause PCS to negate. Also supports changing the command word at the frame size boundaries.	
CONTC	Continuing command	Indicates that this is a new command word for the existing continuous transfer. When CONTC = 1, the command word must only be written to the transmit and command FIFO on a frame boundary.	Y
RXMSK	Receive data mask	Masks the receive data and does not store the masked receive data to the receive FIFO or perform receive data matching. This option is useful for half-duplex transfers or to specify which fields are compared during receive data matching.	Y
TXMSK	Transmit data mask	Masks the transmit data; masked transmit data is not pulled from the transmit FIFO, and the output data pin is 3-stated (unless otherwise configured by CFGR1[OUTCFG]). This option is useful for half-duplex transfers.	Y
WIDTH	Transfer width	Specifies the number of bits shifted on each SCK pulse. • 1-bit transfers support traditional SPI bus transfers in either half-duplex or full-duplex data formats. • 2-bit and 4-bit half-duplex transfers are useful for interfacing to QuadSPI memory devices, and either TXMSK or RXMSK must also be 1.	Y
FRAMESZ	Frame size	Configures the frame size in number of bits equal to (FRAMESZ + 1). • The minimum frame size is 8 bits. • The minimum word size is 2 bits; a frame size of 33 bits (or similar) is not supported. • If the frame size is larger than 32 bits, then the frame is divided into multiple words of 32 bits; each word is loaded from the transmit FIFO and stored in the receive FIFO separately. • If the size of the frame is not divisible by 32, then the last load of the transmit FIFO and store of the receive FIFO contains the remaining bits. For example, a 72-bit transfer consists of 3 words: the first and second words are 32 bits, and the third word is 8 bits.	Y

70.3.1.1.1 SPI bus transfers

LPSPI initiates a SPI bus transfer when all of the following conditions are true:

- Data is written to the transmit FIFO.
- The HREQ pin is asserted (or the HREQ function is disabled).
- LPSPI is enabled.

To perform the SPI bus transfer, LPSPI uses the attributes configured in Transmit Command (TCR) and uses the timing parameters in Clock Configuration (CCR).

The SPI bus transfer ends after the number of bits indicated by the FRAMESZ value have been transferred (provided CONT = 0), or at the end of a word when a new transmit command word is at the top of the transmit and command FIFO. When LPSPI is disabled, the SPI bus transfers end after the transmit FIFO is empty and LPSPI is idle.

The HREQ input is only checked on the next time that LPSPI goes idle (LPSPI completes the current transmit FIFO and there are no attribute updates in TCR.

70.3.1.1.2 Circular FIFO

The transmit and command FIFO supports a circular FIFO feature. This feature enables the LPSPI master to (periodically) repeat a short data transfer that fits within the transmit and command FIFO, without requiring additional FIFO accesses. When the circular FIFO is enabled (CFGR0[CIRFIFO] = 1), the current state of the FIFO read pointer is saved and the status flags do not update. After the FIFO is empty and LPSPI is idle, the FIFO read pointer is restored with the saved version, so the contents of the transmit and command FIFO are not permanently pulled from the FIFO while Circular FIFO mode is enabled.

70.3.1.2 Receive FIFO and data match

The receive FIFO stores received data during SPI bus transfers. When TCR[RXMSK] = 1, the received data is discarded instead of being stored in the receive FIFO.

- Received data is written to the receive FIFO at the end of the frame.
- During a multiple-word or continuous transfer, the received data is also written to the receive FIFO at the same time the new transmit data is read from the transmit FIFO.
- During a continuous transfer, if the transmit FIFO is empty, then the received data is only written to the receive FIFO after the transmit FIFO is written or after TCR is written to end the frame.

LPSPI provides a receive data match function that can match received data against one of two words in DMR0 and DMR1, or against a masked data word. The received data match function can also be configured to compare only the first one or two received data words since the start of the frame.

- Received data that is already discarded due to the TCR[RXMSK] field cannot cause the data match flag to set, and delays the receive data match on the first received data word, until all discarded data is received.
- You can configure the receive data match function to discard all received data until a data match is detected, using CFGR0[RDMO].
- After a receive data match, to allow all subsequent data to be received, write 0 to the CFGR0[RDMO] field, then write 0 to SR[DMF].

70.3.1.3 Timing parameters

The timing parameters that are used for all SPI bus transfers are relative to the LPSPI functional clock divided by the TCR[PRESCALE] selection. Although you cannot change Clock Configuration (CCR) when the LPSPI module is busy, to support interfacing to different slave devices at different frequencies, you can change the TCR[PRESCALE] selection between SPI bus transfers using Transmit Command (TCR).

NOTE

The minimum value below is the minimum counter value, but the clock configuration register values must also satisfy the data sheet specs based on the LPSPI functional clock frequency and prescaler value.

Table 70-4. Timing parameters

Clock Configuration (CCR)		Description	Min	Max
Field	Name			
SCKDIV	SCK divider	Configures the SCK clock period to (SCKDIV + 2) cycles. When SCK Divider is configured to an odd number of cycles, the first half of the SCK cycle is one cycle longer than the second half of the SCK cycle.	0 (2 cycles)	255 (257 cycles)
DBT	Delay between transfers (PCS negation to PCS assertion)	Configures the minimum delay between PCS negation and the next PCS assertion to (DBT + 2) cycles. When the command word is updated between transfers, there is a minimum of (DBT ÷ 2) + 1 cycles between the command word update and any change on PCS pins.	0 (2 cycles)	255 (257 cycles)
DBT	Delay between transfers (last SCK edge to first SCK edge)	Configures the delay during a continuous transfer between the last SCK edge of a frame and the first SCK edge of the continuing frame to (DBT + 1) cycles. This is useful when the external slave requires a large delay between different words of an SPI bus transfer.	0 (1 cycle)	255 (256 cycles)
PCSSCK	PCS-to-SCK delay	Configures the minimum delay between PCS assertion and the first SCK edge to (PCSSCK + 1) cycles.	0 (1 cycle)	255 (256 cycles)
SCKPCS	SCK-to-PCS delay	Configures the minimum delay between the last SCK edge and the PCS negation to (SCKPCS + 1) cycles.	0 (1 cycle)	255 (256 cycles)

This figure shows the timing settings controlled by:

- TCR[CPHA]
- TCR[CPOL]
- CCR[SCKPCS]
- CCR[PCSSCK]

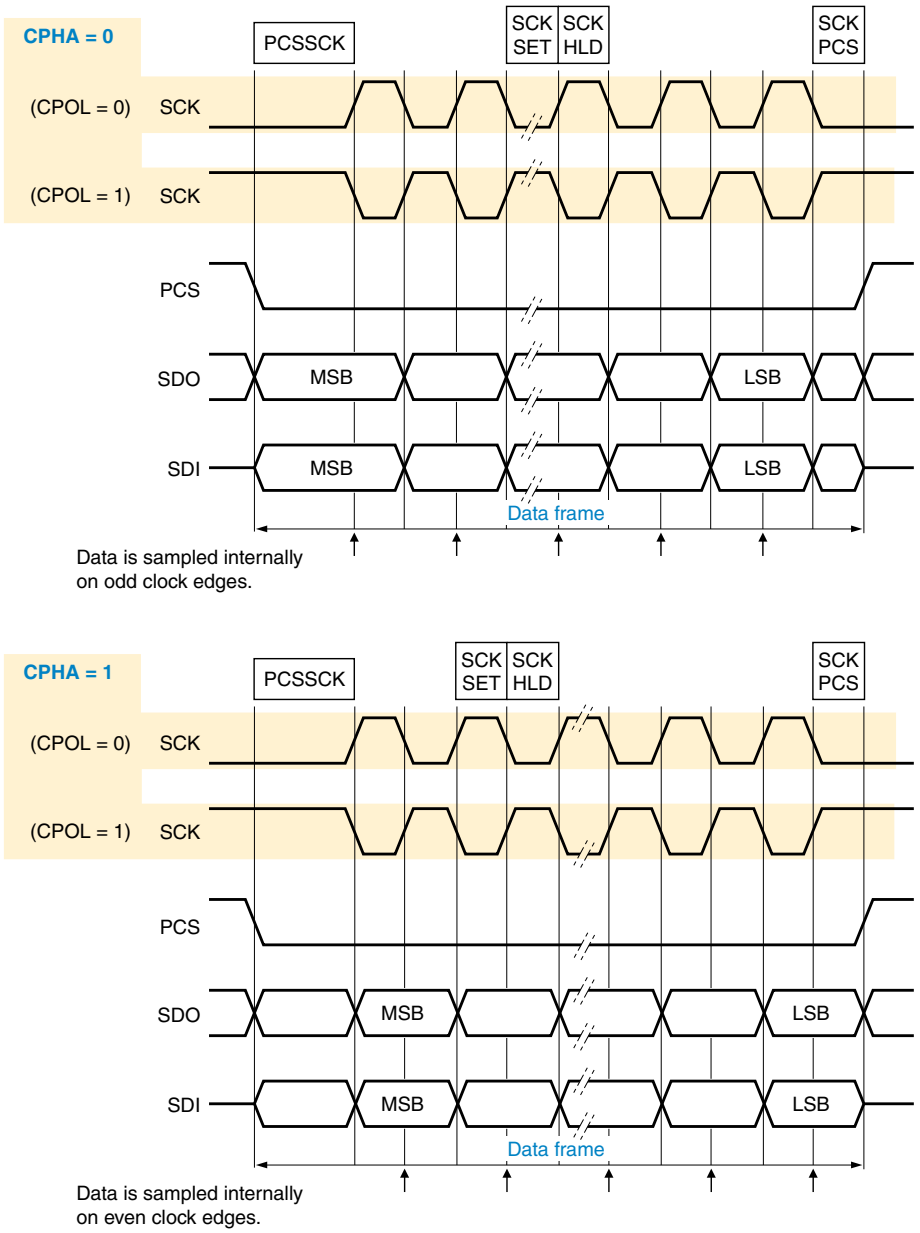

Figure 70-2. Clock phase (TCR[CPHA]) timing diagram example

70.3.1.4 Pin configuration

- To swap directions or support half-duplex transfers on the same pin, you can configure the SIN and SOUT pins using CFGR1[PINCFG].
- To specify whether an output data pin (SOUT, for example) 3-states when PCS is negated, or if the output data pin retains the last value, use CFGR1[OUTCFG].
- When configuring for half-duplex transfers, you must configure the output data pins to 3-state when PCS is negated (CFGR1[OUTCFG] = 1).

- When performing half-duplex 2-bit transfers, you can set CFGR1[PCSCFG] to any value.
- When performing half-duplex 4-bit transfers, you must set CFGR1[PCSCFG] to 1h.

70.3.1.5 Clock loopback

Configure the LPSPI master to use one of the following clocks to sample the input data:

- The SCK output clock
- A delayed version of the SCK output clock

The delayed version of the SCK is chosen by the SCK pin output delay, plus the SCK pin input delay, and is selected by writing 1 to CFGR1[SAMPLE]. Enabling the loopback version of the SCK can improve the setup time of the input data from the slave.

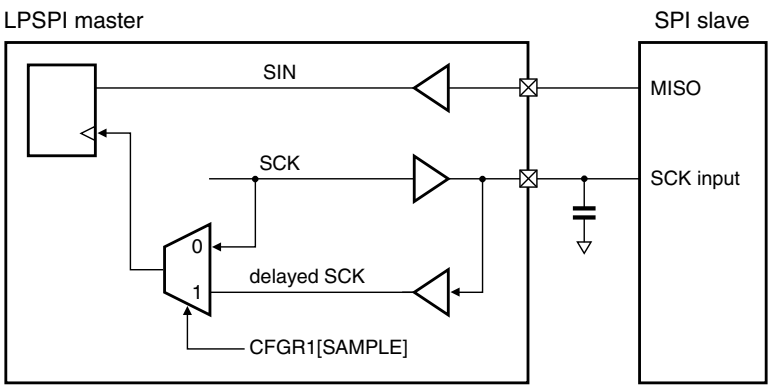

Figure 70-3. Clock loopback

See the chip data sheet for the specific input setup time in Master Loopback mode.

70.3.2 Slave mode

LPSPI slave mode:

- Uses the same shift register and logic that master mode uses.
- Does not use Clock Configuration Register (CCR).
- Requires that Transmit Command (TCR) remain static (unchanging) during SPI bus transfers.

70.3.2.1 Transmit and command FIFO commands

Before enabling LPSPI in Slave mode, initialize Transmit Command (TCR), although TCR does not update until after LPSPI is enabled. After LSPI is enabled, only change TCR when LPSPI is idle. In Slave mode, the LPSPI command word in TCR controls SPI attributes. Before the PCS input asserts, the transmit FIFO must be filled with transmit data, or the transmit error flag sets.

Table 70-5. Command word in Slave mode

Transmit Command (TCR)		Description
Field	Name	
CPOL	Clock polarity	Specifies the polarity of the external SCK input.
CPHA	Clock phase	Specifies the clock phase of transfer.
PRESCALE	Prescaler value	Specifies the LPSPI functional clock prescaler.
PCS	Peripheral chip select	Specifies which PCS is used. The polarity of PCS is static and configured by CFGR1[PCSPOL]. If CFGR1[PCSCFG] is not equal to zero, then do not select the PCS[3:2] pins.
LSBF	LSB first	Specifies whether LSB (bit 0) or MSB (bit 31 for a 32-bit word) is transmitted or received first.
BYSW	Byte swap	Enables byte swap on each 32-bit word when transmitting and receiving data. Byte swapping can be useful when interfacing to devices that organize data as big-endian.
CONT	Continuous transfer	When continuous transfer is selected in Slave mode, after the number of bits indicated by FRAMESZ are transferred, the LPSPI will passthrough and transmit the received data until the next PCS negation. Whatever is shifted in on the receive data is shifted out as transmit data as if there were a 32-bit shift register.
CONTC	Continuing command	This field is reserved in Slave mode.
RXMSK	Receive data mask	Masks the receive data; LPSPI does not store masked receive data to the receive FIFO or perform receive data matching. This option is useful for half-duplex transfers or to specify which fields are compared during receive data matching.
TXMSK	Transmit data mask	Masks the transmit data, so that the masked transmit data is not pulled from transmit FIFO, and the output data pin is 3-stated (unless otherwise specified by CFGR1[OUTCFG]). This option is useful for half-duplex transfers.
WIDTH	Transfer width	Specifies the number of bits shifted on each SCK pulse. • 1-bit transfers support traditional SPI bus transfers in either half-duplex or full-duplex data formats.
FRAMESZ	Frame size	Specifies the frame size in number of bits equal to (FRAMESZ + 1). • The minimum frame size is 8 bits. • The minimum word size is 2 bits; a frame size of 33 bits (or similar) is not supported. • If the frame size is larger than 32 bits, then the frame is divided into multiple words of 32 bits; each word is loaded from the transmit FIFO and stored in the receive FIFO separately. • If the size of the frame is not divisible by 32, then the last load of the transmit FIFO and store of the receive FIFO contain the remainder bits. For example, a 72-bit transfer consists of 3 words: the first and second words are 32 bits, and the third word is 8 bits.

70.3.2.2 Receive FIFO and data match

The receive FIFO stores receive data during SPI bus transfers. When TCR[RXMSK] = 1, the received data is discarded instead of storing the received data in the receive FIFO.

Receive data supports a receive data match function that can match received data against one of two words in the DMR0 and DMR1 registers or against a masked data word. The data match function can also be configured to compare only the first one or two received data words since the start of the frame.

- Received data that is already discarded because TCR[RXMSK] = 1 cannot cause the data match to set, and delays the match on the first received data word, until all discarded data is received.
- The receiver match function can also be configured to discard all received data until a data match is detected, using the CFGR0[RDMO] bit.
- After a receive data match, to allow all subsequent data to be received, first clear the CFGR0[RDMO] bit, then clear the SR[DMF] bit.

70.3.2.3 Clocked interface

LPSPI supports interfacing to external masters that provide only clock and data pins (PCS is not required). This interface requires:

- Writing 1 to TCR[CPHA] (data is changed on the leading edge of SCK and captured on the following edge).
- Configuring the PCS input to be always asserted (CFGR1[PCSPOLn] = 1). For example, to configure PCS[0] to be always asserted, write 1 to PCSPOL[0], and do not configure PCS[0] in the pin muxing. The chip-level drives PCS to a certain value (ideally 1), CFGR1[PCSPOL*n*] could be used to invert that value.
- Writing 1 to CFGR1[AUTOPCS] to enable automatic PCS generation. When CFGR1[AUTOPCS] = 1, a minimum of four LPSPI functional clock cycles (divided by the TCR[PRESCALE] selection) is required between the last SCK edge of one word and the first SCK edge of the next word.

70.3.3 Low-power modes

Table 70-6. Low-power modes

Chip mode	LPSPI operation
Run	Normal operation
Stop	Can continue operating in Stop mode if CR[DOZEN] = 0 and LPSPI is using an external or internal clock source that remains operating during Stop mode

70.3.4 Debug mode

Table 70-7. Debug mode

Chip mode	LPSPI operation
Debug (the core is in Debug/Halted mode)	Can continue operating in Debug mode, if the CR[DBGEN] = 1.

70.3.5 Interrupts and DMA requests

The following table lists the Slave mode sources (status flags) that can generate LPSPI interrupts and LPSPI slave transmit and receive DMA requests.

Table 70-8. Interrupts and DMA requests

Status (SR)		Description	Can generate		
Status flag	Name		Interrupt?	DMA request?	Low-power wake-up?
TDF	Transmit data flag	Data can be written to transmit FIFO, as configured by the transmit FIFO watermark FCR[TXWATER]	Y	TX	Y
RDF	Receive data flag	Data can be read from the receive FIFO, as configured by the receive FIFO watermark FCR[RXWATER]	Y	RX	Y
WCF	Word complete flag	Word is complete, the last bit of the word has been sampled	Y	N	Y
FCF	Frame complete flag	Frame is complete, and PCS has deasserted	Y	N	Y
TCF	Transfer complete flag	Transfer is complete, PCS has deasserted, and the transmit and command FIFO is empty	Y	N	Y
TEF	Transmit error flag	Indicates a transmit and command FIFO underrun. In Master mode when CFGR1[NOSTALL] = 0 (transfers stall when transmit FIFO is empty), the Transmit Error Flag cannot set.	Y	N	Y

Table continues on the next page...

Table 70-8. Interrupts and DMA requests (continued)

Status (SR)		Description	Can generate		
Status flag	Name		Interrupt?	DMA request?	Low-power wake-up?
REF	Receive error flag	Indicates a receive FIFO overflow.	Y	N	Y
DMF	Data match flag	Indicates that the received data has matched the configured data match value	Y	N	Y
MBF	Module busy flag	LPSPI is busy performing a SPI bus transfer	N	N	N

70.3.6 Clocks

Table 70-9. LPSPI clocks

LPSPI functional clock	• Asynchronous to the bus clock. • If the LPSPI functional clock remains enabled in low-power modes, then LPSPI can perform SPI bus transfers and low-power wakeups, in both Master and Slave modes. • LPSPI divides the functional clock by a prescaler; the resulting frequency must be at least 2 times faster than the SPI external clock frequency (SCK).

External clock	• The LPSPI shift register is clocked directly by the SCK clock.
	• How the SCK clock is generated or supplied depends upon the mode (Master or Slave):
	  • In Master mode: the SCK clock is generated internally.
	  • In Slave mode: the SCK clock is supplied externally.

Bus clock	The bus clock is only used for bus accesses to the LPSPI control and configuration registers. The bus clock frequency must be high enough to support the data bandwidth requirements of the LPSPI registers, including the FIFOs.

See the chip-specific LPSPI information.

70.3.7 Resets

Table 70-10. Resets

Chip reset	Resets the LPSPI logic and registers to their default state.
Software reset	• Resets the LPSPI logic and registers to their default state, except for the Control Register. • The LPSPI software reset is controlled using CR[RST].
FIFO resets	• Resets the transmit and command FIFO and the receive FIFO. • The Reset Transmit FIFO field, CR[RTF], and the Reset Receive FIFO field, CR[RRF], are write only. • After being reset, a FIFO is empty.

70.3.8 Peripheral triggers

The connection of the LPSPI peripheral triggers to other peripherals depend upon the specific device being used.

Table 70-11. Peripheral triggers

Trigger	Description	Notes
Frame output trigger	The frame output trigger is an idle high signal, which: • Asserts at the end of each frame (when PCS deasserts) • Remains asserted until PCS next asserts	LPSPI generates two output triggers that can be connected to other peripherals on the chip.
Word output trigger	The word output trigger: • Asserts at the end of each received word • remains asserted for 1 SCK period	
Input trigger	To control the start of an LPSPI bus transfer, the LPSPI input trigger can be selected instead of the HREQ input. • The LPSPI input trigger is synchronized, and must assert for at least 2 cycles of the LPSPI functional clock divided by the PRESCALE configuration, so that the input trigger can be detected. • When the LPSPI module is busy, the HREQ input (and therefore the LPSPI input trigger) is ignored. • Both HREQ and the LPSPI input trigger are ignored when the module is busy. They are used to start a new transfer when the module is idle.	

70.4 Signals

Table 70-12. Signals

Signal	Name	Description	I/O
SCK	Serial clock	• Input in Slave mode • Output in Master mode	I/O
PCS[0]	Peripheral chip select	• Input in Slave mode • Output in Master mode	I/O
PCS[1] / HREQ	Peripheral chip select or host request	Host request pin is selected when CFGR0[HREN] = 1 and CFGR0[HRSEL] = 0 • Input in either Slave mode or when used as master host request • Output in Master mode	I/O
PCS[2] / DATA[2]	Peripheral chip select or data pin 2 during parallel data transfers	When CFGR1[PCSCFG] = 0: • Input in Slave mode • Output in Master mode When CFGR1[PCSCFG] = 1: • Input in half-duplex parallel data receive transfers • Output in half-duplex parallel data transmit transfers	I/O

Table continues on the next page...

Table 70-12. Signals (continued)

Signal	Name	Description	I/O
PCS[3] / DATA[3]	Peripheral chip select or data pin 3 during parallel data transfers	When CFGR1[PCSCFG] = 0: • Input in Slave mode • Output in Master mode When CFGR1[PCSCFG] = 1: • Input in half-duplex parallel data receive transfers • Output in half-duplex parallel data transmit transfers	I/O
SOUT / DATA[0]	Serial data output	Can be configured as serial data input signal • Used as data pin 0 in half-duplex parallel data transfers	I/O
SIN / DATA[1]	Serial data input	Can be configured as serial data output signal • Used as data pin 1 in half-duplex parallel data transfers	I/O

70.5 Memory map and registers

NOTE

- Writing to a read-only register or reading a write-only register can cause bus errors.
- LPSPI does not check values programmed in registers for validity, so you must take care to write valid values only.

70.5.1 LPSPI register descriptions

70.5.1.5.4 Fields

Field	Function
31-25 —	Reserved
24	Module Busy Flag

Table continues on the next page...

Field	Function
MBF	In Master mode, indicates that there is data to transmit and LPSPI is able to transmit (for example, HREQ is asserted). It deasserts after the PCS pin deasserts and the LPSPI master has waited half the CCR[DBT] time with no new data to transmit. Slave mode asserts this flag when LPSPI is enabled and PCS is asserted. 0b - LPSPI is idle 1b - LPSPI is busy
23-14 —	Reserved
13 DMF	Data Match Flag Indicates that received data matches DMR0[MATCH0] and/or DMR1[MATCH1] (as configured by CFGR1[MATCFG]). 0b - No match 1b - Match
12 REF	Receive Error Flag Indicates a receive FIFO overflow error. When this flag is set: 1. End the transfer. 2. Empty the Receive FIFO. 3. Clear this flag. 4. Restart the transfer from the beginning. 0b - No overflow 1b - Overflow
11 TEF	Transmit Error Flag Indicates a Transmit FIFO underrun error. When this flag is set: 1. End the transfer. 2. Clear this flag. 3. Restart the transfer from the beginning. 0b - No underrun 1b - Underrun
10 TCF	Transfer Complete Flag In Master mode, indicates that all transfers have completed and that LPSPI has returned to Idle state and the transmit FIFO is empty. 0b - Not complete 1b - Complete
9 FCF	Frame Complete Flag Indicates that a frame transfer has completed, when the PCS deasserts. 0b - Not complete 1b - Complete
8 WCF	Word Complete Flag Indicates that the last bit of a received word is sampled. 0b - Not complete 1b - Complete
7-2 —	Reserved
1 RDF	Receive Data Flag Indicates that the number of words in the receive FIFO is greater than the value in FCR[RXWATER]. 0b - Receive data not ready

Table continues on the next page...

Field	Function
	1b - Receive data is ready
0 TDF	Transmit Data Flag Indicates that the number of words in the transmit FIFO is equal to or less than the value in FCR[TXWATER]. 0b - Transmit data not requested 1b - Transmit data is requested

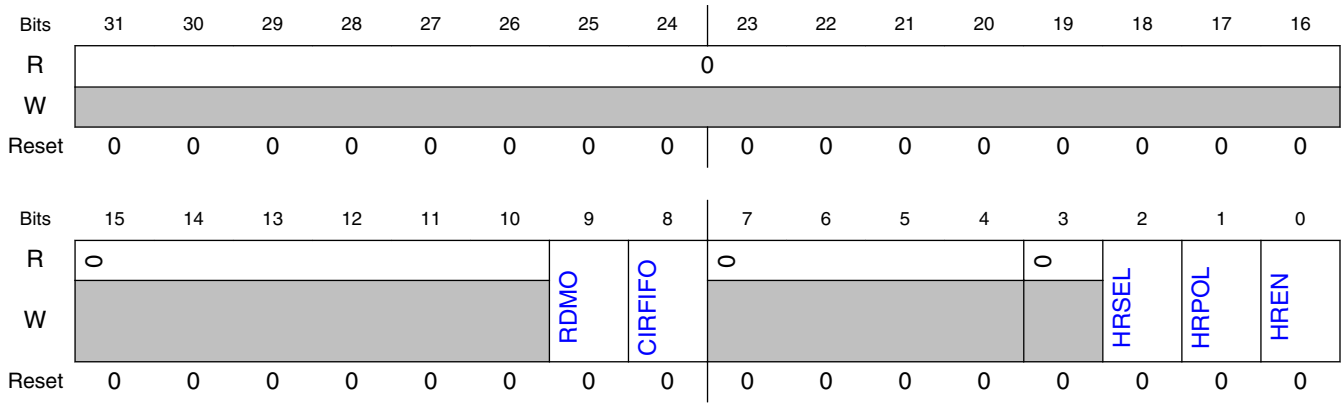
70.5.1.8.3 Diagram



70.5.1.8.4 Fields

Field	Function
31-10 —	Reserved
9 RDMO	Receive Data Match Only When enabled, all received data that does not cause the Data Match Flag (SR[DMF]) to assert is discarded. • Write 1 to this field when LPSPI is idle and SR[DMF] = 0. • After SR[DMF] = 1, this field is ignored. • To ensure that no receive data is lost when disabling RDMO, write 0 to this field before clearing SR[DMF]. See CFGR1[MATCFG] for the received data matching options. When disabled, all received data is stored in the receive FIFO. 0b - Disable 1b - Enable
8 CIRFIFO	Circular FIFO Enable When enabled, the transmit FIFO read pointer is saved to a temporary register. The transmit FIFO is emptied as in normal operation, but when LPSPI is idle and the transmit FIFO is empty, the read pointer value is restored from the temporary register. This restoring of the read pointer causes the contents of the transmit FIFO to be cycled through repeatedly. **NOTE:** The read pointer is restored for as long as this field is 1. Writing additional words to the FIFO when this field is 1 adds them to the end of the FIFO, up to the size of the transmit FIFO. 0b - Disable 1b - Enable
7-4 —	Reserved
3 —	Reserved
2	Host Request Select

Table continues on the next page...

Field	Function
HRSEL	Specifies the source of the host request input. When the host request function is enabled with the HREQ pin, the PCS[1] function is disabled. 0b - HREQ pin 1b - Input trigger
1 HRPOL	Host Request Polarity Specifies the polarity of the HREQ pin. 0b - Active high if CFGR1[PCSPOL] bit 1 is 0 1b - Active low if CFGR1[PCSPOL] bit 1 is 0
0 HREN	Host Request Enable In Master mode, allows LPSPI to start a new SPI bus transfer only if the host request input is asserted. When LPSPI is busy, the host request input is ignored. 0b - Disable 1b - Enable

70.5.1.12.4 Fields

Field	Function
31-24 SCKPCS	SCK-to-PCS Delay In Master mode: configures the delay from the last SCK edge to the PCS negation. • The delay is equal to (SCKPCS + 1) cycles of the LPSPI functional clock divided by the prescaler selected (see TCR[PRESCALE]). • The minimum delay is 1 cycle.

Table continues on the next page...

Field	Function
	See Figure 70-2.
23-16 PCSSCK	PCS-to-SCK Delay In Master mode: configures the delay from the PCS assertion to the first SCK edge. • The delay is equal to (PCSSCK + 1) cycles of the LPSPI functional clock divided by the prescaler selected (see TCR[PRESCALE]). • The minimum delay is 1 cycle. See Figure 70-2.

15-8
DBT
	Delay Between Transfers
	In Master mode:
	• Configures the delay from the PCS negation to the next PCS assertion.
	  • The delay is equal to (DBT + 2) cycles of the LPSPI functional clock divided by the prescaler selected (see TCR[PRESCALE]).
	  • The minimum delay is 2 cycles.
	  • Half of the delay occurs before PCS assertion and the other half of the delay occurs after PCS negation. If the command word is updated between 2 transfers, then the command word is updated halfway between the PCS negation of the last transfer and PCS assertion of the next transfer.
	  • The command word sets which PCS signal is used (of PCS[3:0]}, the polarity/phase of the SCK signal, and the prescaler selected.
	• Configures the delay from the last SCK edge of a transfer word and the first SCK edge of the next transfer word, in a continuous transfer.
	  • The delay is equal to (DBT + 1) cycles of the LPSPI functional clock divided by the prescaler selected (see TCR[PRESCALE]).
	  • The minimum delay is 1 cycle.

7-0 SCKDIV	SCK Divider In Master mode, configures the divide ratio of the SCK pin. • The SCK period is equal to (SCKDIV + 2) cycles of LPSPI functional clock divided by the prescaler selected (see TCR[PRESCALE]). • The minimum SCK period is 2 cycles. • If the SCK period is an odd number of cycles, then the first half of the SCK period is 1 cycle longer than the second half of the SCK period. Baud rate = Function clock / (2^PRESCALE * (SCKDIV+2))

70.5.1.15 Transmit Command (TCR)

70.5.1.15.1 Offset

Register	Offset
TCR	60h

70.5.1.15.2 Function

Writes to either this register or Transmit Data (TDR) push the data into the transmit FIFO, in the order written. Only write to this register using 32-bit writes. Writes are tagged and cause the command register to update, after that entry reaches the top of the FIFO and the LPSPI is enabled. This allows changes to the command word and the transmit data itself to be interleaved. That is, the writes to the two registers can be interleaved (write command word, then data word, then command word, and so on). Changing the command word causes all subsequent SPI bus transfers to be performed using the new command word.

- **In Master mode,** writing a new command word does not initiate a new transfer, unless TXMSK is 1. Transfers are initiated by transmit data in the transmit FIFO, or by a new command word (with TXMSK = 1). Hardware writes 0 to TXMSK when the PCS deasserts.
- **In Master mode,** if the command word is changed before an existing frame has completed, then the existing frame terminates and the command word then updates. The command word can be changed during a continuous transfer, if CONTC of the new command word is 1 and the command word is written on a frame size boundary.
- **In Slave mode,** the command word should be changed only when LPSPI is idle and there is no SPI bus transfer.

Avoid resetting the Transmit FIFO after writing to the Transmit Command Register, wait for the command register to update from the FIFO first.

Avoid register reading problems: Reading the Transmit Command Register returns the current state of the command register. Reading the Transmit Command Register at the same time that the Transmit Command Register is loaded from the transmit FIFO, can return an incorrect Transmit Command Register value. It is recommended to:

- Read the Transmit Command Register when the transmit FIFO is empty,
- Read the Transmit Command Register more than once and then compare the returned values.

70.5.1.15.4 Fields

Field	Function
31 CPOL	Clock Polarity Specifies the value of SCK when it is idle. This field can only be updated when PCS deasserted. See Figure 70-2. 0b - Inactive low 1b - Inactive high
30 CPHA	Clock Phase This field can only be updated when PCS deasserted. See Figure 70-2. 0b - Captured. Data is captured on the leading edge of SCK and changed on the following edge of SCK 1b - Changed. Data is changed on the leading edge of SCK and captured on the following edge of SCK
29-27 PRESCALE	Prescaler Value For all SPI bus transfers, this value is applied to Clock Configuration (CCR) clock. This field can only be updated when PCS deasserted. 000b - Divide by 1 001b - Divide by 2 010b - Divide by 4 011b - Divide by 8 100b - Divide by 16 101b - Divide by 32 110b - Divide by 64 111b - Divide by 128
26 —	Reserved
25-24 PCS	Peripheral Chip Select Configures the peripheral chip select used for the transfer. The Peripheral Chip Select field is only updated when PCS deasserted.

Table continues on the next page...

Field	Function
	NOTE: The entire PCS field is not fully supported in every LPSPI module instance. See the chip-specific LPSPI information. 00b - Transfer using PCS[0] 01b - Transfer using PCS[1] 10b - Transfer using PCS[2] 11b - Transfer using PCS[3]
23 LSBF	LSB First 0b - Data is transferred MSB first 1b - Data is transferred LSB first
22 BYSW	Byte Swap Swaps the contents of [31:24] with [7:0] and [23:16] with [15:8] for each transmit data word read from the FIFO and for each received data word stored to the FIFO (or compared with match registers). 0b - Disabled 1b - Enabled
21 CONT	Continuous Transfer • In Master mode, CONT keeps the PCS asserted at the end of the frame size, until a command word is received that starts a new frame. • In Slave mode, when CONT is enabled, LPSPI only transmits the first FRAMESZ bits; after which LPSPI transmits received data (assuming a 32-bit shift register) until the next PCS negation. 0b - Continuous transfer is disabled 1b - Continuous transfer is enabled
20 CONTC	Continuing Command In Master mode, this field enables the command word to be changed within a continuous transfer. • The initial command word must enable continuous transfer (CONT = 1). • The continuing command must have CONTC = 1. • The continuing command word must be loaded on a frame size boundary. For example, if the continuous transfer has a frame size of 64-bits, then a continuing command word must be loaded on a 64-bit boundary. 0b - Command word for start of new transfer 1b - Command word for continuing transfer
19 RXMSK	Receive Data Mask Masks receive data (receive data is not stored in receive FIFO). 0b - Normal transfer 1b - Receive data is masked
18 TXMSK	Transmit Data Mask Masks transmit data (no data is loaded from transmit FIFO and the output pin is 3-stated). In Master mode, TXMSK initiates a new transfer which cannot be aborted by another command word. TXMSK automatically transitions to 0 at the end of the transfer. 0b - Normal transfer 1b - Mask transmit data
17-16 WIDTH	Transfer Width Configures serial (1-bit) or parallel transfers. For half-duplex parallel transfers, either Receive Data Mask (RXMSK) or Transmit Data Mask (TXMSK) must be 1. 00b - 1-bit transfer 01b - 2-bit transfer 10b - 4-bit transfer 11b - Reserved
15-12	Reserved

Table continues on the next page...

Field	Function
—	
11-0 FRAMESZ	Frame Size Configures the frame size in number of bits equal to (FRAMESZ + 1). • The minimum frame size is 8 bits • The minimum word size is 2 bits; a frame size of 33 bits is not supported. • If the frame size is larger than 32 bits, then the frame is divided into multiple words of 32 bits; each word is loaded from the transmit FIFO and stored in the receive FIFO separately. • If the size of the frame is not divisible by 32, then the last load of the transmit FIFO and store of the receive FIFO contains the remainder bits. For example, a 72-bit transfer consists of 3 words: the first and second words are 32 bits, and the third word is 8 bits.

70.5.1.16 Transmit Data (TDR)

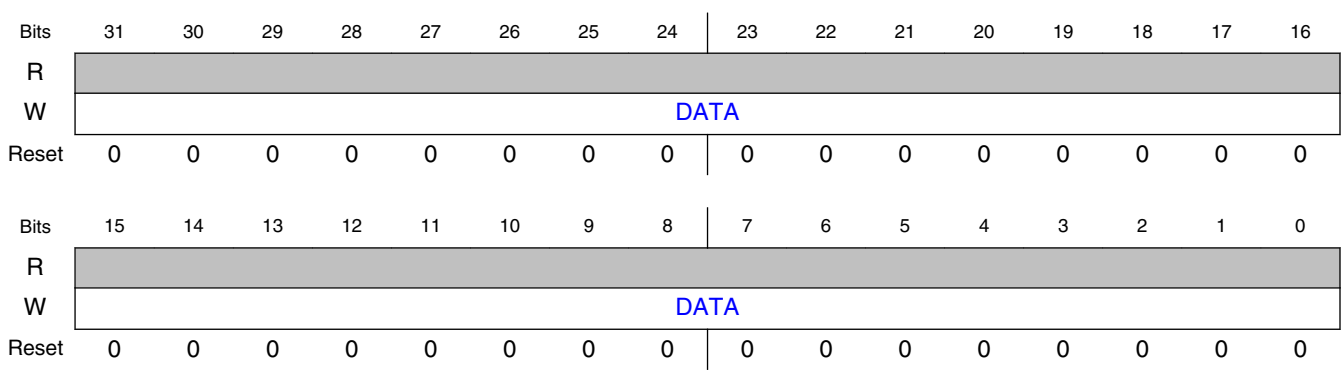
70.5.1.16.1 Offset

Register	Offset
TDR	64h

70.5.1.16.2 Function

Writes to either Transmit Command (TCR) or this register push the data into the transmit FIFO, in the order that the data is written. You can write to TDR using 32-, 16-, or 8-bit writes, but each write pushes data into the FIFO with zero pushed in unwritten bytes.

70.5.1.16.3 Diagram



70.5.1.16.4 Fields

Field	Function
31-0 DATA	Transmit Data Both 8- and 16-bit writes of transmit data zero-extend the data written and push the data into the transmit FIFO. To zero-extend 8- and 16-bit writes (to 32 bits), means that the higher order (most significant) empty parts of the 8-bit and 16-bit writes are filled with zeroes.

71.2 Overview

The Low Power Universal Asynchronous Receiver/Transmitter (LPUART) module provides asynchronous, serial communication capability with external devices. LPUART supports non-return-to-zero (NRZ) encoding format and IrDA compatible infrared (low-speed) SIR format. The LPUART can continue operating while the processor is in low-power mode if an appropriate peripheral clock is available.

71.2.1 Block diagram

The following figure shows the transmitter portion of the LPUART.

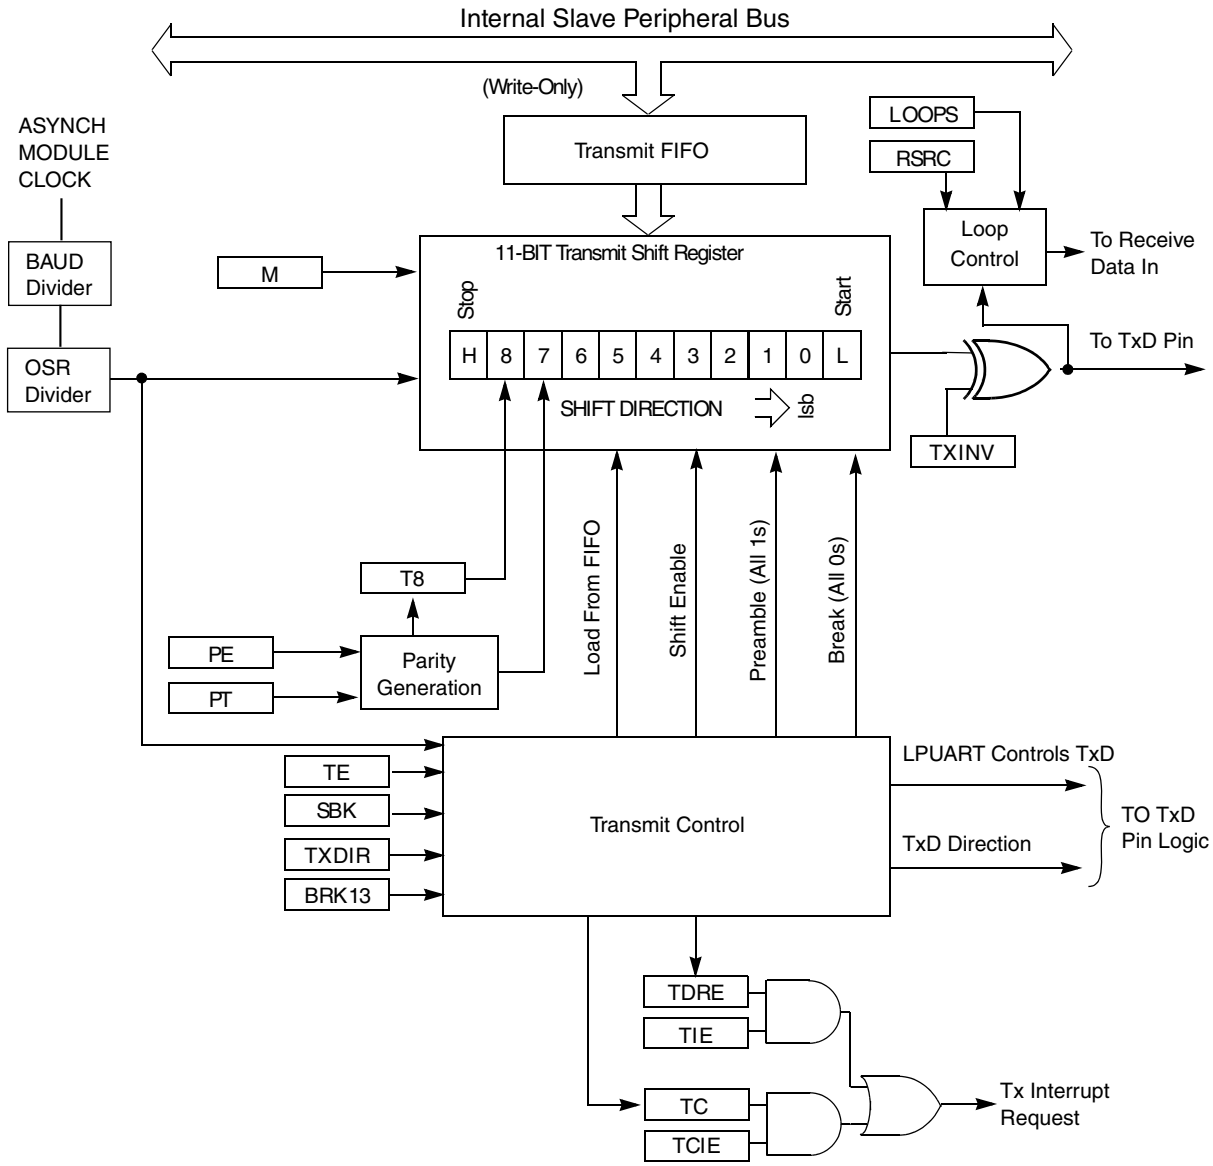

Figure 71-1. LPUART transmitter block diagram

The following figure shows the receiver portion of the LPUART.

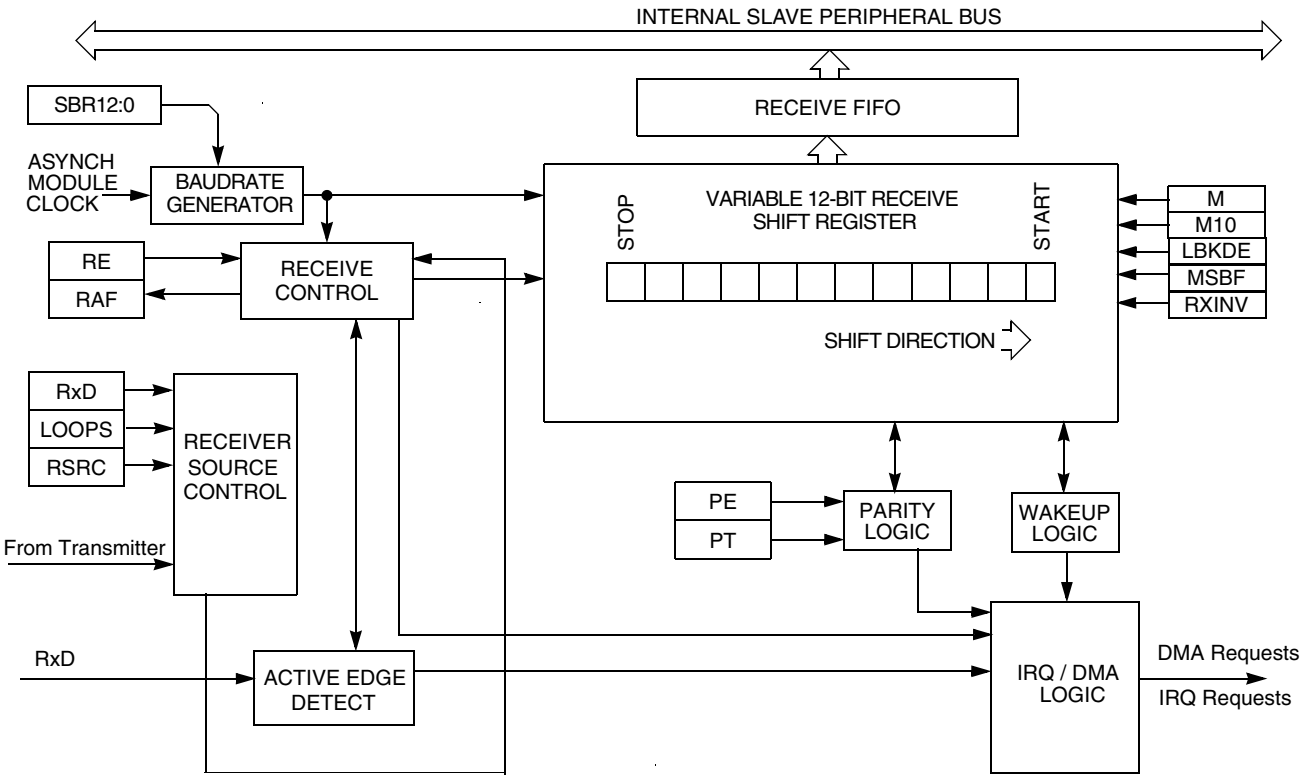

Figure 71-2. LPUART receiver block diagram

71.2.2 Features

Following are the features of the LPUART module.

- Full-duplex, standard non-return-to-zero (NRZ) format
- Programmable baud rates (13-bit modulo divider) with configurable oversampling ratio from 4x to 32x
- Asynchronous operation of transmit and receive baud rate with respect to the bus clock:
  - Baud rate can be configured independently of the bus clock frequency
  - Supports operation in Stop modes
- Interrupt, DMA or polled operation:
  - Transmit data register empty and transmission complete
  - Receive data register full
  - Receive overrun, parity error, framing error, and noise error
  - Idle receiver detect
  - Active edge on receive pin
  - Break detect supporting LIN
  - Receive data match
- Hardware parity generation and checking
- Programmable 7-bit, 8-bit, 9-bit or 10-bit character length

- Programmable 1-bit or 2-bit stop bits
- Support for three receiver wakeup methods:
  - Idle line wakeup
  - Address mark wakeup
  - Receive data match
- Automatic address matching to reduce ISR overhead:
  - Address mark matching
  - Idle line address matching
  - Address match start, address match end
- Optional 13-bit/11-bit break character generation
- Configurable idle length detection supporting 1, 2, 4, 8, 16, 32, 64, or 128 idle characters
- Selectable transmitter output and receiver input polarity
- Hardware flow control support for request to send (RTS) and clear to send (CTS) signals
- Selectable IrDA 1.4 return-to-zero-inverted (RZI) format with programmable pulse width
- Independent FIFO structure for transmit and receive
  - Separate configurable watermark for receive and transmit requests
  - Option for receiver to assert request after a configurable number of idle characters if receive FIFO is not empty

71.3 Functional description

The LPUART supports full-duplex, asynchronous, NRZ serial communication and comprises a baud rate generator, transmitter, and receiver block. The transmitter and receiver operate independently, although they use the same baud rate generator. The following describes each of the blocks of the LPUART.

71.3.1 Modes of operation

71.3.1.1 Stop mode

The LPUART remains functional during Stop mode, provided the CTRL[DOZEEN] bit is clear and the asynchronous transmit and receive clock remain enabled. The LPUART can generate an interrupt or DMA request to cause a wakeup from Stop mode.

If the LPUART is disabled in Stop mode, then it can generate a wakeup via the STAT[RXEDGIF] flag if the receiver detects an active edge.

71.3.1.2 Wait mode

The LPUART can be configured to Stop in Wait modes, when the CTRL[DOZEEN] bit is set. The transmitter and receiver finish transmitting/receiving the current word.

71.3.1.3 Debug mode

The LPUART remains functional in debug mode.

71.3.2 Clocking and Resets

Table 71-2. Clocks

LPUART Functional clock	The LPUART functional clock is asynchronous to the bus clock and can remain enabled in low power modes to support transmit and/or receive, including low power wakeups.
Bus clock	The bus clock is only used for bus accesses to the control and configuration registers. The bus clock frequency must be sufficient to support the data bandwidth requirements of the LPUART transmit and receive registers, including the FIFOs.

Table 71-3. Resets

Chip reset	The logic and registers for the LPUART transmitter and receiver are reset to their default state on a chip reset.
Software reset	Resets the LPUART logic and registers to their default state, except for the Global Register. The LPUART software reset is in the Global Register GLOBAL[RST].
FIFO reset	The LPUART implements write-only control bits that reset the transmit FIFO (FIFO[TXFLUSH]) and receive FIFO (FIFO[RXFLUSH]). After a FIFO is reset, that FIFO is empty.

71.3.3 Baud rate generation

A 13-bit modulus counter in the baud rate generator derives the baud rate for both the receiver and the transmitter. The value from 1 to 8191 written to BAUD[SBR] determines the baud clock divisor for the asynchronous LPUART baud clock. The baud rate clock drives the receiver, while the transmitter is driven by a bit clock which is generated from baud rate clock divided by the over sampling ratio (OSR). Depending on the over sampling ratio, the receiver has an acquisition rate of 4 to 32 samples per bit time.

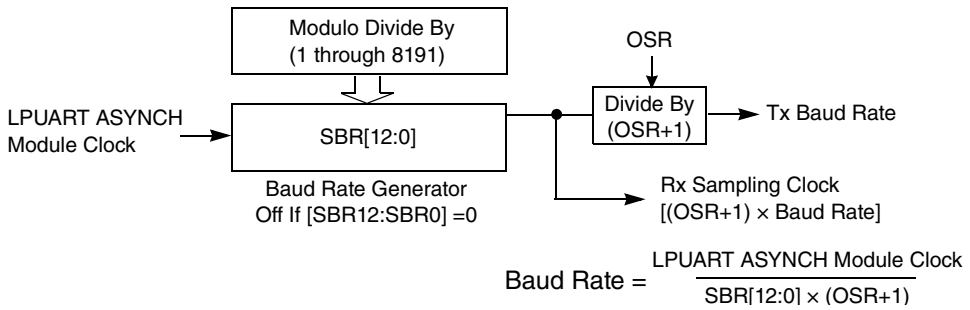

Figure 71-3. LPUART baud rate generation

Baud rate generation is subject to two sources of error:

- Integer division of the asynchronous LPUART baud clock may not give the exact target frequency.
- Synchronization with the asynchronous LPUART baud clock can cause phase shift.

The baud rate generation is a free-running counter that continues whenever the transmitter or receiver is enabled. The transmitter bit clock continues whenever the transmitter is enabled; each transmitted character aligns to the next edge of the transmit bit clock.

In general, configuring OSR for a higher oversampling ratio and/or sampling on both edges of the clock slightly improves the LPUART tolerance to baud rate mismatch between the received data and the LPUART configured baud rate. However, the three data samples in each bit will also be closer together which may impact noise sensitivity.

71.3.4 Transmitter functional description

This section describes the overall block diagram for the LPUART transmitter, as well as specialized functions for sending break and idle characters.

The transmitter output (TXD) idle state defaults to logic high; the transmitter output is inverted by setting CTRL[TXINV]. CTRL[TXINV] is cleared following reset. The transmitter is enabled by setting the CTRL[TE] bit. This queues a preamble character that is one full character frame of the idle state. The transmitter then remains idle until data is available in the transmit FIFO. Programs store data into the transmit FIFO by writing to the DATA register.

The central element of the LPUART transmitter is the transmit shift register that is 9-bit to 13-bit long depending on the setting in the CTRL[M], CTRL[M7], BAUD[M10] and BAUD[SBNS] control bits. For the remainder of this section, assume CTRL[M], CTRL[M7], BAUD[M10] and BAUD[SBNS] are cleared, selecting the normal 8-bit data

mode. In 8-bit data mode, the shift register holds a start bit, eight data bits, and a stop bit. When the transmit shift register is available for a new character, the value waiting in the transmit data register is transferred to the transmit shift register, synchronized with the baud rate clock, and the transmit data register empty (STAT[TDRE]) status flag is set to indicate another character may be written to the transmit FIFO at the DATA register.

If no new character is waiting in the transmit FIFO after a stop bit is shifted out of the TXD pin, the transmitter sets the transmit complete flag and enters an idle mode, with TXD high, waiting for more characters to transmit.

Writing 0 to CTRL[TE] does not immediately disable the transmitter. The current transmit activity in progress must first be completed (that could include a data character, idle character or break character), although the transmitter does not start transmitting another character.

71.3.4.1 Send break and queued idle

The CTRL[SBK] bit sends break characters originally used to gain the attention of old teletype receivers. Break characters are a full character time of logic 0, 9-bit to 12-bit times including the start and stop bits. A longer break of 13-bit times can be enabled by setting STAT[BRK13]. Normally, a program waits for STAT[TDRE] to become set to indicate the last character of a message has moved to the transmit shifter, write 1, and then write 0 to the CTRL[SBK] bit. This action queues a break character to be sent as soon as the shifter is available. If CTRL[SBK] remains 1 when the queued break moves into the shifter, synchronized to the baud rate clock, an additional break character is queued. When the LPUART is the receiving device, a break character is received as 0s in all data bits and a framing error (STAT[FE] = 1) is detected.

A break character can also be transmitted by writing to the DATA register with DATA[FRETSC] set and the data bits clear. This supports transmitting the break character as part of the normal data stream and also allows the DMA to transmit a break character.

When idle-line wakeup is used, a full character time of idle (logic 1) is needed between messages to wake up any sleeping receivers. Normally, a program waits for STAT[TDRE] to become set to indicate the last character of a message has moved to the transmit shifter, write 0, and then write 1 to the CTRL[TE] bit. This action queues an idle character to be sent as soon as the shifter is available. As long as the character in the shifter does not finish while CTRL[TE] is cleared, the LPUART transmitter never actually releases control of the TXD pin.

An idle character can also be transmitted by writing to the DATA register with DATA[FRETSC] and DATA[T9] set, and all other bits cleared. This supports transmitting the idle character as part of the normal data stream and also allows the DMA to transmit a idle character.

The length of the break character is affected by the STAT[BRK13], CTRL[M], CTRL[M7], BAUD[M10] and BAUD[SNBS] bits as shown below.

Table 71-4. Break character length

BRK13	M	M10	M7	SBNS	Break character length
0	0	0	0	0	10 bit times
0	0	0	0	1	11 bit times
0	0	0	1	0	9 bit times
0	0	0	1	1	10 bit times
0	1	0	X	0	11 bit times
0	1	0	X	1	12 bit times
0	X	1	X	0	12 bit times
0	X	1	X	1	13 bit times
1	0	0	0	0	13 bit times
1	0	0	0	1	13 bit times
1	0	0	1	0	12 bit times
1	0	0	1	1	12 bit times
1	1	0	X	0	14 bit times
1	1	0	X	1	14 bit times
1	X	1	X	0	15 bit times
1	X	1	X	1	15 bit times

71.3.4.2 Hardware flow control

The transmitter supports hardware flow control by gating the transmission with the value of CTS_B. If the clear-to-send operation is enabled, the character is transmitted when CTS_B is asserted. If CTS_B is deasserted in the middle of a transmission with characters remaining in the transmitter FIFO, the character in the transmit shift register will be complete; any characters in the FIFO will wait for the CTS_B to assert again and TXD remains in the mark state (idle state) until CTS_B is reasserted. The CTS_B pin must assert for longer than one bit period to guarantee a new transmission is started when the transmitter is idle with data to send.

If the clear-to-send operation is disabled, the transmitter ignores the state of CTS_B.

The transmitter's CTS_B signal can be enabled even if the same LPUART receiver's RTS_B signal is disabled.

71.3.4.3 Transceiver driver enable

The transmitter can use RTS_B as an enable signal for the driver of an external transceiver. See Transceiver driver enable using RTS_B for details. If the request-to-send operation is enabled, when a character is placed into an empty transmit shift register, RTS_B asserts one bit time before the start bit is transmitted. RTS_B remains asserted for the whole time that the transmit shift register has any characters. RTS_B deasserts one bit time after all characters in the transmit FIFO and shift register are completely sent, including the last stop bit. In other words, when RTS_B is used as a transceiver enable, the RTS_B asserts 1 bit time before the transmitter starts transmitting and negates 1 bit time after the transmitter goes idle.

Transmitting a break character also asserts RTS_B, with the same assertion and deassertion timing as having a character in the transmit shift register.

The transmitter's RTS_B signal asserts only when the transmitter is enabled. However, the transmitter's RTS_B signal is unaffected by its CTS_B signal. RTS_B remains asserted until the transfer is completed, even if the transmitter is disabled mid-way through a data transfer.

71.3.4.4 Transceiver driver enable using RTS_B

RS-485 is a multiple drop communication protocol in which the LPUART transceiver's driver is 3-stated unless the LPUART is driving. The RTS_B signal can be used by the transmitter to enable the driver of a transceiver. The polarity of RTS_B can be matched to the polarity of the transceiver's driver enable signal.

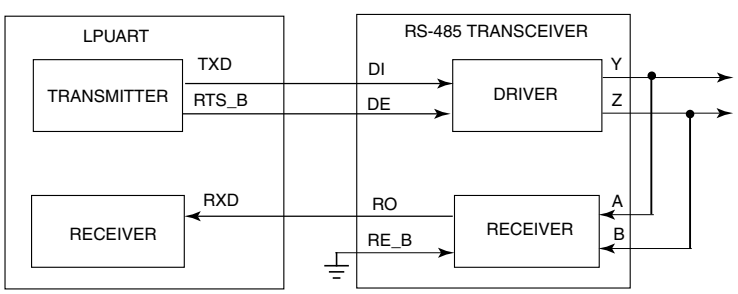

Figure 71-4. Transceiver driver enable using RTS_B

In the figure, the receiver enable signal is asserted. Another option for this connection is to connect RTS_B to both DE and RE_B. The transceiver's receiver is disabled while driving. A pullup can pull RXD to a non-floating value during this time. This option can be refined further by operating the LPUART in single wire mode, freeing the RXD pin for other uses.

71.3.5 Receiver functional description

In this section, the receiver block diagram is a guide for the overall receiver functional description. Next, the data sampling technique used to reconstruct receiver data is described in more detail. Finally, different variations of the receiver wakeup function are explained.

The receiver input is inverted by setting STAT[RXINV]. The receiver is enabled by setting the CTRL[RE] bit. Character frames consist of a start bit of logic 0, seven to ten data bits (msb or lsb first), and one or two stop bits of logic 1. For information about 7-bit, 9-bit or 10-bit data mode, refer to Data Modes. For the remainder of this discussion, assume the LPUART is configured for normal 8-bit data mode.

After receiving the stop bit into the receive shifter, and provided the receive data register is not already full, the data character is transferred to the receive data register and the receive data register full (STAT[RDRF]) status flag is set. If [RDRF] was already set indicating the receive data register (buffer) was already full, the overrun (OR) status flag is set and the new data is lost.

Since the LPUART receiver is separate from the receive FIFO, the receive shift register can be receiving the next word when the receive FIFO is full and it is only at the end of the character that the next data is written into the receive FIFO, potentially triggering the overrun flag if FIFO is full.

When a program detects that the receive data register is full (STAT[RDRF] = 1), it gets the data from the receive data register by reading the DATA register. Refer to Interrupts and status flags for details about flag clearing.

71.3.5.1 Data sampling technique

The LPUART receiver supports a configurable oversampling rate of between 4× and 32× of the baud rate clock for sampling. The receiver starts by taking logic level samples at the oversampling rate times the baud rate to search for a falling edge on the RXD serial data input pin. A falling edge is defined as a logic 0 sample after three consecutive logic 1 samples. The oversampling baud rate clock divides the bit time into 4 to 32 segments from 1 to OSR (where OSR is the configured oversampling ratio). When a falling edge is

located, three more samples are taken at (OSR/2), (OSR/2)+1, and (OSR/2)+2 to make sure this was a real start bit and not merely noise. If at least two of these three samples are 0, the receiver assumes it is synchronized to a received character. If another falling edge is detected before the receiver is considered synchronized, the receiver restarts the sampling from the first segment.

The receiver then samples each bit time, including the start and stop bits, at (OSR/2), (OSR/2)+1, and (OSR/2)+2 to determine the logic level for that bit. The logic level is interpreted to be that of the majority of the samples taken during the bit time. If any sample in any bit time, including the start and stop bits, in a character frame fails to agree with the logic level for that bit, the noise flag (STAT[NF]) is set when the received character is transferred to the receive FIFO.

When the LPUART receiver is configured to sample on both edges of the baud rate clock (that is, when BAUD[BOTHEDGE]=1), the number of segments in each received bit is effectively doubled (from 1 to OSR×2). The start and data bits are then sampled at OSR, OSR+1 and OSR+2. Sampling on both edges of the clock must be enabled for oversampling rates of 4× to 7× and is optional for higher oversampling rates.

The "synchronization" is a feature of the LPUART module to synchronize the internal oversampling counter with detected falling edge on Rx signal, and to adjust the data sampling window. The falling edge detection needs three consecutive '1' prior to '1'->'0' transition. After the initial falling edge detection for the start bit, the circuit continuously monitors the next falling edge, and resets the counter once another falling edge is detected. This is called "resynchronization".

- When LPUART_BAUD[RESYNCDIS] = 0, this falling edge detection and resynchronization is performed not only for the start bit but also for the rest of character reception after the start bit.
- When LPUART_BAUD[RESYNCDIS] = 1, the falling edge detection and resynchronization is performed only for the start bit. The use case for disabling the resynchronization is protocols that require this (for example, LIN 2.1 prohibits resynchronization within a byte).

  See the following table and figure.

Table 71-5. LPUART resynchronization

Resynchronization	LPUART_BAUD[RESYNCDIS]=0	LPUART_BAUD[RESYNCDIS]=1
For the starting bit falling edge	Yes	Yes
For every falling edges after the start bit	Yes	No

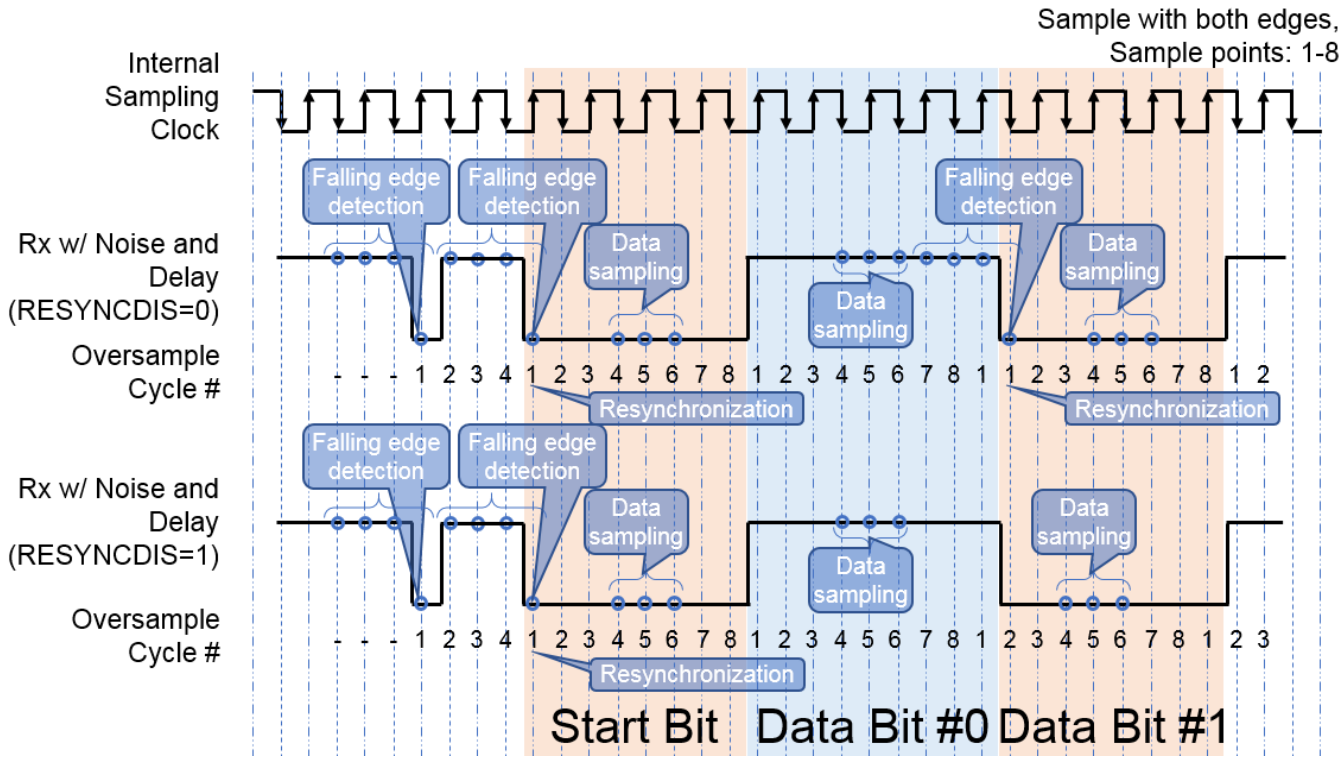

Figure 71-5. LPUART resynchronization

71.3.5.2 Receiver wakeup operation

Receiver wakeup and receiver address matching is a hardware mechanism that allows an LPUART receiver to ignore the characters in a message intended for a different receiver.

During receiver wakeup, all receivers evaluate the first character(s) of each message, and as soon as they determine the message is intended for a different receiver, they write logic 1 to the receiver wake up control bit (CTRL[RWU]). When CTRL[RWU] and STAT[RWUID] bit are set, the status flags associated with the receiver, with the exception of the idle bit, STAT[IDLE], are inhibited from setting, thus eliminating the software overhead for handling the unimportant message characters. At the end of a message, all receivers automatically force CTRL[RWU] to 0 so all receivers wake up in time to look at the first character(s) of the next message.

During receiver address matching, the address matching is performed in hardware and the LPUART receiver ignores all characters that do not meet the address match requirements.

Table 71-6. Receiver Wakeup Options

RWU	MA1 | MA2	MATCFG	WAKE:RWUID	Receiver Wakeup
0	0	X	X	Normal operation

Table continues on the next page...

Table 71-6. Receiver Wakeup Options (continued)

RWU	MA1 | MA2	MATCFG	WAKE:RWUID	Receiver Wakeup
1	0	00	00	Receiver wakeup on idle line, IDLE flag not set
1	0	00	01	Receiver wakeup on idle line, IDLE flag set
1	0	00	10	Receiver wakeup on address mark
1	1	11	10	Receiver wakeup on data match
0	1	00	X0	Address mark address match, IDLE flag not set for discarded characters
0	1	00	X1	Address mark address match, IDLE flag set for discarded characters
0	1	01	X0	Idle line address match
0	1	10	X0	Match On and Match Off, IDLE flag not set for discarded characters
0	1	10	X1	Match On and Match Off, IDLE flag set for discarded characters

71.3.5.2.1 Idle-line wakeup

When CTRL[WAKE] is cleared, the receiver is configured for idle-line wakeup. In this mode, CTRL[RWU] is cleared automatically when the receiver detects a full character time of the idle-line level. The CTRL[M], CTRL[M7], and BAUD[M10] control bits select 7-bit to 10-bit data mode and the BAUD[SBNS] bit selects 1-bit or 2-bit stop bit number that determines how many bit times of idle are needed to constitute a full character time, 9 to 13 bit times because of the start and stop bits.

When CTRL[RWU] is 1 and STAT[RWUID] is 0, the idle condition that wakes up the receiver does not set the STAT[IDLE] flag. The receiver wakes up and waits for the first data character of the next message that sets the STAT[RDRF] flag and generates an interrupt if enabled. When STAT[RWUID] is 1, any idle condition sets the STAT[IDLE] flag and generates an interrupt if enabled, regardless of whether CTRL[RWU] is 0 or 1.

The idle-line type (CTRL[ILT]) control bit selects one of two ways to detect an idle line.

- When CTRL[ILT] is cleared, the idle bit counter starts after the start bit so the stop bit and any logic 1s at the end of a character count toward the full character time of idle.
- When CTRL[ILT] is set, the idle bit counter does not start until after the stop bit time, so the idle detection is not affected by the data in the last character of the previous message.

71.3.5.2.2 Address-mark wakeup

When CTRL[WAKE] is set, the receiver is configured for address-mark wakeup. In this mode, CTRL[RWU] is cleared automatically when the receiver detects a logic 1 in the most significant bit of the received character. When parity is enabled, the second most significant bit is used for address-mark wakeup.

Address-mark wakeup allows messages to contain idle characters, but requires one bit be reserved for use in address frames. The logic 1 in the most significant bit (or second most significant bit when parity is enabled) of an address frame clears the CTRL[RWU] bit and sets the STAT[RDRF] flag. In this case, the character with the address-mark bit is received even though the receiver was sleeping during most of this character time.

71.3.5.2.3 Data match wakeup

When CTRL[RWU] is set, CTRL[WAKE] is set and BAUD[MATCFG] equals 11, the receiver is configured for data match wakeup. In this mode, CTRL[RWU] is cleared automatically when the receiver detects a character that matches MATCH[MA1] field when BAUD[MAEN1] is set, or that matches MATCH[MA2] when BAUD[MAEN2] is set.

71.3.5.2.4 Address Match operation

Address match operation is enabled when the BAUD[MAEN1] or BAUD[MAEN2] bit is set and BAUD[MATCFG] is equal to 00. In this function, a character received by the RXD pin with a logic 1 in the most significant bit (or second most significant bit when parity is enabled) is considered an address and is compared with the associated MATCH[MA1] or MATCH[MA2] field. The character is only transferred to the receive buffer, and STAT[RDRF] is set, if the comparison matches. All subsequent characters received with a logic 0 in the most significant bit (or second most significant bit when parity is enabled) are considered to be data associated with the address and are transferred to the receive FIFO. If no marked address match occurs then no transfer is made to the receive FIFO, and all following characters with logic zero in the most significant bit (or

second most significant bit when parity is enabled) are also discarded. If both the BAUD[MAEN1] and BAUD[MAEN2] bits are negated, the receiver operates normally and all data received is transferred to the receive FIFO.

Address match operation functions in the same way for both MATCH[MA1] and MATCH[MA2] fields.

- If only one of BAUD[MAEN1] and BAUD[MAEN2] is asserted, a marked address is compared only with the associated match register field and data is transferred to the receive FIFO only on a match.
- If BAUD[MAEN1] and BAUD[MAEN2] are asserted, a marked address is compared with both match registers and data is transferred only on a match with either of the MATCH[MA1] or MATCH[MA2] fields.

71.3.5.2.5 Idle Match operation

Idle match operation is enabled when the BAUD[MAEN1] or BAUD[MAEN2] bit is set and BAUD[MATCFG] is equal to 01. In this function, the first character received by the RXD pin after an idle line condition is considered an address and is compared with the associated MATCH[MA1] or MATCH[MA2] field. The character is transferred only to the receive buffer, and STAT[RDRF] is set, if the comparison matches. All subsequent characters are considered to be data associated with the address and are transferred to the receive FIFO until the next idle line condition is detected. If no address match occurs then no transfer is made to the receive FIFO, and all following frames until the next idle condition are also discarded. If both the BAUD[MAEN1] and BAUD[MAEN2] bits are negated, the receiver operates normally and all data received is transferred to the receive FIFO.

Idle match operation functions in the same way for both MATCH[MA1] or MATCH[MA2] fields.

- If only one of BAUD[MAEN1] and BAUD[MAEN2] is asserted, the first character after an idle line is compared only with the associated match register and data is transferred to the receive FIFO only on a match.
- If BAUD[MAEN1] and BAUD[MAEN2] are asserted, the first character after an idle line is compared with both MATCH[MA1] or MATCH[MA2] fields and data is transferred only on a match with either of the fields.

71.3.5.2.6 Match On Match Off operation

Match on, match off operation is enabled when both BAUD[MAEN1] and BAUD[MAEN2] are set and BAUD[MATCFG] is equal to 10. In this function, a character received by the RXD pin that matches MATCH[MA1] is received and transferred to the receive buffer, and STAT[RDRF] is set. All subsequent characters are considered to be data and are also transferred to the receive FIFO, until a character is received that matches MATCH[MA2] field. The character that matches MATCH[MA2] and all following characters are discarded; this continues until another character that matches MATCH[MA1] is received. If both the BAUD[MAEN1] and BAUD[MAEN2] bits are negated, the receiver operates normally and all data received is transferred to the receive FIFO.

NOTE

Match on, match off operation requires both BAUD[MAEN1] and BAUD[MAEN2] to be asserted.

71.3.5.3 Hardware flow control

To support hardware flow control, the receiver can be programmed to automatically deassert and assert RTS_B.

- RTS_B remains asserted until the transfer is complete, even if the transmitter is disabled midway through a data transfer. See Transceiver driver enable using RTS_B for more details.
- If the receiver request-to-send functionality is enabled, the receiver automatically deasserts RTS_B if the number of characters in the receiver data register is full or a start bit is detected that causes the receiver data register to be full.
- The receiver asserts RTS_B when the number of characters in the receiver data register is not full and has not detected a start bit that causes the receiver data register to be full. It is not affected if STAT[RDRF] is asserted.
- Even if RTS_B is deasserted, the receiver continues to receive characters until the receive FIFO is overrun.
- If the receiver request-to-send functionality is disabled, the receiver RTS_B remains deasserted.

71.3.6 Additional LPUART functions

The following sections describe additional LPUART functions.

71.3.6.1 Data Modes

The LPUART transmitter and receiver can be configured to operate in 7-bit data mode by setting CTRL[M7], 9-bit data mode by setting the CTRL[M] or 10-bit data mode by setting BAUD[M10]. In 9-bit mode, there is a ninth data bit and in 10-bit mode, there is a tenth data bit.

When performing 8-bit writes to the transmit FIFO, the 9th and 10th bit are pushed into the FIFO from CTRL[T8] and CTRL[T9]. For coherent 8-bit writes, write to CTRL[T8] and CTRL[T9] before writing to DATA[7:0], but if values in CTRL[T8] or CTRL[T9] do not need to change then it is not necessary to update CTRL[T8] and CTRL[T9] before every 8-bit write to the DATA register.

When performing 16-bit or 32-bit writes to the transmit FIFO, all 10-bits are pushed into the transmit FIFO from the write data.

When performing 8-bit reads of the receive FIFO, the 9th and 10th bit are held in CTRL[R8] and CTRL[R9] but should be read before reading the DATA register. A 16-bit or 32-bit read of the receive FIFO will return all 10-bits in the DATA register.

The 9-bit data mode is typically used with parity to allow eight bits of data plus the parity in the ninth bit, or it is used with address-mark wakeup so the ninth data bit can serve as the wakeup bit. The 10-bit data mode is typically used with parity and address-mark wakeup so the ninth data bit can serve as the wakeup bit and the tenth bit as the parity bit. In custom protocols, the ninth and/or tenth bits can also serve as software-controlled markers.

71.3.6.2 Idle length

An idle character is a character where the start bit, all data bits and stop bits are in the mark position (idle state, generally logic 1). The CTRL[ILT] bit can be configured to start detecting an idle character from the previous start bit (any data bits and stop bits count towards the idle character detection) or from the previous stop bit.

The number of idle characters that must be received before an idle line condition is detected can also be configured using the CTRL[IDLECFG] field. This field configures the number of idle characters that must be received before the STAT[IDLE] flag is set, the STAT[RAF] flag is cleared and the DATA[IDLINE] flag is set with the next received character.

Idle-line wakeup and idle match operation are also affected by the CTRL[IDLECFG] field. When address match or match on/off operation is enabled, setting the STAT[RWUID] bit causes any discarded characters to be treated as if they were idle characters.

71.3.6.3 Loop mode

When CTRL[LOOPS] is set, the CTRL[RSRC] bit chooses between loop mode (CTRL[RSRC] = 0) or single-wire mode (CTRL[RSRC] = 1). Loop mode is sometimes used to check software, independent of connections in the external system, to help isolate system problems. In this mode, the transmitter output is internally connected to the receiver input and the RXD pin is not used by the LPUART.

71.3.6.4 Single-wire operation

When CTRL[LOOPS] is set, the CTRL[RSRC] bit chooses between loop mode (CTRL[RSRC] = 0) or single-wire mode (CTRL[RSRC] = 1). Single-wire mode implements a half-duplex serial connection. The receiver is internally connected to the transmitter output and to the TXD pin (the RXD pin is not used).

In single-wire mode, the CTRL[TXDIR] bit controls the direction of serial data on the TXD pin. When CTRL[TXDIR] is cleared, the TXD pin is an input to the receiver and the transmitter is temporarily disconnected from the TXD pin so an external device can send serial data to the receiver. When CTRL[TXDIR] is set, the TXD pin is an output driven by the transmitter, the internal loop back connection is disabled, and as a result the receiver cannot receive characters that are sent out by the transmitter.

71.3.7 Infrared interface

The LPUART provides the capability of transmitting narrow pulses to an IR LED and receiving narrow pulses and transforming them to serial bits, which are sent to the LPUART. The IrDA physical layer specification defines a half-duplex infrared communication link for exchanging data. The full standard includes data rates up to 16 Mbits/s. The LPUART IrDA support is limited to SIR mode which supports data rates only between 2.4 kbits/s and 115.2 kbits/s.

The LPUART has an infrared transmit encoder and receive decoder. The infrared decoder converts the received character from the IrDA format to the NRZ format used by the receiver. It also has a OSR oversampling baud rate clock counter that filters noise and indicates when a 1 is received. The LPUART transmits serial bits of data that are encoded by the infrared submodule to transmit a narrow pulse for every zero bit. No pulse is transmitted for every one bit. When receiving data, the IR pulses are detected using an IR photo diode (external to LPUART) and transformed to CMOS levels by the IR receive decoder. The narrow pulses are then stretched by the infrared receive decoder to get back

to a serial bit stream to be received by the LPUART. The polarity of transmitted pulses and expected receive pulses can be inverted so that a direct connection can be made to external IrDA transceiver modules that use active high pulses.

The infrared submodule receives its clock sources from the LPUART. One of these two clocks are selected in the infrared submodule to generate either 1/OSR, 2/OSR, 3/OSR, or 4/OSR narrow pulses during transmission.

71.3.7.1 Infrared transmit encoder

The infrared transmit encoder converts serial bits of data from transmit shift register to the TXD signal. A narrow pulse is transmitted for a 0 bit and no pulse for a 1 bit. The narrow pulse is sent at the start of the bit with a duration of 1/OSR, 2/OSR, 3/OSR, or 4/OSR of a bit time. A narrow low pulse is transmitted for a 0 bit when CTRL[TXINV] is cleared, while a narrow high pulse is transmitted for a 0 bit when CTRL[TXINV] is set.

71.3.7.2 Infrared receive decoder

The infrared receive block converts data from the RXD signal to the receive shift register. A narrow pulse is expected for each 0 received and no pulse is expected for each 1 received. A narrow low pulse is expected for a 0 bit when STAT[RXINV] is cleared, while a narrow high pulse is expected for a 0 bit when STAT[RXINV] is set. This receive decoder meets the edge jitter requirement as defined by the IrDA serial infrared physical layer specification.

71.3.7.3 Start bit detection

When STAT[RXINV] is cleared, the first falling edge of the received character corresponds to the start bit. The infrared decoder resets its counter. At this time, the receiver also begins its start bit detection process. After the start bit is detected, the receiver synchronizes its bit times to this start bit time. For the rest of the character reception, the infrared decoder's counter and the receiver's bit time counter count independently from each other.

71.3.7.4 Noise filtering

Any further rising edges detected during the first half of the infrared decoder counter are ignored by the decoder. Any pulses less than one oversampling baud clock can be undetected by it regardless of whether it is seen in the first or second half of the count.

71.3.7.5 Low-bit detection

During the second half of the decoder count, a rising edge is decoded as a 0, which is sent to the receiver. The decoder counter is also reset.

71.3.7.6 High-bit detection

At OSR oversampling baud rate clocks after the previous rising edge, if a rising edge is not seen, then the decoder sends a 1 to the receiver.

If the next bit is a 0, which arrives late, then a low-bit is detected according to Low-bit detection. The value sent to the receiver is changed from 1 to a 0. Then, if a noise pulse occurs outside the receiver's bit time sampling period, then the delay of a 0 is not recorded as noise.

71.3.8 Interrupts and status flags

The LPUART transmitter has two status flags that can optionally generate hardware interrupt requests. Transmit Data Register Empty (STAT[TDRE]) indicates when there is room in the transmit FIFO to write another transmit character to the DATA register. If the Transmit Interrupt Enable (CTRL[TIE]) bit is set, a hardware interrupt is requested when STAT[TDRE] is set. Transmit complete (STAT[TC]) indicates that the transmitter is finished transmitting all data, preamble, and break characters and is idle with TXD at the inactive level. This flag is often used in systems with modems to determine when it is safe to turn off the modem. If the transmit complete interrupt enable (CTRL[TCIE]) bit is set, a hardware interrupt is requested when STAT[TC] is set. Instead of hardware interrupts, software polling may be used to monitor the STAT[TDRE] and STAT[TC] status flags if the corresponding CTRL[TIE] or CTRL[TCIE] local interrupt masks are cleared.

When a program detects that the receive data register is full (STAT[RDRF] = 1), it gets the data from the receive data register by reading the DATA register. The STAT[RDRF] flag is cleared by reading the DATA register.

The IDLE status flag includes logic that prevents it from getting set repeatedly when the RXD line remains idle for an extended period of time. IDLE is cleared by writing 1 to the STAT[IDLE] flag. After STAT[IDLE] has been cleared, it cannot become set again until the receiver has received at least one new character and has set STAT[RDRF].

If the associated error is detected in the received character that caused STAT[RDRF] to be set, the error flags — noise flag (STAT[NF]), framing error (STAT[FE]), and parity error flag (STAT[PF]) — are set at the same time as STAT[RDRF]. These flags are not set in overrun cases.

If STAT[RDRF] is already set when a new character is ready to be transferred from the receive shifter to the receive FIFO, the overrun (STAT[OR]) flag is set instead of the data along with any associated STAT[NF], STAT[FE], or STAT[PF] condition is lost.

If the received character matches the contents of MATCH[MA1] and/or MATCH[MA2] then the STAT[MA1F] and/or STAT[MA2F] flags are set at the same time that STAT[RDRF] is set.

At any time, an active edge on the RXD serial data input pin causes the STAT[RXEDGIF] flag to set. The STAT[RXEDGIF] flag is cleared by writing a 1 to it. This function depends on the receiver being enabled (CTRL[RE] = 1).

71.3.9 Peripheral Triggers

The connection of the LPUART peripheral triggers with other peripherals are device specific.

71.3.9.1 Output Triggers

The LPUART generates the following output triggers that can be connected to other peripherals on the device.

- The transmit word trigger asserts at the end of each transmitted word, it negates after one bit period.
- The receive word trigger asserts at the end of each received word that is written to the receive FIFO, for one oversampling clock period.
- The receive idle trigger asserts when the idle flag would set, for one oversampling clock period.

71.3.9.2 Input Trigger

The LPUART supports one peripheral input trigger, that can be configured in one of the following ways.

- The CTS function must be enabled. The input trigger can be connected in place of the CTS_B pin input. The input trigger must assert for longer than one bit clock period when the transmitter is idle with data to send to guarantee a new transmission.
- The input trigger can modulate the transmit data output (trigger is logically ANDed with the TXD output). The input trigger is expected to be a free running clock (carrier signal) generated from a timer or PWM source with a frequency that is greater than the bit clock frequency. The carrier signal must not toggle faster than the maximum supported bit time.
- The input trigger can be connected in place of the RXD pin input. The input trigger is expected to be generated from a receive data source, such as analog comparator or external pin.

71.4 External signals

Signal	Description	I/O
TXD	Transmit data. This pin is normally an output, but is an input (tristated) in single wire mode whenever the transmitter is disabled or transmit direction is configured for receive data.	I/O
RXD	Receive data.	I
CTS_B	Clear to send.	I
RTS_B	Request to send.	O

71.5 Register definition

The LPUART includes registers to control baud rate, select options, report status, and store transmit/receive data. Access to an address outside the valid memory map generates a bus error.

NOTE

Writing a Read-Only (RO) register or reading a Write-Only (WO) register can cause bus errors. This module does not check if programmed values in the registers are correct; the application software must ensure that valid programmed values are being written.

71.5.1 LPUART register descriptions

71.5.1.1 LPUART memory map

LPUART1 base address: 4007_C000h

LPUART2 base address: 4008_0000h

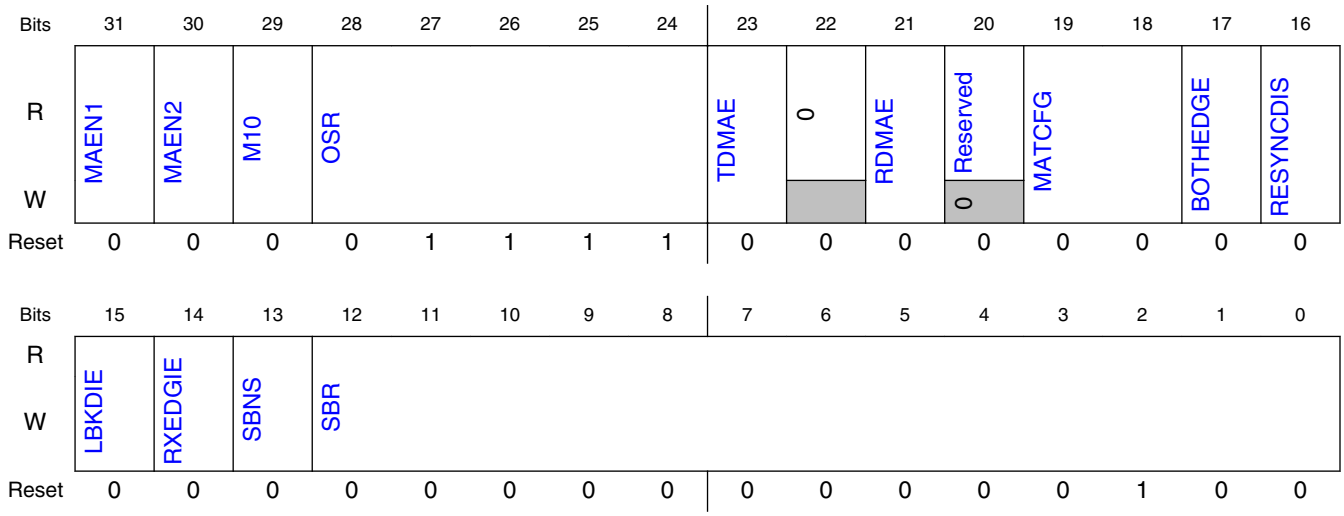
71.5.1.6.2 Diagram



71.5.1.6.3 Fields

Field	Description
31 MAEN1	Match Address Mode Enable 1 0 - Normal operation. 1 - Enables automatic address matching or data matching mode for MATCH[MA1].
30 MAEN2	Match Address Mode Enable 2 0 - Normal operation. 1 - Enables automatic address matching or data matching mode for MATCH[MA2].
29 M10	10-bit Mode select The M10 bit causes a tenth bit to be part of the serial transmission. This bit should be changed only when the transmitter and receiver are both disabled. 0 - Receiver and transmitter use 7-bit to 9-bit data characters. 1 - Receiver and transmitter use 10-bit data characters.
28-24 OSR	Oversampling Ratio This field configures the oversampling ratio for the receiver. This field should be changed only when the transmitter and receiver are both disabled. 00000 - Writing 0 to this field results in an oversampling ratio of 16 00001 - Reserved 00010 - Reserved 00011 - Oversampling ratio of 4, requires BOTHEDGE to be set. 00100 - Oversampling ratio of 5, requires BOTHEDGE to be set. 00101 - Oversampling ratio of 6, requires BOTHEDGE to be set. 00110 - Oversampling ratio of 7, requires BOTHEDGE to be set. 00111 - Oversampling ratio of 8.

Table continues on the next page...

Field	Description
	01000 - Oversampling ratio of 9. 01001 - Oversampling ratio of 10. 01010 - Oversampling ratio of 11. 01011 - Oversampling ratio of 12. 01100 - Oversampling ratio of 13. 01101 - Oversampling ratio of 14. 01110 - Oversampling ratio of 15. 01111 - Oversampling ratio of 16. 10000 - Oversampling ratio of 17. 10001 - Oversampling ratio of 18. 10010 - Oversampling ratio of 19. 10011 - Oversampling ratio of 20. 10100 - Oversampling ratio of 21. 10101 - Oversampling ratio of 22. 10110 - Oversampling ratio of 23. 10111 - Oversampling ratio of 24. 11000 - Oversampling ratio of 25. 11001 - Oversampling ratio of 26. 11010 - Oversampling ratio of 27. 11011 - Oversampling ratio of 28. 11100 - Oversampling ratio of 29. 11101 - Oversampling ratio of 30. 11110 - Oversampling ratio of 31. 11111 - Oversampling ratio of 32.
23 TDMAE	Transmitter DMA Enable TDMAE configures the transmit data register empty flag, STAT[TDRE], to generate a DMA request. 0 - DMA request disabled. 1 - DMA request enabled.
22 —	Reserved
21 RDMAE	Receiver Full DMA Enable RDMAE configures the receiver data register full flag, STAT[RDRF], to generate a DMA request. 0 - DMA request disabled. 1 - DMA request enabled.
20 —	Reserved
19-18 MATCFG	Match Configuration Configures the match addressing mode used. This field should be changed only when the transmitter and receiver are both disabled.

Table continues on the next page...

Field	Description
	00 - Address Match Wakeup 01 - Idle Match Wakeup 10 - Match On and Match Off 11 - Enables RWU on Data Match and Match On/Off for transmitter CTS input
17 BOTHEDGE	Both Edge Sampling Enables sampling of the received data on both edges of the baud rate clock, effectively doubling the number of times the receiver samples the input data for a given oversampling ratio. This bit must be set for oversampling ratios between x4 and x7 and is optional for higher oversampling ratios. This bit should be changed only when the receiver is disabled. 0 - Receiver samples input data using the rising edge of the baud rate clock. 1 - Receiver samples input data using the rising and falling edge of the baud rate clock.
16 RESYNCDIS	Resynchronization Disable When set, this field disables the resynchronization of the received data word when a data one followed by data zero transition is detected. This bit should be changed only when the receiver is disabled. 0 - Resynchronization during received data word is supported. 1 - Resynchronization during received data word is disabled.
15 LBKDIE	LIN Break Detect Interrupt Enable LBKDIE enables the LIN break detect flag, STAT[LBKDIF], to generate interrupt requests. 0 - Hardware interrupts from STAT[LBKDIF] flag are disabled (use polling). 1 - Hardware interrupt is requested when STAT[LBKDIF] flag is 1.
14 RXEDGIE	RX Input Active Edge Interrupt Enable Enables the receive input active edge, STAT[RXEDGIF], to generate interrupt requests. Changing CTRL[LOOPS] or CTRL[RSRC] when RXEDGIE is set can cause the STAT[RXEDGIF] flag to set. 0 - Hardware interrupts from STAT[RXEDGIF] are disabled. 1 - Hardware interrupt is requested when STAT[RXEDGIF] flag is 1.
13 SBNS	Stop Bit Number Select SBNS determines whether data characters have one or two stop bits. This bit should be changed only when the transmitter and receiver are both disabled. 0 - One stop bit. 1 - Two stop bits.
12-0 SBR	Baud Rate Modulo Divisor. The 13 bits in SBR[12:0] set the modulo divide rate for the baud rate generator. When SBR is 1 - 8191, the baud rate equals "baud clock / ((OSR+1) * SBR)". The 13-bit baud rate setting [SBR12:SBR0] must be updated only when the transmitter and receiver are both disabled (CTRL[RE] and CTRL[TE] are both 0).

71.5.1.7.3 Fields

Field	Description
31 LBKDIF	LIN Break Detect Interrupt Flag LBKDIF is set when the LIN break detect circuitry is enabled and a LIN break character is detected. Writing a 1 clears the LBKDIF field. 0 - No LIN break character has been detected. 1 - LIN break character has been detected.
30 RXEDGIF	RXD Pin Active Edge Interrupt Flag RXEDGIF is set whenever the receiver is enabled and an active edge (falling if RXINV = 0, rising if RXINV=1,) on the RXD pin occurs. To clear RXEDGIF, write a 1 to the RXEDGIF field. 0 - No active edge on the receive pin has occurred. 1 - An active edge on the receive pin has occurred.
29 MSBF	MSB First Setting this bit reverses the order of the bits that are transmitted and received on the wire. This bit does not affect the polarity of the bits, the location of the parity bit, or the location of the start or stop bits. This bit should be changed only when the transmitter and receiver are both disabled. 0 - LSB (bit0) is the first bit that is transmitted following the start bit. Further, the first bit received after the start bit is identified as bit0.

Table continues on the next page...

Field	Description
	1 - MSB (identified as bit9, bit8, bit7 or bit6) is the first bit that is transmitted following the start bit depending on the setting of CTRL[M], CTRL[PE] and BAUD[M10]. .
28 RXINV	Receive Data Inversion Setting this bit reverses the polarity of the received data input. This bit should be changed only when the receiver is disabled. **NOTE:** Setting RXINV inverts the RXD input for all cases: data bits, start and stop bits, break, and idle. 0 - Receive data not inverted. 1 - Receive data inverted.
27 RWUID	Receive Wake Up Idle Detect For RWU on idle character, RWUID controls whether the idle character that wakes up the receiver sets the IDLE bit. For address match wakeup, RWUID controls if the IDLE bit is set when the address does not match. This bit should be changed only when the receiver is disabled. 0 - During receive standby state (RWU = 1), the IDLE bit does not get set upon detection of an idle character. During address match wakeup, the IDLE bit does not set when an address does not match. 1 - During receive standby state (RWU = 1), the IDLE bit gets set upon detection of an idle character. During address match wakeup, the IDLE bit does set when an address does not match.
26 BRK13	Break Character Generation Length BRK13 selects a longer transmitted break character length. The state of this bit does not affect the detection of a framing error. This bit should be changed only when the transmitter is disabled. A break character can be sent by setting CTRL[SBK] or by writing the transmit FIFO with DATA[FRETSC] set and DATA[R9T9] clear. 0 - Break character is transmitted with length of 9 to 13 bit times. 1 - Break character is transmitted with length of 12 to 15 bit times.
25 LBKDE	LIN Break Detection Enable LBKDE selects a longer break character detection length. While LBKDE is set, receive data is not stored in the receive FIFO. **NOTE:** The LBKDE bit enables the LIN break detect circuit and disables writing receive data to FIFO. So it essentially ignores all characters except a LIN break. 0 - LIN break detect is disabled, normal break character can be detected. 1 - LIN break detect is enabled. LIN break character is detected at length of 11 bit times (if M = 0) or 12 (if M = 1) or 13 (M10 = 1).
24 RAF	Receiver Active Flag RAF is set when the receiver detects the beginning of a valid start bit, and RAF is cleared automatically when the receiver detects an idle line. 0 - LPUART receiver idle waiting for a start bit. 1 - LPUART receiver active (RXD input not idle).
23 TDRE	Transmit Data Register Empty Flag When the transmit FIFO is enabled, TDRE is set when the number of datawords in the transmit FIFO is equal to or less than the number indicated by WATER[TXWATER]. To clear TDRE, write to the DATA register until the number of words in the transmit FIFO is greater than the number indicated by WATER[TXWATER]. When the transmit FIFO is disabled, TDRE is set when the transmit DATA register is empty. To clear TDRE, write to the DATA register. TDRE is not affected by a character that is in the process of being transmitted; it is updated at the start of each transmitted character.

Table continues on the next page...

Field	Description
	0 - Transmit FIFO level is greater than watermark. 1 - Transmit FIFO level is equal or less than watermark.
22 TC	Transmission Complete Flag TC is cleared when there is a transmission in progress or when a preamble or break character is loaded. TC is set when the transmit buffer is empty and no data, preamble, or break character is being transmitted. When TC is set, the transmit data output signal becomes idle (logic 1). TC is cleared by writing to the DATA register to transmit new data, queuing a preamble by clearing and then setting CTRL[TE], queuing a break character by writing 1 to CTRL[SBK]. 0 - Transmitter active (sending data, a preamble, or a break). 1 - Transmitter idle (transmission activity complete).
21 RDRF	Receive Data Register Full Flag When the receive FIFO is enabled, RDRF is set when the number of datawords in the receive buffer is greater than the number indicated by WATER[RXWATER]. To clear RDRF, read the DATA register until the number of datawords in the receive FIFO is equal to or less than the number indicated by WATER[RXWATER]. When the receive FIFO is disabled, RDRF is set when the receive buffer (the DATA register) is full. To clear RDRF, read the DATA register. A character that is in the process of being received does not cause a change in RDRF until the entire character is received. Even if RDRF is set, the character continues to be received until an overrun condition occurs once the entire character is received. 0 - Receive FIFO level is less than watermark. 1 - Receive FIFO level is equal or greater than watermark.
20 IDLE	Idle Line Flag IDLE is set when the LPUART receive line becomes idle for a full character time after a period of activity. When CTRL[ILT] is cleared, the receiver starts counting idle bit times after the start bit. If the receive character is all 1s, these bit times and the stop bits time count toward the full character time of logic high, 10 to 13 bit times, needed for the receiver to detect an idle line. When CTRL[ILT] is set, the receiver doesn't start counting idle bit times until after the stop bits. The stop bits and any logic high bit times at the end of the previous character do not count toward the full character time of logic high needed for the receiver to detect an idle line. To clear IDLE, write logic 1 to the IDLE flag. After IDLE has been cleared, it cannot be set again until after a new character is stored in the receive buffer or a LIN break character has set the LBKDIF flag . IDLE is set only once even if the receive line remains idle for an extended period. 0 - No idle line detected. 1 - Idle line is detected.
19 OR	Receiver Overrun Flag OR is set when software fails to prevent the receive data register from overflowing with data. The OR bit is set immediately after the stop bit has been completely received for the dataword that overflows the buffer and all the other error flags (FE, NF, and PF) are prevented from setting. The data in the shift register is lost, but the data already in the LPUART data registers is not affected. If LBKDE is enabled and a LIN Break is detected, the OR field asserts if LBKDIF is not cleared before the next data character is received. While the OR flag is set, no additional data is stored in the receive FIFO even if sufficient room exists. To clear OR, write logic 1 to the OR flag. 0 - No overrun. 1 - Receive overrun (new LPUART data lost).
18 NF	Noise Flag

Table continues on the next page...

Field	Description
	The advanced sampling technique used in the receiver takes three samples in each of the received bits. If any of these samples disagrees with the rest of the samples within any bit time in the frame then noise is detected for that character. NF is set whenever the next character to be read from the DATA register is received with noise detected within the character. To clear NF, write logic 1 to the NF field. 0 - No noise detected. 1 - Noise detected in the received character in the DATA register.
17 FE	Framing Error Flag FE is set whenever the next character to be read from the DATA register is received with logic 0 detected where a stop bit was expected. To clear FE, write logic 1 to the FE field. 0 - No framing error detected. This does not guarantee the framing is correct. 1 - Framing error.
16 PF	Parity Error Flag PF is set whenever the next character to be read from the DATA register is received when parity is enabled (PE = 1) and the parity bit in the received character does not agree with the expected parity value. To clear PF, write a logic 1 to the PF field. 0 - No parity error. 1 - Parity error.
15 MA1F	Match 1 Flag MA1F is set whenever the next character to be read from the DATA register matches MA1. To clear MA1F, write a logic 1 to the MA1F field. 0 - Received data is not equal to MA1 1 - Received data is equal to MA1
14 MA2F	Match 2 Flag MA2F is set whenever the next character to be read from the DATA register matches MA2. To clear MA2F, write a logic 1 to the MA2F field. 0 - Received data is not equal to MA2 1 - Received data is equal to MA2

71.5.1.8.3 Fields

Field	Description
31 R8T9	Receive Bit 8 / Transmit Bit 9 R8 is the ninth data bit received when the LPUART is configured for 9-bit or 10-bit data formats. When reading 9-bit or 10-bit data, read R8 before reading the DATA register. T9 is the tenth data bit transmitted when the LPUART is configured for 10-bit data formats. When writing 10-bit data, write T9 before writing the DATA register. If T9 does not need to change from its previous value, such as when it is used to generate address mark or parity, then it need not be written each time the DATA register is written. **NOTE:** R8 is a read-only bit and T9 is a write-only bit, the value read is different from the value written.
30 R9T8	Receive Bit 9 / Transmit Bit 8 R9 is the tenth data bit received when the LPUART is configured for 10-bit data formats. When reading 10-bit data, read R9 before reading the DATA register T8 is the ninth data bit transmitted when the LPUART is configured for 9-bit or 10-bit data formats. When writing 9-bit or 10-bit data, write T8 before writing the DATA register. If T8 does not need to change from its previous value, such as when it is used to generate address mark or parity, then it need not be written each time the DATA register is written. **NOTE:** R9 is a read-only bit and T8 is a write-only bit, the value read is different from the value written.

Table continues on the next page...

Field	Description
29 TXDIR	TXD Pin Direction in Single-Wire Mode When the LPUART is configured for single-wire half-duplex operation (LOOPS = RSRC = 1), this bit determines the direction of data at the TXD pin. When clearing TXDIR, the transmitter finishes receiving the current character (if any) before the receiver starts receiving data from the TXD pin. 0 - TXD pin is an input in single-wire mode. 1 - TXD pin is an output in single-wire mode.
28 TXINV	Transmit Data Inversion Setting this bit reverses the polarity of the transmitted data output. **NOTE:** Setting TXINV inverts the TXD output for all cases: data bits, start and stop bits, break, and idle. 0 - Transmit data not inverted. 1 - Transmit data inverted.
27 ORIE	Overrun Interrupt Enable This bit enables the overrun flag (OR) to generate hardware interrupt requests. 0 - OR interrupts disabled; use polling. 1 - Hardware interrupt is requested when OR is set.
26 NEIE	Noise Error Interrupt Enable This bit enables the noise flag (NF) to generate hardware interrupt requests. 0 - NF interrupts disabled; use polling. 1 - Hardware interrupt is requested when NF is set.
25 FEIE	Framing Error Interrupt Enable This bit enables the framing error flag (FE) to generate hardware interrupt requests. 0 - FE interrupts disabled; use polling. 1 - Hardware interrupt is requested when FE is set.
24 PEIE	Parity Error Interrupt Enable This bit enables the parity error flag (PF) to generate hardware interrupt requests. 0 - PF interrupts disabled; use polling). 1 - Hardware interrupt is requested when PF is set.
23 TIE	Transmit Interrupt Enable Enables STAT[TDRE] to generate interrupt requests. 0 - Hardware interrupts from TDRE disabled. 1 - Hardware interrupt is requested when TDRE flag is 1.
22 TCIE	Transmission Complete Interrupt Enable for TCIE enables the transmission complete flag, TC, to generate interrupt requests. 0 - Hardware interrupts from TC disabled. 1 - Hardware interrupt is requested when TC flag is 1.
21 RIE	Receiver Interrupt Enable Enables STAT[RDRF] to generate interrupt requests. 0 - Hardware interrupts from RDRF disabled. 1 - Hardware interrupt is requested when RDRF flag is 1.

Table continues on the next page...

Field	Description
20 ILIE	Idle Line Interrupt Enable ILIE enables the idle line flag, STAT[IDLE], to generate interrupt requests. 0 - Hardware interrupts from IDLE disabled; use polling. 1 - Hardware interrupt is requested when IDLE flag is 1.
19 TE	Transmitter Enable Enables the LPUART transmitter. TE can also be used to queue an idle preamble by clearing and then setting TE. When TE is cleared, this register bit reads as 1 until the transmitter has completed the current character and the TXD pin is tristated. A single idle character can also be queued by writing to the transmit FIFO with DATA[FRETSC] set and DATA[R9T9] set. 0 - Transmitter disabled. 1 - Transmitter enabled.
18 RE	Receiver Enable Enables the LPUART receiver. When RE is written to 0, this register bit reads as 1 until the receiver finishes receiving the current character (if any). 0 - Receiver disabled. 1 - Receiver enabled.
17 RWU	Receiver Wakeup Control This field can be set to place the LPUART receiver in a standby state. RWU automatically clears when an RWU event occurs, that is, an IDLE event when CTRL[WAKE] is clear or an address match when CTRL[WAKE] is set and STAT[RWUID] is clear. **NOTE:** RWU must be set only with CTRL[WAKE] = 0 (wakeup on idle) if the channel is currently not idle. This can be determined by STAT[RAF]. If the flag is set to wake up an IDLE event and the channel is already idle, it is possible that the LPUART will discard data. This is because the data must be received or a LIN break detected after an IDLE is detected before IDLE is allowed to be reasserted. 0 - Normal receiver operation. 1 - LPUART receiver in standby waiting for wakeup condition.
16 SBK	Send Break Writing a 1 and then a 0 to SBK queues a break character in the transmit data stream. Additional break characters of 9 to 13 bits, or 12 to 15 bits if STAT[BRK13] is set, bit times of logic 0 are queued as long as SBK is set. Depending on the timing of the set and clear of SBK relative to the character currently being transmitted, a second break character may be queued before software clears SBK. If software takes too long to clear SBK (for example, it is not cleared by the end of the 1st break character), then a 2nd break character is sent. This is compared to queuing a break character through the transmit FIFO which guarantees only one is sent. A single break character can also be queued by writing to the transmit FIFO with DATA[FRETSC] set and DATA[R9T9] clear. 0 - Normal transmitter operation. 1 - Queue break character(s) to be sent.
15 MA1IE	Match 1 Interrupt Enable 0 - MA1F interrupt disabled 1 - MA1F interrupt enabled
14	Match 2 Interrupt Enable

Table continues on the next page...

Field	Description
MA2IE	0 - MA2F interrupt disabled 1 - MA2F interrupt enabled
13-12 —	Reserved
11 M7	7-Bit Mode Select This bit should be changed only when the transmitter and receiver are both disabled. 0 - Receiver and transmitter use 8-bit to 10-bit data characters. 1 - Receiver and transmitter use 7-bit data characters.
10-8 IDLECFG	Idle Configuration Configures the number of idle characters that must be received before the IDLE flag is set. 000 - 1 idle character 001 - 2 idle characters 010 - 4 idle characters 011 - 8 idle characters 100 - 16 idle characters 101 - 32 idle characters 110 - 64 idle characters 111 - 128 idle characters
7 LOOPS	Loop Mode Select When LOOPS is set, the RXD pin is disconnected from the LPUART and the transmitter output is internally connected to the receiver input. The transmitter and the receiver must be enabled to use the loop function. 0 - Normal operation - RXD and TXD use separate pins. 1 - Loop mode or single-wire mode where transmitter outputs are internally connected to receiver input (see RSRC bit).
6 DOZEEN	Doze Enable 0 - LPUART is enabled in Doze mode. 1 - LPUART is disabled in Doze mode .
5 RSRC	Receiver Source Select This field has no meaning or effect unless the LOOPS field is set. When LOOPS is set, the RSRC field determines the source for the receiver shift register input. 0 - Provided LOOPS is set, RSRC is cleared, selects internal loop back mode and the LPUART does not use the RXD pin. 1 - Single-wire LPUART mode where the TXD pin is connected to the transmitter output and receiver input.
4 M	9-Bit or 8-Bit Mode Select 0 - Receiver and transmitter use 8-bit data characters. 1 - Receiver and transmitter use 9-bit data characters.
3 WAKE	Receiver Wakeup Method Select Determines which condition wakes the LPUART when RWU=1:

Table continues on the next page...

Field	Description
	• Address mark in the bit preceding the stop bit (or bit preceding the parity bit when parity is enabled) of the received data character. • An idle condition on the receive pin input signal. 0 - Configures RWU for idle-line wakeup. 1 - Configures RWU with address-mark wakeup.
2 ILT	Idle Line Type Select Determines when the receiver starts counting logic 1s as idle character bits. The count begins either after a valid start bit or after the stop bit. If the count begins after the start bit, then a string of logic 1s preceding the stop bit can cause false recognition of an idle character. Beginning the count after the stop bit avoids false idle character recognition, but requires properly synchronized transmissions. **NOTE:** In case the LPUART is programmed with ILT = 1, a logic 0 is automatically shifted after a received stop bit, therefore resetting the idle count. 0 - Idle character bit count starts after start bit. 1 - Idle character bit count starts after stop bit.
1 PE	Parity Enable Enables hardware parity generation and checking. When parity is enabled, the bit immediately before the stop bit is treated as the parity bit. 0 - No hardware parity generation or checking. 1 - Parity enabled.
0 PT	Parity Type Provided parity is enabled (PE = 1), this bit selects even or odd parity. Odd parity means the total number of logic 1 bits in the data character, including the parity bit, is odd. Even parity means the total number of 1s in the data character, including the parity bit, is even. 0 - Even parity. 1 - Odd parity.

71.5.1.9 LPUART Data Register (DATA)

NOTE

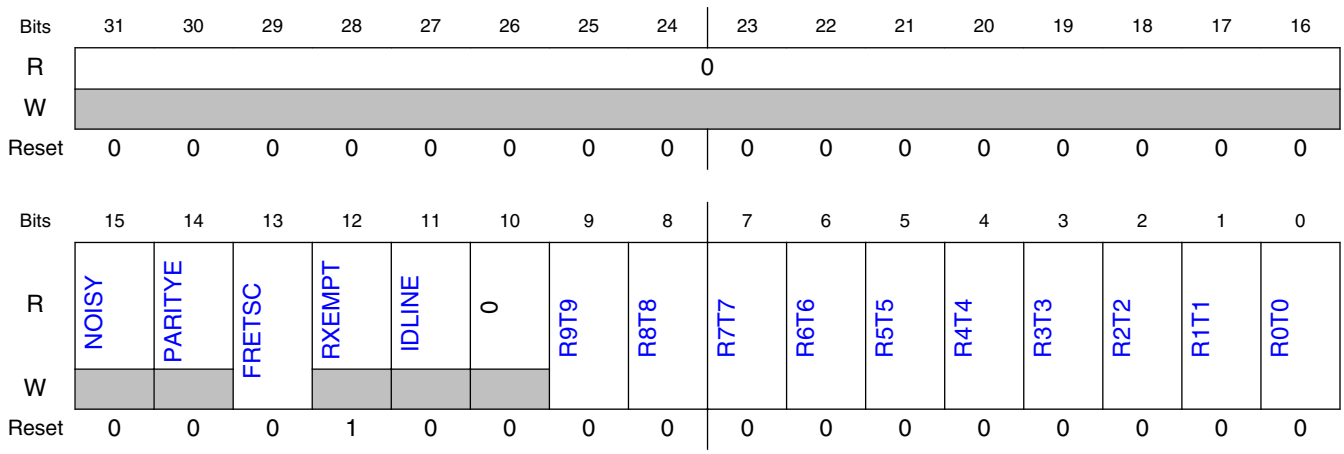
This register is two separate registers. Reads return the contents of the read-only receive FIFO and writes go to the write-only transmit FIFO.

Reads and writes of this register are also involved in the automatic flag clearing mechanisms for some of the LPUART status flags. This register can be written using 8-bit, 16-bit or 32-bit writes. An 8-bit write to DATA[7:0] will push { R8T9, R9T8, DATA[7:0] } the transmit FIFO with TSC clear. A 16-bit or 32-bit write will push the data written into the FIFO and does not update the value in R8T9 or R9T8.

71.5.1.9.1 Offset

Register	Offset
DATA	1Ch

71.5.1.9.2 Diagram



71.5.1.9.3 Fields

Field	Description
31-16 —	Reserved
15 NOISY	Noisy Data Received The current received dataword contained in DATA[R9:R0] is received with noise. 0 - The dataword is received without noise. 1 - The data is received with noise.
14 PARITYE	Parity Error The current received dataword contained in DATA[R9:R0] is received with a parity error. 0 - The dataword is received without a parity error. 1 - The dataword is received with a parity error.
13 FRETSC	Frame Error / Transmit Special Character For reads, indicates the current received dataword contained in DATA[R9:R0] was received with a frame error. For writes, indicates a break or idle character is to be transmitted instead of the contents in DATA[T9:T0]. T9 is used to indicate a break character when 0 and a idle character when 1, the contents of DATA[T8:T0] should be zero. 0 - The dataword is received without a frame error on read, or transmit a normal character on write. 1 - The dataword is received with a frame error, or transmit an idle or break character on transmit.
12	Receive Buffer Empty

Table continues on the next page...

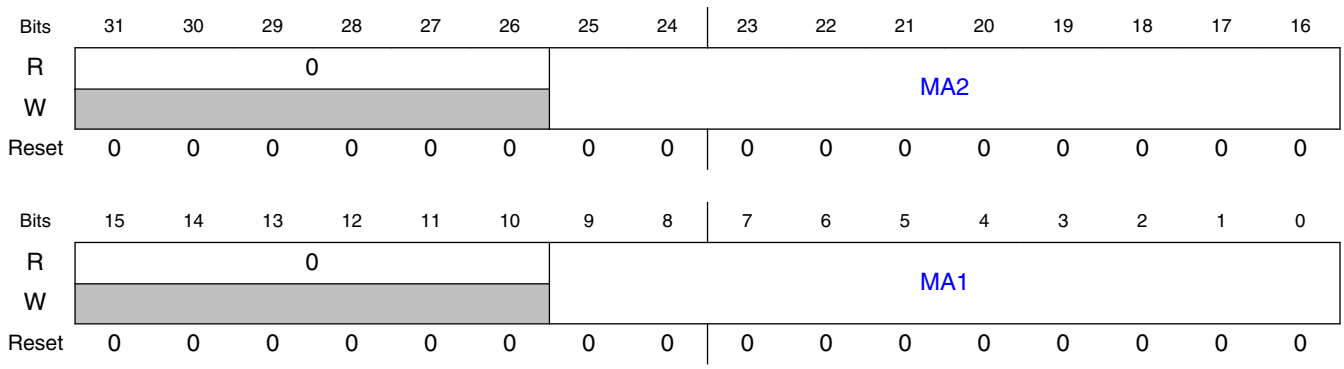
Field	Description
RXEMPT	Asserts when there is no data in the receive buffer. This field does not take into account data that is in the receive shift register. 0 - Receive buffer contains valid data. 1 - Receive buffer is empty, data returned on read is not valid.
11 IDLINE	Idle Line Indicates the receiver line was idle before receiving the character in DATA[9:0]. Unlike the IDLE flag, this bit can set for the first character received when the receiver is first enabled. 0 - Receiver was not idle before receiving this character. 1 - Receiver was idle before receiving this character.
10 —	Reserved
9 R9T9	R9T9 Read receive FIFO bit 9 or write transmit FIFO bit 9.
8 R8T8	R8T8 Read receive FIFO bit 8 or write transmit FIFO bit 8.
7 R7T7	R7T7 Read receive FIFO bit 7 or write transmit FIFO bit 7.
6 R6T6	R6T6 Read receive FIFO bit 6 or write transmit FIFO bit 6.
5 R5T5	R5T5 Read receive FIFO bit 5 or write transmit FIFO bit 5.
4 R4T4	R4T4 Read receive FIFO bit 4 or write transmit FIFO bit 4.
3 R3T3	R3T3 Read receive FIFO bit 3 or write transmit FIFO bit 3.
2 R2T2	R2T2 Read receive FIFO bit 2 or write transmit FIFO bit 2.
1 R1T1	R1T1 Read receive FIFO bit 1 or write transmit FIFO bit 1.
0 R0T0	R0T0 Read receive FIFO bit 0 or write transmit FIFO bit 0.

71.5.1.10 LPUART Match Address Register (MATCH)

71.5.1.10.1 Offset

Register	Offset
MATCH	20h

71.5.1.10.2 Diagram



71.5.1.10.3 Fields

Field	Description
31-26 —	Reserved
25-16 MA2	Match Address 2 The MA1 and MA2 fields are compared to input data addresses when the most significant bit is set and the associated BAUD[MAEN] bit is set. If a match occurs, the following data is transferred to the DATA register. If a match fails, the following data is discarded. Software should only write a MAx field when the associated BAUD[MAEN] bit is clear.
15-10 —	Reserved
9-0 MA1	Match Address 1 The MA1 and MA2 fields are compared to input data addresses when the most significant bit is set and the associated BAUD[MAEN] bit is set. If a match occurs, the following data is transferred to the DATA register. If a match fails, the following data is discarded. Software should only write a MAx field when the associated BAUD[MAEN] bit is clear.

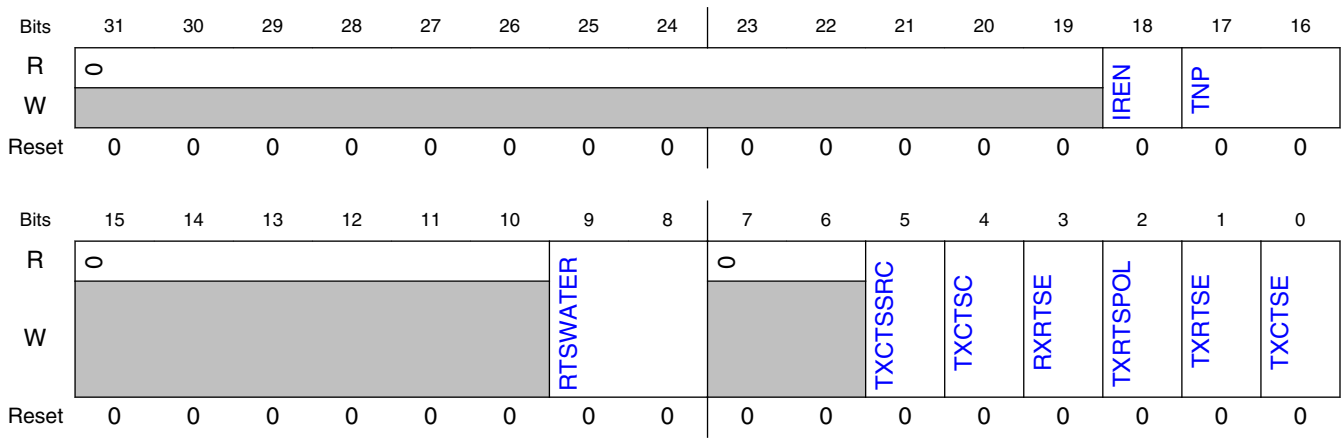
71.5.1.11 LPUART Modem IrDA Register (MODIR)

The MODIR register controls options for setting the modem configuration.

71.5.1.11.1 Offset

Register	Offset
MODIR	24h

71.5.1.11.2 Diagram



71.5.1.11.3 Fields

Field	Description
31-19 —	Reserved
18 IREN	Infrared enable Enables/disables the infrared modulation/demodulation. This bit should be changed only when the transmitter and receiver are both disabled. 0 - IR disabled. 1 - IR enabled.
17-16 TNP	Transmitter narrow pulse Configures whether the LPUART transmits a 1/OSR, 2/OSR, 3/OSR or 4/OSR narrow pulse when IR is enabled. This bit should be changed only when the transmitter and receiver are both disabled. The IR pulse width should be configured to less than half of the oversampling ratio. Common pulse widths are 3/16, 1/16, 1/32 or 1/4 of the bit length. These can be configured by selecting the appropriate oversample ratio and pulse width. 00 - 1/OSR. 01 - 2/OSR. 10 - 3/OSR. 11 - 4/OSR.
15-10	Reserved

Table continues on the next page...

Register definition

Field	Description
—	
9-8 RTSWATER	Receive RTS Configuration Configures the assertion and negation of the RX RTS_B output. The RX RTS_B output negates when the number of empty words in the receive FIFO is greater or equal to RTSWATER. If RTSWATER is configured to zero, RTS_B negates when the receive FIFO is full. For the purpose of RX RTS_B generation, the number of words in the receive FIFO updates when a start bit is detected. This supports additional latency between RTS_B negation and the external transmitter ceasing transmission. If both RX RTS_B and address/data matching is enabled, then RTS_B could assert at the end of a character if there is not a match. This field should be changed only when the receiver is disabled.
7-6 —	Reserved
5 TXCTSSRC	Transmit CTS Source Configures the source of the CTS input. 0 - CTS input is the CTS_B pin. 1 - CTS input is an internal connection to the receiver address match result.
4 TXCTSC	Transmit CTS Configuration Configures if the CTS state is checked at the start of each character or only when the transmitter is idle. 0 - CTS input is sampled at the start of each character. 1 - CTS input is sampled when the transmitter is idle.
3 RXRTSE	Receiver request-to-send enable Allows the RTS output to control the CTS input of the transmitting device to prevent receiver overrun. This bit should be changed only when the receiver is disabled. **NOTE:** Do not set both RXRTSE and TXRTSE. 0 - The receiver has no effect on RTS. 1 - RTS is deasserted if the receiver data register is full or a start bit has been detected that would cause the receiver data register to become full. RTS is asserted if the receiver data register is not full and has not detected a start bit that would cause the receiver data register to become full.
2 TXRTSPOL	Transmitter request-to-send polarity Controls the polarity of the transmitter RTS. TXRTSPOL does not affect the polarity of the receiver RTS. RTS remains negated in the active low state unless TXRTSE is set. This bit should be changed only when the transmitter is disabled. 0 - Transmitter RTS is active low. 1 - Transmitter RTS is active high.
1 TXRTSE	Transmitter request-to-send enable Controls RTS before and after a transmission. This bit should be changed only when the transmitter is disabled. 0 - The transmitter has no effect on RTS. 1 - When a character is placed into an empty transmit shift register, RTS asserts one bit time before the start bit is transmitted. RTS deasserts one bit time after all characters in the transmitter FIFO and shift register are completely sent, including the last stop bit.
0 TXCTSE	Transmitter clear-to-send enable TXCTSE controls the operation of the transmitter. TXCTSE can be set independently from the state of TXRTSE and RXRTSE.

Field	Description
	0 - CTS has no effect on the transmitter. 1 - Enables clear-to-send operation. The transmitter checks the state of CTS each time it is ready to send a character. If CTS is asserted, the character is sent. If CTS is deasserted, the signal TXD remains in the mark state and transmission is delayed until CTS is asserted. Changes in CTS as a character is being sent do not affect its transmission.

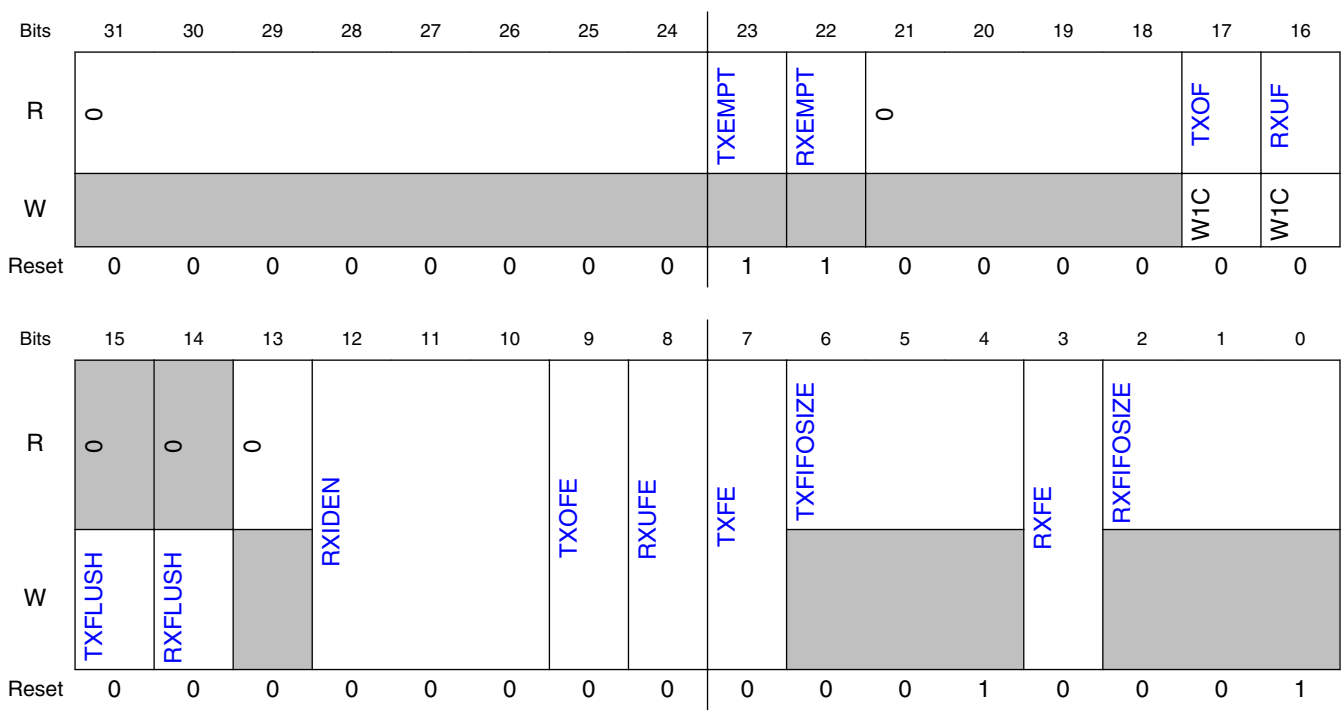
71.5.1.12 LPUART FIFO Register (FIFO)

This register provides the ability for the programmer to turn on and off FIFO functionality. It also provides the size of the FIFO that has been implemented. This register may be read at any time. This register must be written only when CTRL[RE] and CTRL[TE] are cleared/not set and when the FIFO is empty.

71.5.1.12.1 Offset

Register	Offset
FIFO	28h

71.5.1.12.2 Diagram



71.5.1.12.3 Fields

Field	Description
31-24 —	Reserved
23 TXEMPT	Transmit FIFO/Buffer Empty Asserts when there is no data in the Transmit FIFO/Buffer. This field does not take into account data that is in the transmit shift register. 0 - Transmit buffer is not empty. 1 - Transmit buffer is empty.
22 RXEMPT	Receive FIFO/Buffer Empty Asserts when there is no data in the Receive FIFO/Buffer. This field does not take into account data that is in the receive shift register. 0 - Receive buffer is not empty. 1 - Receive buffer is empty.
21-18 —	Reserved
17 TXOF	Transmitter FIFO Overflow Flag Indicates that more data has been written to the transmit FIFO than it can hold. This field asserts regardless of the value of TXOFE. However, an interrupt is issued to the host only if TXOFE is set. Write 1 to clear this flag. 0 - No transmit FIFO overflow has occurred since the last time the flag was cleared. 1 - At least one transmit FIFO overflow has occurred since the last time the flag was cleared.
16 RXUF	Receiver FIFO Underflow Flag Indicates that more data has been read from the receive FIFO than was present. This field asserts regardless of the value of RXUFE. However, an interrupt is issued to the host only if RXUFE is set. Write a logic 1 to clear RXUF. 0 - No receive FIFO underflow has occurred since the last time the flag was cleared. 1 - At least one receive FIFO underflow has occurred since the last time the flag was cleared.
15 TXFLUSH	Transmit FIFO Flush Writing to this field causes all data that is stored in the transmit FIFO to be flushed. This does not affect data that is in the transmit shift register. 0 - No flush operation occurs. 1 - All data in the transmit FIFO is cleared out.
14 RXFLUSH	Receive FIFO Flush Writing to this field causes all data that is stored in the receive FIFO to be flushed. This does not affect data that is in the receive shift register. 0 - No flush operation occurs. 1 - All data in the receive FIFO/buffer is cleared out.
13 —	Reserved
12-10	Receiver Idle Empty Enable

Table continues on the next page...

Field	Description
RXIDEN	When set, enables the assertion of RDRF when the receiver is idle for a number of idle characters and the FIFO is not empty. 000 - Disable RDRF assertion due to partially filled FIFO when receiver is idle. 001 - Enable RDRF assertion due to partially filled FIFO when receiver is idle for 1 character. 010 - Enable RDRF assertion due to partially filled FIFO when receiver is idle for 2 characters. 011 - Enable RDRF assertion due to partially filled FIFO when receiver is idle for 4 characters. 100 - Enable RDRF assertion due to partially filled FIFO when receiver is idle for 8 characters. 101 - Enable RDRF assertion due to partially filled FIFO when receiver is idle for 16 characters. 110 - Enable RDRF assertion due to partially filled FIFO when receiver is idle for 32 characters. 111 - Enable RDRF assertion due to partially filled FIFO when receiver is idle for 64 characters.
9 TXOFE	Transmit FIFO Overflow Interrupt Enable When this field is set, the TXOF flag generates an interrupt to the host. 0 - TXOF flag does not generate an interrupt to the host. 1 - TXOF flag generates an interrupt to the host.
8 RXUFE	Receive FIFO Underflow Interrupt Enable When this field is set, the RXUF flag generates an interrupt to the host. 0 - RXUF flag does not generate an interrupt to the host. 1 - RXUF flag generates an interrupt to the host.
7 TXFE	Transmit FIFO Enable When this field is set, the built-in FIFO structure for the transmit buffer is enabled. The size of the FIFO structure is indicated by TXFIFOSIZE. If this field is not set, the transmit buffer operates as a FIFO of depth one dataword regardless of the value in TXFIFOSIZE. Both CTRL[TE] and CTRL[RE] must be cleared prior to changing this field. 0 - Transmit FIFO is not enabled. Buffer depth is 1. 1 - Transmit FIFO is enabled. Buffer depth is indicated by TXFIFOSIZE.
6-4 TXFIFOSIZE	Transmit FIFO Buffer Depth The maximum number of transmit datawords that can be stored in the transmit buffer. This field is read-only. 000 - Transmit FIFO/Buffer depth = 1 dataword. 001 - Transmit FIFO/Buffer depth = 4 datawords. 010 - Transmit FIFO/Buffer depth = 8 datawords. 011 - Transmit FIFO/Buffer depth = 16 datawords. 100 - Transmit FIFO/Buffer depth = 32 datawords. 101 - Transmit FIFO/Buffer depth = 64 datawords. 110 - Transmit FIFO/Buffer depth = 128 datawords. 111 - Transmit FIFO/Buffer depth = 256 datawords
3 RXFE	Receive FIFO Enable When this field is set, the built-in FIFO structure for the receive buffer is enabled. The size of the FIFO structure is indicated by the RXFIFOSIZE field. If this field is not set, the receive buffer operates as a FIFO of depth one dataword regardless of the value in RXFIFOSIZE. Both CTRL[TE] and CTRL[RE] must be cleared prior to changing this field.

Table continues on the next page...

Field	Description
	0 - Receive FIFO is not enabled. Buffer depth is 1. 1 - Receive FIFO is enabled. Buffer depth is indicted by RXFIFOSIZE.
2-0 RXFIFOSIZE	Receive FIFO Buffer Depth The maximum number of receive datawords that can be stored in the receive buffer before an overrun occurs. This field is read-only. 000 - Receive FIFO/Buffer depth = 1 dataword. 001 - Receive FIFO/Buffer depth = 4 datawords. 010 - Receive FIFO/Buffer depth = 8 datawords. 011 - Receive FIFO/Buffer depth = 16 datawords. 100 - Receive FIFO/Buffer depth = 32 datawords. 101 - Receive FIFO/Buffer depth = 64 datawords. 110 - Receive FIFO/Buffer depth = 128 datawords. 111 - Receive FIFO/Buffer depth = 256 datawords.

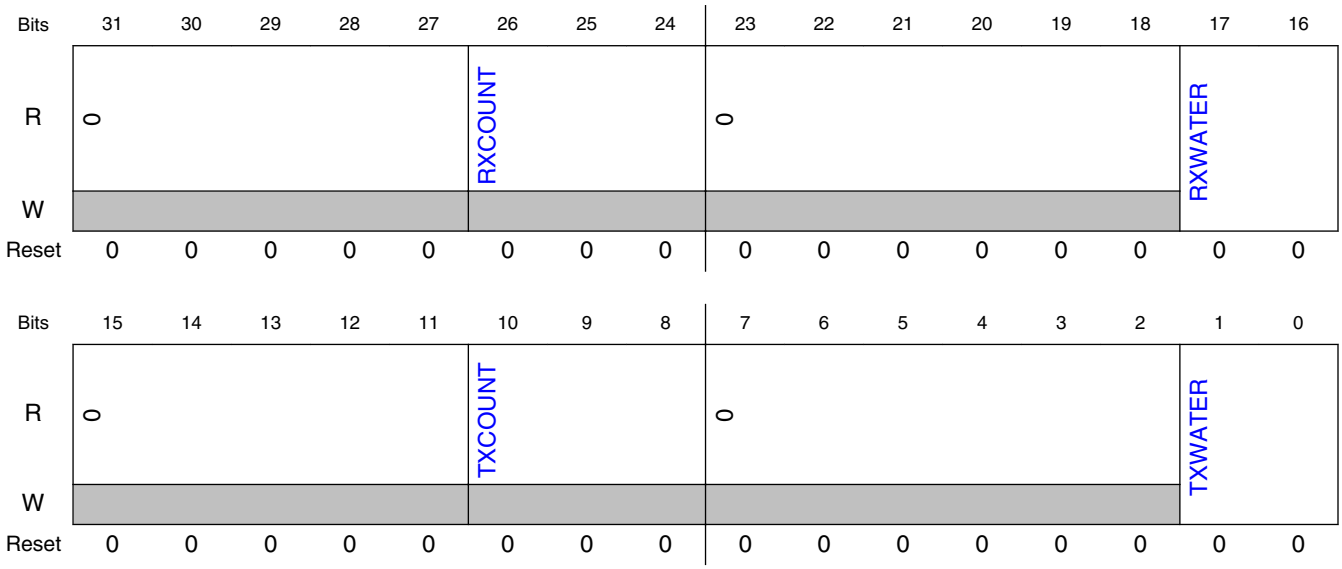
71.5.1.13 LPUART Watermark Register (WATER)

This register provides the ability to set a programmable threshold for notification of needing additional transmit data. This register may be read at any time but must be written only when CTRL[TE] is not set.

71.5.1.13.1 Offset

Register	Offset
WATER	2Ch

71.5.1.13.2 Diagram



71.5.1.13.3 Fields

Field	Description
31-27 —	Reserved
26-24 RXCOUNT	Receive Counter The value in this register indicates the number of datawords that are in the receive FIFO/buffer. If a dataword is being received, that is, in the receive shift register, it is not included in the count. This value may be used in conjunction with FIFO[RXFIFOSIZE] to calculate how much room is left in the receive FIFO/buffer.
23-18 —	Reserved
17-16 RXWATER	Receive Watermark When the number of datawords in the receive FIFO/buffer is greater than the value in this register field, an interrupt or a DMA request is generated. For proper operation, the value in RXWATER must be set to be less than the receive FIFO/buffer size as indicated by FIFO[RXFIFOSIZE] and FIFO[RXFE].
15-11 —	Reserved
10-8 TXCOUNT	Transmit Counter The value in this register indicates the number of datawords that are in the transmit FIFO/buffer. If a dataword is being transmitted, that is, in the transmit shift register, it is not included in the count. This value may be used in conjunction with FIFO[TXFIFOSIZE] to calculate how much room is left in the transmit FIFO/buffer.
7-2 —	Reserved
1-0	Transmit Watermark

Register definition

Field	Description
TXWATER	When the number of datawords in the transmit FIFO/buffer is equal to or less than the value in this register field, an interrupt or a DMA request is generated. For proper operation, the value in TXWATER must be set to be less than the size of the transmit buffer/FIFO size as indicated by FIFO[TXFIFOSIZE] and FIFO[TXFE].

Chapter 72
Timers Overview

72.1 Overview

The following timers are supported in this chip:

- General Purpose Timer (GPT): A 32-bit up-counter with 12-bit pre-scaler
- Periodic Interrupt Timer (PIT): A 32-bit counter timer that features programmable count modulus, clock division features etc.
- Quad Timer (TMR): It provides four timer channels with variety of controls for individual and multi-channel features
- Quadrature Decoder (QDC): It provides interfacing capability to position/speed sensors
- Enhanced FlexPWM: It contains PWM submodules each of which is set up to control a single half bridge power stage
- Watchdog Timer (WDOG1,2): The WDOG1 and WDOG2 protect against system failures by providing a method by which to escape from unexpected events or programming errors
- Watchdog timer (WDOG3,4): It is a high reliability independent timer that is available for system use
- External Watchdog Monitor (EWM): It is designed to monitor external circuits, as well as the MCU software flow

72.1.1 General Purpose Timer (GPT)

The GPT has a 32-bit up-counter. The timer counter value can be captured in a register using an event on an external pin. The capture trigger can be programmed to be a rising or/and falling edge. The GPT also features output compare event generation, when the timer matches a preset value, GPT can generate an interrupt for software and a compare event signal on output pins for external hardware.

The GPT has a 12-bit pre-scaler, which provides a programmable clock frequency derived from multiple clock sources.

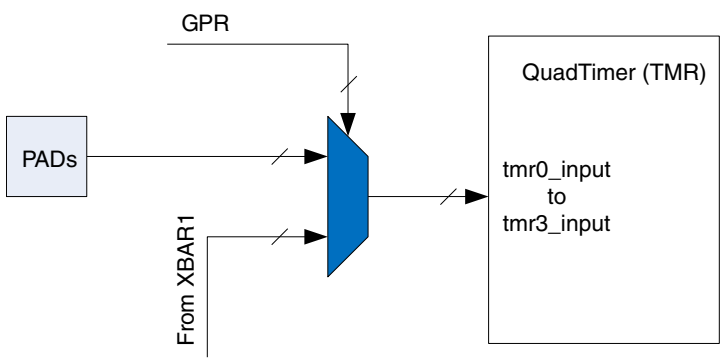
72.1.2 Periodic Interrupt Timer (PIT)

The PIT is a basic 32 bit counter timer. It features 32-bit counter timer, programmable count modulus, clock division features, interrupt generation, and ability to chain adjacent timers to achieve longer interval

72.1.3 Quad Timer (TMR)

The quad-timer provides four timer channels. Specific features include up/down count, cascading of counters, programmable modulo, count once/repeated, counter preload, compare registers with preload, shared use of input signals, prescaler controls, independent capture/compare, fault input control, programmable input filters, and multi-channel synchronization.

As shown in diagram below, input of QTimer can be sourced from PADs or XBAR1:



72.1.4 Enhanced Flex Pulse Width Modulator (eFlexPWM)

This module can generate various switching patterns, including highly sophisticated waveforms. Each module shall be configured with 4 channels supporting A, B, and X PWM output. All channels are configured for standard edge placement and have their capture function enabled.

72.1.5 Quadrature Decoder (QDC)

The enhanced Quadrature Decoder module provides interfacing capability to position/ speed sensors used in industrial motor control applications. It has five input signals: PHASEA, PHASEB, INDEX, TRIGGER, and HOME. This module is used to decode shaft position, revolution count and speed.

72.1.6 Watchdog Timer (WDOG1,2)

The WDOG1 and WDOG2 protect against system failures by providing a method by which to escape from unexpected events or programming errors.

After WDOG1 and WDOG2 are activated, it must be serviced by the software on a periodic basis. If servicing does not take place, the timer times out. Upon timeout, the WDOG1 asserts the internal system reset signal, WDOG_RESET_B_DEB to the System Reset Controller (SRC); and WDOG2 asserts interrupt to SNVS to report the security violation condition.

Main features of the WDOG1 and WDOG2 module are:

- Configurable timeout counter with timeout periods from 0.5 to 128 seconds which, after timeout expiration, result in the assertion of WDOG_RESET_B_DEB reset signal
- Time resolution of 0.5 seconds
- Configurable timeout counter that can be programmed to run or stop during low power modes
- Configurable timeout counter that can be programmed to run or stop during DEBUG mode
- Programmable interrupt generation prior to timeout

72.1.7 Watchdog Timer (WDOG3,4)

The WDOG module is an high reliability independent timer that is available for system use. It provides a safety feature to ensure that software is executing as planned and that the CPU is not stuck in an infinite loop or executing unintended code. If the WDOG module is not serviced (refreshed) within a certain period, it resets the CPU (WDOG3 for M7 and WDOG4 for M4).

Main features of the WDOG module are:

- Configurable independent clock source input from bus clock
- Programmable time-out period

- Robust write sequence for counter refresh
- Windowed refresh option
- Optional timeout interrupt to allow post-processing diagnostics
- Configuration bits are write-once-after-reset to ensure watchdog configuration cannot be mistakenly altered
- Robust write sequence for unlocking write-once control/configuration bits

The WDOG3/WDOG4 clock can be sourced from:

- 1MHz RC OSC
- 32KHz clock generated by 32 KHZ XTALOSC which could be automatically switched to 32KHz RC OSC upon XTAL clock loss
- IP Bus Clock

72.1.8 External Watchdog Monitor (EWM)

The External Watchdog Monitor provides a back-up mechanism to the internal WDOG that can reset the system. The EWM differs from the internal WDOG in that it does not reset the system.

The EWM, if allowed to time-out, provides an independent trigger pin that when asserted resets or places an external circuit into a safe mode.

The EWM clock can be sourced from:

- lpo_clk_0: 16MHz RC Oscillator
- lpo_clk_1: 1MHz RC Oscillator
- lpo_clk_2: 32KHz clock generated by 32 KHZ XTALOSC which could be automatically switched to 32KHz RC OSC upon XTAL clock loss
- lpo_clk_3: IP Bus Clock

NOTE

In this device, PWM*x*_EXTB is not applicable. It also does not support external ADC input. Also there is **no** NanoEdge placement block in this device.

73.2 Overview

The Enhanced Flex Pulse Width Modulator (eFlexPWM) module contains PWM submodules, each of which can be used to control a single half-bridge power stage. Fault channel support is provided.

eFlexPWM generates various switching patterns, including highly sophisticated waveforms. It can be used to control all known motor types and is ideal for controlling different Switched Mode Power Supplies (SMPS) topologies.

73.2.1 Block diagram

The following figure shows the eFlexPWM block diagram.

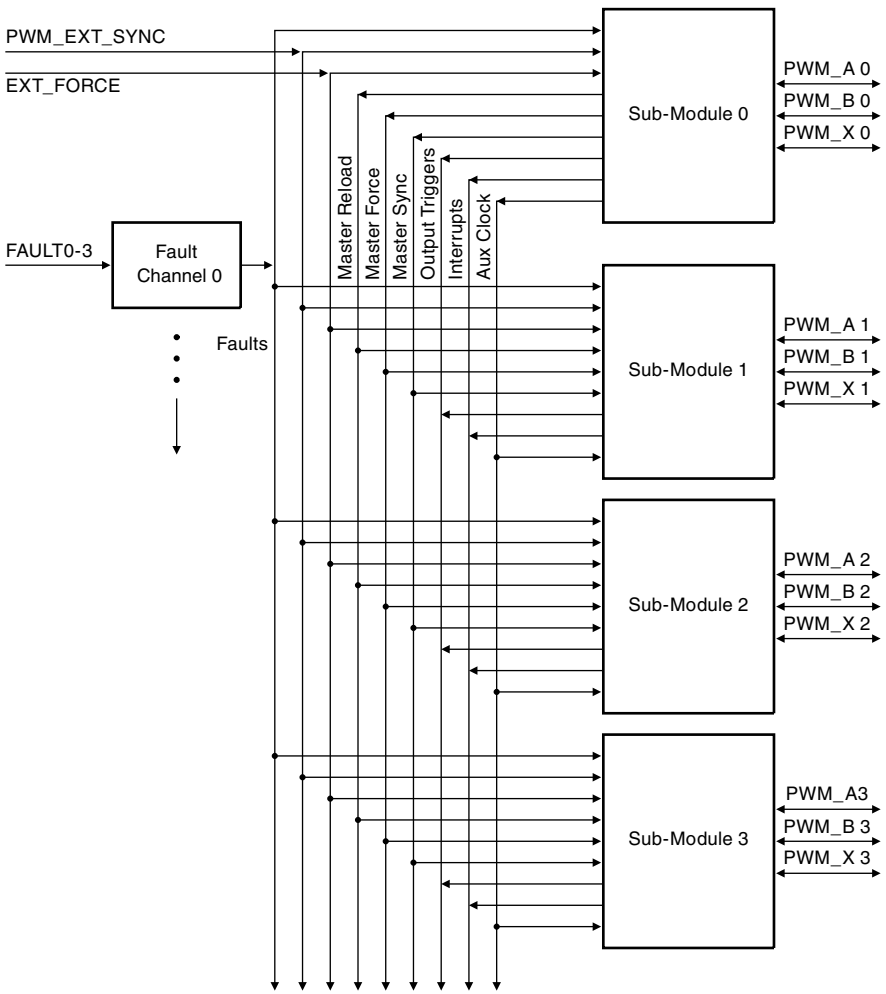

Figure 73-1. eFlexPWM block diagram

73.2.2 Features

Following are the features of eFlexPWM:

- 16-bit resolution for center, edge-aligned, and asymmetrical PWMs
- Dithering to simulate enhanced resolution when fine edge placement is not available
- PWM outputs that can operate as complementary pairs or independent channels
- Ability to accept signed numbers for PWM generation
- Independent control of both edges of each PWM output
- Support for synchronization to external hardware or other PWM

- Double buffered PWM registers
  - Integral reload rates from 1 to 16
  - Half cycle reload capability
- Multiple output trigger events can be generated per PWM cycle via hardware
- Support for double switching PWM outputs
- Fault inputs can be assigned to control multiple PWM outputs
- Programmable filters for fault inputs
- Independently programmable PWM output polarity
- Independent top and bottom deadtime insertion
- Each complementary pair can operate with its own PWM frequency and deadtime values
- Individual software control for each PWM output
- All outputs can be programmed to change simultaneously via a FORCE_OUT event
- PWM_X pin can optionally output a third PWM signal from each submodule
- Channels not used for PWM generation can be used for buffered output compare functions and for input capture functions
- Enhanced dual edge capture functionality

73.3 Functional description

73.3.1 eFlexPWM submodule

The following figure shows the Submodule Block Diagram of eFlexPWM.

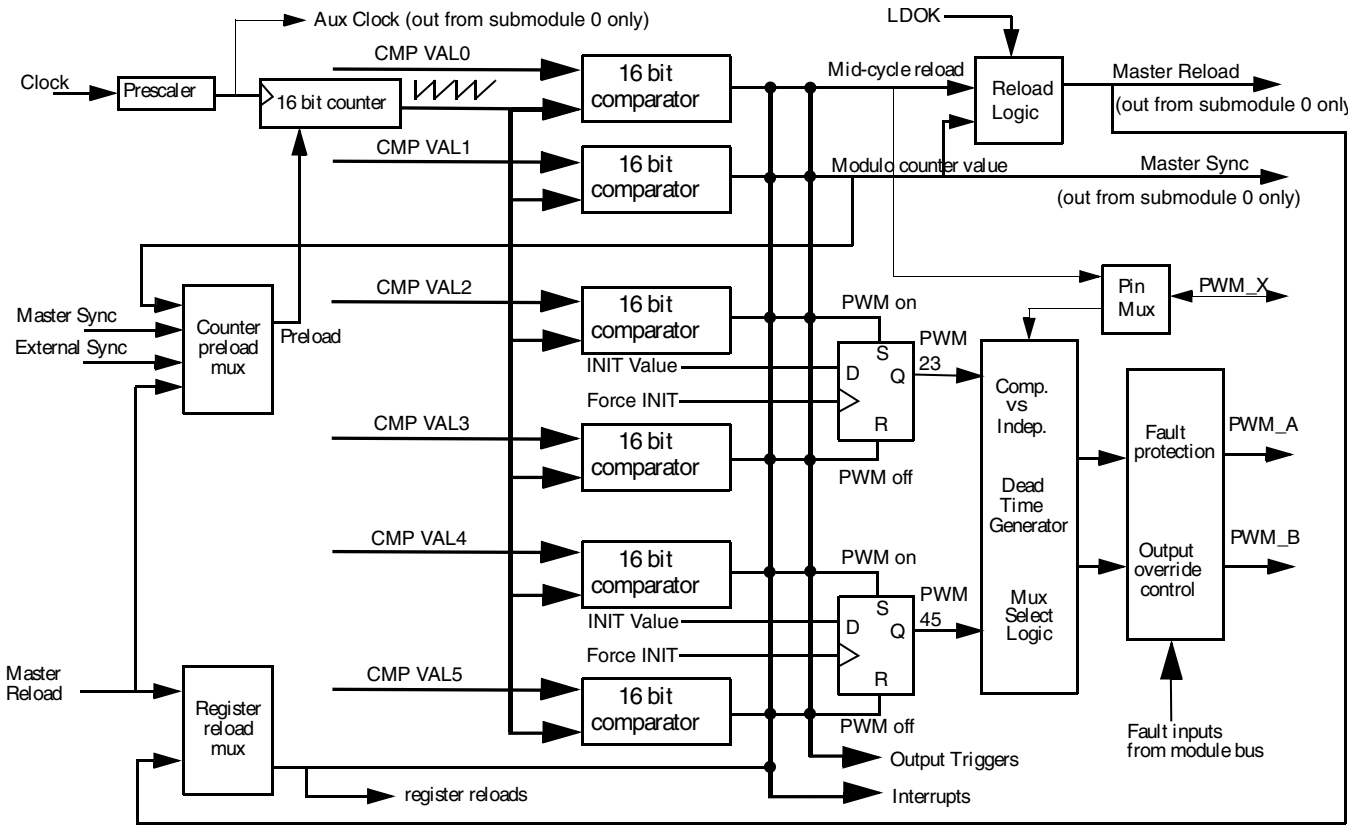

Figure 73-2. Submodule block diagram

73.3.2 eFlexPWM capabilities

This section describes some capabilities of the eFlexPWM module.

73.3.2.1 Center aligned PWMs

Each submodule has its own timer that is capable of generating PWM signals on two output pins. The edges of each of these signals are controlled independently as shown in Figure 73-3.

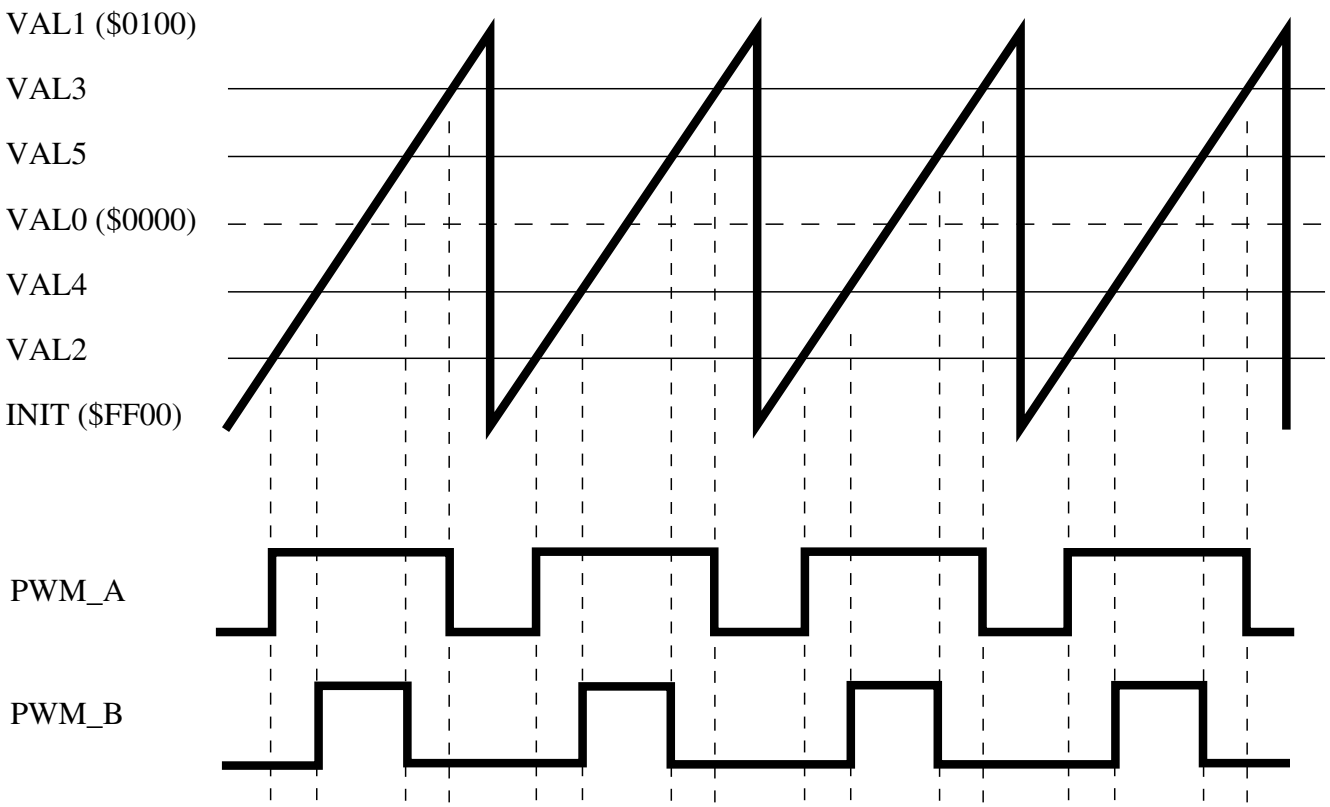

Figure 73-3. Center aligned PWM example

The submodule timers only count in the up direction and then reset to the INIT value. Instead of having a single value that determines pulse width, there are two values that must be specified: the turn-on edge and the turn-off edge. This double-action edge generation provides the user control over the pulse width and also the relative alignment of the signal. As a result, there is no need to support separate PWM alignment modes since the PWM alignment mode is inherently a function of the turn-on and turn-off edge values.

Figure 73-3 also illustrates an additional enhancement to the PWM generation process. When the counter resets, it is reloaded with a user-specified value, which may or may not be zero. If the value chosen happens to be the 2's complement of the modulus value, then the PWM generator operates in "signed" mode. This means if each PWM's turn-on and turn-off edge values are same in numbers but different in their sign, the "on" portion of the output signal is centered around a count value of zero. Therefore, only one PWM value is calculated in software and then this value and its negative are provided to the submodule as the turn-off and turn-on edges respectively. This technique results in a pulse width consists of an odd number of timer counts. If all PWM signal edge calculations follow this convention, then the signals will be center aligned with each other, which is the goal. The center alignment between the signals is not restricted to

symmetry around the zero count value, as any other number would also work. However, centering on zero provides the greatest range in signed mode and also simplifies the calculations.

73.3.2.2 Edge aligned PWMs

Figure 73-4 shows the results of edge aligned operation when the turn-on edge for each pulse is specified to be the INIT value. Therefore, only the turn-off edge value needs to be periodically updated to change the pulse width.

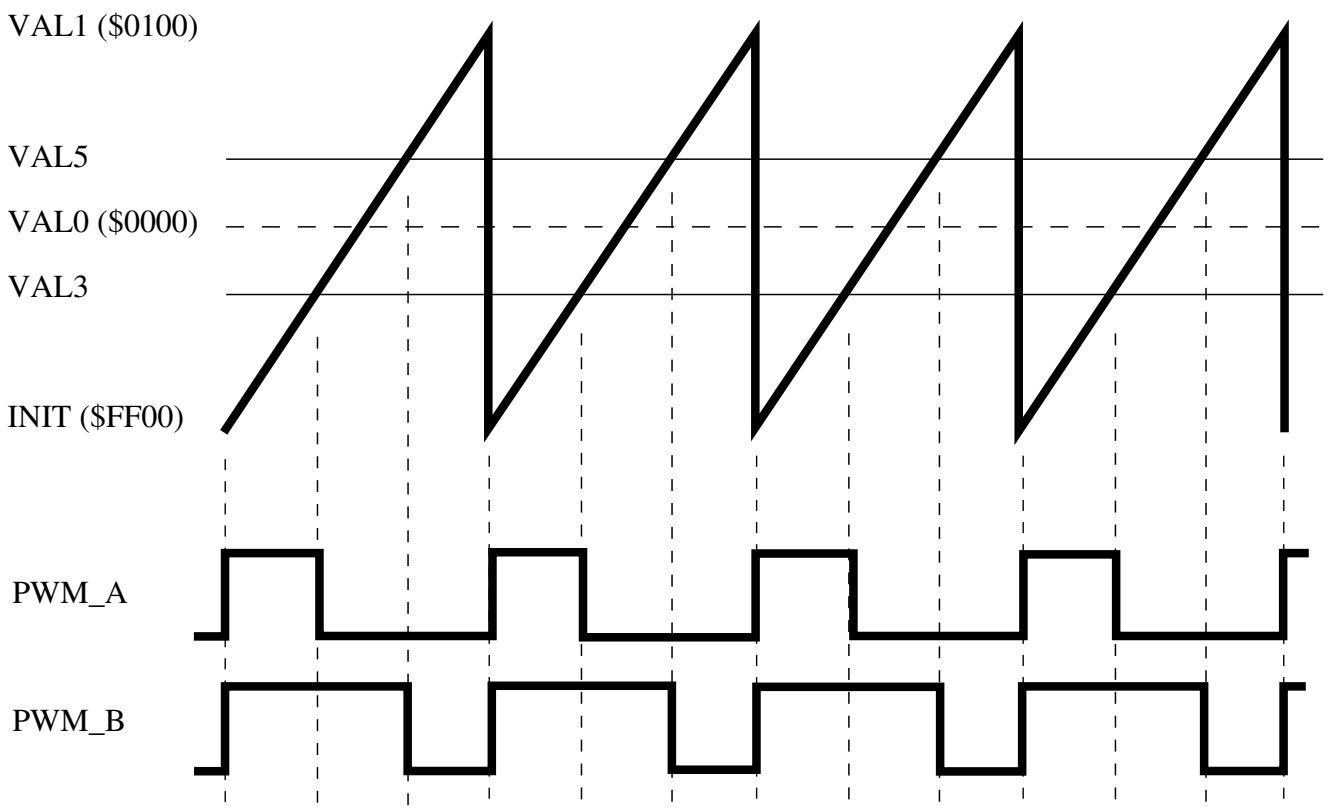

Figure 73-4. Edge aligned example (INIT=VAL2=VAL4)

With edge aligned PWMs, another example of the benefits of signed mode can be seen. Use "bipolar" PWMs to drive an H-bridge, where a 50% duty cycle results in zero volts on the load. Duty cycles less than 50% generate negative load voltages and duty cycles greater than 50% generate positive load voltages. If the module is set to signed mode operation (the INIT and VAL1 values are the same number with opposite signs), then there is a direct proportionality between the PWM turn-off edge value and the motor inverter voltage, including the sign. Therefore, signed mode of operation simplifies the software interface to the eFlexPWM module since no offset calculations are required to translate the output variable control algorithm to the voltage on an H-Bridge load.

73.3.2.3 Phase shifted PWMs

In the previous sections, the benefits of the signed mode of operation were discussed in the context of simplifying the required software calculations by eliminating the requirement to bias up signed variables before applying them to the module. However, if numerical biases are applied to the turn-on and turn-off edges of different PWM signals, the signals will be phase shifted to each other, as shown in Figure 73-5. This results in certain advantages when applied to a power stage. For example, when operating a multi-phase inverter at a low modulation index, all of the PWM switching edges from the different phases occur at the same time. This can be troublesome from a noise standpoint, especially if ADC readings of the inverter must be scheduled near those times. Phase shifting the PWM signals can open up timing windows between the switching edges to allow a signal to be sampled by the ADC. However, phase shifting does not affect the duty cycle so average load voltage is not affected.

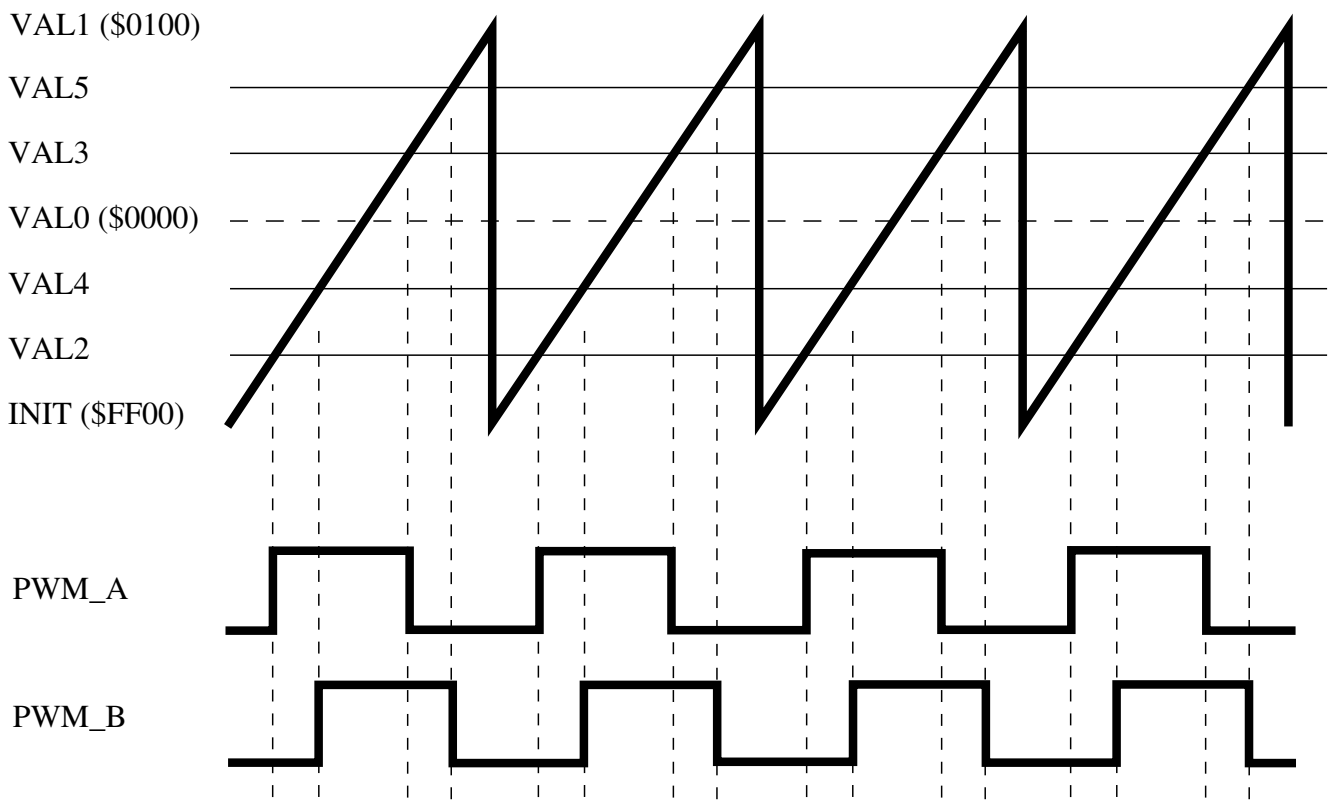

Figure 73-5. Phase shifted outputs - example for 1 submodule

An additional benefit of phase shifted PWMs is shown in Figure 73-6. In this case, an H-Bridge circuit is driven by 4 PWM signals to control the voltage waveform on the primary of a transformer. Both left and right side PWMs are configured to generate a square wave with 50% duty cycle. This works for the H-Bridge since no narrow pulse widths are generated reducing the high frequency switching requirements of the

transistors. The RMS value of this waveform is directly controlled by the amount of phase shift of the square waves. Regardless of the phase shift, no DC component appears in the load voltage as long as the duty cycle of each square wave remains at 50% suitable for transformer loads. As a result, this topology is frequently used in industrial welders to adjust the amount of energy delivered to the weld arc.

Note

The square wave on the right side of the H-Bridge is phase shifted compared to the left side of the H-Bridge. As a result, the transformer primary sees the bottom waveform across its terminals.

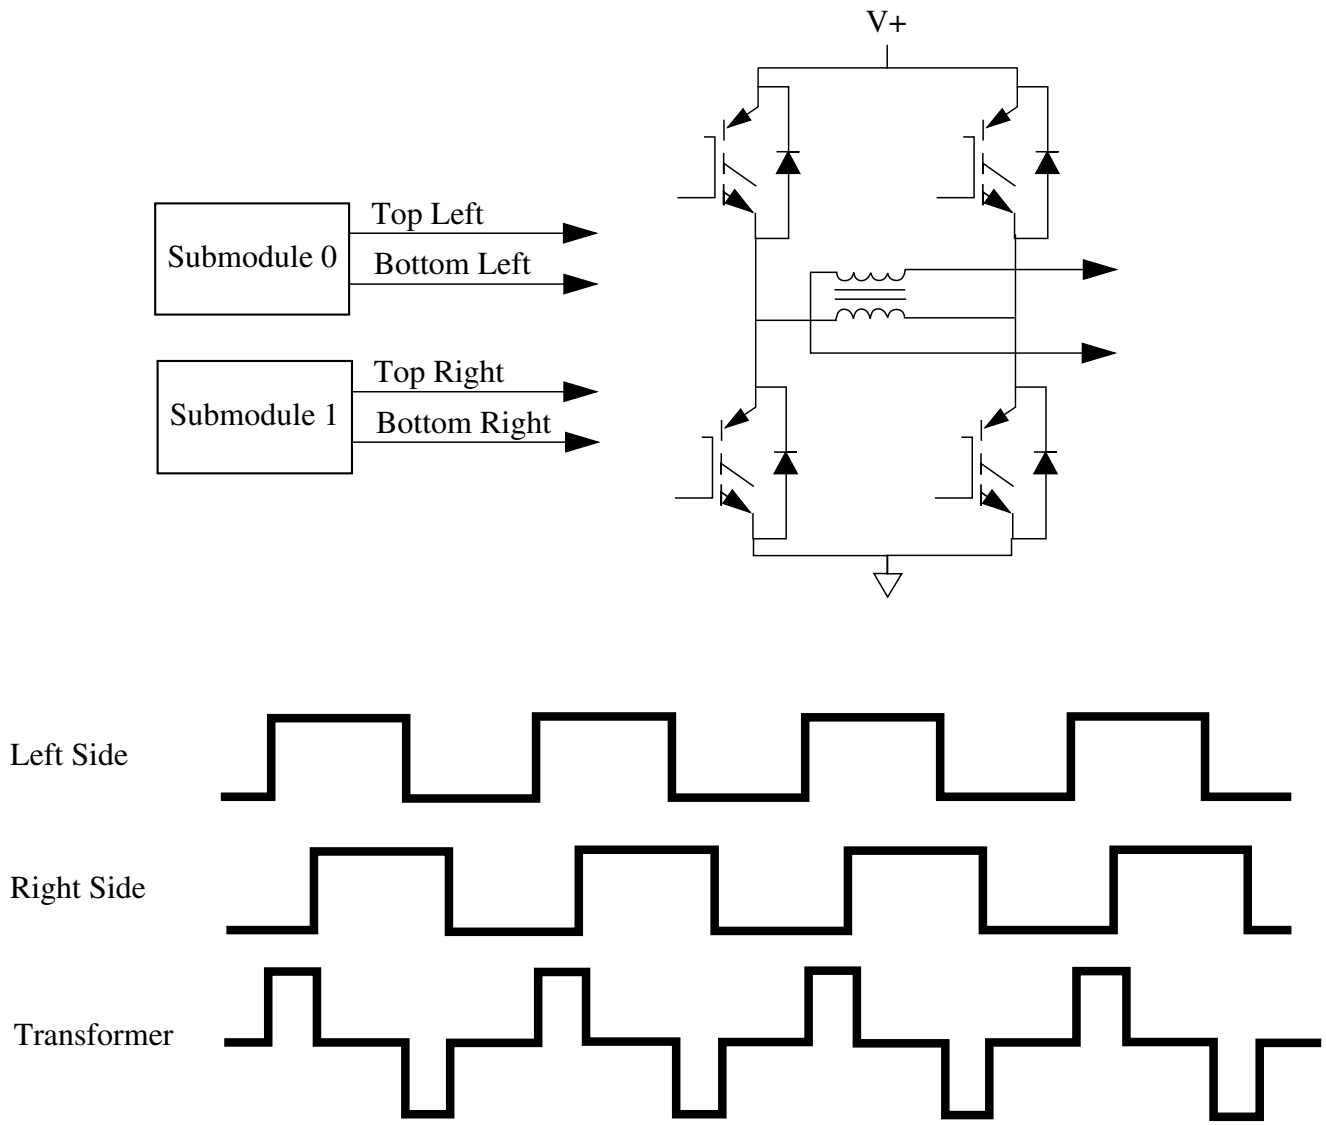

Figure 73-6. Phase Shifted PWMs Applied to a Transformer Primary

73.3.2.4 Double switching PWMs

Double switching PWM output is supported to aid in single shunt current measurement and three-phase reconstruction. This method supports two independent rising edges and two independent falling edges per PWM cycle. The VAL2 and VAL3 registers are used to generate the even channel (labeled as PWM_A in Figure 73-7) while VAL4 and VAL5 are used to generate the odd channel. The two channels (PWM23 or PWM_A and PWM45 or PWM_B from force out logic) are combined using XOR logic (force out logic) as the following figure shows. The DBLPWM signal can be run through the deadtime insertion logic.

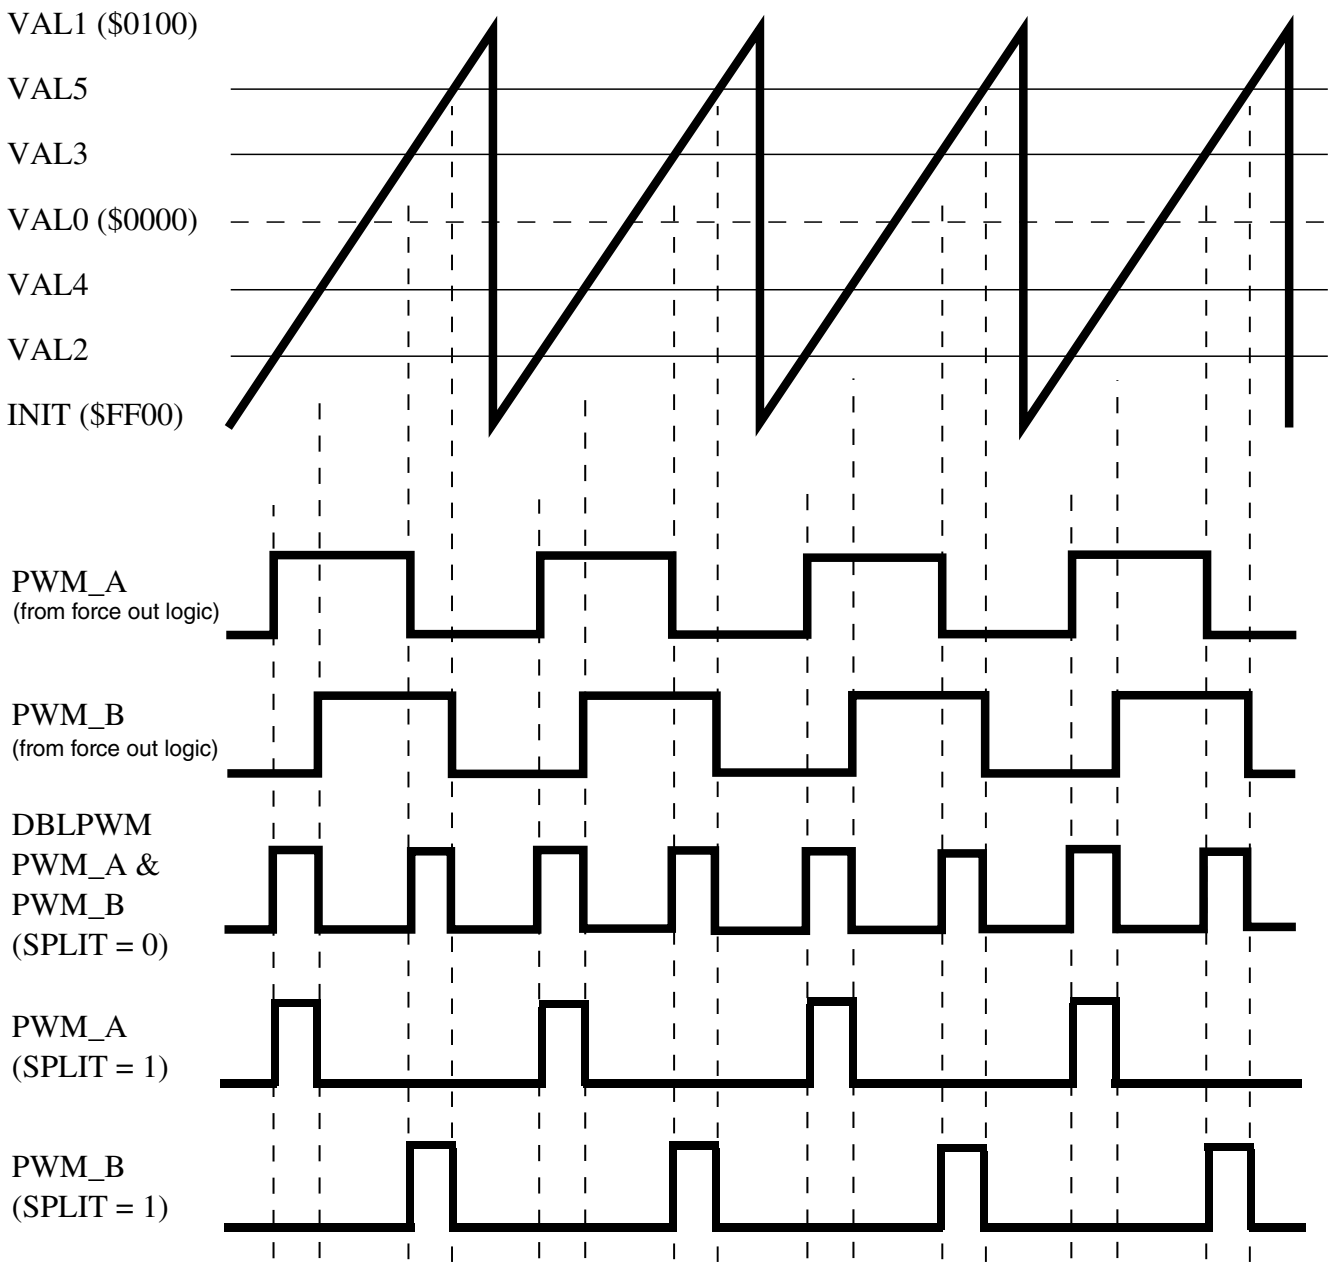

Figure 73-7. Double switching output example

73.3.2.5 ADC triggering

In cases where the timing of the ADC triggering is critical, it must be scheduled as a hardware event instead of software activated. With this eFlexPWM module, multiple ADC triggers can be generated in hardware per PWM cycle without the requirement of another timer module. Figure 73-8 shows how this is accomplished. When specifying a complementary mode of operation, only two edge comparators are required to generate the output PWM signals for a given submodule. This means the other comparators are free to perform other functions. In this example, the software does not need to quickly respond after the first conversion to set up other conversions that must occur in the same PWM cycle.

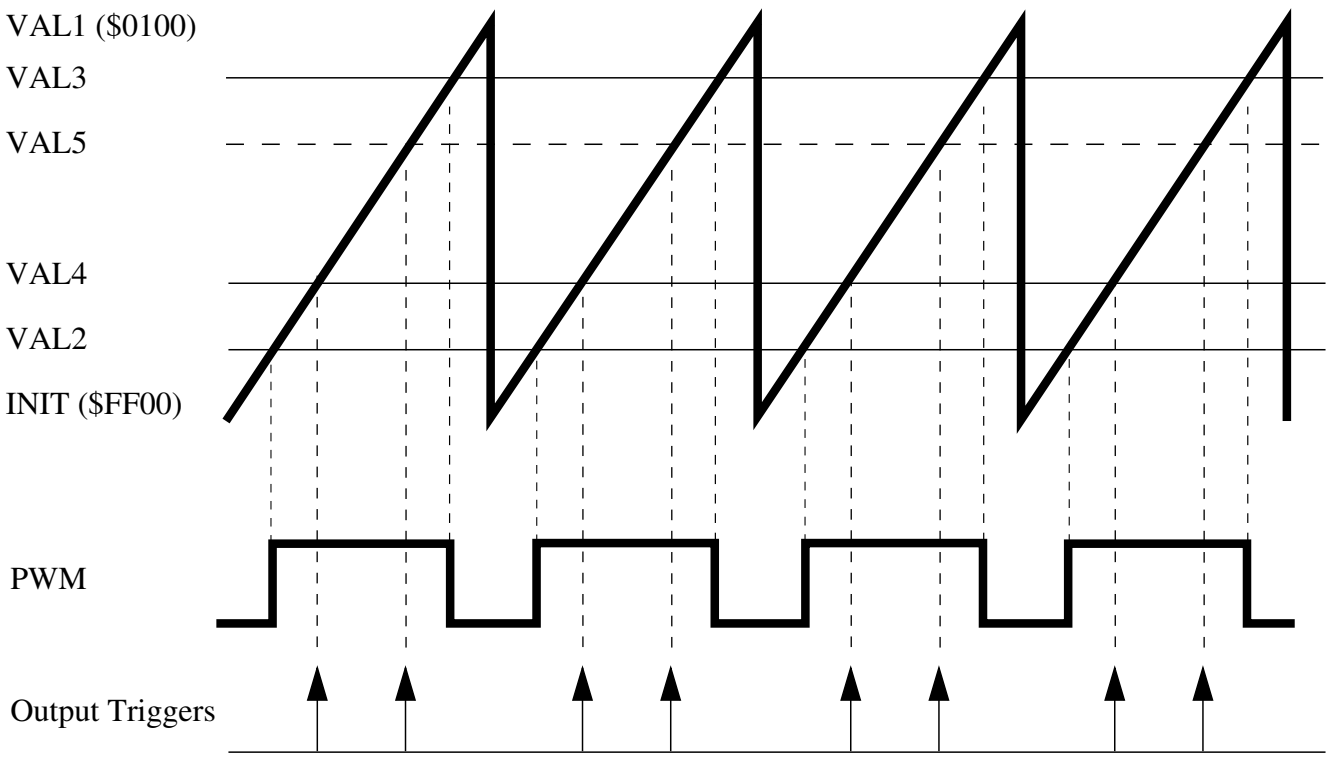

Figure 73-8. Multiple output trigger generation in hardware

Because each submodule has its own timer, it is possible for each submodule to run at a different frequency. One of the options possible with this eFlexPWM module is to have one or more submodules running at a lower frequency, but still synchronized to the timer in submodule0. Figure 73-9 shows how this feature can be used to schedule ADC triggers over multiple PWM cycles. You can use the lower-frequency submodule to control the sampling frequency of the software control algorithm where multiple ADC triggers can now be scheduled over the entire sampling period. In Figure 73-9, *all* submodule comparators are shown being used for ADC trigger generation.

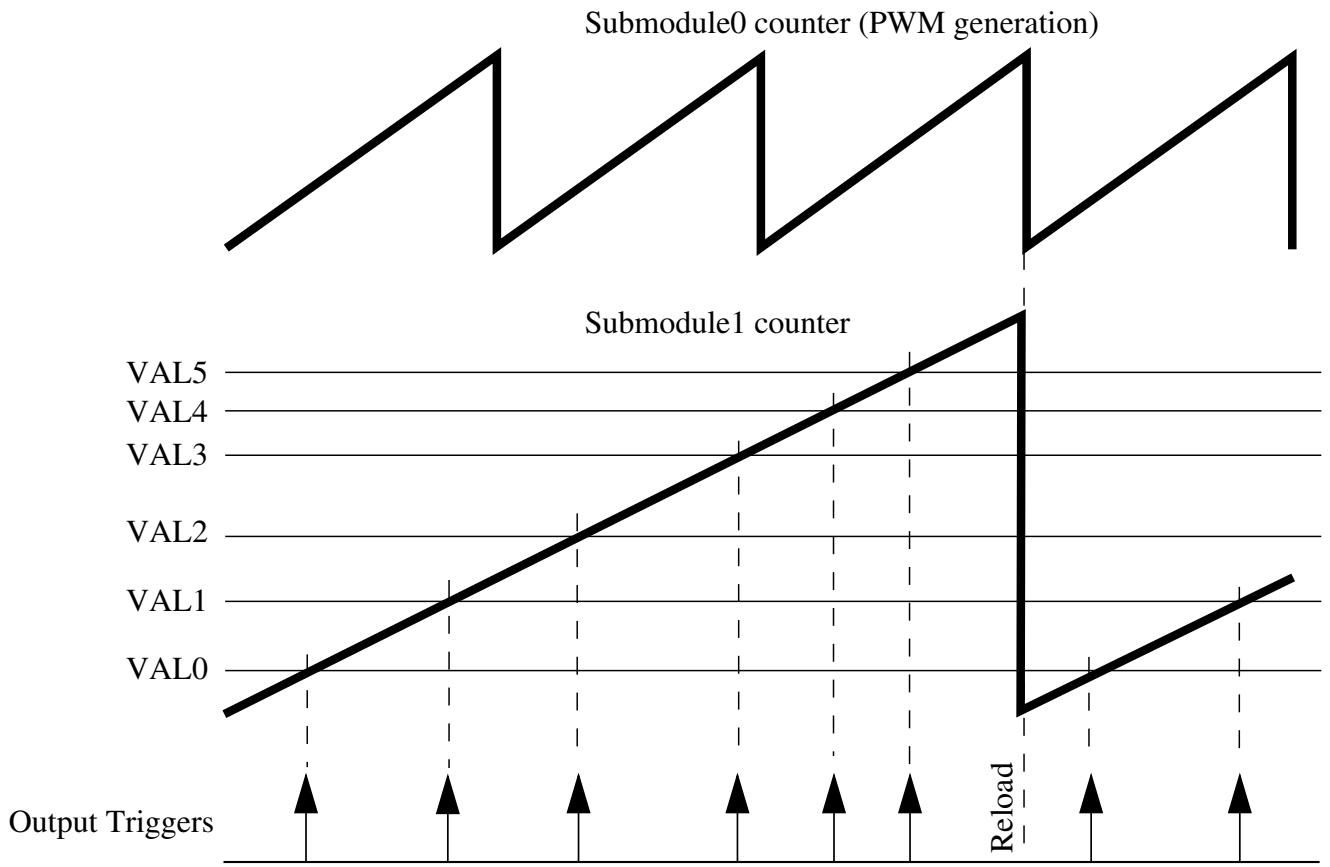

Figure 73-9. Multiple output triggers over several PWM cycles

73.3.2.6 Enhanced capture capabilities (E-Capture)

When a PWM pin is not used for PWM generation, it can be used to perform input captures. For PWM generation, both edges of the PWM signals are specified via separate compare register values. When programmed for input capture, both of these registers work on the same pin to capture multiple edges, toggling from one to the other in either a free running or one-shot fashion. Programming the desired edge of each capture circuit, period, and pulse width of an input signal can easily be measured without the requirement to re-arm the circuit. In addition, each edge of the input signal can clock an 8-bit counter where the counter output is compared to a user specified value (EDGCMP). When the counter output equals EDGCMP, the value of the submodule timer is captured and the counter is automatically reset. This feature counts a specified number of edge events and then performs a capture and interrupt. The following figure illustrates some of the functionality of the E-Capture circuit.

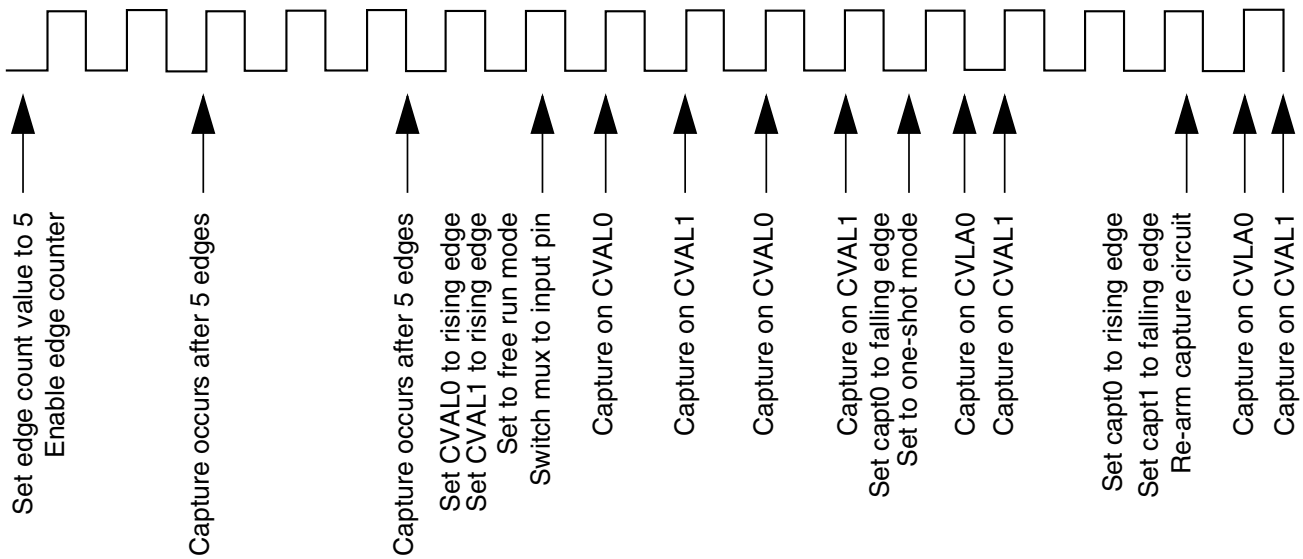

Figure 73-10. Capture capabilities of the E-Capture circuit

When a submodule is used for PWM generation, its timer counts up to the modulus value used to specify the PWM frequency and then is re-initialized. Therefore, using this timer for input captures on one of the other pins (for example, PWM_X) has limited utility since it does not count through all of the numbers and the timer reset represents a discontinuity in the 16-bit number range. However, when measuring a signal that is synchronous to the PWM frequency, the timer modulus range is suited for the application. As shown in Figure 73-11, the output of a PWM power stage is connected to the PWM_X pin that is configured for free running input captures. Specifically, the CVAL0 capture circuitry is programmed for rising edges and the CVAL1 capture circuitry is set for falling edges. This results in new load pulse width data acquired every PWM cycle. To calculate the pulse width, subtract the CVAL0 register value from the CVAL1 register value. This measurement is beneficial when performing deadtime distortion correction on a half bridge circuit driving an inductive load. Also, these values can be directly compared to the VALx registers responsible for generating the PWM outputs to obtain a measurement of system propagation delays. For details, refer to the separate discussion of deadtime distortion correction.

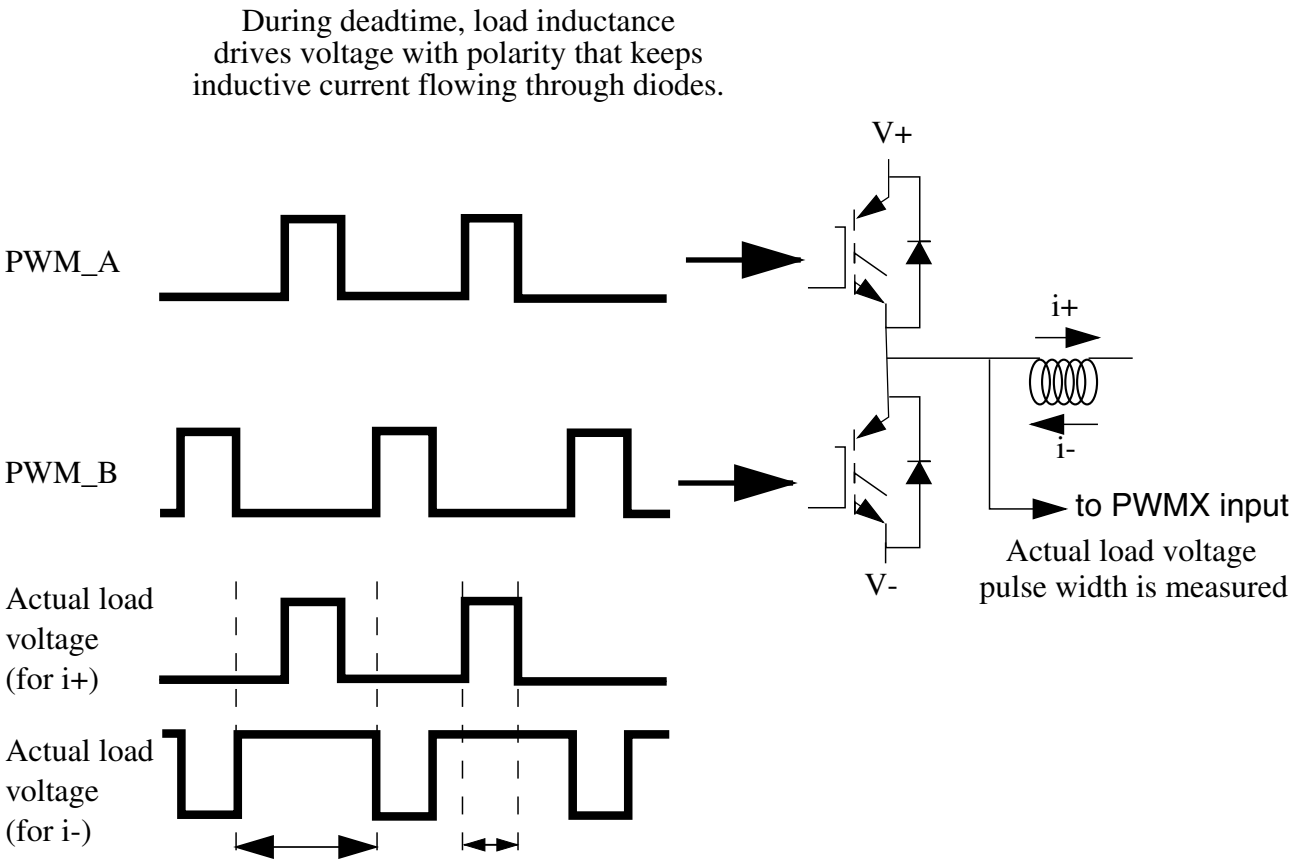

Figure 73-11. Output pulse width measurement possible with the E-capture circuit

73.3.2.7 Synchronous switching of multiple outputs

Before the PWM signals are routed to the output pins, they are processed by a hardware block that permits all submodule outputs to be switched synchronously. This feature is useful in commutated motor applications where the next commutation state can be laid in ahead of time and then immediately switched to the outputs when the appropriate condition or time is reached. All the changes occur immediately after the trigger event occurs eliminating any interrupt latency and also the changes occurs synchronously on all submodule outputs.

The synchronous output switching is accomplished via a signal called FORCE_OUT. This signal originates from the local FORCE bit within the submodule, from submodule0, or from external to the eFlexPWM module, and in most cases, is supplied from an external timer channel configured for output compare. In a typical application, software sets up the desired states of the output pins in preparation for the next FORCE_OUT event. This selection lays dormant until the FORCE_OUT signal transitions and then all

outputs are switched simultaneously. The signal switching is performed upstream from the deadtime generator so that any abrupt changes that occur do not violate deadtime on the power stage when in complementary mode.

Figure 73-12 shows an application that can benefit from this feature. On a brushless DC motor in many cases, it is required to spin the motor without need of hall-effect sensor feedback. Instead, the back EMF of the motor phases is monitored and this information is used to schedule the next commutation event. The top waveforms of Figure 73-12 represent these back EMF signals. Timer compare events (represented by the long vertical lines in the diagram) are scheduled based on the zero crossings of the back-EMF waveforms. The eFlexPWM module is configured via software ahead of time with the next state of the PWM pins in anticipation of the compare event. When it happens, the output compare of the timer drives the FORCE_OUT signal which immediately changes the state of the PWM pins to the next commutation state with no software latency.

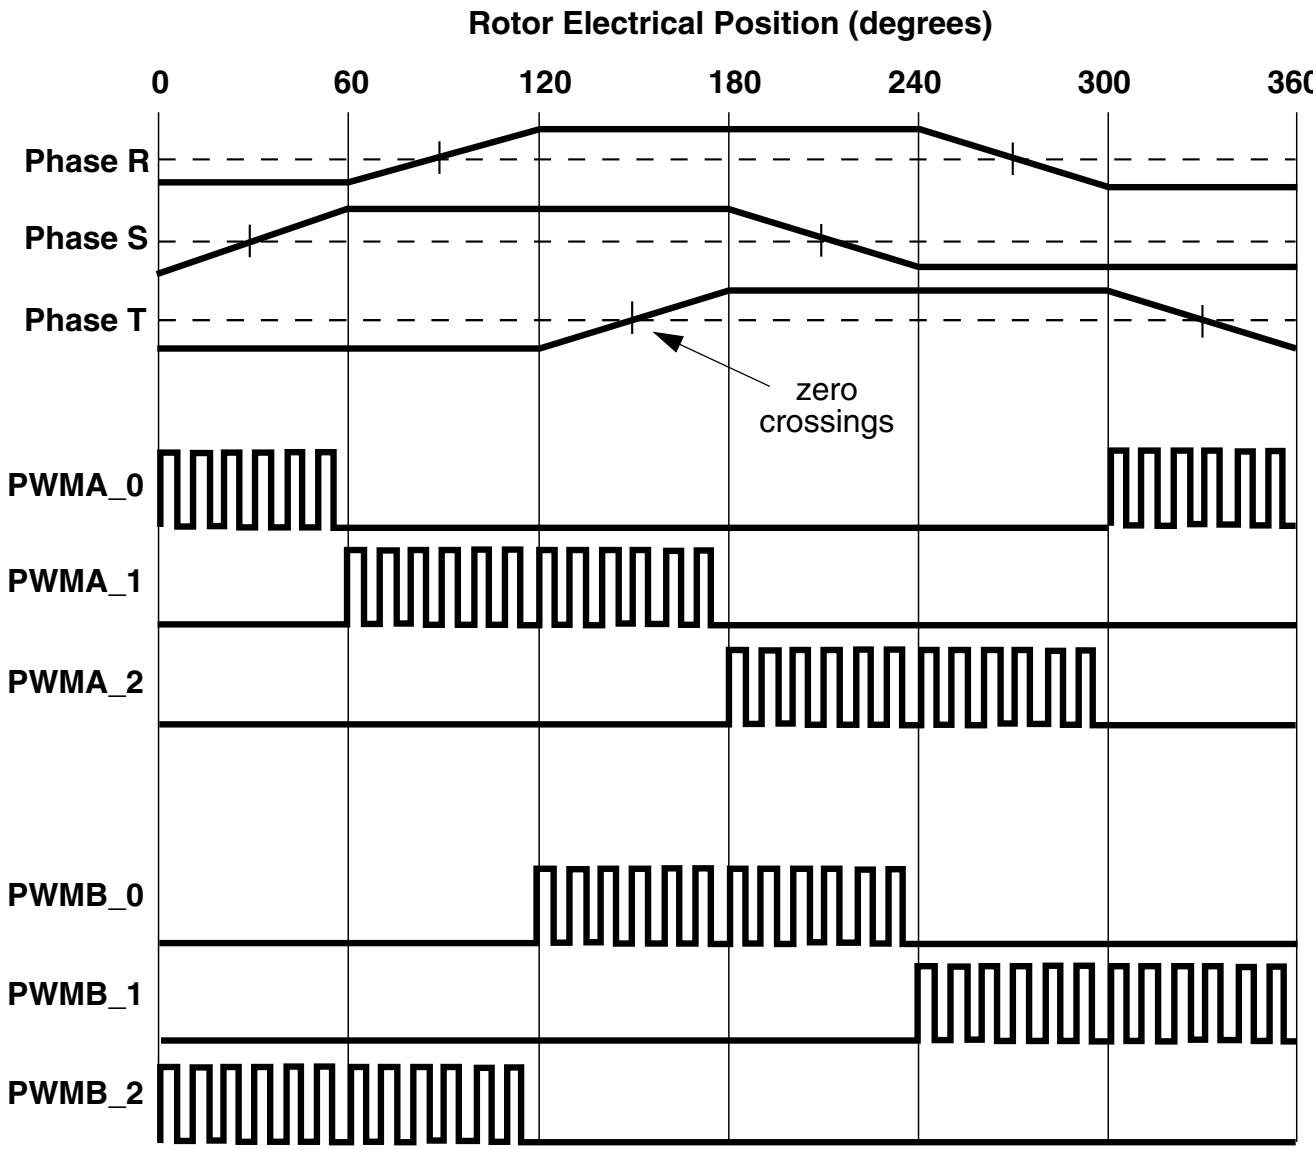

Figure 73-12. Sensorless BLDC commutation using the force out function

73.3.3 Operation

This section describes the implementation of various sections of eFlexPWM in detail.

The following figure is a high-level block diagram of output PWM generation.

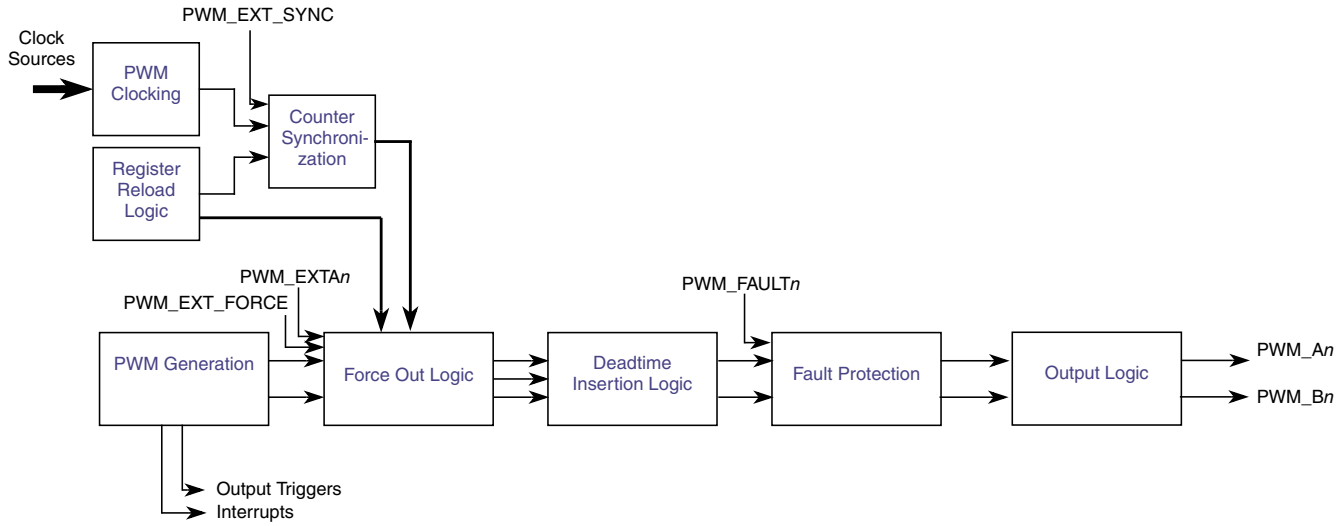

Figure 73-13. High-level output PWM generation block diagram

73.3.3.1 Register reload logic

The register reload logic is used to determine when the outer set of registers for all double buffered register pairs will be transferred to the inner set of registers. The register reload event can be scheduled to occur every "n" PWM cycles using CTRL[LDFQ] and CTRL[FULL], which is defined by VAL1 register. A half cycle reload option is also supported (CTRL[HALF]) where the reload can take place in the middle of a PWM cycle. The half cycle point is defined by the VAL0 register and does not have to be exactly in the middle of the PWM cycle.

As shown in Figure 73-14 the reload signal from submodule0 can be broadcast as the Master Reload signal allowing the reload logic from submodule0 to control the reload of registers in other submodules.

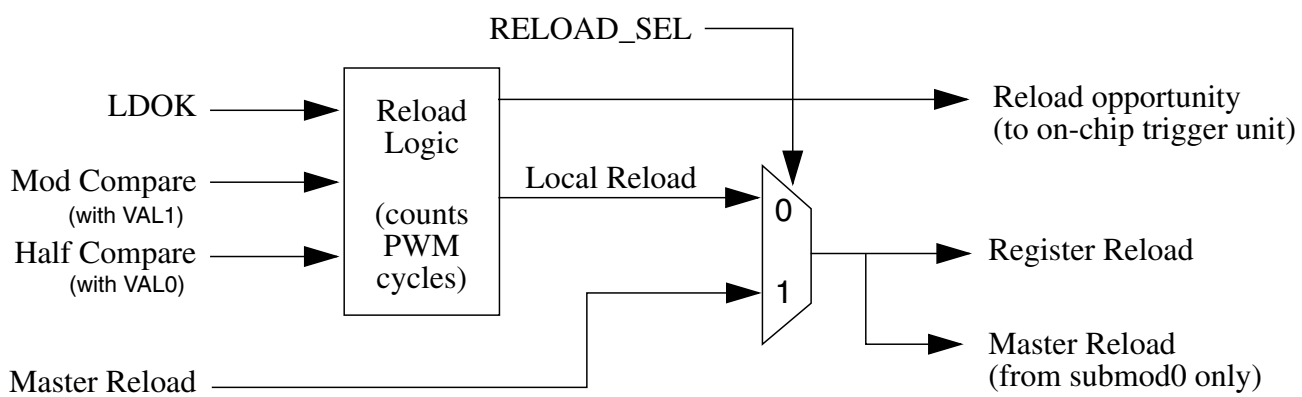

Figure 73-14. Register reload logic of each submodule

73.3.3.2 Counter synchronization

As shown in Figure 73-15, the 16-bit counter counts up until its output equals VAL1 which is used to specify the counter modulus value. The resulting compare causes a rising edge to occur on the Local Synchronization signal which is one of four possible sources used to cause the 16-bit counter to be initialized with INIT. If Local Synchronization is selected as the counter initialization signal, VAL1 within the submodule effectively controls the timer period (and then the PWM frequency generated by that submodule), and everything operates or functions at a local level.

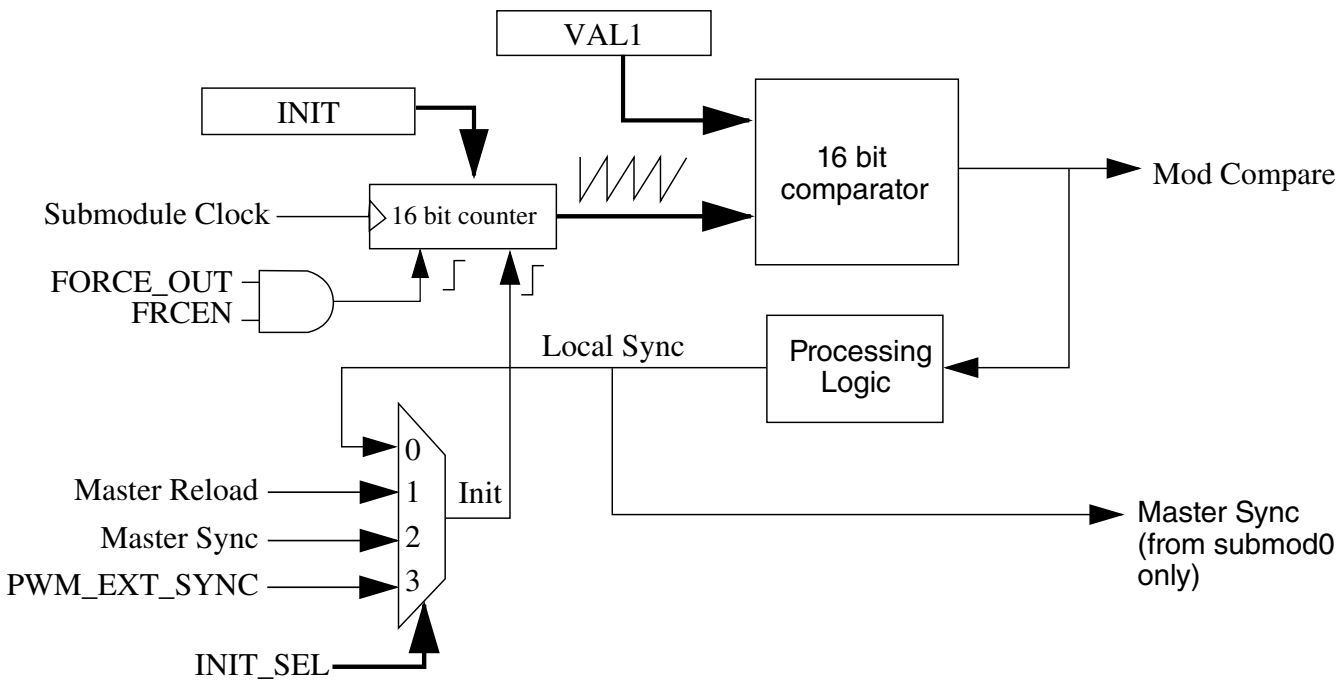

Figure 73-15. Counter synchronization for each submodule

The Master Synchronization signal originates as the Local Sync from submodule0. If configured to do so, the timer period of any submodule can be locked to the period of the timer in submodule0.

The PWM_EXT_SYNC signal originates on chip or off chip depending on the system architecture. This signal may be selected as the source for counter initialization so that an external source can control the period of all submodules.

If the Master Reload signal is selected as the source for counter initialization, then the period of the counter will be locked to the register reload frequency of submodule0. Since the reload frequency is commensurate to the sampling frequency of the software control algorithm, the submodule counter period is equal the sampling period. As a result, this

timer can be used to generate output compares or output triggers over the entire sampling period which may consist of several PWM cycles. The Master Reload signal can only originate from submodule0.

The counter can optionally initialize upon the assertion of the FORCE_OUT signal assuming that CTRL2[FRCEN] is set. As shown in Figure 73-15, this constitutes a second initialization input into the counter, which causes the counter to initialize regardless of which signal is selected as the counter initialization signal. A forced initialization causes a register reload if MCTRL[LDOK] is set.

The counter can be initialized by FORCE_OUT signal only when MCTRL[RUN] = 1 or CTLR2[CLK_SEL] = 2 which chooses auxiliary clock from SM0.

The FORCE_OUT signal is provided mainly for commutated applications. When PWM signals are commutated on an inverter controlling a brushless DC motor, it is necessary to restart the PWM cycle at the beginning of the commutation interval. This action effectively resynchronizes the PWM waveform to the commutation timing. Otherwise, the average voltage applied to a motor winding integrated over the entire commutation interval will be a function of the timing between the asynchronous commutation event for the PWM cycle. The effect is more critical at higher motor speeds where each commutation interval may consist of only a few PWM cycles. If the counter is not initialized at the start of each commutation interval, the result is an oscillation caused by the beating between the PWM frequency and the commutation frequency.

73.3.3.3 PWM generation

Figure 73-16 illustrates how PWM generation is accomplished in each submodule. In each case, two comparators and associated VALx registers are utilized for each PWM output signal. One comparator and VALx register are used to control the turn-on edge, while a second comparator and VALx register control the turn-off edge.

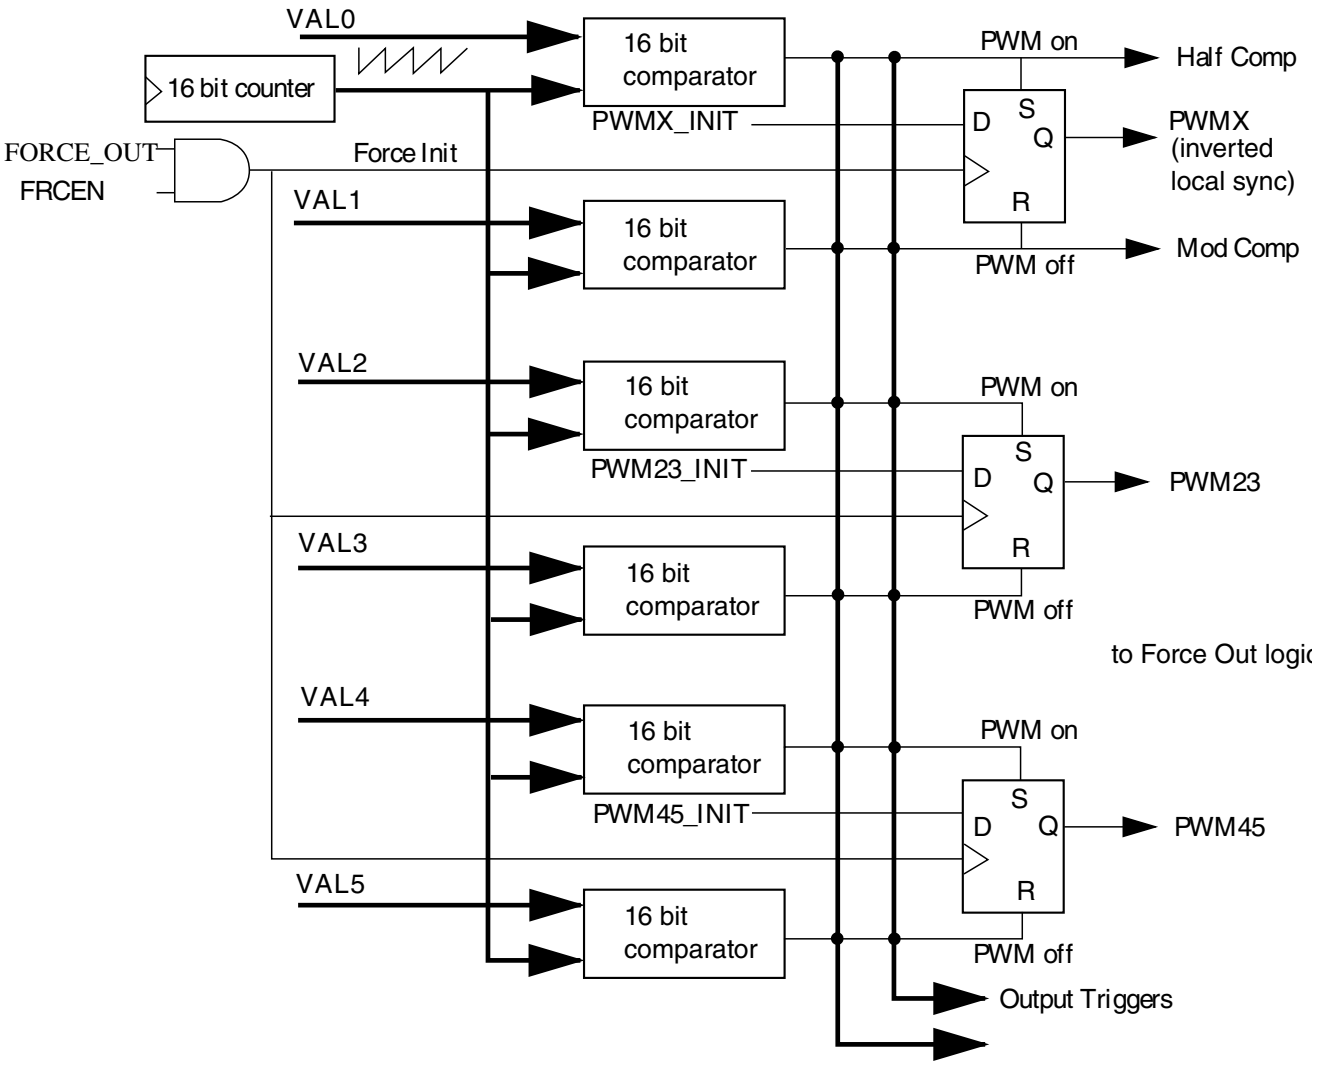

Figure 73-16. PWM Generation Hardware of each submodule

The generation of the Local Synchronization signal is performed exactly the same way as the other PWM signals in the submodule. While comparator 0 causes a falling edge of the Local Synchronization signal, comparator 1 generates a rising edge. Comparator 1 is also hardwired to the reload logic to generate the full cycle reload indicator.

If VAL1 is controlling the modulus of the counter and VAL0 is half of the VAL1 register minus the INIT value, then the half cycle reload pulse occurs exactly half way through the timer count period and the Local Synchronization will have a 50% duty cycle. On the other hand, if the VAL1 and VAL0 registers are not required for register reloading or counter initialization, they can be used to modulate the duty cycle of the Local Synchronization signal, effectively turning it into an auxiliary PWM signal (PWM_X) assuming that the PWM_X pin is not being used for another function such as input capture or deadtime distortion correction. Including the Local Synchronization signal, each submodule is capable of generating three PWM signals where software has complete control over each edge of each of the signals.

If the comparators and edge value registers are not required for PWM generation, they can be used for other functions such as output compares, generating output triggers, or generating interrupts at timed intervals.

The 16-bit comparators shown in Figure 73-16 are "equal to" comparators. In addition, if both the set and reset of the flip-flop are asserted, then the flop output goes to 0.

73.3.3.4 Output compare capabilities

By using the VALx registers in conjunction with the submodule timer and 16-bit comparators, buffered output compare functionality can be achieved with no additional hardware required. Specifically, the following output compare functions are possible:

- An output compare sets the output high
- An output compare sets the output low
- An output compare generates an interrupt
- An output compare generates an output trigger

In PWM generation, an output compare is initiated by programming a VALx register for a timer compare, which in turn causes the output of the D flip-flop to either set or reset. For example, if an output compare is desired on the PWM_A signal that sets it high, VAL2 would be programmed with the counter value where the output compare should take place. However, to prevent the D flip-flop from being reset again after the compare has occurred, the VAL3 register must be programmed to a value out of the modulus range of the counter. Therefore, a comparison that would result in resetting the D flip-flop output would never occur. Conversely, if an output compare is desired on the PWM_A signal that sets it low, the VAL3 register is programmed with the appropriate count value and the VAL2 register is programmed with a value out of the counter modulus range. Regardless of whether a high compare or low compare is programmed, an interrupt, or output trigger can be generated when the compare event occurs.

73.3.3.5 Force out logic

For each submodule, the software can select between eight signal sources for the FORCE_OUT signal depending on the chip architecture:

1. Local CTRL2[FORCE]
2. Master Force signal from submodule0
3. Local Reload signal
4. Master Reload signal from submodule0

5. Local Synchronization signal
6. Master Synchronization signal from submodule0
7. EXT_SYNC signal from on or off chip
8. EXT_FORCE signal from on or off chip

The local signals are used to change the signals on the output pins of the submodule without regard for synchronization with other submodules. However, if it is required that all signals on all submodule outputs change at the same time, the Master, EXT_SYNC, or EXT_FORCE signals must be selected.

Figure 73-17 illustrates the Force logic. The SEL23 and SEL45 fields each choose from one of four signals that can be supplied to the submodule outputs: the PWM signal, the inverted PWM signal, a binary level specified by software via the OUT23 and OUT45 bits, or the PWM_EXTA alternate external control signals. The selection can be determined ahead of time, and when a FORCE_OUT event occurs, these values are presented to the signal selection mux that immediately switches the requested signal to the output of the mux for further processing downstream.

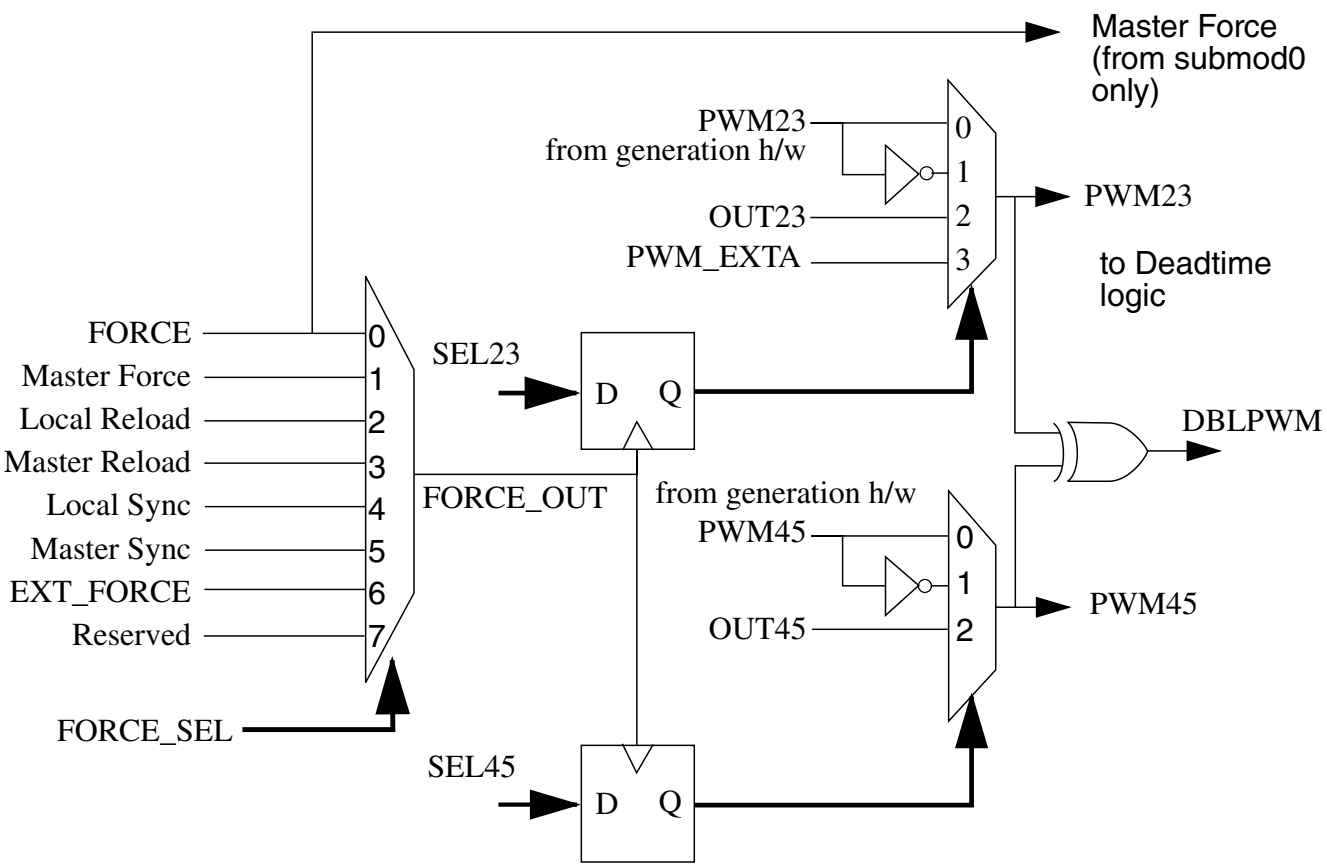

Figure 73-17. Force out logic for each submodule

The local CTRL2[FORCE] signal of submodule0 can be broadcast as the Master Force signal to other submodules. This feature allows the CTRL2[FORCE] of submodule0 to synchronously update all of the submodule outputs at the same time. The EXT_FORCE signal originates from outside the eFlexPWM module from a source such as a timer or digital comparators in the Analog-to-Digital Converter.

73.3.3.6 Independent or complementary channel operation

Writing a logic one to CTRL2[INDEP] configures the pair of PWM outputs as two independent PWM channels. Each PWM output is controlled by its own VALx pair operating independently of the other output.

Writing a logic zero to CTRL2[INDEP] configures the PWM output as a pair of complementary channels. The PWM pins are paired as shown in Figure 73-18 in complementary channel operation. The signal that is connected to the output pin (PWM23 or PWM45) is determined by MCTRL[IPOL].

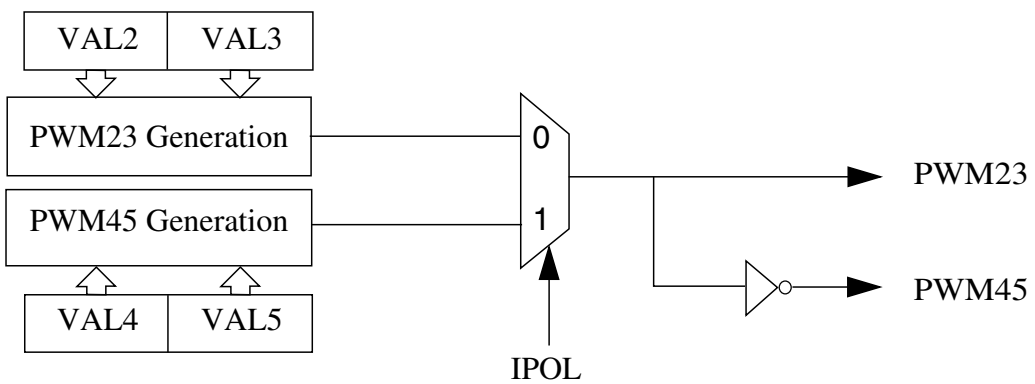

Figure 73-18. Complementary channel pair for each submodule

The complementary channel operation is for driving top and bottom transistors in a motor drive circuit, as shown in Figure 73-19.

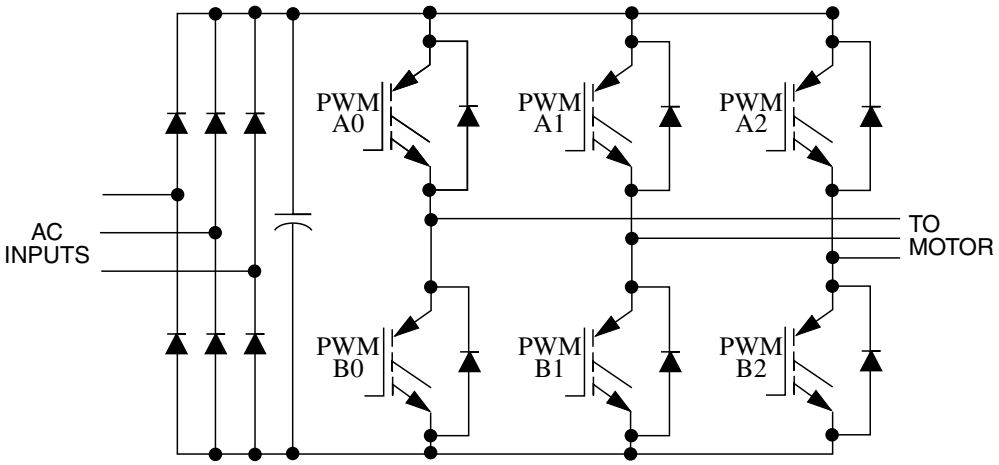

Figure 73-19. Typical 3 phase AC motor drive

The complementary operation allows the use of the deadtime insertion feature.

73.3.3.7 Deadtime insertion logic

The following figure shows the deadtime insertion logic of each submodule which is used to create non-overlapping complementary signals when not in independent mode.

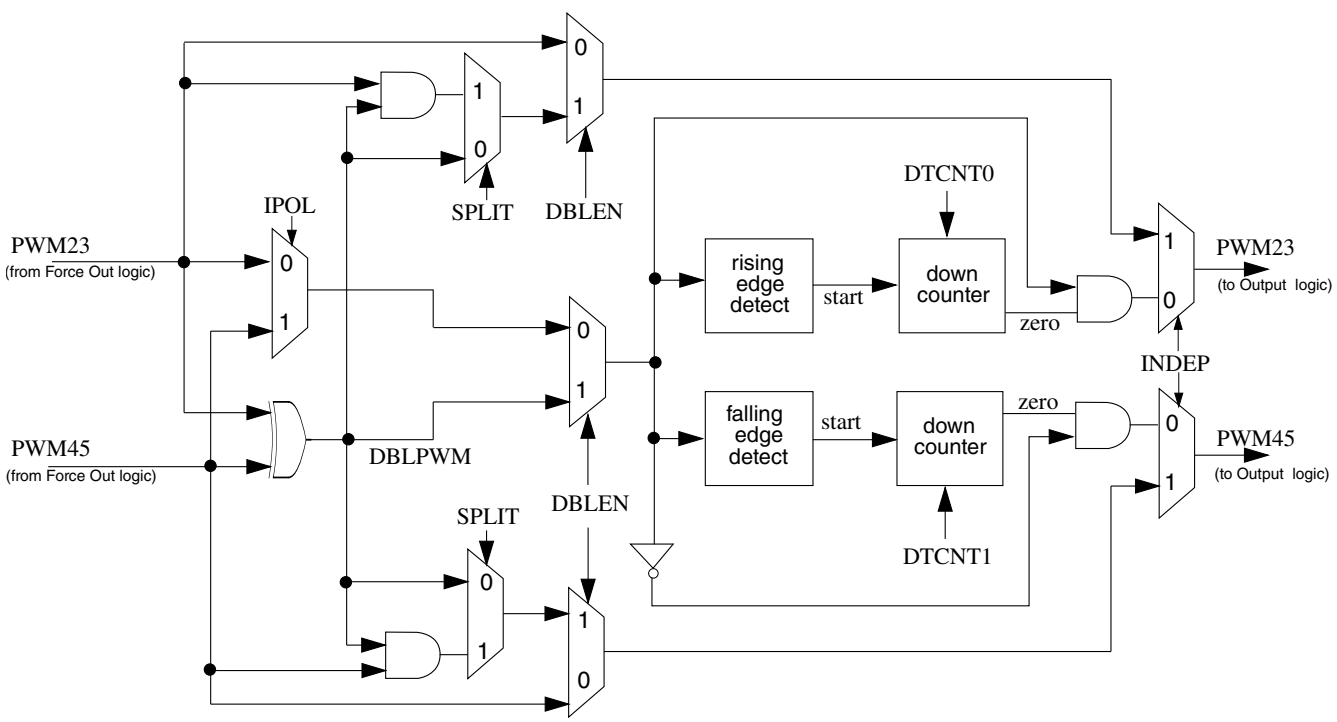

Figure 73-20. Deadtime Insertion Logic for each submodule

While in the complementary mode, a PWM pair can be used to drive top/bottom transistors, as shown in the figure. When the top PWM channel is active, the bottom PWM channel is inactive, and vice versa.

Note

To avoid short-circuiting the DC bus and endangering the transistor, there must be no overlap of conducting intervals between the top and bottom transistors. But the transistor's characteristics make its switching-off time longer than switching-on time. To avoid the conducting overlap of top and bottom transistors, deadtime needs to be inserted in the switching period, as shown in Figure 73-21.

The deadtime generators automatically insert software-selectable activation delays into the pair of PWM outputs. The deadtime registers (DTCNT0 and DTCNT1) specify the number of IPBus clock cycles to use for deadtime delay. Every time the deadtime generator inputs change state, deadtime is inserted. Deadtime forces both PWM outputs in the pair to the inactive state.

When deadtime is inserted in complementary PWM signals connected to an inverter driving an inductive load, the PWM waveform on the inverter output will have a different duty cycle than what appears on the output pins of the eFlexPWM module. This results in a distortion in the voltage applied to the load. A method of correcting this, adding to or subtracting from the PWM value used, is discussed next.

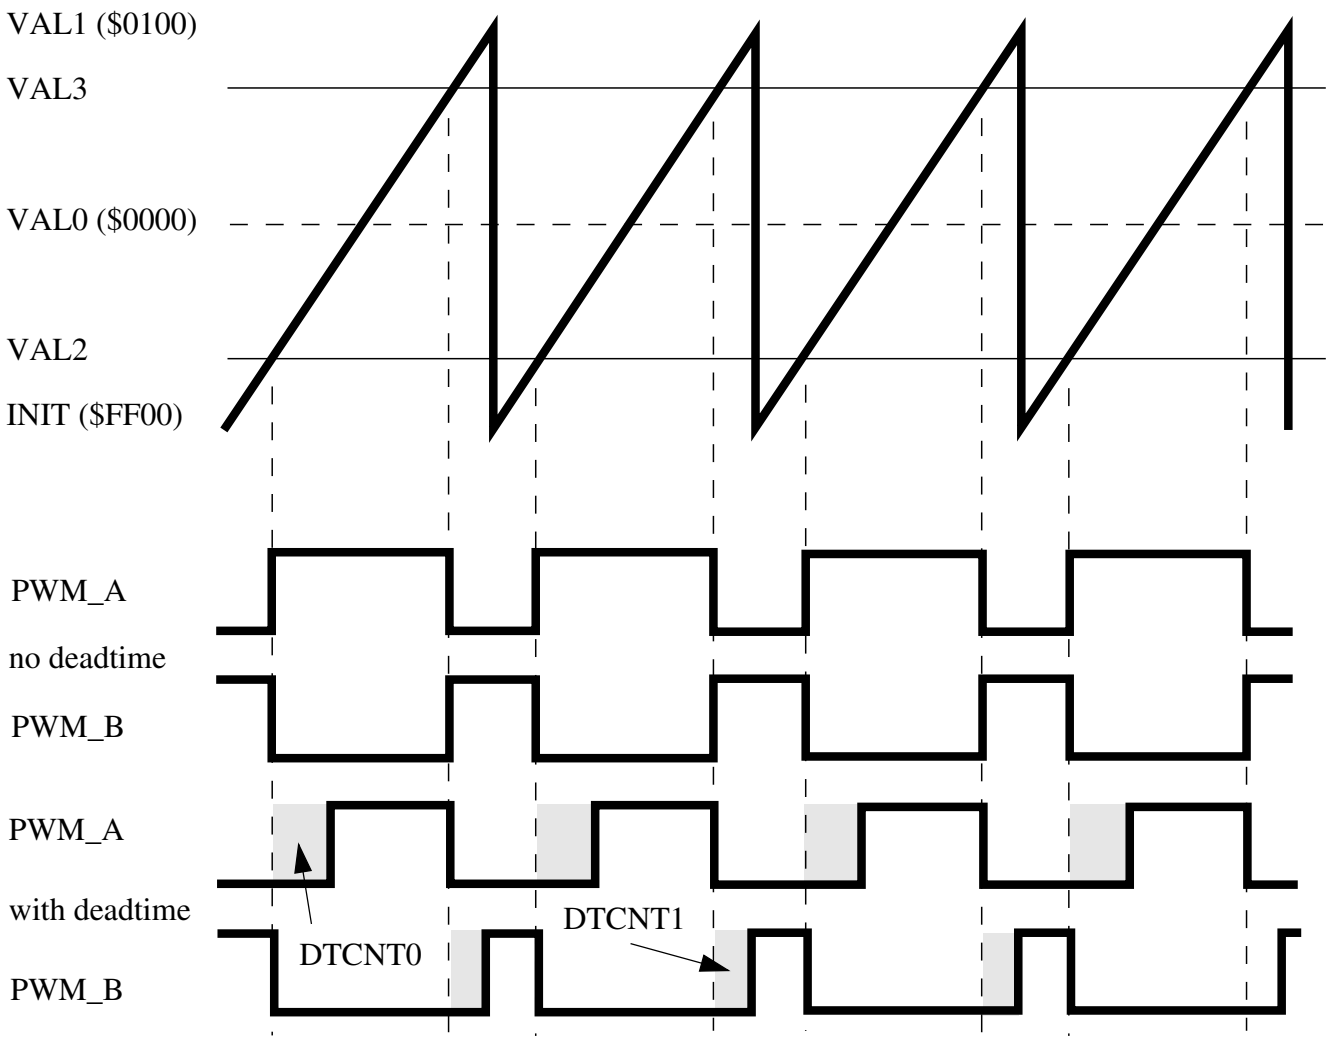

Figure 73-21. Deadtime insertion

73.3.3.7.1 Top/Bottom correction

In complementary mode, either the top or the bottom transistor controls the output voltage. However, deadtime has to be inserted to avoid overlap of conducting interval between the top and bottom transistor. Both transistors in complementary mode are off during deadtime, allowing the output voltage to be determined by the current status of load and introducing distortion in the output voltage, as shown in Figure 73-22. On AC induction motors running open-loop, the distortion typically manifests itself as poor low-speed performance, such as torque ripple and rough operation.

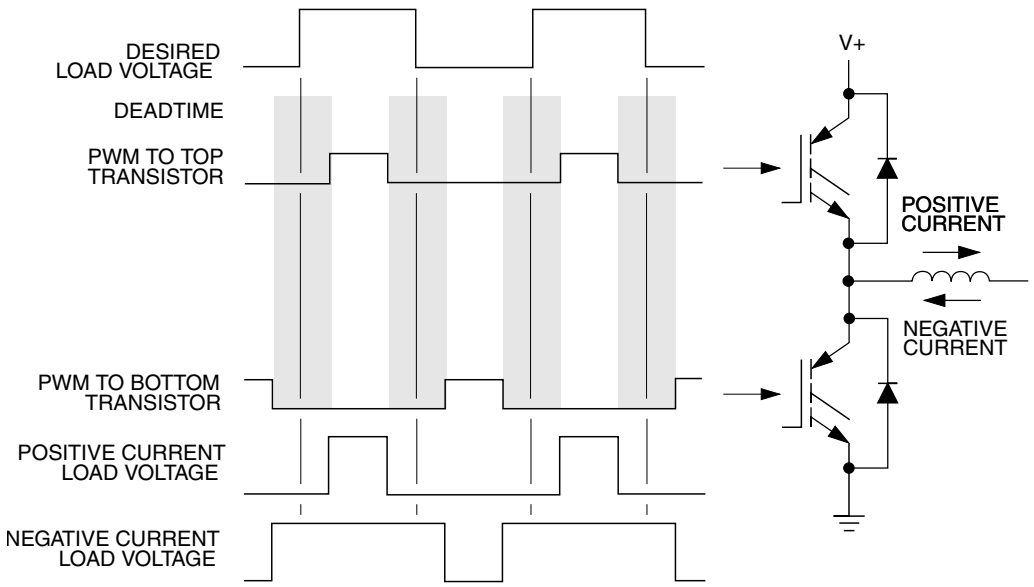

Figure 73-22. Deadtime distortion

During deadtime, load inductance distorts output voltage by keeping current flowing through the diodes. This deadtime current flow creates a load voltage that varies with the current direction. With a positive current flow, the load voltage during deadtime is equal to the bottom supply, putting the top transistor in control. With a negative current flow, the load voltage during deadtime is equal to the top supply putting the bottom transistor in control.

Remembering that the original PWM pulse widths were shortened by deadtime insertion, the averaged sinusoidal output is less than the desired value. However, when deadtime is inserted, it distorts in the motor current waveform inverter outputs. This distortion is aggravated by different turn-on and turn-off delays of each of the transistors. By giving the eFlexPWM module information on which transistor is controlling at a given time this distortion can be corrected.

For a typical circuit in complementary channel operation, only one of the transistors is effective in controlling the output voltage at any given time. This depends on the direction of the motor inverter current for that pair, as shown in Figure 73-22. To correct distortion one of two different factors must be added to the desired PWM value, depending on whether the top or bottom transistor is controlling the output voltage. Therefore, the software is responsible for calculating both compensated PWM values prior to placing them in the VALx registers. Either the VAL2/VAL3 or the VAL4/VAL5 register pair controls the pulse width at any given time. For a given PWM pair, whether the VAL2/VAL3 or VAL4/VAL5 pair is active depends on either:

- The state of the current status pin, PWMX, for that driver
- The state of the odd/even correction bit, MCTRL[IPOL], for that driver

To correct deadtime distortion, the software can decrease or increase the value in the appropriate VALx register.

- In edge-aligned operation, decreasing or increasing the PWM value by a correction value equal to the deadtime typically compensates for deadtime distortion.
- In center-aligned operation, decreasing or increasing the PWM value by a correction value equal to one-half the deadtime typically compensates for deadtime distortion.

73.3.3.7.2 Manual correction

To detect the current status, the voltage on each PWMX pin is sampled twice in a PWM period, at the end of each deadtime. The value is stored in CTRL[DT]. CTRL[DT] is a timing marker indicating when to toggle between PWM value registers. The software can then set MCTRL[IPOL] to switch between VAL2/VAL3 and VAL4/VAL5 register pairs according to CTRL[DT] values.

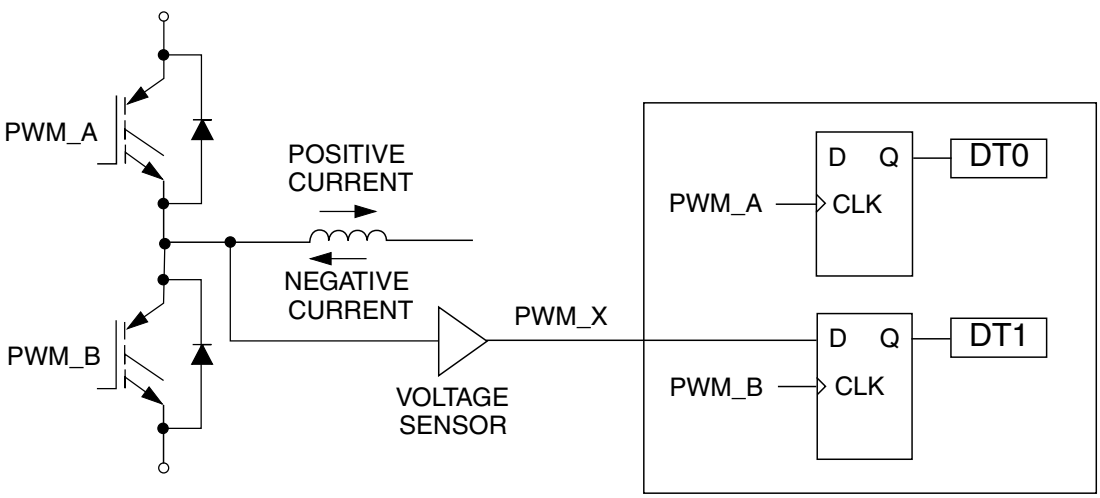

Figure 73-23. Current-status sense scheme for deadtime correction

Both D flip-flops latch low, CTRL[DT] = 00, during deadtime periods if the current is large and flowing out of the complementary circuit. See the preceding figure. Both D flip-flops latch the high, CTRL[DT] = 11, during deadtime periods if the current is also large and flowing into the complementary circuit.

However, under low-current, the output voltage of the complementary circuit during deadtime is between the high and low levels. The current cannot free-wheel through the opposition anti-body diode, regardless of polarity, giving additional distortion when the current crosses zero. Sampled results are CTRL[DT] = b10. Thus, the best time to change one PWM value register to another is just before the current zero crossing.

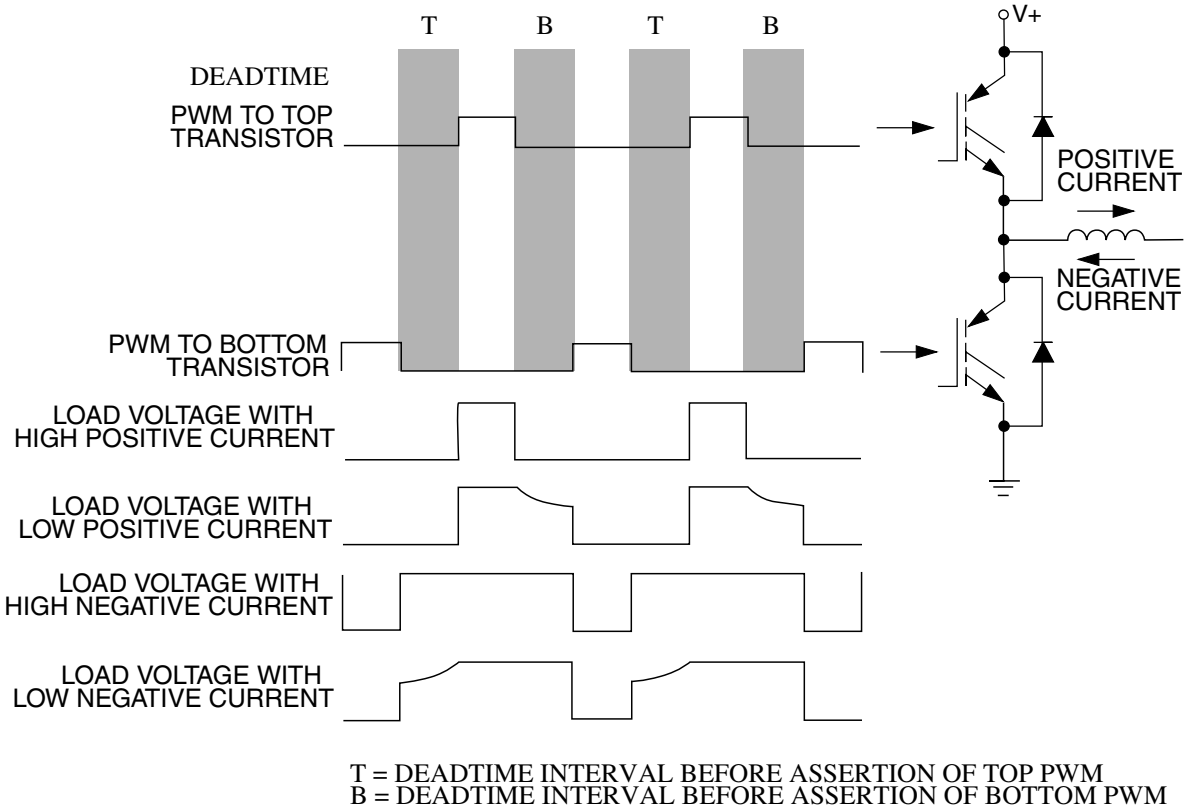

Figure 73-24. Output voltage waveforms

73.3.3.8 Fractional delay logic

For applications where more resolution than a single IPBus clock period is needed, the fractional delay logic can be used to achieve fine resolution on the rising and falling edges of the PWM_A and PWM_B outputs. Enable the use of the fractional delay logic by setting FRCTRL[FRACx_EN]. The FRACVALx registers act as a fractional clock cycle addition to the turn-on and turn-off count specified by the VAL2, VAL3, VAL4, or VAL5 registers. The FRACVAL1 register acts as a fractional increase in the PWM period as defined by VAL1. If FRACVAL1 is programmed to a non-zero value, then the largest value for the VAL1 register is 0xFFFE for unsigned usage or 0x7FFE for signed usage. This limit is required to avoid counter rollovers when accumulating the fractional additional period.

Both the fractional enables (1, 23, 45) and the fractional values (1-5) are double buffered and reloaded at the same time as the value registers.

Each PWM cycle, the value compare point is increased by 1 when there is overflow on the double buffered value of the fractional register plus the 5-bit accumulated fractional value. The accumulated fractional value starts at zero, so it is impossible to overflow the first PWM cycle.

At the end of each PWM cycle, if the corresponding fractional enable is set then the accumulated fractional value increments by the fractional value (double buffered value). The accumulated fractional value is 5-bits, so in the case of overflow only the remainder is kept. If the corresponding fractional enable is clear, then the accumulated fractional value is reset. This is the only way to reset the accumulated fractional value.

The accumulated fractional values are not accessible to software.

To fine-tune the PWM period using the FRACVAL1 register, if you want a period of 100.25 clock cycles, program VAL1 with 0x0064 and FRACVAL1 with 0x4000. The fractional value will accumulate so that every 4 PWM cycles will be 1 clock cycle longer (101 instead of 100). The rising and falling edges of the PWM outputs will also use the accumulated fraction to delay their edges and maintain a consistent 100.25 cycles spacing between corresponding edges from one cycle to the next.

The results of the fractional delay logic depend on whether or not the PWM submodule has an analog NanoEdge placer block available. With fractional delay enabled, PWM works in digital dithering mode: the value of FRACVALx is accumulated in each PWM period; when the accumulated value of FRACVALx overflows, VALx increments one in the next PWM period.

73.3.3.8.1 Fractional delay logic without NanoEdge placement block

For submodules that are not supported by the NanoEdge placer, the PWM can use dithering to simulate fine edge control. Enable this feature by setting the FRCTRL[FRAC1_EN], FRCTRL[FRAC23_EN], and FRCTRL[FRAC45_EN] bits. The PWM period or the PWM edges will dither from the nearest whole number values to achieve an average value that is equivalent to the programmed fractional value. The added cycles are based on the accumulation of the fractional component. For example, if you want the PWM period to be 50.25 clock cycles, then program VAL1 with 0x0032 and FRACVAL1 with 0x4000. The PWM period will be 50 cycles long most of the time, but will occasionally be 51 cycles long to achieve a long-term average of 50.25 cycles.

In submodules that are not supported by a NanoEdge placer, the clock frequency is not required to be any specific value to achieve proper operation.

73.3.3.9 Output logic

The following figure shows the output logic of each submodule including how each PWM output has individual fault disabling, polarity control, and output enable. This allows for maximum flexibility when interfacing with the external circuitry.

The PWM23 and PWM45 signals which are output from the deadtime logic (as shown in Figure 73-25) are positive true signals. In other words, a high level on these signals should result in the corresponding transistor in the PWM inverter being turned ON. The voltage level required at the PWM output pin to turn the transistor ON or OFF is a function of the logic between the pin and the transistor. Therefore, it is imperative that the user program OCTRL[POLA] and OCTRL[POLB] before enabling the output pins. A fault condition can result in the PWM output being put in a high-impedance state, forced to a logic 1 state, or forced to a logic 0 state, depending on the values programmed into the OCTRL[PWMxFS] fields.

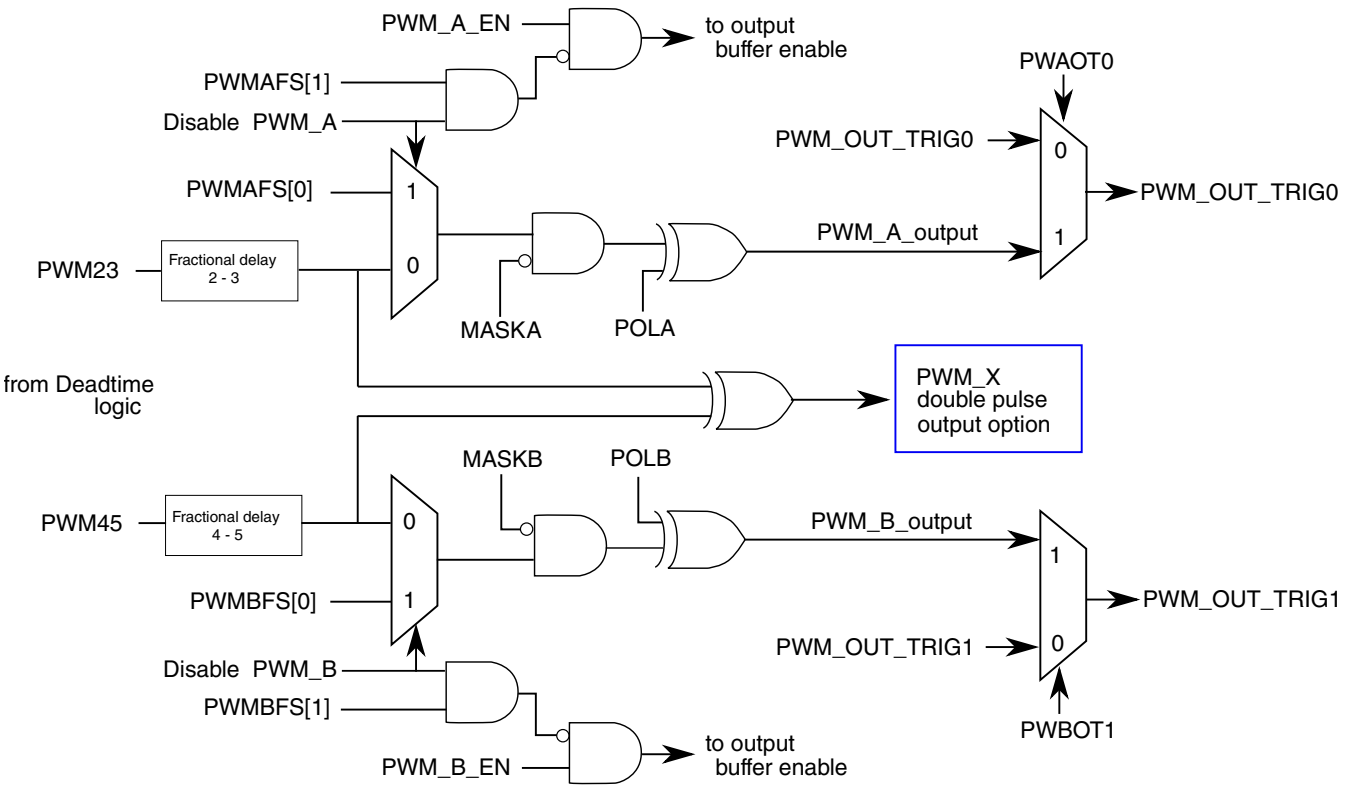

Figure 73-25. Output logic for each submodule

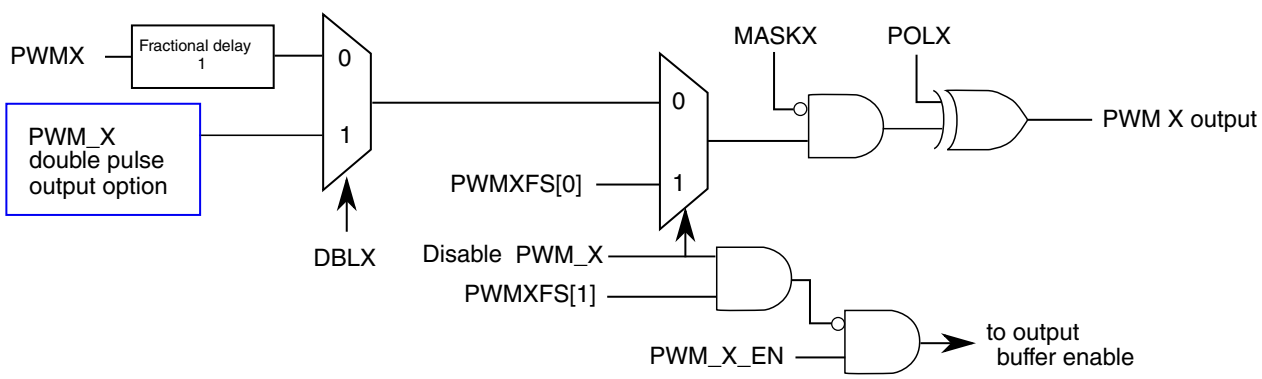

Figure 73-26. Output logic continued

73.3.3.10 E-Capture

The Enhanced Capture (E-Capture) logic is designed to measure both edges of an input signal. As a result, when a submodule pin is configured for input capture, the CVALx registers associated with that pin are used to record the edge values.

The following figure shows block diagram of the E-Capture circuit. Upon entering the pin input, the signal is split into two paths. One goes straight to a mux input where software can select to pass the signal directly to the capture logic for processing. The other path connects the signal to an 8-bit counter which counts both the rising and falling edges of the signal. The output of this counter is compared to an 8-bit value that is specified by the user (EDGCMPx) and when the two values are equal, the comparator generates a pulse that resets the counter. This pulse is also supplied to the mux input where software can select it to be processed by the capture logic. This feature permits the E-Capture circuit to count up to 256 edge events before initiating a capture event. This feature is useful for dividing down high frequency signals for capture processing so that capture interrupts do not overwhelm the CPU. Also, this feature can be used to generate an interrupt after "n" events have been counted.

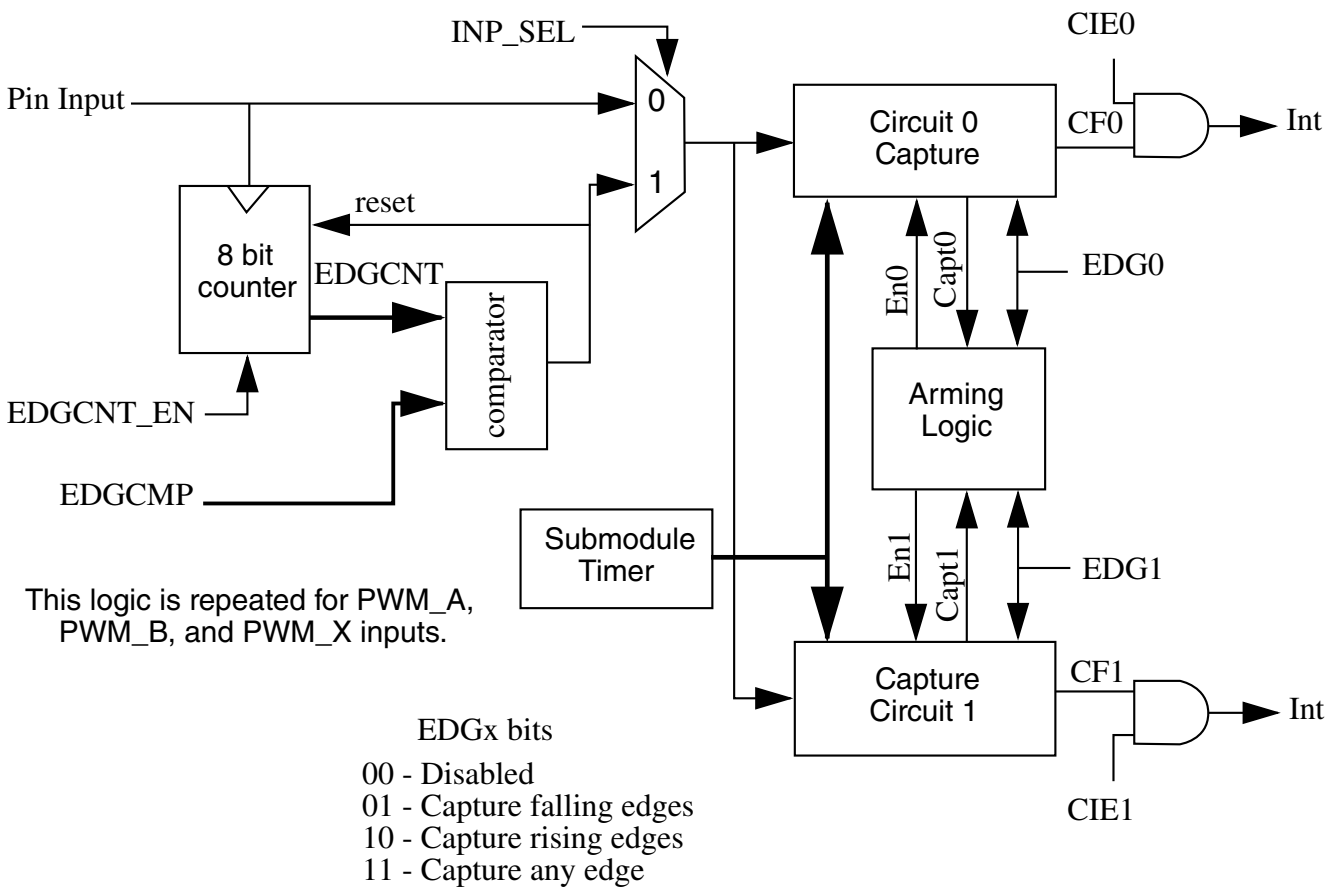

Figure 73-27. Enhanced capture (E-Capture) logic

Based on the mode selection, the mux selects either the pin input or the compare output from the count/compare circuit to be processed by the capture logic. The selected signal is routed to two separate capture circuits which work in tandem to capture sequential edges of the signal. The type of edge to be captured by each circuit is determined by CAPTCTRLx[EDGx1] and CAPTCTRLx[EDGx0], whose functionality is listed in the above figure. Also, controlling the operation of the capture circuits is the arming logic which allows captures to be performed in a free running (continuous) or one shot mode. In free running mode, the capture sequences will be performed indefinitely. If both capture circuits are enabled, they will work together in a ping-pong style where a capture event from one circuit leads to the arming of the other and vice versa. In one shot mode, only one capture sequence will be performed. If both capture circuits are enabled, capture circuit 0 is first armed and when a capture event occurs, capture circuit 1 is armed. Once the second capture occurs, further captures are disabled until another capture sequence is initiated. Both capture circuits are also capable of generating an interrupt to the CPU.

73.3.3.11 Fault protection

Fault protection can control any combination of PWM output pins. Faults are generated by a logic one on any of the FAULTx pins. This polarity can be changed via FCTRL[FLVL]. Each FAULTx pin can be mapped arbitrarily to any of the PWM outputs. When fault protection hardware disables PWM outputs, the PWM generator continues to run, only the output pins are forced to logic 0, logic 1, or high impedance depending on the values of OCTRL[PWMxFS].

The fault decoder disables PWM pins selected by the fault logic and the disable mapping (DISMAPn) registers. The following figure shows an example of the fault disable logic. Each bank of bits in DISMAPn control the mapping for a single PWM pin. See the following table.

The fault protection is enabled even when the module is not enabled. Therefore, a fault is latched in and must be cleared to prevent an interrupt when the module is enabled.

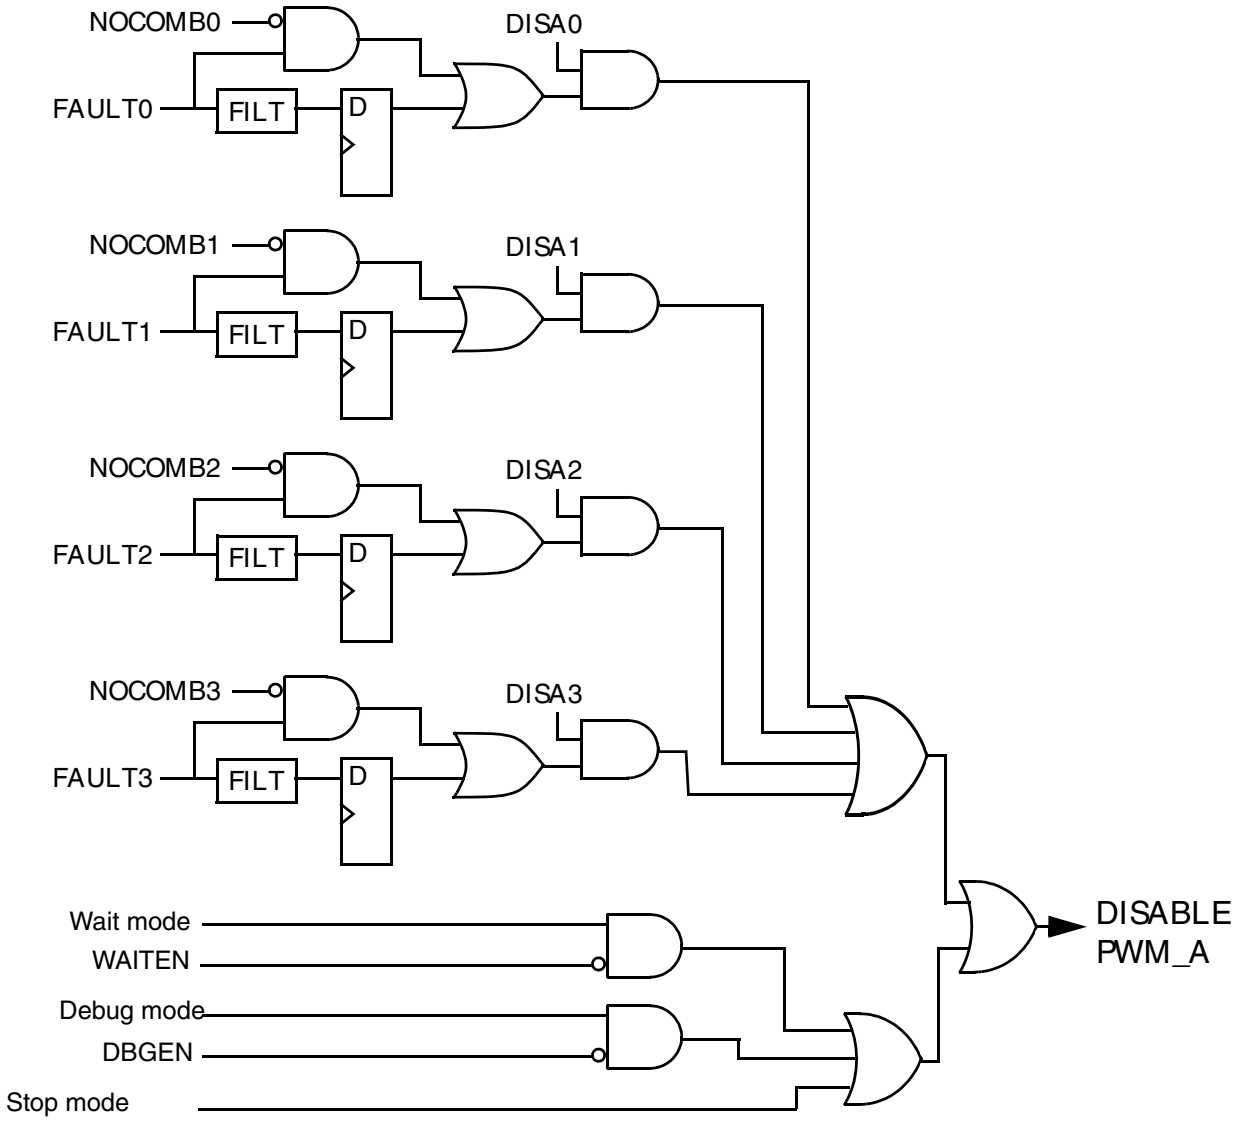

Figure 73-28. Fault decoder for PWM_A

Table 73-2. Fault Mapping

PWM Pin for 1 submodule	Controlling Register Bits
PWM_A	DISMAP0[DIS0A]
PWM_B	DISMAP0[DIS0B]
PWM_X	DISMAP0[DIS0X]

73.3.3.11.1 Fault pin filter

Each fault pin has a programmable filter that can be bypassed. The sampling period of the filter can be adjusted with FFILT[FILT_PER]. The number of consecutive samples that must agree before an input transition is recognized can be adjusted using FFILT[FILT_CNT]. Setting FFILT[FILT_PER] to all 0 disables the input filter for a given FAULTx pin.

Upon detecting a logic 0 on the filtered FAULTx pin (or a logic 1 if FCTRL[FLVLx] is set), the corresponding FSTS[FFPINx] and FSTS[FFLAGx] bits are set. FSTS[FFPINx] remains set as long as the filtered FAULTx pin is zero. Clear FSTS[FFLAGx] by writing a logic 1 to FSTS[FFLAGx].

If the FIEx, FAULTx pin interrupt enable bit is set, FSTS[FFLAGx] generates a CPU interrupt request. The interrupt request latch remains set until:

- Software clears FSTS[FFLAGx] by writing a logic one to the bit
- Software clears the FIEx bit by writing a logic zero to it
- A reset occurs

Even with the filter enabled, there is a combinational path from the FAULTx inputs to the PWM pins, which in turn bypasses the filter when FCTRL20[NOCOMBx] = 0. This logic is also capable of holding a fault condition in the event of loss of clock to the eFlexPWM module.

73.3.3.11.2 Automatic fault clearing

Setting an automatic clearing mode bit, FCTRL[FAUTOx] configures faults from the FAULTx pin for automatic clearing.

When FCTRL[FAUTOx] is set, disabled PWM pins are enabled when the FAULTx pin returns to logic one and a new PWM full or half cycle begins. See the following figure. If FSTS[FFULLx] is set and the fault condition on FAULTx disappears, then the disabled PWM pins are enabled at the start of next full cycle. If FSTS[FHALFx] is set, then the disabled PWM pins are enabled at the start of a half cycle. Clearing FSTS[FFLAGx] does not affect disabled PWM pins when FCTRL[FAUTOx] is set.

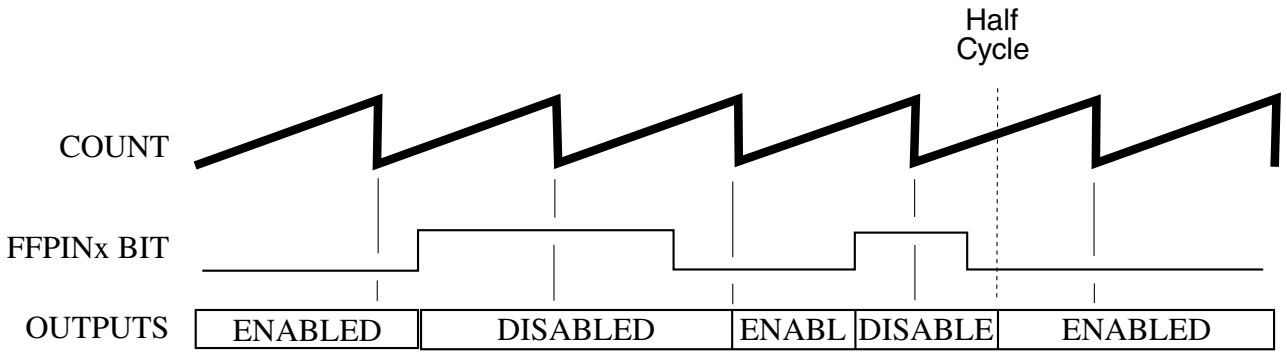

Figure 73-29. Automatic fault clearing

73.3.3.11.3 Manual fault clearing

Clearing the automatic clearing mode bit, FCTRL[FAUTOx], configures faults from the FAULTx pin for manual clearing:

- If the fault safety mode bits FCTRL[FSAFEx] are clear, then PWM pins disabled by the FAULTx pins are enabled when:
  - Software clears the corresponding FSTS[FFLAGx] flag
  - The pins are enabled when the next PWM full or half cycle begins regardless of the logic level detected by the filter at the FAULTx pin, as shown in Figure 73-30. If FSTS[FFULLx] is set, then the disabled PWM pins are enabled at the start of a full cycle. If FSTS[FHALFx] is set, then the disabled PWM pins are enabled at the start of a half cycle.
- If the fault safety mode bits FCTRL[FSAFEx] are set, then PWM pins disabled by the FAULTx pins are enabled when:
  - Software clears the corresponding FSTS[FFLAGx] flag
  - The filter detects a logic zero on the FAULTx pin at the start of the next PWM full or half cycle boundary, as shown in Figure 73-31. If FSTS[FFULLx] is set, then the disabled PWM pins are enabled at the start of a full cycle. If FSTS[FHALFx] is set, then the disabled PWM pins are enabled at the start of a half cycle.

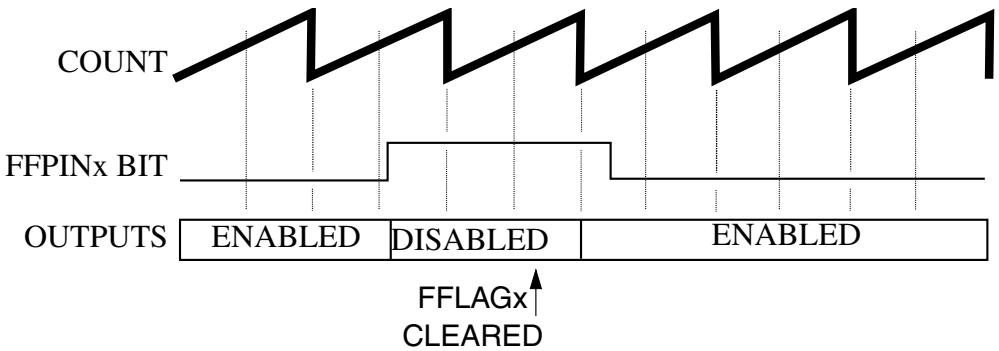

Figure 73-30. Manual fault clearing (FCTRL[FSAFEx] = 0, FSTS[FFULLx] = 1)

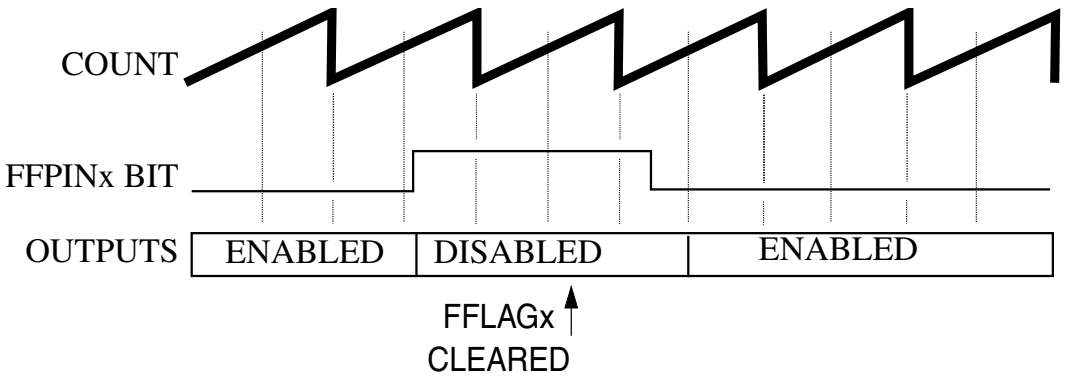

Figure 73-31. Manual fault clearing (FCTRL[FSAFEx] = 1, FSTS[FHALFx] = 1)

Note

Fault protection also applies during software output control when the SEL23 and SEL45 fields are set to select OUT23 and OUT45 bits or PWM_EXTA. Fault clearing still occurs at half or full PWM cycle boundaries while the PWM generator is engaged, MCTRL[RUN] equals one. But the OUTx bits can control the PWM pins while the PWM generator is off, MCTRL[RUN] equals zero. Thus, fault clearing occurs at IPBus cycles while the PWM generator is off and at the start of PWM cycles when the generator is engaged.

73.3.3.11.4 Fault testing

FTST[FTEST] is used to simulate a fault condition on each of the fault inputs within that fault channel.

73.3.3.12 PWM generator loading

73.3.3.12.1 Load enable

MCTRL[LDOK] enables loading of the following PWM generator parameters.

- The prescaler divisor: from CTRL[PRSC]
- The PWM period and pulse width: from the INIT, FRACVALx, and VALx registers

MCTRL[LDOK] allows the software to finish calculating all of these PWM parameters so they can be synchronously updated. The CTRL[PRSC], INIT, and VALx registers are loaded by software into a set of outer buffers. When MCTRL[LDOK] is set, these values are transferred to an inner set of registers at the beginning of the next PWM reload cycle to be used by the PWM generator when CTRL[LDMOD] is cleared. These values can be transferred to the inner set of registers immediately upon setting MCTRL[LDOK] if CTRL[LDMOD] is set. Set MCTRL[LDOK] by reading it when it is a logic zero and then writing a logic one to it. After loading, MCTRL[LDOK] is automatically cleared.

73.3.3.12.2 Load frequency

CTRL[LDFQ] selects an integral loading frequency of one to 16 PWM reload opportunities. CTRL[LDFQ] takes effect at every PWM reload opportunity, regardless of the state of MCTRL[LDOK]. CTRL[HALF] and CTRL[FULL] control reload timing. If CTRL[FULL] is set, a reload opportunity occurs at the end of every PWM cycle when the count equals VAL1. If CTRL[HALF] is set, a reload opportunity occurs at the half cycle when the count equals VAL0. If both CTRL[HALF] and CTRL[FULL] are set, a reload opportunity occurs twice per PWM cycle when the count equals VAL1 and when it equals VAL0.

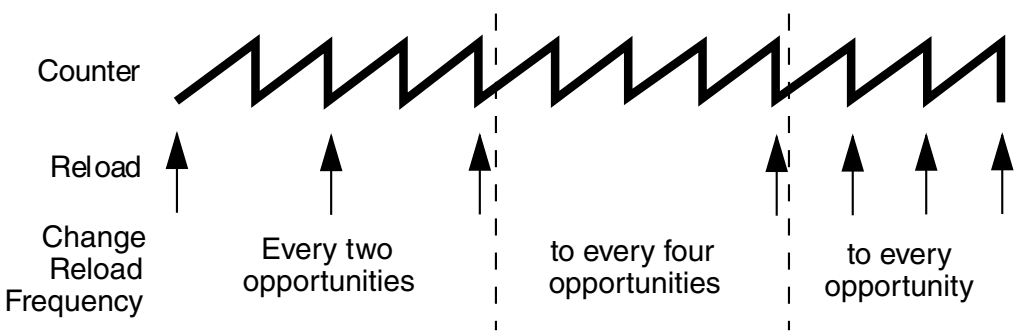

Figure 73-32. Full cycle reload frequency change

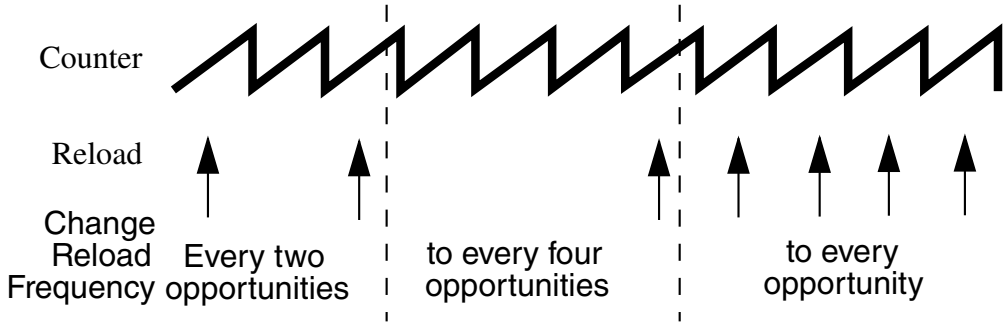

Figure 73-33. Half cycle reload frequency change

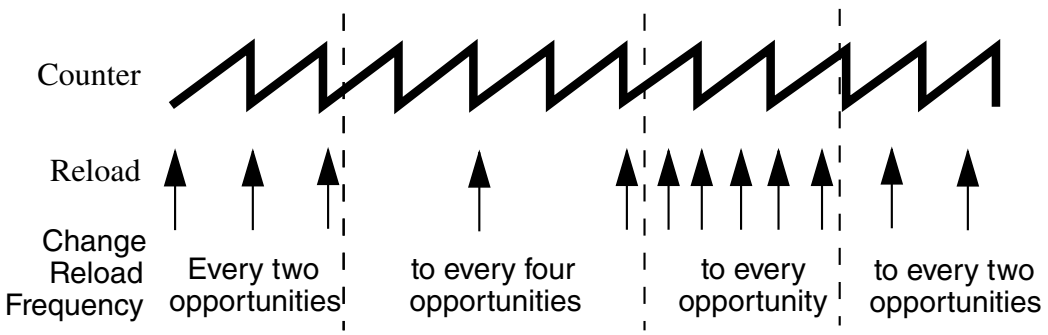

Figure 73-34. Full and half cycle reload frequency change

73.3.3.12.3 Reload flag

At every reload opportunity the PWM Reload Flag (STS[RF]) is set. Setting STS[RF] happens even if an actual reload is prevented by MCTRL[LDOK]. If the PWM reload interrupt enable bit INTEN[RIE] is set, the STS[RF] flag generates CPU interrupt requests allowing software to calculate new PWM parameters in real time. When INTEN[RIE] is not set, reloads still occur at the selected reload rate without generating CPU interrupt requests.

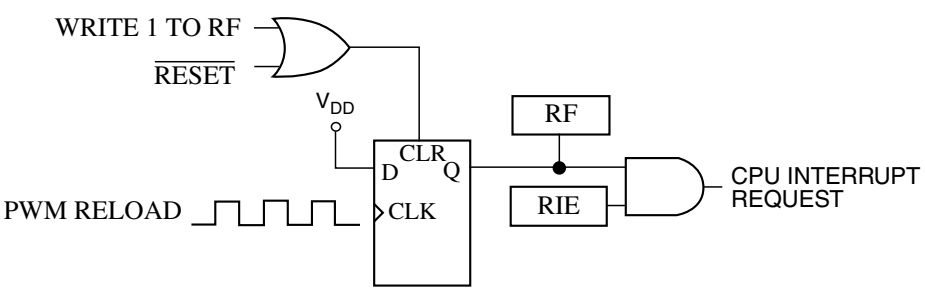

Figure 73-35. PWMF reload interrupt request

73.3.3.12.4 Reload errors

When one of the INIT, VALx, FRACVALx, or CTRL[PRSC] registers is updated (written by software), the STS[RUF] flag is set to indicate the data in the set of double buffered registers is not coherent. STS[RUF] is cleared by a successful reload which consists of the reload signal while MCTRL[LDOK] is set. If STS[RUF] is set and MCTRL[LDOK] is clear when the reload signal occurs, a reload error takes place and STS[REF] is set. If STS[RUF] is clear when a reload signal asserts, then the data is coherent and no error is flagged.

73.3.3.12.5 Initialization

Initialize all registers and then set MCTRL[LDOK] before setting MCTRL[RUN].

Note

If MCTRL[LDOK] is not set, setting MCTRL[RUN] also sets the STS[RF] flag. To prevent a CPU interrupt request, clear INTEN[RIE] before setting MCTRL[RUN].

The PWM generator uses the last values loaded if MCTRL[RUN] is cleared and then set while MCTRL[LDOK] equals zero.

When MCTRL[RUN] is cleared:

- The STS[RF] flag and pending CPU interrupt requests are not cleared
- All fault circuitry remains active
- Software/external output control remains active
- Deadtime insertion continues during software/external output control

73.3.4 Power modes

Be careful when using this module in Stop, Wait, and Debug operating modes.

CAUTION

Some applications (such as three-phase AC motors) require regular software updates for proper operation. Failure to provide regular software updates could result in destroying the hardware setup.

To accommodate this situation, PWM outputs are placed in their inactive states in Stop mode, and they can optionally be placed in inactive states in Wait and Debug modes. PWM outputs are reactivated (assuming they were active beforehand) when these modes are exited.

Table 73-3. Modes when PWM operation is restricted

Mode	Description
Stop	PWM outputs are inactive.
Wait	PWM outputs are driven or inactive as a function of CTRL2[WAITEN].
Debug	PWM outputs are driven or inactive as a function of CTRL2[DBGEN].

73.3.5 Clocking

Figure 73-36 shows the logic used to generate the main counter clock. Each submodule can select between three clock signals: the IPBus clock, EXT_CLK, and AUX_CLK. The EXT_CLK goes to all of the submodules. The AUX_CLK signal is broadcast from submodule0 and can be selected as the clock source by other submodules so that the 3-bit prescaler and MCTRL[RUN] from submodule0 can control all of the submodules.

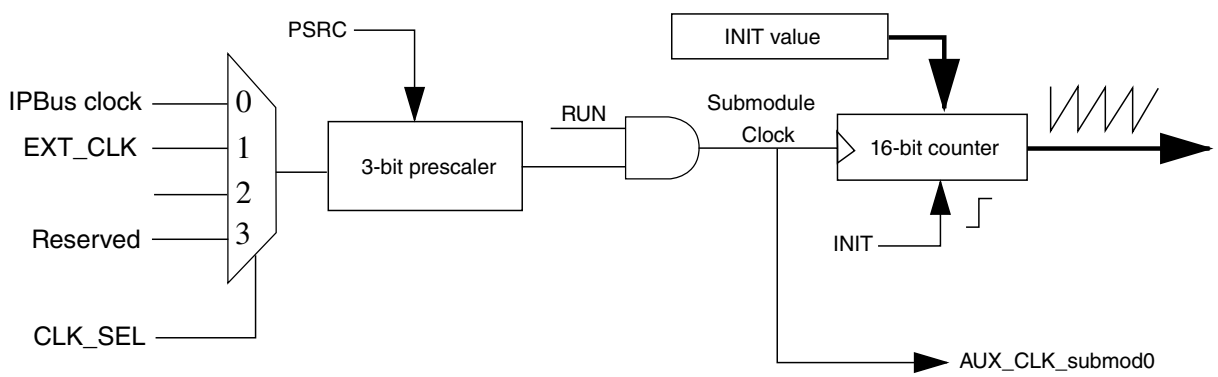

Figure 73-36. Clocking Block Diagram for PWM Submodule 0

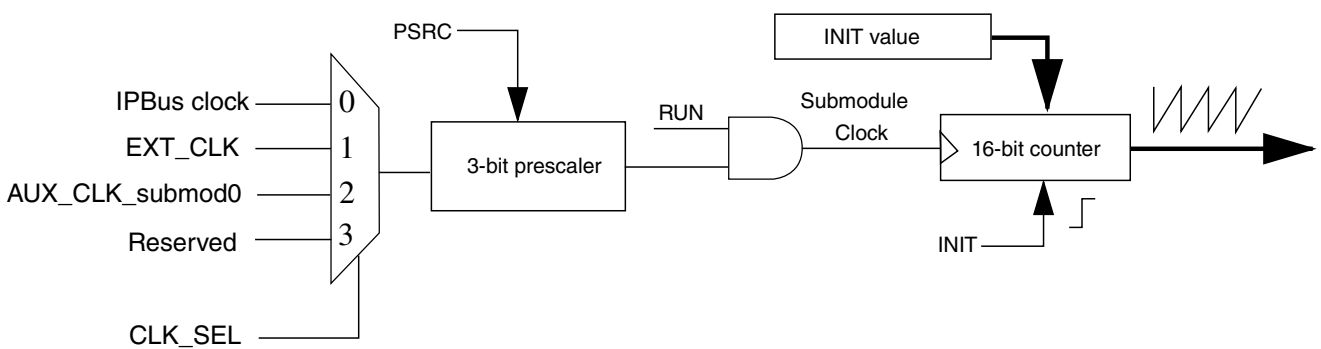

Figure 73-37. Clocking Block Diagram for all other PWM Submodules

To permit lower PWM frequencies, the prescaler produces the PWM clock frequency by dividing the IPBus clock frequency by 1, 2, 4, 8, 16, 32, 64, or 128. The prescaler bits, CTRL[PRSC], select the prescaler divisor. This prescaler is buffered and will not be used by the PWM generator until MCTRL[LDOK] is set and a new PWM reload cycle begins or CTRL[LDMOD] is set.

73.3.6 Resets

All eFlexPWM registers are reset to their default values upon any system reset.

The reset forces all registers to their reset states and tristates the PWM outputs.

73.3.7 Interrupts

Each of the submodules within the eFlexPWM module can generate an interrupt from several sources. The fault logic can also generate interrupts. The interrupt service routine (ISR) must check the related interrupt enables and interrupt flags to determine the actual cause of the interrupt.

Table 73-4. Interrupt Summary

Core Interrupt	Interrupt Flag	Interrupt Enable	Name	Description
PWM_CMP0	SM0STS[CMPF]	SM0INTEN[CMPIE]	Submodule 0 compare interrupt	Compare event has occurred
PWM_CAP0	SM0STS[CFA1], SM0STS[CFA0], SM0STS[CFB1], SM0STS[CFB0], SM0STS[CFX1], SM0STS[CFX0]	SM0INTEN[CFA1IE], SM0INTEN[CFA0IE], SM0INTEN[CFB1IE], SM0INTEN[CFB0IE], SM0INTEN[CFX1IE], SM0INTEN[CFX0IE]	Submodule 0 input capture interrupt	Input capture event has occurred
PWM_RELOAD0	SM0STS[RF]	SM0INTEN[RIE]	Submodule 0 reload interrupt	Reload event has occurred
PWM_CMP1	SM1STS[CMPF]	SM1INTEN[CMPIE]	Submodule 1 compare interrupt	Compare event has occurred
PWM_CAP1	SM1STS[CFA1], SM1STS[CFA0], SM1STS[CFB1], SM1STS[CFB0], SM1STS[CFX1], SM1STS[CFX0]	SM1INTEN[CFA1IE], SM1INTEN[CFA0IE], SM1INTEN[CFB1IE], SM1INTEN[CFB0IE], SM1INTEN[CFX1IE], SM1INTEN[CFX0IE]	Submodule 1 input capture interrupt	Input capture event has occurred

Table continues on the next page...

Table 73-4. Interrupt Summary (continued)

Core Interrupt	Interrupt Flag	Interrupt Enable	Name	Description
PWM_RELOAD1	SM1STS[RF]	SM1INTEN[RIE]	Submodule 1 reload interrupt	Reload event has occurred
PWM_CMP2	SM2STS[CMPF]	SM2INTEN[CMPIE]	Submodule 2 compare interrupt	Compare event has occurred
PWM_CAP2	SM2STS[CFA1], SM2STS[CFA0], SM2STS[CFB1], SM2STS[CFB0], SM2STS[CFX1], SM2STS[CFX0]	SM2INTEN[CFA1IE], SM2INTEN[CFA0IE], SM2INTEN[CFB1IE], SM2INTEN[CFB0IE], SM2INTEN[CFX1IE], SM2INTEN[CFX0IE	Submodule 2 input capture interrupt	Input capture event has occurred
PWM_RELOAD2	SM2STS[RF]	SM2INTEN[RIE]	Submodule 2 reload interrupt	Reload event has occurred
PWM_CMP3	SM3STS[CMPF]	SM3INTEN[CMPIE]	Submodule 3 compare interrupt	Compare event has occurred
PWM_CAP3	SM3STS[CFA1], SM3STS[CFA0], SM3STS[CFB1], SM3STS[CFB0], SM3STS[CFX1], SM3STS[CFX0]	SM3INTEN[CFA1IE], SM3INTEN[CFA0IE], SM3INTEN[CFB1IE], SM3INTEN[CFB0IE], SM3INTEN[CFX1IE], SM3INTEN[CFX0IE	Submodule 3 input capture interrupt	Input capture event has occurred
PWM_RELOAD3	SM3STS[RF]	SM3INTEN[RIE]	Submodule 3 reload interrupt	Reload event has occurred
PWM_RERR	SM0STS[REF]	SM0INTEN[REIE]	Submodule 0 reload error interrupt	Reload error has occurred
	SM1STS[REF]	SM1INTEN[REIE]	Submodule 1 reload error interrupt

	SM3STS[REF]	SM3INTEN[REIE]	Submodule 3 reload error interrupt	
PWM_FAULT	FSTS[FFLAG]	FCTRL[FIE]	Fault input interrupt	Fault condition has been detected

73.3.8 DMA

Each submodule can request a DMA read access for its capture FIFOs and a DMA write request for its double buffered registers.

Table 73-5. DMA summary

DMA request	DMA enable	Name	Description
Submodule 0 read request	SM0DMAEN[CX0DE]	SM0 Capture FIFO X0 read request	SM0CVAL0 contains a value to be read
Submodule 0 read request	SM0DMAEN[CX1DE]	SM0 Capture FIFO X1 read request	SM0CVAL1 contains a value to be read
Submodule 0 read request	SM0DMAEN[CA0DE]	SM0 Capture FIFO A0 read request	SM0CVAL2 contains a value to be read
Submodule 0 read request	SM0DMAEN[CA1DE]	SM0 Capture FIFO A1 read request	SM0CVAL3 contains a value to be read
Submodule 0 read request	SM0DMAEN[CB0DE]	SM0 Capture FIFO B0 read request	SM0CVAL4 contains a value to be read
Submodule 0 read request	SM0DMAEN[CB1DE]	SM0 Capture FIFO B1 read request	SM0CVAL5 contains a value to be read
Submodule 0 read request	SM0DMAEN[CAPTDE]	SM0 Capture FIFO read request source select	Selects source of submodule0 read DMA request
Submodule 0 write request	SM0DMAEN[VALDE]	SM0VALx write request	SM0VALx and SM0FRACVALx registers need to be updated
Submodule 1 read request	SM1DMAEN[CX0DE]	SM1 Capture FIFO X0 read request	SM1CVAL0 contains a value to be read
Submodule 1 read request	SM1DMAEN[CX1DE]	SM1 Capture FIFO X1 read request	SM1CVAL1 contains a value to be read
Submodule 1 read request	SM1DMAEN[CA0DE]	SM1Capture FIFO A0 read request	SM1CVAL2 contains a value to be read
Submodule 1 read request	SM1DMAEN[CA1DE]	SM1 Capture FIFO A1 read request	SM1CVAL3 contains a value to be read
Submodule 1 read request	SM1DMAEN[CB0DE]	SM1 Capture FIFO B0 read request	SM1CVAL4 contains a value to be read
Submodule 1 read request	SM1DMAEN[CB1DE]	SM1 Capture FIFO B1 read request	SM1CVAL5 contains a value to be read
Submodule 1 read request	SM1DMAEN[CAPTDE]	SM1 Capture FIFO read request source select	Selects source of submodule1 read DMA request
Submodule 1 write request	SM1DMAEN[VALDE]	SM1VALx write request	SM1VALx and SM1FRACVALx registers need to be updated
Submodule 2 read request	SM2DMAEN[CX0DE]	SM2 Capture FIFO X0 read request	SM2CVAL0 contains a value to be read
Submodule 2 read request	SM2DMAEN[CX1DE]	SM2 Capture FIFO X1 read request	SM2CVAL1 contains a value to be read
Submodule 2 read request	SM2DMAEN[CA0DE]	SM2 Capture FIFO A0 read request	SM2CVAL2 contains a value to be read
Submodule 2 read request	SM2DMAEN[CA1DE]	SM2 Capture FIFO A1 read request	SM2CVAL3 contains a value to be read
Submodule 2 read request	SM2DMAEN[CB0DE]	SM2 Capture FIFO B0 read request	SM2CVAL4 contains a value to be read
Submodule 2 read request	SM2DMAEN[CB1DE]	SM2 Capture FIFO B1 read request	SM2CVAL5 contains a value to be read

Submodule 3 write request	SM3DMAEN[VALDE]	SM3VALx write request	SM3VALx and SM3FRACVALx registers need to be updated

73.4 External signals

The PWM has pins named PWM_An, PWM_Bn, PWM_Xn, FAULTn, EXT_SYNC, EXT_FORCE, and PWMn_EXTA. The PWM also has an on-chip input called EXT_CLK and an output signal called PWMn_OUT_TRIGx.

73.4.1 PWM_An and PWM_Bn - External PWM output pair

These pins are the output pins of the PWM channels. These pins can be independent PWM signals or a complementary pair. When not needed as an output, they can be used as inputs to the input capture circuitry.

73.4.2 PWM_Xn - Auxiliary PWM output signal

These pins are the auxiliary output pins of the PWM channels. They can be independent PWM signals. When not needed as an output, they can be used as inputs to the input capture circuitry or used to detect the polarity of the current flowing through the complementary circuit at deadtime correction.

73.4.3 FAULTn - Fault Inputs

These are input pins for disabling selected PWM outputs.

73.4.4 EXT_SYNC - External synchronization signal

These input signals allow a source external to the PWM to initialize the PWM counter. Therefore, the PWM can be synchronized to external circuitry.

73.4.5 EXT_FORCE - External output force signal

This input signal allows a source external to the PWM to force an update of the PWM outputs. Therefore, the PWM can be synchronized to external circuitry.

73.4.6 PWMn_EXTA - Alternate PWM control signals

These pins allow an alternate source to control the PWM_An and PWM_Bn outputs. Typically, the PWMn_EXTA input (depending on the state of MCTRL[IPOL]) is used for the generation of a complementary pair. Typical control signals include ADC conversion high/low limits, TMR outputs, GPIO inputs, and comparator outputs.

For pin input details, see chip-specific eFlexPWM information.

73.4.7 PWMn_OUT_TRIG0 and PWMn_OUT_TRIG1 - Output triggers

These outputs allow the PWM submodules to control timing of ADC conversions. See the description of the SMnTCTRL[OUT_TRIG_EN] for information about how to enable these outputs and how the compare registers match up to the output triggers.

73.4.8 EXT_CLK - External clock signal

This signal allows a source external to the PWM (typically a timer or an off-chip source) to control the PWM clocking. Therefore, the PWM can be synchronized to the timer, or multiple chips can be synchronized to each other.

73.5 eFlexPWM register descriptions

The address of a register is the sum of a base address and an address offset. The base address is defined at the core level, and the address offset is defined at the module level. The eFlexPWM module has a set of registers for each PWM submodule, for the configuration logic, and for each fault channel.

Note

While the registers are 16-bit wide, they can be accessed in pairs as 32-bit registers, if the pairs are word-aligned.

Submodule registers are repeated for each PWM submodule. To designate which submodule that they are in, register names are prefixed with SMx(x=0,1...). The base address of submodule 0 is the same as the base address for the eFlexPWM module as a whole. The base address of submodule 1 is offset 0x60 from the base address for the eFlexPWM module as a whole. This 0x60 offset is based on the number of registers in a submodule.The base address of submodule 2 is equal to the base address of submodule 1 plus this same 0x60 offset.The pattern repeats for the base address of submodule 3.

The base address of the configuration registers is equal to the base address of the eFlexPWM module as a whole plus an offset of 0x180.

73.5.1 eFlexPWM memory map

PWM1 base address: 4018_C000h

PWM2 base address: 4019_0000h

PWM3 base address: 4019_4000h

73.5.3 Initial Count Register (SM0INIT - SM3INIT)

73.5.3.1 Offset

Register	Offset
SM0INIT	2h
SM1INIT	62h
SM2INIT	C2h
SM3INIT	122h

73.5.3.2 Function

The 16-bit signed value in this buffered register defines the initial count value for the eFlexPWM module in PWM clock periods. This is the value loaded into the submodule counter when local sync, master sync, or master reload is asserted (based on the value of CTRL2[INIT_SEL]) or when CTRL2[FORCE] is asserted and force init is enabled. For PWM operation, the buffered contents of this register are loaded into the counter at the start of every PWM cycle. This register is not byte accessible.

Note

The INIT register is buffered. The value written does not take effect until MCTRL[LDOK] is set and the next PWM load cycle begins or CTRL[LDMOD] is set. This register cannot be written when MCTRL[LDOK] is set. Reading INIT reads the value in a buffer and not necessarily the value the PWM generator is currently using.

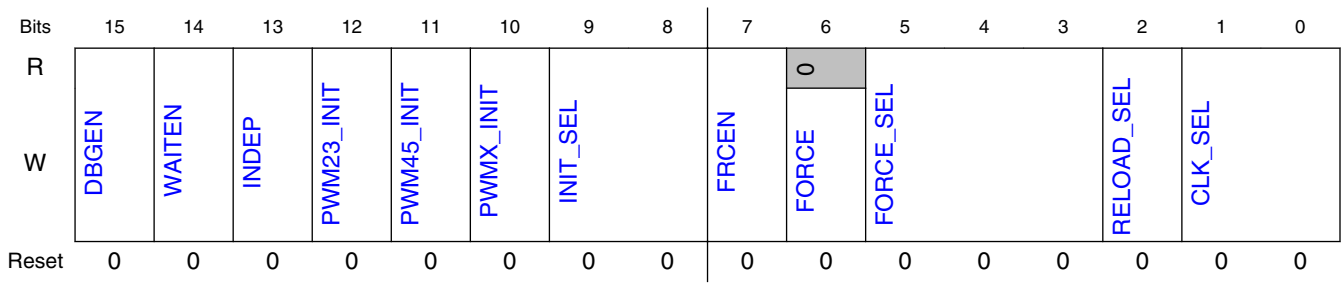
SM1CTRL2	64h
SM2CTRL2	C4h
SM3CTRL2	124h

73.5.4.2 Function

Contains control fields for clock select and forcing output and initialization.

73.5.4.3 Diagram



73.5.4.4 Fields

Field	Function
15 DBGEN	Debug Enable When set to one, the PWM continues to run while the chip is in Debug mode. If the device enters Debug mode and this bit is zero, then the PWM outputs are disabled until Debug mode is exited. At that point, the PWM pins resume operation as programmed in the PWM registers. For certain types of motors (such as 3-phase AC), it is imperative that this bit be left in its default state (in which the PWM is disabled in Debug mode). Failure to do so could result in damage to the motor or inverter. For other types of motors (example: DC motors), this bit might safely be set to one, enabling the PWM in Debug mode. The key point is PWM parameter updates will not occur in Debug mode. Any motors requiring such updates should be disabled during Debug mode. If in doubt, leave this bit set to zero.
14 WAITEN	Wait Enable When set to one, the PWM continues to run while the chip is in Wait mode. In this mode, the peripheral clock continues to run but the CPU clock does not. If the device enters Wait mode and this bit is zero, then the PWM outputs are disabled until Wait mode is exited. At that point the PWM pins resume operation as programmed in the PWM registers. For certain types of motors (such as 3-phase AC), it is imperative that this bit be left in its default state (in which the PWM is disabled in Wait mode). Failure to do so could result in damage to the motor or inverter. For other types of motors (example: DC motors), this bit might safely be set to one, enabling the PWM in Wait mode. The key point is PWM parameter updates will not occur in this mode. Any motors requiring such updates should be disabled during Wait mode. If in doubt, leave this bit set to zero.
13 INDEP	Independent or Complementary Pair Operation This bit determines if the PWM_A and PWM_B channels are independent PWMs or a complementary PWM pair. 0b - PWM_A and PWM_B form a complementary PWM pair. 1b - PWM_A and PWM_B outputs are independent PWMs.
12	PWM23 Initial Value

Table continues on the next page...

Field	Function
PWM23_INIT	This bit determines the initial value for PWM23 and the value to which it is forced when FORCE_INIT is asserted.
11 PWM45_INIT	PWM45 Initial Value This bit determines the initial value for PWM45 and the value to which it is forced when FORCE_INIT is asserted.
10 PWMX_INIT	PWM_X Initial Value This bit determines the initial value for PWM_X and the value to which it is forced when FORCE_INIT is asserted.
9-8 INIT_SEL	Initialization Control Select These bits control the source of the INIT signal which goes to the counter. 00b - Local sync (PWM_X) causes initialization. 01b - Master reload from submodule 0 causes initialization. This setting should not be used in submodule 0 as it forces the INIT signal to logic 0. The submodule counter will only re-initialize when a master reload occurs. 10b - Master sync from submodule 0 causes initialization. This setting should not be used in submodule 0 as it forces the INIT signal to logic 0. 11b - EXT_SYNC causes initialization.
7 FRCEN	Force Enable This bit allows the CTRL2[FORCE] signal to initialize the counter without regard to the signal selected by CTRL2[INIT_SEL]. This is a software controlled initialization. A forced initialization will also assert the register reload if MCTRL[LDOK] is set. 0b - Initialization from a FORCE_OUT is disabled. 1b - Initialization from a FORCE_OUT is enabled.
6 FORCE	Force Initialization If CTRL2[FORCE_SEL] is set to 000, writing a 1 to this bit results in a FORCE_OUT event. This causes the following actions to be taken: • The PWM_A and PWM_B output pins assume values based on DTSRCSEL[SMxSEL23] and DTSRCSEL[SMxSEL45]. • If CTRL2[FRCEN] is set, the counter value is initialized with the INIT register value only when the submodule MCTRL[RUN] = 1 or CTRL2[CLK_SEL] = 2.
5-3 FORCE_SEL	Force Select This bit determines the source of the FORCE OUTPUT signal for this submodule. 000b - The local force signal, CTRL2[FORCE], from this submodule is used to force updates. 001b - The master force signal from submodule 0 is used to force updates. This setting should not be used in submodule 0 as it holds the FORCE OUTPUT signal to logic 0. 010b - The local reload signal from this submodule is used to force updates without regard to the state of LDOK. 011b - The master reload signal from submodule0 is used to force updates if LDOK is set. This setting should not be used in submodule0 as it holds the FORCE OUTPUT signal to logic 0. 100b - The local sync signal from this submodule is used to force updates. 101b - The master sync signal from submodule0 is used to force updates. This setting should not be used in submodule0 as it holds the FORCE OUTPUT signal to logic 0. 110b - The external force signal, EXT_FORCE, from outside the eFlexPWM module causes updates. 111b - The external sync signal, EXT_SYNC, from outside the eFlexPWM module causes updates.
2 RELOAD_SEL	Reload Source Select This bit determines the source of the RELOAD signal for this submodule. When this bit is set, MCTRL[LDOK[0]] for submodule 0 should be used since the local MCTRL[LDOK] will be ignored. 0b - The local RELOAD signal is used to reload registers.

Table continues on the next page...

Field	Function
	1b - The master RELOAD signal (from submodule 0) is used to reload registers. This setting should not be used in submodule 0 as it forces the RELOAD signal to logic 0.
1-0 CLK_SEL	Clock Source Select These bits determine the source of the clock signal for this submodule. 00b - The IPBus clock is used as the clock for the local prescaler and counter. 01b - EXT_CLK is used as the clock for the local prescaler and counter. 10b - Submodule 0's clock (AUX_CLK) is used as the source clock for the local prescaler and counter. This setting should not be used in submodule 0 as it forces the clock to logic 0. 11b - Reserved

73.5.5 Control Register (SM0CTRL - SM3CTRL)

73.5.5.1 Offset

Register	Offset
SM0CTRL	6h
SM1CTRL	66h
SM2CTRL	C6h
SM3CTRL	126h

73.5.5.2 Function

Includes control settings for timing, loading, and buffering.

73.5.5.3 Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	LDFQ				HALF	FULL	DT		COMPMODE	PRSC			SPLIT	LDMOD	DBLX	DBLEN
W																
Reset	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0

73.5.5.4 Fields

Field	Function
15-12 LDFQ	Load Frequency These buffered bits select the PWM load frequency. Reset clears LDFQ, selecting loading every PWM opportunity. A PWM opportunity is determined by HALF and FULL. **Note:** LDFQ takes effect when the current load cycle is complete, regardless of the state of MCTRL[LDOK]. Reading LDFQ reads the buffered values and not necessarily the values currently in effect. 0000b - Every PWM opportunity 0001b - Every 2 PWM opportunities 0010b - Every 3 PWM opportunities 0011b - Every 4 PWM opportunities 0100b - Every 5 PWM opportunities 0101b - Every 6 PWM opportunities 0110b - Every 7 PWM opportunities 0111b - Every 8 PWM opportunities 1000b - Every 9 PWM opportunities 1001b - Every 10 PWM opportunities 1010b - Every 11 PWM opportunities 1011b - Every 12 PWM opportunities 1100b - Every 13 PWM opportunities 1101b - Every 14 PWM opportunities 1110b - Every 15 PWM opportunities 1111b - Every 16 PWM opportunities
11 HALF	Half Cycle Reload This bit enables half-cycle reloads. A half cycle is defined by when the submodule counter matches the VAL0 register and does not have to be halfway through the PWM cycle. 0b - Half-cycle reloads disabled. 1b - Half-cycle reloads enabled.
10 FULL	Full Cycle Reload This bit enables full-cycle reloads. A full cycle is defined by when the submodule counter matches the VAL1 register. Either CTRL[HALF] or CTRL[FULL] must be set to move the buffered data into the registers used by the PWM generators or CTRL[LDMOD] must be set. If both CTRL[HALF] and CTRL[FULL] are set, then reloads can occur twice per cycle. 0b - Full-cycle reloads disabled. 1b - Full-cycle reloads enabled.
9-8 DT	Deadtime These bits reflect the sampled values of the PWM_X input at the end of each deadtime. Sampling occurs at the end of deadtime 0 for DT[0] and the end of deadtime 1 for DT[1]. Reset clears these bits.
7 COMPMODE	Compare Mode This bit controls how comparisons are made between the VAL* registers and the PWM submodule counter. This bit can be written one time after which it requires a reset to release the bit for writing again. 0b - The VAL* registers and the PWM counter are compared using an "equal to" method. This means that PWM edges are only produced when the counter is equal to one of the VAL* register values. This implies that a PWM_A output that is high at the end of a period maintains this state until a match with VAL3 clears the output in the following period. 1b - The VAL* registers and the PWM counter are compared using an "equal to or greater than" method. This means that PWM edges are produced when the counter is equal to or greater than one of the VAL* register values. This implies that a PWM_A output that is high at the end of a

Table continues on the next page...

Field	Function
	period could go low at the start of the next period if the starting counter value is greater than (but not necessarily equal to) the new VAL3 value.
6-4 PRSC	Prescaler These buffered bits select the divide ratio of the PWM clock frequency selected by CTRL2[CLK_SEL]. **Note:** Reading CTRL[PRSC] reads the buffered values and not necessarily the values currently in effect. CTRL[PRSC] takes effect at the beginning of the next PWM cycle and only when the load okay bit MCTRL[LDOK] is set, or CTRL[LDMOD] is set. This field cannot be written when MCTRL[LDOK] is set. 000b - Prescaler 1. PWM clock frequency = f_{clk} 001b - Prescaler 2. PWM clock frequency = f_{clk} /2 010b - Prescaler 4. PWM clock frequency = f_{clk} /4 011b - Prescaler 8. PWM clock frequency = f_{clk} /8 100b - Prescaler 16. PWM clock frequency = f_{clk} /16 101b - Prescaler 32. PWM clock frequency = f_{clk} /32 110b - Prescaler 64. PWM clock frequency = f_{clk} /64 111b - Prescaler 128. PWM clock frequency = f_{clk} /128
3 SPLIT	Split the DBLPWM signal to PWM_A and PWM_B This bit is used in independent mode when DBLEN is set. This bit allows the two PWM pulses generated by DBLEN to be split with one pulse on PWM_A and one on PWM_B. The two pulses within the same PWM period are created by an XOR function of the PWM_A and PWM_B sources. The splitting function causes PWM_A to output the pulse that occurs when the PWM_A source is 1 and the PWM_B source is 0. The PWM_B output occurs when the PWM_B source is 1 and the PWM_A source is 0. (See Double switching PWMs .) 0b - DBLPWM is not split. PWM_A and PWM_B each have double pulses. 1b - DBLPWM is split to PWM_A and PWM_B.
2 LDMOD	Load Mode Select This bit selects the timing of loading the buffered registers for this submodule. 0b - Buffered registers of this submodule are loaded and take effect at the next PWM reload if MCTRL[LDOK] is set. 1b - Buffered registers of this submodule are loaded and take effect immediately upon MCTRL[LDOK] being set. In this case, it is not necessary to set CTRL[FULL] or CTRL[HALF].
1 DBLX	PWM_X Double Switching Enable This bit enables the double switching behavior on PWM_X. When this bit is set, the PWM_X output shall be the exclusive OR combination of PWM_A and PWM_B prior to polarity and masking considerations. 0b - PWM_X double pulse disabled. 1b - PWM_X double pulse enabled.
0 DBLEN	Double Switching Enable This bit enables the double switching PWM behavior (See Double switching PWMs). 0b - Double switching disabled. 1b - Double switching enabled.

73.5.6 Value Register 0 (SM0VAL0 - SM3VAL0)

73.5.6.1 Offset

Register	Offset
SM0VAL0	Ah
SM1VAL0	6Ah
SM2VAL0	CAh
SM3VAL0	12Ah

73.5.6.2 Function

Note

The VAL0 register is buffered. The value written does not take effect until MCTRL[LDOK] is set and the next PWM load cycle begins or CTRL[LDMOD] is set. VAL0 cannot be written when MCTRL[LDOK] is set. Reading VAL0 reads the value in a buffer. It is not necessarily the value that the PWM generator is currently using.

73.5.6.3 Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	VAL0															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

73.5.6.4 Fields

Field	Function
15-0 VAL0	Value 0 The 16-bit signed value in this buffered register defines the mid-cycle reload point for the PWM in PWM clock periods. This value also defines when the PWM_X signal is set and the local sync signal is reset. This register is not byte accessible. **Note:** The actual behavior takes effect when counter equal VAL0+1.

73.5.7 Fractional Value Register 1 (SM0FRACVAL1 - SM3FRACVAL1)

73.5.7.1 Offset

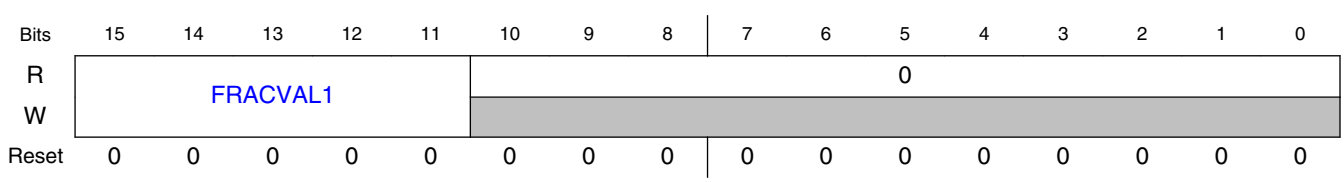
Register	Offset
SM0FRACVAL1	Ch
SM1FRACVAL1	6Ch
SM2FRACVAL1	CCh
SM3FRACVAL1	12Ch

73.5.7.2 Function

NOTE

The FRACVAL1 register is buffered. The value written does not take effect until MCTRL[LDOK] is set and the next PWM load cycle begins or CTRL[LDMOD] is set. FRACVAL1 cannot be written when MCTRL[LDOK] is set. Reading FRACVAL1 reads the value in a buffer and not necessarily the value the PWM generator is currently using.

73.5.7.3 Diagram



73.5.7.4 Fields

Field	Function
15-11 FRACVAL1	Fractional Value 1 These bits act as a fractional addition to the value in the VAL1 register which controls the PWM period.

Table continues on the next page...

Field	Function
	With fractional delay enabled, PWM works in digital dithering mode. The PWM period is computed in terms of IPBus clock cycles. This fractional portion is accumulated at the end of every cycle until an additional whole IPBus cycle is reached. At this time the value being used for VAL1 is temporarily incremented, and the PWM period is extended by one clock to compensate for the accumulated fractional values.
10-0 —	Reserved

73.5.8 Value Register 1 (SM0VAL1 - SM3VAL1)

73.5.8.1 Offset

Register	Offset
SM0VAL1	Eh
SM1VAL1	6Eh
SM2VAL1	CEh
SM3VAL1	12Eh

73.5.8.2 Function

Note

The VAL1 register is buffered. The value written does not take effect until MCTRL[LDOK] is set and the next PWM load cycle begins or CTRL[LDMOD] is set. VAL1 cannot be written when MCTRL[LDOK] is set. Reading VAL1 reads the value in a buffer. It is not necessarily the value that the PWM generator is currently using.

When using FRACVAL1, limit the maximum value of VAL1 to 0xFFFE for unsigned applications or to 0x7FFE for signed applications, to avoid counter rollovers caused by accumulating the fractional period defined by FRACVAL1.

If the VAL1 register defines the timer period (Local Sync is selected as the counter initialization signal), a 100% duty cycle cannot be achieved on the PWM_X output. After the count reaches VAL1, the PWM_X output is low for a minimum of

one count every cycle. When the Master Sync signal (only originated by the Local Sync from submodule 0) is used to control the timer period, the VAL1 register can be free for other functions such as PWM generation without the duty cycle limitation.

73.5.8.3 Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	VAL1															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

73.5.8.4 Fields

Field	Function
15-0 VAL1	Value 1 The 16-bit signed value written to this buffered register defines the modulo count value (maximum count) for the submodule counter. When reaching this count value, the counter reloads itself with the contents of the INIT register and asserts the local sync signal while resetting PWM_X. This register is not byte accessible. **Note:** The actual behavior takes effect when the counter equals VAL1+1.

73.5.9 Fractional Value Register 2 (SM0FRACVAL2 - SM3FRACVAL2)

73.5.9.1 Offset

Register	Offset
SM0FRACVAL2	10h
SM1FRACVAL2	70h
SM2FRACVAL2	D0h
SM3FRACVAL2	130h

73.5.9.2 Function

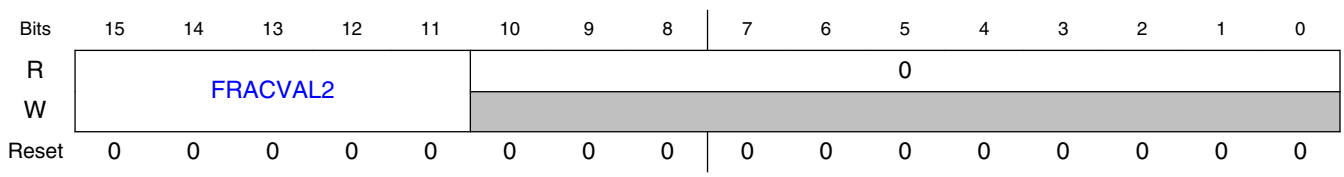
NOTE

The FRACVAL2 register is buffered. The value written does not take effect until MCTRL[LDOK] is set and the next PWM load cycle begins or CTRL[LDMOD] is set. FRACVAL2 cannot be written when MCTRL[LDOK] is set. Reading FRACVAL2 reads the value in a buffer and not necessarily the value the PWM generator is currently using.

NOTE

FRCTRL[FRAC23_EN] should be set to 0 when the values of VAL2 and VAL3 cause the high or low time of the PWM output to be 3 cycles or less.

73.5.9.3 Diagram



73.5.9.4 Fields

Field	Function
15-11 FRACVAL2	Fractional Value 2 These bits act as a fractional addition to the value in the VAL2 register which controls the PWM_A turn on timing. It is also used to control the fractional addition to the turn off delay of PWM_B when MCTRL[IPOLx]=0 in complementary mode, CTRL2[INDEP]=0. With fractional delay enabled, PWM works in digital dithering mode. The PWM_A turn on delay is computed in terms of IPBus clock cycles. This fractional portion is accumulated at the end of every cycle until an additional whole IPBus cycle is reached. At this time the value being used for VAL2 is temporarily incremented, and the PWM_A turn on delay is extended by one clock to compensate for the accumulated fractional values.

73.5.19.4 Fields

Field	Function
15 —	Reserved
14 RUF	Registers Updated Flag This bit is set when one of the INIT, VALx, FRACVALx, or CTRL[PRSC] registers has been written, which indicates potentially non-coherent data in the set of double buffered registers. Clear this bit by a proper reload sequence consisting of a reload signal while MCTRL[LDOK] = 1. Reset clears this bit. 0b - No register update has occurred since last reload. 1b - At least one of the double buffered registers has been updated since the last reload.
13 REF	Reload Error Flag This bit is set when a reload cycle occurs while MCTRL[LDOK] is 0 and the double buffered registers are in a non-coherent state (STS[RUF] = 1). Clear this bit by writing a logic one to this location. Reset clears this bit. 0b - No reload error occurred. 1b - Reload signal occurred with non-coherent data and MCTRL[LDOK] = 0.

Table continues on the next page...

Field	Function
12 RF	Reload Flag This bit is set at the beginning of every reload cycle regardless of the state of MCTRL[LDOK]. Clear this bit by writing a logic one to this location when DMAEN[VALDE] is clear (non-DMA mode). This bit can also be cleared by the DMA done signal when DMAEN[VALDE] is set (DMA mode) . Reset clears this bit. 0b - No new reload cycle since last STS[RF] clearing 1b - New reload cycle since last STS[RF] clearing
11 CFA1	Capture Flag A1 This bit is set when a capture event occurs on the Capture A1 circuit . This bit is cleared by writing a one to this bit position if DMAEN[CA1DE] is clear (non-DMA mode) or by the DMA done signal if DMAEN[CA1DE] is set (DMA mode). This bit can be cleared when word count of the corresponding FIFO is less than water mark level. Reset clears this bit.
10 CFA0	Capture Flag A0 This bit is set when a capture event occurs on the Capture A0 circuit . This bit is cleared by writing a one to this bit position if DMAEN[CA0DE] is clear (non-DMA mode) or by the DMA done signal if DMAEN[CA0DE] is set (DMA mode). This bit can be cleared when word count of the corresponding FIFO is less than water mark level. Reset clears this bit.
9 CFB1	Capture Flag B1 This bit is set when a capture event occurs on the Capture B1 circuit . This bit is cleared by writing a one to this bit position if DMAEN[CB1DE] is clear (non-DMA mode) or by the DMA done signal if DMAEN[CB1DE] is set (DMA mode). This bit can be cleared when word count of the corresponding FIFO is less than water mark level. Reset clears this bit.
8 CFB0	Capture Flag B0 This bit is set when a capture event occurs on the Capture B0 circuit . This bit is cleared by writing a one to this bit position if DMAEN[CB0DE] is clear (non-DMA mode) or by the DMA done signal if DMAEN[CB0DE] is set (DMA mode). This bit can be cleared when word count of the corresponding FIFO is less than water mark level. Reset clears this bit.
7 CFX1	Capture Flag X1 This bit is set when a capture event occurs on the Capture X1 circuit . This bit is cleared by writing a one to this bit position if DMAEN[CX1DE] is clear (non-DMA mode) or by the DMA done signal if DMAEN[CX1DE] is set (DMA mode). This bit can be cleared when word count of the corresponding FIFO is less than water mark level. Reset clears this bit.
6 CFX0	Capture Flag X0 This bit is set when a capture event occurs on the Capture X0 circuit . This bit is cleared by writing a one to this bit position if DMAEN[CX0DE] is clear (non-DMA mode) or by the DMA done signal if DMAEN[CX0DE] is set (DMA mode). This bit can be cleared when word count of the corresponding FIFO is less than water mark level. Reset clears this bit.
5-0 CMPF	Compare Flags These bits are set when the submodule counter value matches the value of one of the VALx registers. Clear these bits by writing a 1 to a bit position. 00_0000b - No compare event has occurred for a particular VALx value. 00_0001b - A compare event has occurred for a particular VALx value.

73.5.20 Interrupt Enable Register (SM0INTEN - SM3INTEN)

73.5.20.1 Offset

Register	Offset

13 REIE	Reload Error Interrupt Enable This bit enables the reload error flag, STS[REF], to generate CPU interrupt requests. Reset clears this bit. 0b - STS[REF] CPU interrupt requests disabled 1b - STS[REF] CPU interrupt requests enabled
12 RIE	Reload Interrupt Enable This bit enables the reload flag, STS[RF], to generate CPU interrupt requests. Reset clears this bit. 0b - STS[RF] CPU interrupt requests disabled 1b - STS[RF] CPU interrupt requests enabled
11 CA1IE	Capture A 1 Interrupt Enable This bit allows the STS[CFA1] flag to create an interrupt request to the CPU. Do not set this bit and DMAEN[CA1DE]. 0b - Interrupt request disabled for STS[CFA1]

Table continues on the next page...

Field	Function
	1b - Interrupt request enabled for STS[CFA1]
10 CA0IE	Capture A 0 Interrupt Enable This bit allows the STS[CFA0] flag to create an interrupt request to the CPU. Do not set this bit and DMAEN[CA0DE]. 0b - Interrupt request disabled for STS[CFA0]. 1b - Interrupt request enabled for STS[CFA0].
9 CB1IE	Capture B 1 Interrupt Enable This bit allows the STS[CFB1] flag to create an interrupt request to the CPU. Do not set this bit and DMAEN[CB1DE]. 0b - Interrupt request disabled for STS[CFB1]. 1b - Interrupt request enabled for STS[CFB1].
8 CB0IE	Capture B 0 Interrupt Enable This bit allows the STS[CFB0] flag to create an interrupt request to the CPU. Do not set this bit and DMAEN[CB0DE]. 0b - Interrupt request disabled for STS[CFB0]. 1b - Interrupt request enabled for STS[CFB0].
7 CX1IE	Capture X 1 Interrupt Enable This bit allows the STS[CFX1] flag to create an interrupt request to the CPU. Do not set this bit and DMAEN[CX1DE]. 0b - Interrupt request disabled for STS[CFX1]. 1b - Interrupt request enabled for STS[CFX1].
6 CX0IE	Capture X 0 Interrupt Enable This bit allows the STS[CFX0] flag to create an interrupt request to the CPU. Do not set this bit and DMAEN[CX0DE]. 0b - Interrupt request disabled for STS[CFX0]. 1b - Interrupt request enabled for STS[CFX0].
5-0 CMPIE	Compare Interrupt Enables These bits enable the STS[CMPF] flags to cause a compare interrupt request to the CPU. 00_0000b - The corresponding STS[CMPF] bit will not cause an interrupt request. 00_0001b - The corresponding STS[CMPF] bit will cause an interrupt request.

73.5.21 DMA Enable Register (SM0DMAEN - SM3DMAEN)

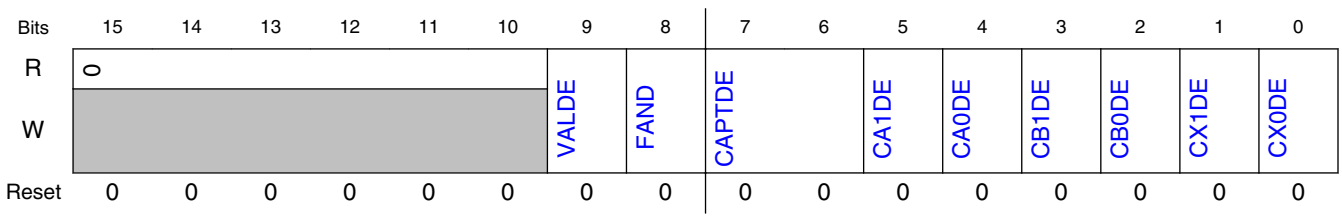
73.5.21.1 Offset

Register	Offset
SM0DMAEN	28h
SM1DMAEN	88h
SM2DMAEN	E8h
SM3DMAEN	148h

73.5.21.2 Function

Contains controls for DMA.

73.5.21.3 Diagram



73.5.21.4 Fields

Field	Function
15-10 —	Reserved
9 VALDE	Value Registers DMA Enable This bit enables DMA write requests for the VALx and FRACVALx registers when STS[RF] is set. Reset clears this bit. 0b - DMA write requests disabled 1b - Enabled. DMA write requests for the VALx and FRACVALx registers enabled
8 FAND	FIFO Watermark AND Control This bit works in conjunction with the DMAEN[CAPTDE] field when it is set to watermark mode (DMAEN[CAPTDE] = 01). While DMAEN[CAxDE], DMAEN[CBxDE], and DMAEN[CXxDE] determine which FIFO watermarks the DMA read request is sensitive to. This bit determines if the selected watermarks are AND'ed together or OR'ed together to create the request. 0b - Selected FIFO watermarks are OR'ed together. 1b - Selected FIFO watermarks are AND'ed together.
7-6 CAPTDE	Capture DMA Enable Source Select These bits select the source of enabling the DMA read requests for the capture FIFOs. Reset clears these bits. 00b - Read DMA requests disabled. 01b - Exceeding a FIFO watermark sets the DMA read request. This requires at least one of DMAEN[CA1DE], DMAEN[CA0DE], DMAEN[CB1DE], DMAEN[CB0DE], DMAEN[CX1DE], or DMAEN[CX0DE] to be set to determine which watermark(s) the DMA request is sensitive. 10b - A local synchronization (VAL1 matches counter) sets the read DMA request. 11b - A local reload (STS[RF] being set) sets the read DMA request.
5 CA1DE	Capture A1 FIFO DMA Enable This bit enables DMA read requests for the Capture A1 FIFO data when STS[CFA1] is set. Reset clears this bit. Do not set this bit and INTEN[CA1IE].

Table continues on the next page...

Field	Function
4 CA0DE	Capture A0 FIFO DMA Enable This bit enables DMA read requests for the Capture A0 FIFO data when STS[CFA0] is set. Reset clears this bit. Do not set both this bit and INTEN[CA0IE].
3 CB1DE	Capture B1 FIFO DMA Enable This bit enables DMA read requests for the Capture B1 FIFO data when STS[CFB1] is set. Reset clears this bit. Do not set both this bit and INTEN[CB1IE].
2 CB0DE	Capture B0 FIFO DMA Enable This bit enables DMA read requests for the Capture B0 FIFO data when STS[CFB0] is set. Reset clears this bit. Do not set both this bit and INTEN[CB0IE].
1 CX1DE	Capture X1 FIFO DMA Enable This bit enables DMA read requests for the Capture X1 FIFO data when STS[CFX1] is set. Reset clears this bit. Do not set both this bit and INTEN[CX1IE].
0 CX0DE	Capture X0 FIFO DMA Enable This bit enables DMA read requests for the Capture X0 FIFO data when STS[CFX0] is set. Reset clears this bit. Do not set both this bit and INTEN[CX0IE].

73.5.22 Output Trigger Control Register (SM0TCTRL - SM3TCTRL)

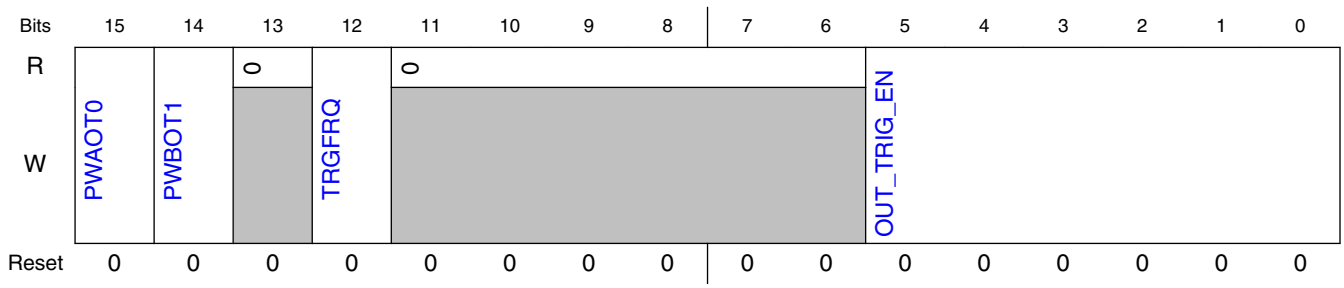
73.5.22.1 Offset

Register	Offset
SM0TCTRL	2Ah
SM1TCTRL	8Ah
SM2TCTRL	EAh
SM3TCTRL	14Ah

73.5.22.2 Function

Contains trigger controls.

73.5.22.3 Diagram



73.5.22.4 Fields

Field	Function
15 PWAOT0	Output Trigger 0 Source Select This bit selects which signal to bring out on the PWM's PWM_OUT_TRIG0 port. The output trigger port is often connected to routing logic on the chip. This control bit allows the PWM_A output signal to be driven onto the output trigger port so it can be sent to the chip routing logic. 0b - Route the PWM_OUT_TRIG0 signal to PWM_OUT_TRIG0 port. 1b - Route the PWM_A output to the PWM_OUT_TRIG0 port.
14 PWBOT1	Output Trigger 1 Source Select This bit selects which signal to bring out on the PWM's PWM_OUT_TRIG1 port. The output trigger port is often connected to routing logic on the chip. This control bit allows the PWM_B output signal to be driven onto the output trigger port so it can be sent to the chip routing logic. 0b - Route the PWM_OUT_TRIG1 signal to PWM_OUT_TRIG1 port. 1b - Route the PWM_B output to the PWM_OUT_TRIG1 port.
13 —	Reserved
12 TRGFRQ	Trigger Frequency This bit allows control over the frequency of the trigger outputs when using non-zero values of CTRL[LDFQ]. 0b - Trigger outputs are generated during every PWM period even if the PWM is not reloaded every period due to CTRL[LDFQ] being non-zero. 1b - Trigger outputs are generated only during the final PWM period prior to a reload opportunity when the PWM is not reloaded every period due to CTRL[LDFQ] being non-zero.
11-6 —	Reserved
5-0 OUT_TRIG_EN	Output Trigger Enables These bits enable the generation of PWM_OUT_TRIG0 and PWM_OUT_TRIG1 outputs based on the counter value matching the value in one or more of the VAL0-5 registers. **NOTE:** Due to delays in creating the PWM outputs, the output trigger signals lead the PWM output edges by 2-3 clock cycles depending on the fractional cycle value being used. 1x_xxxxb - PWM_OUT_TRIG1 will set when the counter value matches the VAL5 value. x1_xxxxb - PWM_OUT_TRIG0 will set when the counter value matches the VAL4 value.

Field	Function
	xx_1xxxb - PWM_OUT_TRIG1 will set when the counter value matches the VAL3 value. xx_x1xxb - PWM_OUT_TRIG0 will set when the counter value matches the VAL2 value. xx_xx1xb - PWM_OUT_TRIG1 will set when the counter value matches the VAL1 value. xx_xxx1b - PWM_OUT_TRIG0 will set when the counter value matches the VAL0 value.

73.5.23 Fault Disable Mapping Register 0 (SM0DISMAP0 - SM3DISMAP0)

73.5.23.1 Offset

Register	Offset
SM0DISMAP0	2Ch
SM1DISMAP0	8Ch
SM2DISMAP0	ECh
SM3DISMAP0	14Ch

73.5.23.2 Function

This register determines which PWM pins are disabled by the fault protection inputs. Reset sets all of the bits in the fault disable mapping register.

73.5.23.3 Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

73.5.23.4 Fields

Field	Function
15-12	Reserved

Table continues on the next page...

Field	Function
—	
11-8 DIS0X	PWM_X Fault Disable Mask 0 Each of the four bits of this field is one-to-one associated with the four FAULTx inputs of fault channel 0. The PWM_X output is turned off if there is a logic 1 on a FAULTx input and a 1 in the corresponding bit of this field. DIS0X[0] is associated with FAULT0. DIS0X[1] is associated with FAULT1. DIS0X[2] is associated with FAULT2. DIS0X[3] is associated with FAULT3. A reset sets all bits in this field.
7-4 DIS0B	PWM_B Fault Disable Mask 0 Each of the four bits of this field is one-to-one associated with the four FAULTx inputs of fault channel 0. The PWM_B output is turned off if there is a logic 1 on a FAULTx input and a 1 in the corresponding bit of this field. DIS0B[0] is associated with FAULT0. DIS0B[1] is associated with FAULT1. DIS0B[2] is associated with FAULT2. DIS0B[3] is associated with FAULT3. A reset sets all bits in this field.
3-0 DIS0A	PWM_A Fault Disable Mask 0 Each of the four bits of this field is one-to-one associated with the four FAULTx inputs of fault channel 0. The PWM_A output is turned off if there is a logic 1 on a FAULTx input and a 1 in the corresponding bit of this field. DIS0A[0] is associated with FAULT0. DIS0A[1] is associated with FAULT1. DIS0A[2] is associated with FAULT2. DIS0A[3] is associated with FAULT3. A reset sets all bits in this field.

73.5.24 Deadtime Count Register 0 (SM0DTCNT0 - SM3DTCNT0)

73.5.24.1 Offset

Register	Offset
SM0DTCNT0	30h
SM1DTCNT0	90h
SM2DTCNT0	F0h
SM3DTCNT0	150h

73.5.24.2 Function

Deadtime operation applies only to complementary channel operation. The values written to the DTCNTx registers are in terms of IPBus clock cycles regardless of the setting of CTRL[PRSC] and/or CTRL2[CLK_SEL]. Reset sets the deadtime count registers to a default value of 0x07FF, selecting a deadtime of 2047 IPBus clock cycles, when fractional delay is not enabled. The DTCNTx registers are not byte accessible.

73.5.24.3 Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	DTCNT0															
Reset	0	0	0	0	0	1	1	1	1	1	1	1	1	1	1	1

73.5.24.4 Fields

Field	Function
15-0 DTCNT0	DTCNT0 The DTCNT0 field is used to control the deadtime during 0 to 1 transitions of the PWM_A output (assuming normal polarity). The DTCNT0 field is interpreted differently depending on whether the fractional delays are enabled or not. • If the fractional delays are disabled (FRCTRL[FRAC23_EN] cleared to 0 when MCTRL[IPOL]=0, or FRCTRL[FRAC45_EN] cleared to 0 when MCTRL[IPOL]=1), then the upper 5 bits of DTCNT0 are ignored and the remaining 11 bits are used to specify the number of PWM clock cycles of deadtime, i.e. the number cycles of deadtime = DTCNT0[10:0] . In this case, the maximum value is 0x07FF which indicates 2047 cycles of deadtime. • If the fractional delays are enabled (FRCTRL[FRAC23_EN] set to 1 when MCTRL[IPOL]=0, or FRCTRL[FRAC45_EN] set to 1 when MCTRL[IPOL]=1), then the upper 11 bits of DTCNT0 represent the number of PWM clock cycles of deadtime, while the lower 5 bits of each register represent the fractional number of cycle. With fractional delay enabled, PWM works in digital dithering mode. When the accumulation of fractional cycles exceeds 1, the whole number specified in DTCNT0[15:5] increments one additional cycle, and the reminder is used for the next fractional cycle accumulation. **NOTE:** It is highly recommended to clear DTCNT0[4:0], to prevent unexpected deadtime increase, when the fractional digital dithering delays are adopted. Then the number of cycles of deadtime = DTCNT0[15:5].

73.5.25 Deadtime Count Register 1 (SM0DTCNT1 - SM3DTCNT1)

73.5.25.1 Offset

Register	Offset
SM0DTCNT1	32h
SM1DTCNT1	92h

Table continues on the next page...

Register	Offset
SM2DTCNT1	F2h
SM3DTCNT1	152h

73.5.25.2 Function

Deadtime operation applies only to complementary channel operation. The values written to the DTCNTx registers are in terms of IPBus clock cycles regardless of the setting of CTRL[PRSC] and/or CTRL2[CLK_SEL]. Reset sets the deadtime count registers to a default value of 0x07FF, selecting a deadtime of 2047 IPBus clock cycles, when fractional delay is not enabled. The DTCNTx registers are not byte accessible.

73.5.25.3 Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	DTCNT1															
Reset	0	0	0	0	0	1	1	1	1	1	1	1	1	1	1	1

73.5.25.4 Fields

Field	Function
15-0 DTCNT1	DTCNT1 The DTCNT1 field is used to control the deadtime during 0 to 1 transitions of the PWM_B output (assuming normal polarity). The DTCNT1 field is interpreted differently depending on whether the fractional delays are enabled or not. • If the fractional delays are disabled (FRCTRL[FRAC23_EN] cleared to 0 when MCTRL[IPOL]=0, or FRCTRL[FRAC45_EN] cleared to 0 when MCTRL[IPOL]=1), then the upper 5 bits of DTCNT1 are ignored and the remaining 11 bits are used to specify the number of PWM clock cycles of deadtime, i.e. the number cycles of deadtime = DTCNT1[10:0] . In this case, the maximum value is 0x07FF which indicates 2047 cycles of deadtime. • If the fractional delays are enabled (FRCTRL[FRAC23_EN] set to 1 when MCTRL[IPOL]=0, or FRCTRL[FRAC45_EN] set to 1 when MCTRL[IPOL]=1), then the upper 11 bits of DTCNT1 represent the number of PWM clock cycles of deadtime, while the lower 5 bits of each register represent the fractional number of cycle. In this case, the maximum value is 0xFFFF which represents 2047 + 31/32 cycles of deadtime. With fractional delay enabled, PWM works in digital dithering mode. When the accumulation of fractional cycles exceeds 1, the whole number specified in DTCNT1[15:5] increments one additional cycle, and the reminder is used for the next fractional cycle accumulation.

Field	Function
	NOTE: It is highly recommended to clear DTCNT1[4:0], to prevent unexpected deadtime increase, when the fractional digital dithering delays are adopted. Then the number of cycles of deadtime = DTCNT1[15:5].

73.5.26 Capture Control A Register (SM0CAPTCTRLA)

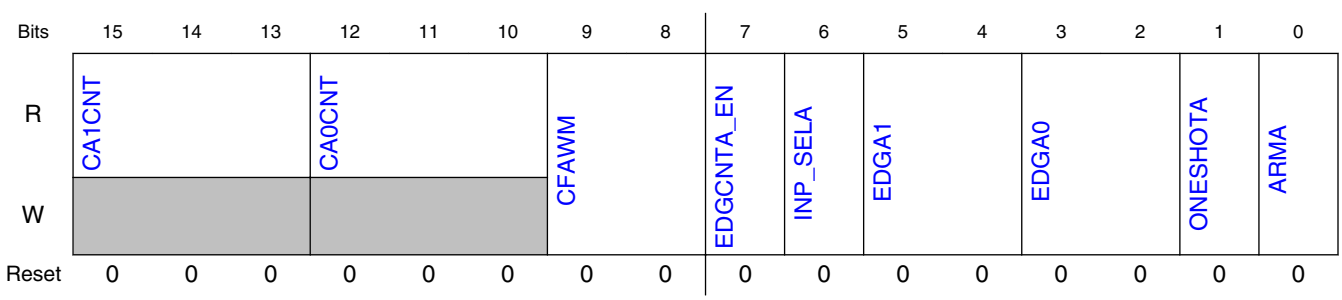
73.5.26.1 Offset

Register	Offset
SM0CAPTCTRLA	34h

73.5.26.2 Function

Contains capture controls for mode A.

73.5.26.3 Diagram



73.5.26.4 Fields

Field	Function
15-13 CA1CNT	Capture A1 FIFO Word Count This field reflects the number of words in the Capture A1 FIFO. (FIFO depth is 1.)
12-10 CA0CNT	Capture A0 FIFO Word Count This field reflects the number of words in the Capture A0 FIFO. (FIFO depth is 1.)

Table continues on the next page...

Field	Function
9-8 CFAWM	Capture A FIFOs Water Mark This field represents the water mark level for capture A FIFOs. The capture flags, STS[CFA1] and STS[CFA0], are not set until the word count of the corresponding FIFO is greater than or equal to this water mark level. (FIFO depth is 1.)
7 EDGCNTA_EN	Edge Counter A Enable This field enables the edge counter which counts rising and falling edges on the PWM_A input signal. 0b - Edge counter disabled and held in reset 1b - Edge counter enabled
6 INP_SELA	Input Select A This field selects between the raw PWM_A input signal and the output of the edge counter/compare circuitry as the source for the input capture circuit. 0b - Raw PWM_A input signal selected as source. 1b - Edge Counter. Output of edge counter/compare selected as source. When this bitfield is set to 1, the internal edge counter is enabled and the rising and/or falling edges specified by the CAPTCTRLA[EDGA0] and CAPTCTRLA[EDGA1] fields are ignored. The software must place a value other than 00 in either or both of the CAPTCTLRA[EDGA0] and/or CAPTCTRLA[EDGA1] fields to enable one or both of the capture registers.
5-4 EDGA1	Edge A 1 These bits control the input capture 1 circuitry by determining which input edges cause a capture event. 00b - Disabled 01b - Capture falling edges 10b - Capture rising edges 11b - Capture any edge
3-2 EDGA0	Edge A 0 These bits control the input capture 0 circuitry by determining which input edges cause a capture event. 00b - Disabled 01b - Capture falling edges 10b - Capture rising edges 11b - Capture any edge
1 ONESHOTA	One Shot Mode A This bit selects between free running and one shot mode for the input capture circuitry. 0b - Free Running. Free running mode is selected if both capture circuits are enabled, then capture circuit 0 is armed first after CAPTCTRLA[ARMA] is set. Once a capture occurs, capture circuit 0 is disarmed, and capture circuit 1 is armed. After capture circuit 1 performs a capture, it is disarmed, and capture circuit 0 is re-armed. The process continues indefinitely. If only one of the capture circuits is enabled, then captures continue indefinitely on the enabled capture circuit. 1b - One Shot. One shot mode is selected if both capture circuits are enabled, then capture circuit 0 is armed first after CAPTCTRLA[ARMA] is set. Once a capture occurs, capture circuit 0 is disarmed and capture circuit 1 is armed. After capture circuit 1 performs a capture, it is disarmed, and CAPTCTRLA[ARMA] is cleared. No further captures are performed until CAPTCTRLA[ARMA] is set again. If only one of the capture circuits is enabled, then a single capture occurs on the enabled capture circuit and CAPTCTRLA[ARMA] is then cleared.
0 ARMA	Arm A Setting this bit high starts the input capture process. This bit can be cleared at any time to disable input capture operation. This bit is self-cleared when in one shot mode and one or more of the enabled capture circuits has had a capture event. 0b - Input capture operation is disabled. 1b - Input capture operation as specified by CAPTCTRLA[EDGAx] is enabled.

73.5.27 Capture Compare A Register (SM0CAPTCOMPA)

73.5.27.1 Offset

Register	Offset
SM0CAPTCOMPA	36h

73.5.27.2 Function

Contains capture and compare values for mode A.

73.5.27.3 Diagram

15-8 EDGCNTA	Edge Counter A This field contains the edge counter value for the PWM_A input capture circuitry.
7-0 EDGCMPA	Edge Compare A This field is the compare value associated with the edge counter for the PWM_A input capture circuitry.

73.5.28 Capture Control B Register (SM0CAPTCTRLB)

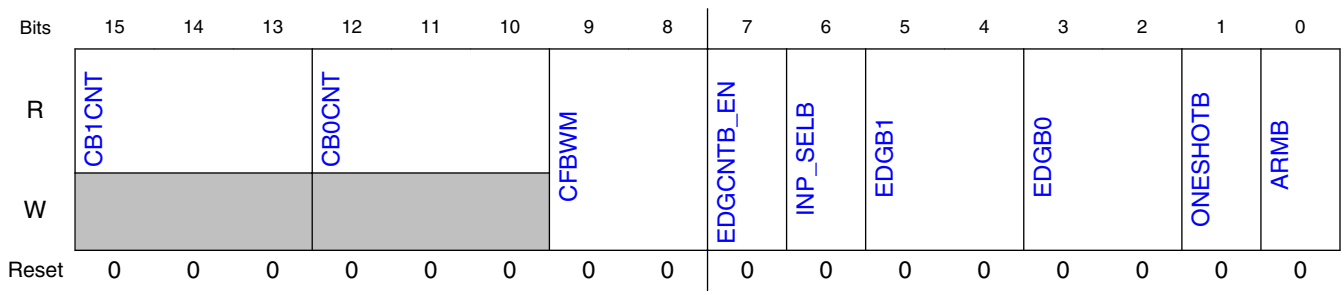
73.5.28.1 Offset

Register	Offset
SM0CAPTCTRLB	38h

73.5.28.2 Function

Contains capture controls for mode B.

73.5.28.3 Diagram



73.5.28.4 Fields

Field	Function
15-13 CB1CNT	Capture B1 FIFO Word Count This field reflects the number of words in the Capture B1 FIFO. (FIFO depth is 1.)
12-10 CB0CNT	Capture B0 FIFO Word Count This field reflects the number of words in the Capture B0 FIFO. (FIFO depth is 1.)
9-8 CFBWM	Capture B FIFOs Water Mark This field represents the water mark level for capture B FIFOs. The capture flags, STS[CFB1] and STS[CFB0], are not set until the word count of the corresponding FIFO is greater than or equal to this water mark level. (FIFO depth is 1.)
7 EDGCNTB_EN	Edge Counter B Enable This field enables the edge counter which counts rising and falling edges on the PWM_B input signal. 0b - Edge counter disabled and held in reset 1b - Edge counter enabled
6 INP_SELB	Input Select B This field selects between the raw PWM_B input signal and the output of the edge counter/compare circuitry as the source for the input capture circuit.

Table continues on the next page...

Field	Function
	0b - Raw PWM_B input signal selected as source. 1b - Edge Counter. Output of edge counter/compare selected as source. When this bitfield is set to 1, the internal edge counter is enabled and the rising and/or falling edges specified by the CAPTCTRLB[EDGB0] and CAPTCTRLB[EDGB1] fields are ignored. The software must place a value other than 00 in either or both of the CAPTCTLRB[EDGB0] and/or CAPTCTRLB[EDGB1] fields to enable one or both of the capture registers.
5-4 EDGB1	Edge B 1 These bits control the input capture 1 circuitry by determining which input edges cause a capture event. 00b - Disabled 01b - Capture falling edges 10b - Capture rising edges 11b - Capture any edge
3-2 EDGB0	Edge B 0 These bits control the input capture 0 circuitry by determining which input edges cause a capture event. 00b - Disabled 01b - Capture falling edges 10b - Capture rising edges 11b - Capture any edge
1 ONESHOTB	One Shot Mode B This bit selects between free running and one shot mode for the input capture circuitry. 0b - Free Running. Free running mode is selected if both capture circuits are enabled, then capture circuit 0 is armed first after CAPTCTRLB[ARMB] is set. Once a capture occurs, capture circuit 0 is disarmed, and capture circuit 1 is armed. After capture circuit 1 performs a capture, it is disarmed, and capture circuit 0 is re-armed. The process continues indefinitely. If only one of the capture circuits is enabled, then captures continue indefinitely on the enabled capture circuit. 1b - One Shot. One shot mode is selected if both capture circuits are enabled, then capture circuit 0 is armed first after CAPTCTRLB[ARMB] is set. Once a capture occurs, capture circuit 0 is disarmed, and capture circuit 1 is armed. After capture circuit 1 performs a capture, it is disarmed, and CAPTCTRLB[ARMB] is cleared. No further captures are performed until CAPTCTRLB[ARMB] is set again. If only one of the capture circuits is enabled, then a single capture occurs on the enabled capture circuit and CAPTCTRLB[ARMB] is then cleared.
0 ARMB	Arm B Setting this bit high starts the input capture process. This bit can be cleared at any time to disable input capture operation. This bit is self-cleared when in one shot mode and one or more of the enabled capture circuits has had a capture event. 0b - Input capture operation is disabled. 1b - Input capture operation as specified by CAPTCTRLB[EDGBx] is enabled.

73.5.29 Capture Compare B Register (SM0CAPTCOMPB)

73.5.29.1 Offset

Field	Function
15-4 —	Reserved
3-0 CVAL5CYC	Capture Value 5 Cycle This field stores the cycle number corresponding to the value captured in CVAL5. This field is incremented each time the counter is loaded with the INIT value at the end of a PWM modulo cycle.

73.5.44 Capture Control A Register (SM1CAPTCTRLA)

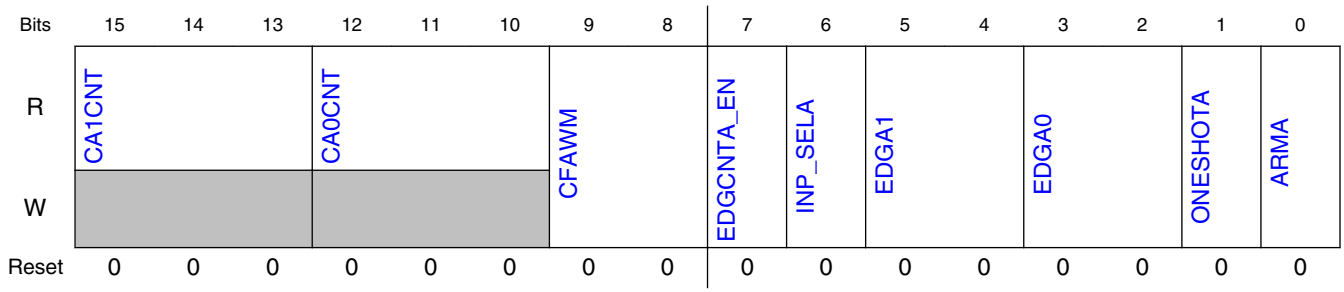
73.5.44.1 Offset

Register	Offset
SM1CAPTCTRLA	94h

73.5.44.2 Function

Contains capture controls for mode A.

73.5.44.3 Diagram



73.5.44.4 Fields

Field	Function
15-13 CA1CNT	Capture A1 FIFO Word Count This field reflects the number of words in the Capture A1 FIFO. (FIFO depth is 1.)
12-10 CA0CNT	Capture A0 FIFO Word Count This field reflects the number of words in the Capture A0 FIFO. (FIFO depth is 1.)
9-8 CFAWM	Capture A FIFOs Water Mark This field represents the water mark level for capture A FIFOs. The capture flags, STS[CFA1] and STS[CFA0], are not set until the word count of the corresponding FIFO is greater than or equal to this water mark level. (FIFO depth is 1.)
7 EDGCNTA_EN	Edge Counter A Enable This field enables the edge counter which counts rising and falling edges on the PWM_A input signal. 0b - Edge counter disabled and held in reset 1b - Edge counter enabled
6 INP_SELA	Input Select A This field selects between the raw PWM_A input signal and the output of the edge counter/compare circuitry as the source for the input capture circuit. 0b - Raw PWM_A input signal selected as source. 1b - Edge Counter. Output of edge counter/compare selected as source. When this bitfield is set to 1, the internal edge counter is enabled and the rising and/or falling edges specified by the CAPTCTRLA[EDGA0] and CAPTCTRLA[EDGA1] fields are ignored. The software must place a value other than 00 in either or both of the CAPTCTLRA[EDGA0] and/or CAPTCTRLA[EDGA1] fields to enable one or both of the capture registers.
5-4 EDGA1	Edge A 1 These bits control the input capture 1 circuitry by determining which input edges cause a capture event.

Table continues on the next page...

Field	Function
	00b - Disabled 01b - Capture falling edges 10b - Capture rising edges 11b - Capture any edge
3-2 EDGA0	Edge A 0 These bits control the input capture 0 circuitry by determining which input edges cause a capture event. 00b - Disabled 01b - Capture falling edges 10b - Capture rising edges 11b - Capture any edge
1 ONESHOTA	One Shot Mode A This bit selects between free running and one shot mode for the input capture circuitry. 0b - Free Running. Free running mode is selected if both capture circuits are enabled, then capture circuit 0 is armed first after CAPTCTRLA[ARMA] is set. Once a capture occurs, capture circuit 0 is disarmed, and capture circuit 1 is armed. After capture circuit 1 performs a capture, it is disarmed, and capture circuit 0 is re-armed. The process continues indefinitely. If only one of the capture circuits is enabled, then captures continue indefinitely on the enabled capture circuit. 1b - One Shot. One shot mode is selected if both capture circuits are enabled, then capture circuit 0 is armed first after CAPTCTRLA[ARMA] is set. Once a capture occurs, capture circuit 0 is disarmed, and capture circuit 1 is armed. After capture circuit 1 performs a capture, it is disarmed, and CAPTCTRLA[ARMA] is cleared. No further captures are performed until CAPTCTRLA[ARMA] is set again. If only one of the capture circuits is enabled, then a single capture occurs on the enabled capture circuit and CAPTCTRLA[ARMA] is then cleared.
0 ARMA	Arm A Setting this bit high starts the input capture process. This bit can be cleared at any time to disable input capture operation. This bit is self-cleared when in one shot mode and one or more of the enabled capture circuits has had a capture event. 0b - Input capture operation is disabled. 1b - Input capture operation as specified by CAPTCTRLA[EDGAx] is enabled.

73.5.45 Capture Compare A Register (SM1CAPTCOMPA)

73.5.45.1 Offset

Register	Offset
SM1CAPTCOMPA	96h

73.5.45.2 Function

Contains capture and compare values for mode A.

73.5.45.3 Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	EDGCNTA								EDGCMPA							
W

73.5.45.4 Fields

Field	Function
15-8 EDGCNTA	Edge Counter A This field contains the edge counter value for the PWM_A input capture circuitry.
7-0 EDGCMPA	Edge Compare A This field is the compare value associated with the edge counter for the PWM_A input capture circuitry.

73.5.46 Capture Control B Register (SM1CAPTCTRLB)

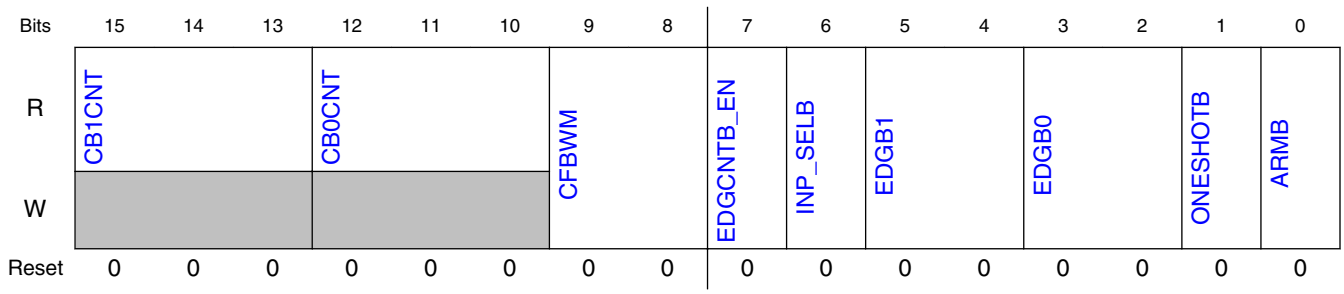
73.5.46.1 Offset

Register	Offset
SM1CAPTCTRLB	98h

73.5.46.2 Function

Contains capture controls for mode B.

73.5.46.3 Diagram



73.5.46.4 Fields

Field	Function
15-13 CB1CNT	Capture B1 FIFO Word Count This field reflects the number of words in the Capture B1 FIFO. (FIFO depth is 1.)
12-10 CB0CNT	Capture B0 FIFO Word Count This field reflects the number of words in the Capture B0 FIFO. (FIFO depth is 1.)
9-8 CFBWM	Capture B FIFOs Water Mark This field represents the water mark level for capture B FIFOs. The capture flags, STS[CFB1] and STS[CFB0], are not set until the word count of the corresponding FIFO is greater than or equal to this water mark level. (FIFO depth is 1.)
7 EDGCNTB_EN	Edge Counter B Enable This field enables the edge counter which counts rising and falling edges on the PWM_B input signal. 0b - Edge counter disabled and held in reset 1b - Edge counter enabled
6 INP_SELB	Input Select B This field selects between the raw PWM_B input signal and the output of the edge counter/compare circuitry as the source for the input capture circuit. 0b - Raw PWM_B input signal selected as source. 1b - Edge Counter. Output of edge counter/compare selected as source. When this bitfield is set to 1, the internal edge counter is enabled and the rising and/or falling edges specified by the CAPTCTRLB[EDGB0] and CAPTCTRLB[EDGB1] fields are ignored. The software must place a value other than 00 in either or both of the CAPTCTLRB[EDGB0] and/or CAPTCTRLB[EDGB1] fields to enable one or both of the capture registers.
5-4 EDGB1	Edge B 1 These bits control the input capture 1 circuitry by determining which input edges cause a capture event. 00b - Disabled 01b - Capture falling edges 10b - Capture rising edges 11b - Capture any edge
3-2 EDGB0	Edge B 0 These bits control the input capture 0 circuitry by determining which input edges cause a capture event.

Table continues on the next page...

Field	Function
	00b - Disabled 01b - Capture falling edges 10b - Capture rising edges 11b - Capture any edge
1 ONESHOTB	One Shot Mode B This bit selects between free running and one shot mode for the input capture circuitry. 0b - Free Running. Free running mode is selected if both capture circuits are enabled, then capture circuit 0 is armed first after CAPTCTRLB[ARMB] is set. Once a capture occurs, capture circuit 0 is disarmed, and capture circuit 1 is armed. After capture circuit 1 performs a capture, it is disarmed, and capture circuit 0 is re-armed. The process continues indefinitely. If only one of the capture circuits is enabled, then captures continue indefinitely on the enabled capture circuit. 1b - One Shot. One shot mode is selected if both capture circuits are enabled, then capture circuit 0 is armed first after CAPTCTRLB[ARMB] is set. Once a capture occurs, capture circuit 0 is disarmed, and capture circuit 1 is armed. After capture circuit 1 performs a capture, it is disarmed, and CAPTCTRLB[ARMB] is cleared. No further captures are performed until CAPTCTRLB[ARMB] is set again. If only one of the capture circuits is enabled, then a single capture occurs on the enabled capture circuit and CAPTCTRLB[ARMB] is then cleared.
0 ARMB	Arm B Setting this bit high starts the input capture process. This bit can be cleared at any time to disable input capture operation. This bit is self-cleared when in one shot mode and one or more of the enabled capture circuits has had a capture event. 0b - Input capture operation is disabled. 1b - Input capture operation as specified by CAPTCTRLB[EDGBx] is enabled.

73.5.47 Capture Compare B Register (SM1CAPTCOMPB)

73.5.47.1 Offset

Register	Offset
SM1CAPTCOMPB	9Ah

73.5.47.2 Function

Contains capture and compare values for mode B.

73.5.47.4 Fields

Field	Function
15-8 EDGCNTB	Edge Counter B This field contains the edge counter value for the PWM_B input capture circuitry.
7-0 EDGCMPB	Edge Compare B This field is the compare value associated with the edge counter for the PWM_B input capture circuitry.

73.5.48 Capture Control X Register (SM1CAPTCTRLX)

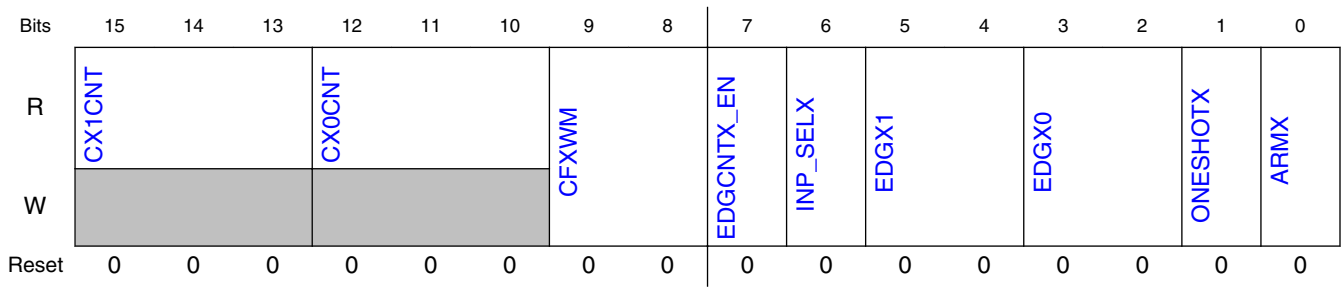
73.5.48.1 Offset

Register	Offset
SM1CAPTCTRLX	9Ch

73.5.48.2 Function

Contains capture controls for mode X.

73.5.48.3 Diagram



73.5.48.4 Fields

Field	Function
15-13 CX1CNT	Capture X1 FIFO Word Count This field reflects the number of words in the Capture X1 FIFO. (FIFO depth is 1.)
12-10 CX0CNT	Capture X0 FIFO Word Count This field reflects the number of words in the Capture X0 FIFO. (FIFO depth is 1.)
9-8 CFXWM	Capture X FIFOs Water Mark This field represents the water mark level for capture X FIFOs. The capture flags, STS[CFX1] and STS[CFX0], are not set until the word count of the corresponding FIFO is greater than or equal to this water mark level. (FIFO depth is 1.)
7 EDGCNTX_EN	Edge Counter X Enable This bit enables the edge counter which counts rising and falling edges on the PWM_X input signal. 0b - Edge counter disabled and held in reset 1b - Edge counter enabled
6 INP_SELX	Input Select X This bit selects between the raw PWM_X input signal and the output of the edge counter/compare circuitry as the source for the input capture circuit. 0b - Raw PWM_X input signal selected as source. 1b - Edge Counter. Output of edge counter/compare selected as source. When this bitfield is set to 1, the internal edge counter is enabled and the rising and/or falling edges specified by the CAPTCTRLX[EDGX0] and CAPTCTRLX[EDGX1] fields are ignored. The software must place a value other than 00 in either or both of the CAPTCTLRX[EDGX0] and/or CAPTCTRLX[EDGX1] fields to enable one or both of the capture registers.
5-4 EDGX1	Edge X 1 These bits control the input capture 1 circuitry by determining which input edges cause a capture event. 00b - Disabled 01b - Capture falling edges 10b - Capture rising edges 11b - Capture any edge
3-2 EDGX0	Edge X 0 These bits control the input capture 0 circuitry by determining which input edges cause a capture event.

Table continues on the next page...

Field	Function
	00b - Disabled 01b - Capture falling edges 10b - Capture rising edges 11b - Capture any edge
1 ONESHOTX	One Shot Mode Aux This field selects between free running and one shot mode for the input capture circuitry. 0b - Free Running. Free running mode is selected if both capture circuits are enabled, then capture circuit 0 is armed first after the ARMX bit is set. Once a capture occurs, capture circuit 0 is disarmed, and capture circuit 1 is armed. After capture circuit 1 performs a capture, it is disarmed, and capture circuit 0 is re-armed. The process continues indefinitely. If only one of the capture circuits is enabled, then captures continue indefinitely on the enabled capture circuit. 1b - One Shot. One shot mode is selected if both capture circuits are enabled, then capture circuit 0 is armed first after the ARMX bit is set. Once a capture occurs, capture circuit 0 is disarmed, and capture circuit 1 is armed. After capture circuit 1 performs a capture, it is disarmed, and the ARMX bit is cleared. No further captures are performed until the ARMX bit is set again. If only one of the capture circuits is enabled, then a single capture occurs on the enabled capture circuit and the ARMX bit is then cleared.
0 ARMX	Arm X Setting this bit high starts the input capture process. This bit can be cleared at any time to disable input capture operation. This bit is self-cleared when in one shot mode and one or more of the enabled capture circuits has had a capture event. 0b - Input capture operation is disabled. 1b - Input capture operation as specified by CAPTCTRLX[EDGXx] is enabled.

73.5.49 Capture Compare X Register (SM1CAPTCOMPX)

73.5.49.1 Offset

Register	Offset
SM1CAPTCOMPX	9Eh

73.5.49.2 Function

73.5.61.4 Fields

Field	Function
15-4 —	Reserved
3-0 CVAL5CYC	Capture Value 5 Cycle This field stores the cycle number corresponding to the value captured in CVAL5. This field is incremented each time the counter is loaded with the INIT value at the end of a PWM modulo cycle.

73.5.62 Capture Control A Register (SM2CAPTCTRLA)

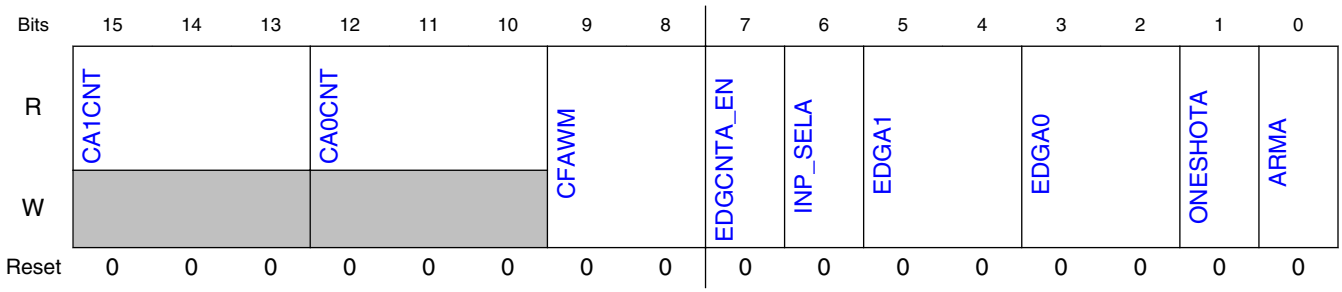
73.5.62.1 Offset

Register	Offset
SM2CAPTCTRLA	F4h

73.5.62.2 Function

Contains capture controls for mode A.

73.5.62.3 Diagram



73.5.62.4 Fields

Field	Function
15-13 CA1CNT	Capture A1 FIFO Word Count This field reflects the number of words in the Capture A1 FIFO. (FIFO depth is 1.)
12-10 CA0CNT	Capture A0 FIFO Word Count This field reflects the number of words in the Capture A0 FIFO. (FIFO depth is 1.)
9-8 CFAWM	Capture A FIFOs Water Mark This field represents the water mark level for capture A FIFOs. The capture flags, STS[CFA1] and STS[CFA0], are not set until the word count of the corresponding FIFO is greater than or equal to this water mark level. (FIFO depth is 1.)
7 EDGCNTA_EN	Edge Counter A Enable This field enables the edge counter which counts rising and falling edges on the PWM_A input signal. 0b - Edge counter disabled and held in reset 1b - Edge counter enabled
6 INP_SELA	Input Select A This field selects between the raw PWM_A input signal and the output of the edge counter/compare circuitry as the source for the input capture circuit. 0b - Raw PWM_A input signal selected as source. 1b - Edge Counter. Output of edge counter/compare selected as source. When this bitfield is set to 1, the internal edge counter is enabled and the rising and/or falling edges specified by the CAPTCTRLA[EDGA0] and CAPTCTRLA[EDGA1] fields are ignored. The software must place a value other than 00 in either or both of the CAPTCTLRA[EDGA0] and/or CAPTCTRLA[EDGA1] fields to enable one or both of the capture registers.
5-4 EDGA1	Edge A 1 These bits control the input capture 1 circuitry by determining which input edges cause a capture event.

Table continues on the next page...

Field	Function
	00b - Disabled 01b - Capture falling edges 10b - Capture rising edges 11b - Capture any edge
3-2 EDGA0	Edge A 0 These bits control the input capture 0 circuitry by determining which input edges cause a capture event. 00b - Disabled 01b - Capture falling edges 10b - Capture rising edges 11b - Capture any edge
1 ONESHOTA	One Shot Mode A This bit selects between free running and one shot mode for the input capture circuitry. 0b - Free Running. Free running mode is selected if both capture circuits are enabled, then capture circuit 0 is armed first after CAPTCTRLA[ARMA] is set. Once a capture occurs, capture circuit 0 is disarmed, and capture circuit 1 is armed. After capture circuit 1 performs a capture, it is disarmed, and capture circuit 0 is re-armed. The process continues indefinitely. If only one of the capture circuits is enabled, then captures continue indefinitely on the enabled capture circuit. 1b - One Shot. One shot mode is selected if both capture circuits are enabled, then capture circuit 0 is armed first after CAPTCTRLA[ARMA] is set. Once a capture occurs, capture circuit 0 is disarmed, and capture circuit 1 is armed. After capture circuit 1 performs a capture, it is disarmed, and CAPTCTRLA[ARMA] is cleared. No further captures are performed until CAPTCTRLA[ARMA] is set again. If only one of the capture circuits is enabled, then a single capture occurs on the enabled capture circuit and CAPTCTRLA[ARMA] is then cleared.
0 ARMA	Arm A Setting this bit high starts the input capture process. This bit can be cleared at any time to disable input capture operation. This bit is self-cleared when in one shot mode and one or more of the enabled capture circuits has had a capture event. 0b - Input capture operation is disabled. 1b - Input capture operation as specified by CAPTCTRLA[EDGAx] is enabled.

73.5.63 Capture Compare A Register (SM2CAPTCOMPA)

73.5.63.1 Offset

Register	Offset
SM2CAPTCOMPA	F6h

73.5.63.2 Function

Contains capture and compare values for mode A.

73.5.63.3 Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	EDGCNTA								EDGCMPA							
W

73.5.63.4 Fields

Field	Function
15-8 EDGCNTA	Edge Counter A This field contains the edge counter value for the PWM_A input capture circuitry.
7-0 EDGCMPA	Edge Compare A This field is the compare value associated with the edge counter for the PWM_A input capture circuitry.

73.5.64 Capture Control B Register (SM2CAPTCTRLB)

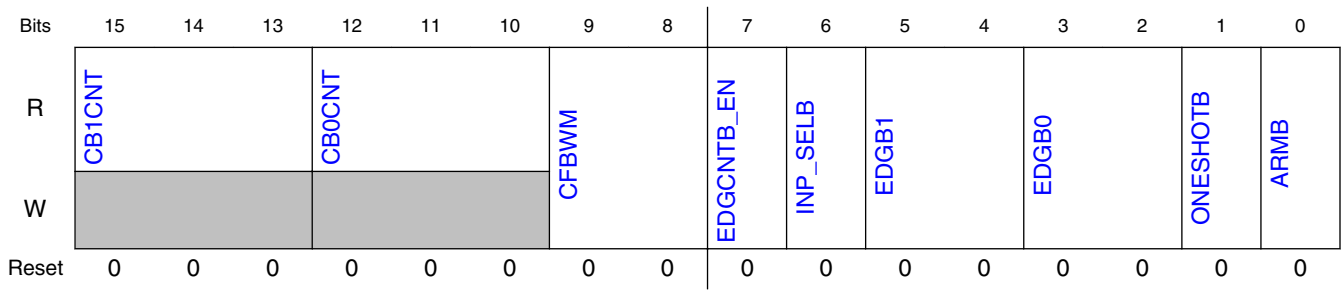
73.5.64.1 Offset

Register	Offset
SM2CAPTCTRLB	F8h

73.5.64.2 Function

Contains capture controls for mode B.

73.5.64.3 Diagram



73.5.64.4 Fields

Field	Function
15-13 CB1CNT	Capture B1 FIFO Word Count This field reflects the number of words in the Capture B1 FIFO. (FIFO depth is 1.)
12-10 CB0CNT	Capture B0 FIFO Word Count This field reflects the number of words in the Capture B0 FIFO. (FIFO depth is 1.)
9-8 CFBWM	Capture B FIFOs Water Mark This field represents the water mark level for capture B FIFOs. The capture flags, STS[CFB1] and STS[CFB0], are not set until the word count of the corresponding FIFO is greater than or equal to this water mark level. (FIFO depth is 1.)
7 EDGCNTB_EN	Edge Counter B Enable This field enables the edge counter which counts rising and falling edges on the PWM_B input signal. 0b - Edge counter disabled and held in reset 1b - Edge counter enabled
6 INP_SELB	Input Select B This field selects between the raw PWM_B input signal and the output of the edge counter/compare circuitry as the source for the input capture circuit. 0b - Raw PWM_B input signal selected as source. 1b - Edge Counter. Output of edge counter/compare selected as source. When this bitfield is set to 1, the internal edge counter is enabled and the rising and/or falling edges specified by the CAPTCTRLB[EDGB0] and CAPTCTRLB[EDGB1] fields are ignored. The software must place a value other than 00 in either or both of the CAPTCTLRB[EDGB0] and/or CAPTCTRLB[EDGB1] fields to enable one or both of the capture registers.
5-4 EDGB1	Edge B 1 These bits control the input capture 1 circuitry by determining which input edges cause a capture event. 00b - Disabled 01b - Capture falling edges 10b - Capture rising edges 11b - Capture any edge
3-2 EDGB0	Edge B 0 These bits control the input capture 0 circuitry by determining which input edges cause a capture event.

Table continues on the next page...

Field	Function
	00b - Disabled 01b - Capture falling edges 10b - Capture rising edges 11b - Capture any edge
1 ONESHOTB	One Shot Mode B This bit selects between free running and one shot mode for the input capture circuitry. 0b - Free Running. Free running mode is selected if both capture circuits are enabled, then capture circuit 0 is armed first after CAPTCTRLB[ARMB] is set. Once a capture occurs, capture circuit 0 is disarmed, and capture circuit 1 is armed. After capture circuit 1 performs a capture, it is disarmed, and capture circuit 0 is re-armed. The process continues indefinitely. If only one of the capture circuits is enabled, then captures continue indefinitely on the enabled capture circuit. 1b - One Shot. One shot mode is selected if both capture circuits are enabled, then capture circuit 0 is armed first after CAPTCTRLB[ARMB] is set. Once a capture occurs, capture circuit 0 is disarmed, and capture circuit 1 is armed. After capture circuit 1 performs a capture, it is disarmed, and CAPTCTRLB[ARMB] is cleared. No further captures are performed until CAPTCTRLB[ARMB] is set again. If only one of the capture circuits is enabled, then a single capture occurs on the enabled capture circuit and CAPTCTRLB[ARMB] is then cleared.
0 ARMB	Arm B Setting this bit high starts the input capture process. This bit can be cleared at any time to disable input capture operation. This bit is self-cleared when in one shot mode and one or more of the enabled capture circuits has had a capture event. 0b - Input capture operation is disabled. 1b - Input capture operation as specified by CAPTCTRLB[EDGBx] is enabled.

73.5.65 Capture Compare B Register (SM2CAPTCOMPB)

73.5.65.1 Offset

Register	Offset
SM2CAPTCOMPB	FAh

73.5.65.2 Function

Contains capture and compare values for mode B.

73.5.65.3 Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

73.5.65.4 Fields

Field	Function
15-8 EDGCNTB	Edge Counter B This field contains the edge counter value for the PWM_B input capture circuitry.
7-0 EDGCMPB	Edge Compare B This field is the compare value associated with the edge counter for the PWM_B input capture circuitry.

73.5.66 Capture Control X Register (SM2CAPTCTRLX)

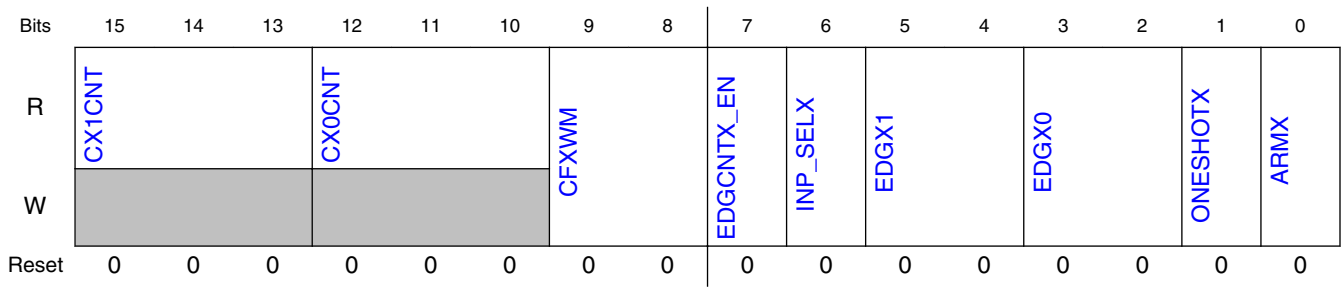
73.5.66.1 Offset

Register	Offset
SM2CAPTCTRLX	FCh

73.5.66.2 Function

Contains capture controls for mode X.

73.5.66.3 Diagram



73.5.66.4 Fields

Field	Function
15-13 CX1CNT	Capture X1 FIFO Word Count This field reflects the number of words in the Capture X1 FIFO. (FIFO depth is 1.)
12-10 CX0CNT	Capture X0 FIFO Word Count This field reflects the number of words in the Capture X0 FIFO. (FIFO depth is 1.)
9-8 CFXWM	Capture X FIFOs Water Mark This field represents the water mark level for capture X FIFOs. The capture flags, STS[CFX1] and STS[CFX0], are not set until the word count of the corresponding FIFO is greater than or equal to this water mark level. (FIFO depth is 1.)
7 EDGCNTX_EN	Edge Counter X Enable This bit enables the edge counter which counts rising and falling edges on the PWM_X input signal. 0b - Edge counter disabled and held in reset 1b - Edge counter enabled
6 INP_SELX	Input Select X This bit selects between the raw PWM_X input signal and the output of the edge counter/compare circuitry as the source for the input capture circuit. 0b - Raw PWM_X input signal selected as source. 1b - Edge Counter. Output of edge counter/compare selected as source. When this bitfield is set to 1, the internal edge counter is enabled and the rising and/or falling edges specified by the CAPTCTRLX[EDGX0] and CAPTCTRLX[EDGX1] fields are ignored. The software must place a value other than 00 in either or both of the CAPTCTLRX[EDGX0] and/or CAPTCTRLX[EDGX1] fields to enable one or both of the capture registers.
5-4 EDGX1	Edge X 1 These bits control the input capture 1 circuitry by determining which input edges cause a capture event. 00b - Disabled 01b - Capture falling edges 10b - Capture rising edges 11b - Capture any edge
3-2 EDGX0	Edge X 0 These bits control the input capture 0 circuitry by determining which input edges cause a capture event.

Table continues on the next page...

Field	Function
	00b - Disabled 01b - Capture falling edges 10b - Capture rising edges 11b - Capture any edge
1 ONESHOTX	One Shot Mode Aux This field selects between free running and one shot mode for the input capture circuitry. 0b - Free Running. Free running mode is selected if both capture circuits are enabled, then capture circuit 0 is armed first after the ARMX bit is set. Once a capture occurs, capture circuit 0 is disarmed, and capture circuit 1 is armed. After capture circuit 1 performs a capture, it is disarmed, and capture circuit 0 is re-armed. The process continues indefinitely. If only one of the capture circuits is enabled, then captures continue indefinitely on the enabled capture circuit. 1b - One Shot. One shot mode is selected if both capture circuits are enabled, then capture circuit 0 is armed first after the ARMX bit is set. Once a capture occurs, capture circuit 0 is disarmed, and capture circuit 1 is armed. After capture circuit 1 performs a capture, it is disarmed, and the ARMX bit is cleared. No further captures are performed until the ARMX bit is set again. If only one of the capture circuits is enabled, then a single capture occurs on the enabled capture circuit and the ARMX bit is then cleared.
0 ARMX	Arm X Setting this bit high starts the input capture process. This bit can be cleared at any time to disable input capture operation. This bit is self-cleared when in one shot mode and one or more of the enabled capture circuits has had a capture event. 0b - Input capture operation is disabled. 1b - Input capture operation as specified by CAPTCTRLX[EDGXx] is enabled.

73.5.67 Capture Compare X Register (SM2CAPTCOMPX)

73.5.67.1 Offset

Register	Offset
SM2CAPTCOMPX	FEh

73.5.67.2 Function

Contains capture and control values for mode X.

73.5.77.4 Fields

Field	Function
15-4 —	Reserved
3-0 CVAL4CYC	Capture Value 4 Cycle This field stores the cycle number corresponding to the value captured in CVAL4. This field is incremented each time the counter is loaded with the INIT value at the end of a PWM modulo cycle.

73.5.78 Capture Value 5 Register (SM2CVAL5)

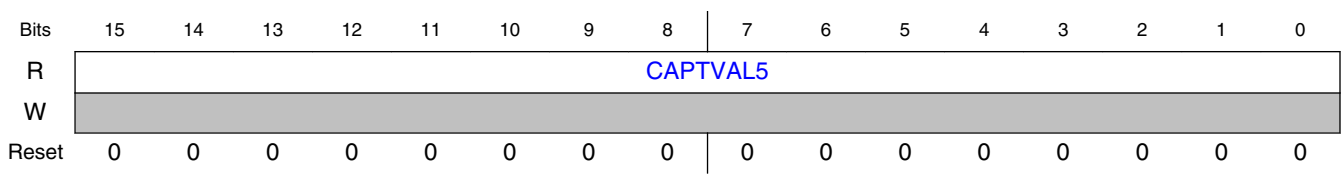
73.5.78.1 Offset

Register	Offset
SM2CVAL5	114h

73.5.78.2 Function

Writing this register generates bus transfer error.

73.5.78.3 Diagram



73.5.78.4 Fields

Field	Function
15-0 CAPTVAL5	Capture Value 5 This field stores the value captured from the submodule counter when this capture occurs is defined by CAPTCTRLB[EDGB1]. Each capture increases the value of CAPTCTRLB[CB1CNT] by 1 until the maximum value is reached. Each read of this field decreases the value of CAPTCTRLB[CB1CNT] by 1 until 0 is reached. This field is not byte accessible.

73.5.79 Capture Value 5 Cycle Register (SM2CVAL5CYC)

73.5.79.1 Offset

Register	Offset
SM2CVAL5CYC	116h

73.5.79.2 Function

Writing this register generates bus transfer error.

73.5.79.3 Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

73.5.79.4 Fields

Field	Function
15-4 —	Reserved
3-0 CVAL5CYC	Capture Value 5 Cycle This field stores the cycle number corresponding to the value captured in CVAL5. This field is incremented each time the counter is loaded with the INIT value at the end of a PWM modulo cycle.

73.5.80 Capture Control A Register (SM3CAPTCTRLA)

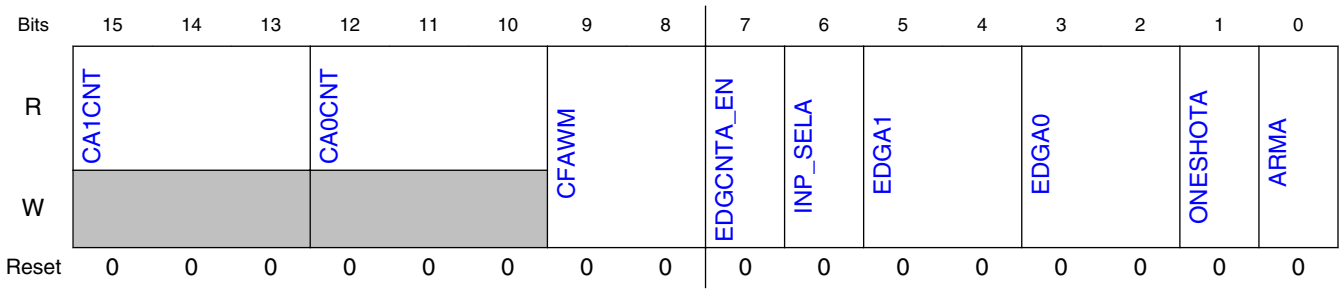
73.5.80.1 Offset

Register	Offset
SM3CAPTCTRLA	154h

73.5.80.2 Function

Contains capture controls for mode A.

73.5.80.3 Diagram



73.5.80.4 Fields

Field	Function
15-13 CA1CNT	Capture A1 FIFO Word Count This field reflects the number of words in the Capture A1 FIFO. (FIFO depth is 1.)
12-10 CA0CNT	Capture A0 FIFO Word Count This field reflects the number of words in the Capture A0 FIFO. (FIFO depth is 1.)
9-8 CFAWM	Capture A FIFOs Water Mark This field represents the water mark level for capture A FIFOs. The capture flags, STS[CFA1] and STS[CFA0], are not set until the word count of the corresponding FIFO is greater than or equal to this water mark level. (FIFO depth is 1.)
7 EDGCNTA_EN	Edge Counter A Enable This field enables the edge counter which counts rising and falling edges on the PWM_A input signal. 0b - Edge counter disabled and held in reset 1b - Edge counter enabled
6 INP_SELA	Input Select A This field selects between the raw PWM_A input signal and the output of the edge counter/compare circuitry as the source for the input capture circuit. 0b - Raw PWM_A input signal selected as source. 1b - Edge Counter. Output of edge counter/compare selected as source. When this bitfield is set to 1, the internal edge counter is enabled and the rising and/or falling edges specified by the CAPTCTRLA[EDGA0] and CAPTCTRLA[EDGA1] fields are ignored. The software must place a value other than 00 in either or both of the CAPTCTLRA[EDGA0] and/or CAPTCTRLA[EDGA1] fields to enable one or both of the capture registers.
5-4 EDGA1	Edge A 1 These bits control the input capture 1 circuitry by determining which input edges cause a capture event.

Table continues on the next page...

Field	Function
	00b - Disabled 01b - Capture falling edges 10b - Capture rising edges 11b - Capture any edge
3-2 EDGA0	Edge A 0 These bits control the input capture 0 circuitry by determining which input edges cause a capture event. 00b - Disabled 01b - Capture falling edges 10b - Capture rising edges 11b - Capture any edge
1 ONESHOTA	One Shot Mode A This bit selects between free running and one shot mode for the input capture circuitry. 0b - Free Running. Free running mode is selected if both capture circuits are enabled, then capture circuit 0 is armed first after CAPTCTRLA[ARMA] is set. Once a capture occurs, capture circuit 0 is disarmed, and capture circuit 1 is armed. After capture circuit 1 performs a capture, it is disarmed, and capture circuit 0 is re-armed. The process continues indefinitely. If only one of the capture circuits is enabled, then captures continue indefinitely on the enabled capture circuit. 1b - One Shot. One shot mode is selected if both capture circuits are enabled, then capture circuit 0 is armed first after CAPTCTRLA[ARMA] is set. Once a capture occurs, capture circuit 0 is disarmed, and capture circuit 1 is armed. After capture circuit 1 performs a capture, it is disarmed, and CAPTCTRLA[ARMA] is cleared. No further captures are performed until CAPTCTRLA[ARMA] is set again. If only one of the capture circuits is enabled, then a single capture occurs on the enabled capture circuit and CAPTCTRLA[ARMA] is then cleared.
0 ARMA	Arm A Setting this bit high starts the input capture process. This bit can be cleared at any time to disable input capture operation. This bit is self-cleared when in one shot mode and one or more of the enabled capture circuits has had a capture event. 0b - Input capture operation is disabled. 1b - Input capture operation as specified by CAPTCTRLA[EDGAx] is enabled.

73.5.81 Capture Compare A Register (SM3CAPTCOMPA)

73.5.81.1 Offset

Register	Offset
SM3CAPTCOMPA	156h

73.5.81.2 Function

Contains capture and compare values for mode A.

73.5.81.3 Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

73.5.81.4 Fields

Field	Function
15-8 EDGCNTA	Edge Counter A This field contains the edge counter value for the PWM_A input capture circuitry.
7-0 EDGCMPA	Edge Compare A This field is the compare value associated with the edge counter for the PWM_A input capture circuitry.

73.5.82 Capture Control B Register (SM3CAPTCTRLB)

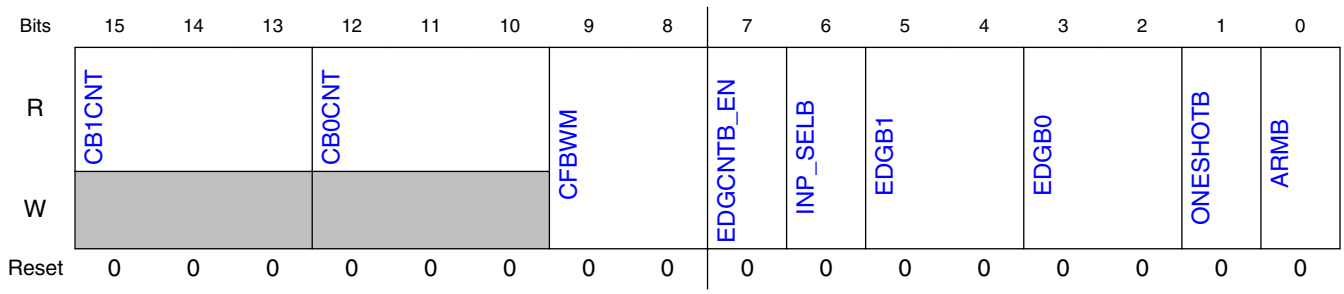
73.5.82.1 Offset

Register	Offset
SM3CAPTCTRLB	158h

73.5.82.2 Function

Contains capture controls for mode B.

73.5.82.3 Diagram



73.5.82.4 Fields

Field	Function
15-13 CB1CNT	Capture B1 FIFO Word Count This field reflects the number of words in the Capture B1 FIFO. (FIFO depth is 1.)
12-10 CB0CNT	Capture B0 FIFO Word Count This field reflects the number of words in the Capture B0 FIFO. (FIFO depth is 1.)
9-8 CFBWM	Capture B FIFOs Water Mark This field represents the water mark level for capture B FIFOs. The capture flags, STS[CFB1] and STS[CFB0], are not set until the word count of the corresponding FIFO is greater than or equal to this water mark level. (FIFO depth is 1.)
7 EDGCNTB_EN	Edge Counter B Enable This field enables the edge counter which counts rising and falling edges on the PWM_B input signal. 0b - Edge counter disabled and held in reset 1b - Edge counter enabled
6 INP_SELB	Input Select B This field selects between the raw PWM_B input signal and the output of the edge counter/compare circuitry as the source for the input capture circuit. 0b - Raw PWM_B input signal selected as source. 1b - Edge Counter. Output of edge counter/compare selected as source. When this bitfield is set to 1, the internal edge counter is enabled and the rising and/or falling edges specified by the CAPTCTRLB[EDGB0] and CAPTCTRLB[EDGB1] fields are ignored. The software must place a value other than 00 in either or both of the CAPTCTLRB[EDGB0] and/or CAPTCTRLB[EDGB1] fields to enable one or both of the capture registers.
5-4 EDGB1	Edge B 1 These bits control the input capture 1 circuitry by determining which input edges cause a capture event. 00b - Disabled 01b - Capture falling edges 10b - Capture rising edges 11b - Capture any edge
3-2 EDGB0	Edge B 0 These bits control the input capture 0 circuitry by determining which input edges cause a capture event.

Table continues on the next page...

Field	Function
	00b - Disabled 01b - Capture falling edges 10b - Capture rising edges 11b - Capture any edge
1 ONESHOTB	One Shot Mode B This bit selects between free running and one shot mode for the input capture circuitry. 0b - Free Running. Free running mode is selected if both capture circuits are enabled, then capture circuit 0 is armed first after CAPTCTRLB[ARMB] is set. Once a capture occurs, capture circuit 0 is disarmed, and capture circuit 1 is armed. After capture circuit 1 performs a capture, it is disarmed, and capture circuit 0 is re-armed. The process continues indefinitely. If only one of the capture circuits is enabled, then captures continue indefinitely on the enabled capture circuit. 1b - One Shot. One shot mode is selected if both capture circuits are enabled, then capture circuit 0 is armed first after CAPTCTRLB[ARMB] is set. Once a capture occurs, capture circuit 0 is disarmed, and capture circuit 1 is armed. After capture circuit 1 performs a capture, it is disarmed, and CAPTCTRLB[ARMB] is cleared. No further captures are performed until CAPTCTRLB[ARMB] is set again. If only one of the capture circuits is enabled, then a single capture occurs on the enabled capture circuit and CAPTCTRLB[ARMB] is then cleared.
0 ARMB	Arm B Setting this bit high starts the input capture process. This bit can be cleared at any time to disable input capture operation. This bit is self-cleared when in one shot mode and one or more of the enabled capture circuits has had a capture event. 0b - Input capture operation is disabled. 1b - Input capture operation as specified by CAPTCTRLB[EDGBx] is enabled.

73.5.83 Capture Compare B Register (SM3CAPTCOMPB)

73.5.83.1 Offset

Register	Offset
SM3CAPTCOMPB	15Ah

73.5.83.2 Function

Contains capture and compare values for mode B.

73.5.83.3 Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

73.5.83.4 Fields

Field	Function
15-8 EDGCNTB	Edge Counter B This field contains the edge counter value for the PWM_B input capture circuitry.
7-0 EDGCMPB	Edge Compare B This field is the compare value associated with the edge counter for the PWM_B input capture circuitry.

73.5.84 Capture Control X Register (SM3CAPTCTRLX)

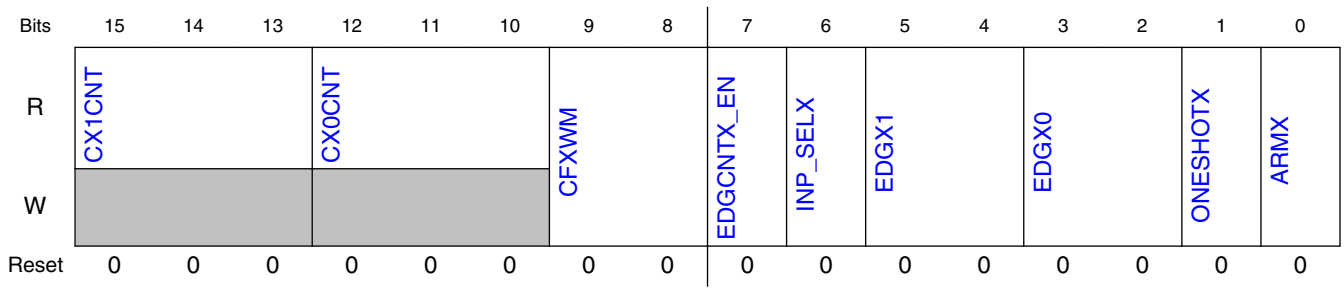
73.5.84.1 Offset

Register	Offset
SM3CAPTCTRLX	15Ch

73.5.84.2 Function

Contains capture controls for mode X.

73.5.84.3 Diagram



73.5.84.4 Fields

Field	Function
15-13 CX1CNT	Capture X1 FIFO Word Count This field reflects the number of words in the Capture X1 FIFO. (FIFO depth is 1.)
12-10 CX0CNT	Capture X0 FIFO Word Count This field reflects the number of words in the Capture X0 FIFO. (FIFO depth is 1.)
9-8 CFXWM	Capture X FIFOs Water Mark This field represents the water mark level for capture X FIFOs. The capture flags, STS[CFX1] and STS[CFX0], are not set until the word count of the corresponding FIFO is greater than or equal this water mark level. (FIFO depth is 1.)
7 EDGCNTX_EN	Edge Counter X Enable This bit enables the edge counter which counts rising and falling edges on the PWM_X input signal. 0b - Edge counter disabled and held in reset 1b - Edge counter enabled
6 INP_SELX	Input Select X This bit selects between the raw PWM_X input signal and the output of the edge counter/compare circuitry as the source for the input capture circuit. 0b - Raw PWM_X input signal selected as source. 1b - Edge Counter. Output of edge counter/compare selected as source. When this bitfield is set to 1, the internal edge counter is enabled and the rising and/or falling edges specified by the CAPTCTRLX[EDGX0] and CAPTCTRLX[EDGX1] fields are ignored. The software must place a value other than 00 in either or both of the CAPTCTLRX[EDGX0] and/or CAPTCTRLX[EDGX1] fields to enable one or both of the capture registers.
5-4 EDGX1	Edge X 1 These bits control the input capture 1 circuitry by determining which input edges cause a capture event. 00b - Disabled 01b - Capture falling edges 10b - Capture rising edges 11b - Capture any edge
3-2 EDGX0	Edge X 0 These bits control the input capture 0 circuitry by determining which input edges cause a capture event.

Table continues on the next page...

Field	Function
	00b - Disabled 01b - Capture falling edges 10b - Capture rising edges 11b - Capture any edge
1 ONESHOTX	One Shot Mode Aux This field selects between free running and one shot mode for the input capture circuitry. 0b - Free Running. Free running mode is selected if both capture circuits are enabled, then capture circuit 0 is armed first after the ARMX bit is set. Once a capture occurs, capture circuit 0 is disarmed, and capture circuit 1 is armed. After capture circuit 1 performs a capture, it is disarmed, and capture circuit 0 is re-armed. The process continues indefinitely. If only one of the capture circuits is enabled, then captures continue indefinitely on the enabled capture circuit. 1b - One Shot. One shot mode is selected if both capture circuits are enabled, then capture circuit 0 is armed first after the ARMX bit is set. Once a capture occurs, capture circuit 0 is disarmed, and capture circuit 1 is armed. After capture circuit 1 performs a capture, it is disarmed, and the ARMX bit is cleared. No further captures are performed until the ARMX bit is set again. If only one of the capture circuits is enabled, then a single capture occurs on the enabled capture circuit and the ARMX bit is then cleared.
0 ARMX	Arm X Setting this bit high starts the input capture process. This bit can be cleared at any time to disable input capture operation. This bit is self-cleared when in one shot mode and one or more of the enabled capture circuits has had a capture event. 0b - Input capture operation is disabled. 1b - Input capture operation as specified by CAPTCTRLX[EDGXx] is enabled.

73.5.85 Capture Compare X Register (SM3CAPTCOMPX)

73.5.85.1 Offset

Register	Offset
SM3CAPTCOMPX	15Eh

73.5.85.2 Function

Contains capture and control values for mode X.

73.5.98.4 Fields

Field	Function
15-12 —	Reserved
11-8 PWMA_EN	PWM_A Output Enables This field enables the PWM_A outputs of submodules 3 - 0, respectively. Set these bits to 0 (output disabled) when a PWM_A pin is being used for input capture. • 0b0 PWM_A output disabled. • 0b1 PWM_A output enabled.
7-4 PWMB_EN	PWM_B Output Enables This field enables the PWM_B outputs of submodules 3 - 0, respectively. Set these bits to 0 (output disabled) when a PWM_B pin is being used for input capture. • 0b0 PWM_B output disabled. • 0b1 PWM_B output enabled.
3-0 PWMX_EN	PWM_X Output Enables This field enables the PWM_X outputs of submodules 3 - 0, respectively. Set these bits to 0 (output disabled) when a PWM_X pin is being used for input capture or deadtime correction. • 0b0 PWM_X output disabled. • 0b1 PWM_X output enabled.

73.5.99 Mask Register (MASK)

73.5.99.1 Offset

Register	Offset
MASK	182h

73.5.99.2 Function

MASK is double buffered and does not take effect until a FORCE_OUT event occurs within the appropriate submodule. Reading MASK reads the buffered values and not necessarily the values currently in effect. This double buffering can be overridden by setting the UPDATE_MASK bits.

73.5.99.3 Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R					MASKA				MASKB				MASKX			
W	UPDATE_MASK															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

73.5.99.4 Fields

Field	Function
15-12 UPDATE_MASK	Update Mask Bits Immediately This field masks or unmasks the PWM_X (X = A, B, or X) outputs of submodules 3 - 0 respectively by forcing the MASK* (* = A, B or X) bits to be immediately updated within submodules 3 - 0, respectively without waiting for a FORCE_OUT event. These self-clearing bits always read as zero. Software may write to any or all of these bits and may set these bits in the same write operation that updates the MASKA, MASKB, and MASKX fields of this register. • 0b0 Normal operation. MASK* bits within the corresponding submodule are not updated until a FORCE_OUT event occurs within the submodule. • 0b1 Immediate operation. MASK* bits within the corresponding submodule are updated on the following clock edge after setting this bit. For example: • UPDATE_MASK[3]=1 updates the mask bits MASKA[3], MASKB[3], and MASKX[3]. • UPDATE_MASK[3:0]=0101 updates the mask bits MASKA[2], MASKA[0], MASKB[2], MASKB[0], MASKX[2], and MASKX[0].
11-8 MASKA	PWM_A Masks

Table continues on the next page...

Field	Function
	This field masks the PWM_A outputs of submodules 3 - 0, respectively by forcing the output to logic 0 prior to consideration of the output polarity. • 0b0 PWM_A output normal. • 0b1 PWM_A output masked. MASKA[3:0] masks PWM_A_3 through PWM_A_0
7-4 MASKB	PWM_B Masks This field masks the PWM_B outputs of submodules 3 - 0, respectively by forcing the output to logic 0 prior to consideration of the output polarity. • 0b0 PWM_B output normal. • 0b1 PWM_B output masked. MASKB[3:0] masks PWM_B_3 through PWM_B_0
3-0 MASKX	PWM_X Masks This field masks the PWM_X outputs of submodules 3 - 0, respectively by forcing the output to logic 0 prior to consideration of the output polarity. • 0b0 PWM_X output normal. • 0b1 PWM_X output masked. MASKX[3:0] masks PWM_X_3 through PWM_X_0

73.5.100 Software Controlled Output Register (SWCOUT)

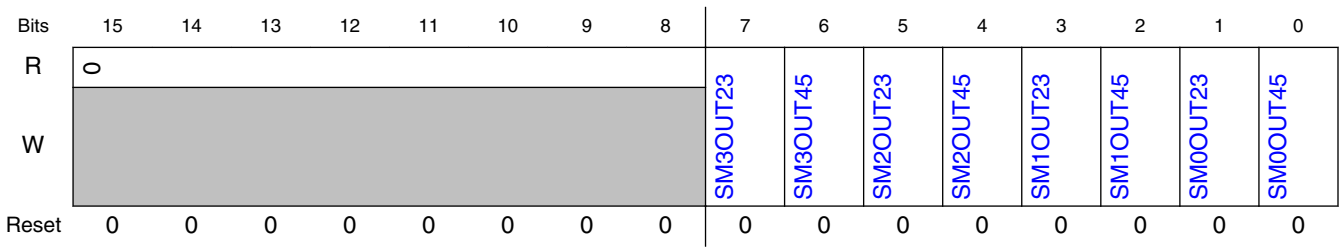
73.5.100.1 Offset

Register	Offset
SWCOUT	184h

73.5.100.2 Function

These bits are double buffered and do not take effect until a FORCE_OUT event occurs within the appropriate submodule. Reading these bits reads the buffered value and not necessarily the value currently in effect.

73.5.100.3 Diagram



73.5.100.4 Fields

Field	Function
15-8 —	Reserved
7 SM3OUT23	Submodule 3 Software Controlled Output 23 This field is used when DTSRCSEL[SM3SEL23] is set to 0b10. It allows software control of which signal is supplied to the deadtime generator of that submodule. 0b - A logic 0 is supplied to the deadtime generator of submodule 3 instead of PWM23. 1b - A logic 1 is supplied to the deadtime generator of submodule 3 instead of PWM23.
6 SM3OUT45	Submodule 3 Software Controlled Output 45 This field is used when DTSRCSEL[SM3SEL45] is set to b10. It allows software control of which signal is supplied to the deadtime generator of that submodule. 0b - A logic 0 is supplied to the deadtime generator of submodule 3 instead of PWM45. 1b - A logic 1 is supplied to the deadtime generator of submodule 3 instead of PWM45.
5 SM2OUT23	Submodule 2 Software Controlled Output 23 This field is used when DTSRCSEL[SM2SEL23] is set to b10. It allows software control of which signal is supplied to the deadtime generator of that submodule. 0b - A logic 0 is supplied to the deadtime generator of submodule 2 instead of PWM23. 1b - A logic 1 is supplied to the deadtime generator of submodule 2 instead of PWM23.
4 SM2OUT45	Submodule 2 Software Controlled Output 45 This field is used when DTSRCSEL[SM2SEL45] is set to b10. It allows software control of which signal is supplied to the deadtime generator of that submodule. 0b - A logic 0 is supplied to the deadtime generator of submodule 2 instead of PWM45. 1b - A logic 1 is supplied to the deadtime generator of submodule 2 instead of PWM45.
3 SM1OUT23	Submodule 1 Software Controlled Output 23 This field is used when DTSRCSEL[SM1SEL23] is set to b10. It allows software control of which signal is supplied to the deadtime generator of that submodule. 0b - A logic 0 is supplied to the deadtime generator of submodule 1 instead of PWM23. 1b - A logic 1 is supplied to the deadtime generator of submodule 1 instead of PWM23.
2 SM1OUT45	Submodule 1 Software Controlled Output 45 This field is used when DTSRCSEL[SM1SEL45] is set to b10. It allows software control of which signal is supplied to the deadtime generator of that submodule.

Table continues on the next page...

Field	Function
	0b - A logic 0 is supplied to the deadtime generator of submodule 1 instead of PWM45. 1b - A logic 1 is supplied to the deadtime generator of submodule 1 instead of PWM45.
1 SM0OUT23	Submodule 0 Software Controlled Output 23 This field is used when DTSRCSEL[SM0SEL23] is set to b10. It allows software control of which signal is supplied to the deadtime generator of that submodule. 0b - A logic 0 is supplied to the deadtime generator of submodule 0 instead of PWM23. 1b - A logic 1 is supplied to the deadtime generator of submodule 0 instead of PWM23.
0 SM0OUT45	Submodule 0 Software Controlled Output 45 This field is used when DTSRCSEL[SM0SEL45] is set to b10. It allows software control of which signal is supplied to the deadtime generator of that submodule. 0b - A logic 0 is supplied to the deadtime generator of submodule 0 instead of PWM45. 1b - A logic 1 is supplied to the deadtime generator of submodule 0 instead of PWM45.

73.5.101 PWM Source Select Register (DTSRCSEL)

73.5.101.1 Offset

Register	Offset
DTSRCSEL	186h

73.5.101.2 Function

The PWM source select bits are double buffered and do not take effect until a FORCE_OUT event occurs within the appropriate submodule. Reading these bits reads the buffered value and not necessarily the value currently in effect.

73.5.101.3 Diagram

Field	Function
SM0SEL23	This field selects possible overrides to the generated SM0PWM23 signal that passes to the deadtime logic upon the occurrence of a FORCE_OUT event in that submodule. 00b - Generated SM0PWM23 signal used by the deadtime logic. 01b - Inverted generated SM0PWM23 signal used by the deadtime logic. 10b - SWCOUT[SM0OUT23] used by the deadtime logic. 11b - PWM0_EXTA signal used by the deadtime logic.
1-0 SM0SEL45	Submodule 0 PWM45 Control Select This field selects possible overrides to the generated SM0PWM45 signal that passes to the deadtime logic upon the occurrence of a FORCE_OUT event in that submodule. 00b - Generated SM0PWM45 signal used by the deadtime logic. 01b - Inverted generated SM0PWM45 signal used by the deadtime logic. 10b - SWCOUT[SM0OUT45] used by the deadtime logic. 11b - Reserved

73.5.102 Master Control Register (MCTRL)

73.5.102.1 Offset

Register	Offset
MCTRL	188h

73.5.102.2 Function

In every 4-bit field in this register, each bit acts on a separate submodule. Accordingly, the description of every bit field refers to the effect of an individual bit.

73.5.102.3 Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	IPOL				RUN				0				LDOK			
W									CLDOK							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

73.5.102.4 Fields

Field	Function
15-12 IPOL	Current Polarity This field corresponds to submodules 3 - 0, respectively. Each bit selects between PWM23 and PWM45 as the source for the generation of the complementary PWM pair output for the corresponding submodule. MCTRL[IPOL] is ignored in independent mode. MCTRL[IPOL] does not take effect until a FORCE_OUT event takes place in the appropriate submodule. Reading MCTRL[IPOL] reads the buffered value and not necessarily the value currently in effect. 0000b - PWM23 is used to generate complementary PWM pair in the corresponding submodule. 0001b - PWM45 is used to generate complementary PWM pair in the corresponding submodule.
11-8 RUN	Run This field enables the clocks to the PWM generator of submodules 3 - 0, respectively. The corresponding MCTRL[RUN] bit must be set for each submodule that is using its input capture functions or is using the local reload as its reload source. When this bit equals zero, the submodule counter is reset, and PWM outputs are held. A reset clears this field. 0000b - PWM counter is stopped, but PWM outputs hold the current state. 0001b - PWM counter is started in the corresponding submodule.
7-4 CLDOK	Clear Load Okay This field corresponds to submodules 3 - 0, respectively. Each write-only bit is used to clear the corresponding bit of MCTRL[LDOK]. Write a 1 to CLDOK to clear the corresponding MCTRL[LDOK] bit. If a reload occurs within a submodule with the corresponding MCTRL[LDOK] bit set at the same time that MCTRL[CLDOK] is written, then the reload in that submodule will not be performed and MCTRL[LDOK] will be cleared. CLDOK bit is self-clearing and always reads as a 0.
3-0 LDOK	Load Okay This field corresponds to submodules 3 - 0, respectively. Each read/set bit loads CTRL[PRSC] and the INIT, FRACVALx, and VALx registers of the corresponding submodule into a set of buffers. The buffered prescaler divisor, submodule counter modulus value, and PWM pulse width take effect at the next PWM reload if CTRL[LDMOD] is clear or if CTRL[LDMOD] is set. Set the corresponding MCTRL[LDOK] bit by reading it when it is logic zero and then writing a logic one to it. The VALx, FRACVALx, INIT, and CTRL[PRSC] registers of the corresponding submodule cannot be written while the corresponding MCTRL[LDOK] bit is set. In Master Reload Mode (CTRL2[RELOAD_SEL]=1), it is necessary to set the LDOK bit corresponding to submodule0; however, it is recommended to also set the LDOK bit of the slave submodules, to prevent unwanted writes to the registers in the slave submodules. The MCTRL[LDOK] bit is automatically cleared after the new values are loaded, or it can be manually cleared before a reload by writing a logic 1 to the appropriate MCTRL[CLDOK] bit. LDOK bits cannot be written with a zero. MCTRL[LDOK] can be set in DMA mode when the DMA indicates that it has completed the update of all CTRL[PRSC], INIT, FRACVALx, and VALx registers in the corresponding submodule. Reset clears LDOK field. 0000b - Do not load new values. 0001b - Load prescaler, modulus, and PWM values of the corresponding submodule.

73.5.103 Fault Control Register (FCTRL0)

73.5.103.1 Offset

Register	Offset
FCTRL0	18Ch

73.5.103.2 Function

For every 4-bit field in this register, the bits act on the fault inputs in order. For example, FLVL bits 15-12 act on faults 3-0, respectively.

73.5.103.3 Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	FLVL				FAUTO				FSAFE				FIE			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

73.5.103.4 Fields

Field	Function
15-12 FLVL	Fault Level This field selects the active logic level of the individual fault inputs 3-0, respectively. A reset clears this field. 0000b - A logic 0 on the fault input indicates a fault condition. 0001b - A logic 1 on the fault input indicates a fault condition.
11-8 FAUTO	Automatic Fault Clearing This field selects automatic or manual clearing of faults 3-0, respectively. A reset clears this field. 0000b - Manual fault clearing. PWM outputs disabled by this fault are not enabled until FSTS[FFLAGx] is clear at the start of a half cycle or full cycle depending on the states of FSTS[FHALF] and FSTS[FFULL]. If neither FFULL nor FHALF is set, then the fault condition cannot be cleared. This is further controlled by FCTRL[FSAFE]. 0001b - Automatic fault clearing. PWM outputs disabled by this fault are enabled when FSTS[FFPINx] is clear at the start of a half cycle or full cycle depending on the states of FSTS[FHALF] and FSTS[FFULL] without regard to the state of FSTS[FFLAGx]. If neither FFULL nor FHALF is set, then the fault condition cannot be cleared.
7-4 FSAFE	Fault Safety Mode This field selects the safety mode during manual fault clearing. A reset clears this field.

Table continues on the next page...

Field	Function
	FSTS[FFPINx] may indicate that a fault condition still exists even though the actual fault signal at the FAULTx pin is clear due to the fault filter latency. 0000b - Normal mode. PWM outputs disabled by this fault are not enabled until FSTS[FFLAGx] is clear at the start of a half cycle or full cycle depending on the states of FSTS[FHALF] and FSTS[FFULL] without regard to the state of FSTS[FFPINx]. If neither FHALF nor FFULL is set, then the fault condition cannot be cleared. The PWM outputs disabled by this fault input will not be re-enabled until the actual FAULTx input signal de-asserts since the fault input will combinationally disable the PWM outputs (as programmed in DISMAPn). 0001b - Safe mode. PWM outputs disabled by this fault are not enabled until FSTS[FFLAGx] is clear and FSTS[FFPINx] is clear at the start of a half cycle or full cycle depending on the states of FSTS[FHALF] and FSTS[FFULL]. If neither FHLAF nor FFULL is set, then the fault condition cannot be cleared.
3-0 FIE	Fault Interrupt Enables This field enables CPU interrupt requests generated by the FAULTx pins. A reset clears this field. **NOTE:** The fault protection circuit is independent of the FIEx bit and is always active. If a fault is detected, the PWM outputs are disabled according to the disable mapping register. 0000b - FAULTx CPU interrupt requests disabled. 0001b - FAULTx CPU interrupt requests enabled.

73.5.104 Fault Status Register (FSTS0)

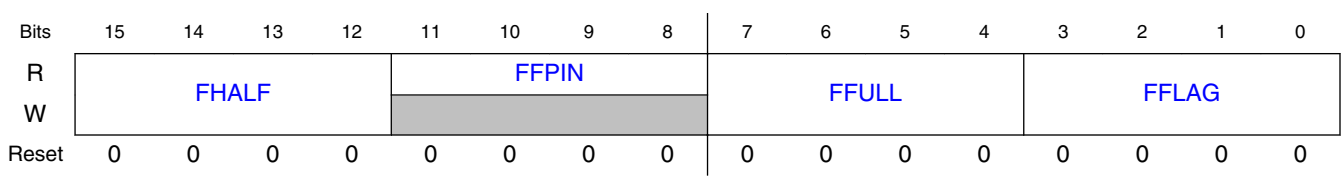
73.5.104.1 Offset

Register	Offset
FSTS0	18Eh

73.5.104.2 Function

Includes controls related to fault conditions.

73.5.104.3 Diagram



73.5.104.4 Fields

Field	Function
15-12 FHALF	Half Cycle Fault Recovery This field is used to control the timing for re-enabling the PWM outputs after a fault condition. These bits apply to both automatic and manual clearing of a fault condition. **NOTE:** Both FHALF and FFULL can be set so that the fault recovery occurs at the start of a full cycle and at the start of a half cycle (as defined by VAL0). If neither FHALF nor FFULL is set, then no fault recovery is possible. 0000b - PWM outputs are not re-enabled at the start of a half cycle. 0001b - PWM outputs are re-enabled at the start of a half cycle (as defined by VAL0).
11-8 FFPIN	Filtered Fault Pins These read-only bits reflect the current state of the filtered FAULTx pins converted to high polarity. A logic 1 indicates that a fault condition exists on the filtered FAULTx pin. A reset has no effect on this field. After the system reset de-asserts, these are the possible values of FFPIN: If FCTRL[FLVL] = 0 and FAULTx = 0, then FFPIN is set to 1. If FCTRL[FLVL] = 0 and FAULTx = 1, then FFPIN is kept as 0. If FCTRL[FLVL] = 1 and FAULTx = 0, then FFPIN is kept as 0. If FCTRL[FLVL] = 1 and FAULTx = 1, then FFPIN is set to 1.
7-4 FFULL	Full Cycle This field is used to control the timing for re-enabling the PWM outputs after a fault condition. These bits apply to both automatic and manual clearing of a fault condition. **NOTE:** Both FHALF and FFULL can be set so that the fault recovery occurs at the start of a full cycle and at the start of a half cycle (as defined by VAL0). If neither FHALF nor FFULL is set, then no fault recovery is possible. 0000b - PWM outputs are not re-enabled at the start of a full cycle 0001b - PWM outputs are re-enabled at the start of a full cycle
3-0 FFLAG	Fault Flags These read-only flags are set within two CPU cycles after a transition to active on the FAULTx pin. Clear this bit by writing a logic one to it. A reset clears this field. While the reset value is 0, these bits may be set to 1 by the time they can be read depending on the state of the fault input signals. After the system reset de-asserts, these are the possible values of FFLAG: If FCTRL[FLVL] = 0 and FAULTx = 0, then FFLAG is set to 1. If FCTRL[FLVL] = 0 and FAULTx = 1, then FFLAG is kept as 0. If FCTRL[FLVL] = 1 and FAULTx = 0, then FFLAG is kept as 0. If FCTRL[FLVL] = 1 and FAULTx = 1, then FFLAG is set to 1. 0000b - No fault on the FAULTx pin. 0001b - Fault on the FAULTx pin.

73.5.105 Fault Filter Register (FFILT0)

73.5.105.1 Offset

Register	Offset
FFILT0	190h

73.5.105.2 Function

The settings in this register are shared among each of the fault input filters within the fault channel.

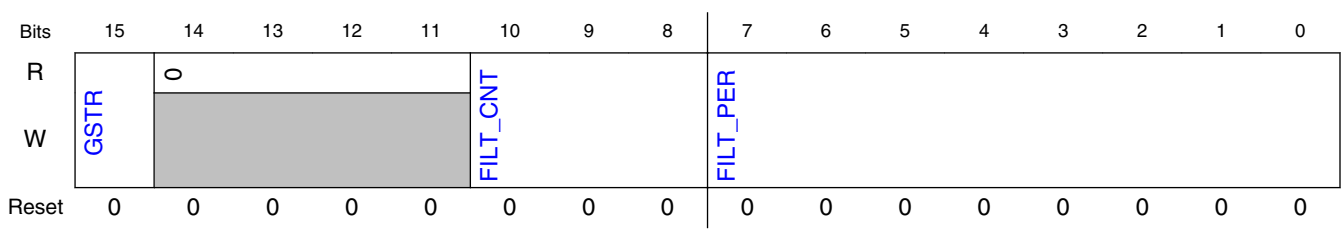
Input filter considerations include:

- Set the FILT_PER value such that the sampling period is larger than the period of the expected noise. This way a noise spike corrupts one sample. Select the FILT_CNT value to reduce and recognize the probability of noisy samples causing an incorrect transition. The probability of an incorrect transition is defined as the probability of an incorrect sample raised to the FILT_CNT+3 power.
- The values of FILT_PER and FILT_CNT must be traded off against the desire for minimal latency in recognizing input transitions. Turning on the input filter (setting FILT_PER to a non-zero value) introduces a latency of ((FILT_CNT+4) x FILT_PER x IPBus clock period).

Note

When the filter is enabled, there is a combinational path to disable the PWM outputs to ensure rapid response to fault conditions, and fault response if the eFlexPWM module loses its clock. The latency induced by the filter will be seen in the time to set FSTS[FFLAG] and FSTS[FFPIN].

73.5.105.3 Diagram



73.5.105.4 Fields

Field	Function
15 GSTR	Fault Glitch Stretch Enable This field is used to enable the fault glitch-stretching logic. This logic ensures that narrow fault glitches are stretched to be at least 2 IPBus clock cycles wide. In some cases, a narrow fault input can cause problems due to the short PWM output shutdown/re-activation time. The stretching logic ensures that a glitch on the fault input, when the fault filter is disabled, will be registered in the fault flags. 0b - Fault input glitch stretching is disabled. 1b - Input fault signals are stretched to at least 2 IPBus clock cycles.
14-11 —	Reserved
10-8 FILT_CNT	Fault Filter Count These bits represent the number of consecutive samples that must agree prior to the input filter accepting an input transition. The number of samples is the decimal value of this field plus three: the bit field value of 0-7 represents 3-10 samples, respectively. The value of FILT_CNT affects the input latency.
7-0 FILT_PER	Fault Filter Period This 8-bit field applies universally to all fault inputs. These bits represent the sampling period (in IPBus clock cycles) of the fault pin input filter. Each input is sampled multiple times at the rate specified by this field. If FILT_PER is 0x00 (default), then the input filter is bypassed. The value of FILT_PER affects the input latency. **NOTE:** When changing values for FILT_PER from one non-zero value to another non-zero value, first write a value of zero to clear the filter.

73.5.106 Fault Test Register (FTST0)

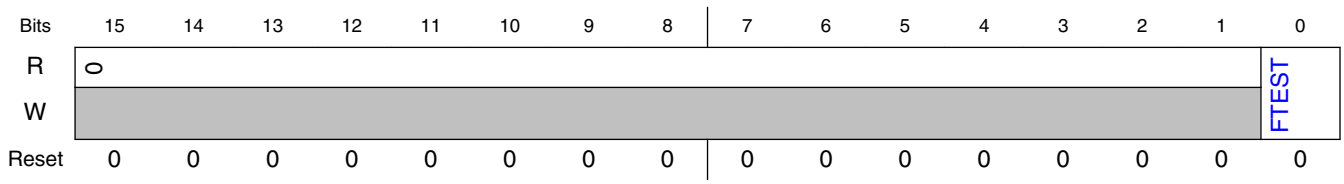
73.5.106.1 Offset

Register	Offset
FTST0	192h

73.5.106.2 Function

Contains FTEST field for fault simulation.

73.5.106.3 Diagram



73.5.106.4 Fields

Field	Function
15-1 —	Reserved
0 FTEST	Fault Test This field is used to simulate a fault condition. Setting this bit causes a simulated fault to be sent into all of the fault filters. The condition propagates to the fault flags and possibly the PWM outputs depending on the DISMAPn settings. Clearing this bit removes the simulated fault condition. 0b - No fault 1b - Cause a simulated fault

73.5.107 Fault Control 2 Register (FCTRL20)

73.5.107.1 Offset

Register	Offset
FCTRL20	194h

73.5.107.2 Function

Controls combinational link from fault inputs to PWM outputs.

73.5.107.3 Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0												NOCOMB			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

73.5.107.4 Fields

Field	Function
15-4 —	Reserved
3-0 NOCOMB	No Combinational Path From Fault Input To PWM Output This field is used to control the combinational path from the fault inputs to the PWM outputs. When these bits are low (default), the corresponding fault inputs have a combinational path to the PWM outputs that are sensitive to these fault inputs (as defined by DISMAP0). This combinational path is a safety feature that ensures the output is disabled even if the SOC has a failure of its clocking system. The combinational path also means that a pulse on the fault input can cause a brief disable of the PWM output even if the fault pulse is not wide enough to get through the input filter and be latched in the fault logic. Setting these bits removes the combinational path and uses the filtered and latched fault signals as the fault source to disable the PWM outputs. This eliminates fault glitches from creating PWM output glitches but also increases the latency to respond to a real fault. 0000b - There is a combinational link from the fault inputs to the PWM outputs. The fault inputs are combined with the filtered and latched fault signals to disable the PWM outputs. 0001b - The direct combinational path from the fault inputs to the PWM outputs is disabled and the filtered and latched fault signals are used to disable the PWM outputs.

74.2 Overview

The General Purpose Timer (GPT) is a 32-bit up-counter with clock source and frequency scaling options to provide a wide range of timing rates for various system applications. External hardware can send the GPT a "capture event" signal on an input pin to load the current timer value into a register for software to read. This capture signal can be configured to trigger the GPT on a rising or/and falling edge. Also, when the timer matches a preset value, the GPT can generate an interrupt for software and a "compare event" signal on output pins for external hardware.

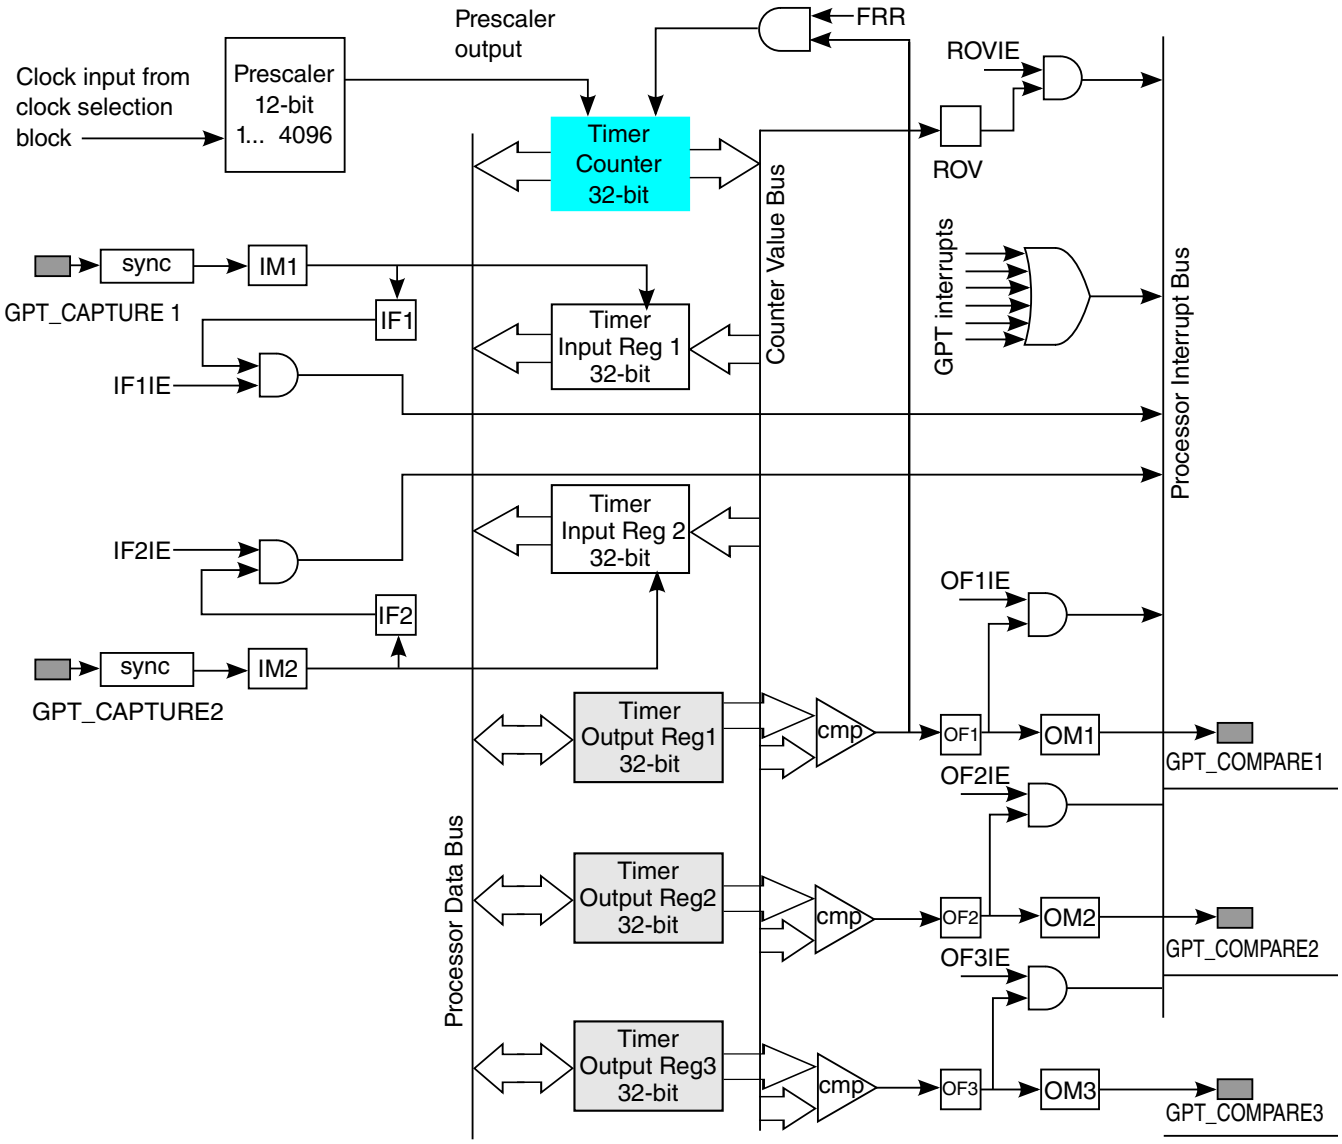

Figure 74-1. GPT Block Diagram

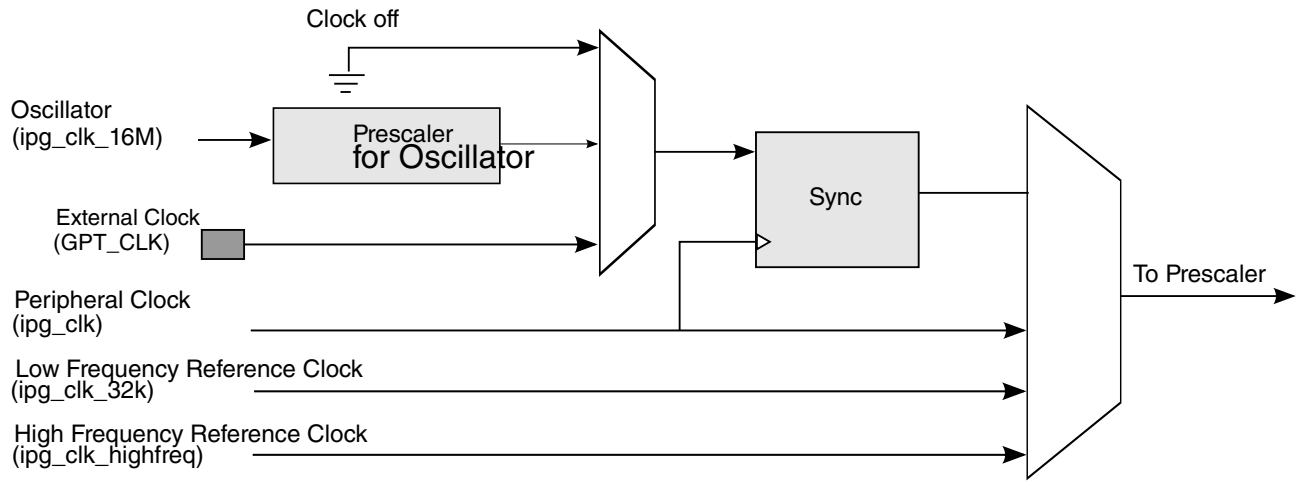

Figure 74-2. GPT Counter Clocks Diagram

74.2.1 Features

- One 32-bit up-counter with clock source selection, including external clock.
- Two input capture channels with a programmable trigger edge.
- Three output compare channels with a programmable output mode. A "forced compare" feature is also available.
- Can be programmed to be *active* in low power and debug modes.
- Interrupt generation at capture, compare, and rollover events.
- Restart or free-run modes for counter operations.

74.3 External Signals

The GPT follows the IP Bus protocol for interfacing with the processor core. The GPT does not have *any interface signals with any other module inside the chip,* except for the clock and reset inputs (from the clock and reset controller module) and for the interrupt signals *to* the processor interrupt handler. There are functional and clock inputs, and functional output signals going outside the chip boundary.

The following table describes all block signals that connect off-chip. Please see IOMUX Controller for GPT pin mux assignments.

Table 74-2. Off-Chip Module Signals

Name	Direction	Function	Reset State	Pull-Up
GPT_CLK	I	Input pin for an external clock that the counter can be operated at.	-	Passive Hysteresis
GPT_CAPTURE1	I	Input pin for a capture event for Input Capture Channel 1.	-	Passive
GPT_CAPTURE2	I	Input pin for a capture event for Input Capture Channel 2.	-	Passive
GPT_COMPARE1	O	Output pin that indicates a "compare event" occurrence in Output Compare Channel 1.	0	Passive
GPT_COMPARE2	O	Output pin that indicates a "compare event" occurrence in Output Compare Channel 2.	0	Passive
GPT_COMPARE3	O	Output pin that indicates a "compare event" occurrence in Output Compare Channel 3.	0	Passive

74.3.1 External Clock Input

The GPT counter can be operated using an external clock from outside the device, and this is the input pin used for that purpose. The external clock input (GPT_CLK) is treated as asynchronous to the peripheral clock (ipg_clk). To ensure proper operations of GPT, the external clock input frequency should be less than 1/4 of frequency of the peripheral clock (ipg_clk). Hysteresis characteristics on this pad will be required because this is a clock input.

74.3.2 Input Capture Trigger Signals

The GPT counter value can be stored in a register, triggered by an event from *outside the device*. A positive / negative edge on these GPT_CAPTURE*n* signals can trigger this capture event. These signals are treated as asynchronous to the peripheral clock (ipg_clk). Only those transitions which occur *at least a single clock cycle* (the clock selected to run the counter) *after the previous recorded transition* are guaranteed to trigger a capture event.

74.3.3 Output Compare Signals

The GPT_COMPARE*n* signals indicate that an output compare event has occurred on the corresponding Output Compare Channel *n*; see Output Compare.

74.4 Clocks

The clock that is input to the prescaler can be selected from multiple clock sources. The following table describes the clock sources for GPT. See Clock Controller Module (CCM) for clock source connection, configuration and gating information.

Table 74-3. GPT Clocks

Clock name	Description
Peripheral Clock (ipg_clk)	This is the internal clock used to access the module registers. If the Peripheral Clock or the External Clock (GPT_CLK) is selected as the Clock Source (CLKSRC=001 or 011), then the Peripheral Clock will be ON in normal GPT operations. In Low Power modes, if the GPT is programmed to be disabled (STOPEN or WAITEN or DOZEN=0), then the Peripheral Clock (ipg_clk) can be switched OFF.
Low Reference Clock (ipg_clk_32k)	This low-frequency 32-kHz reference clock (provided by the CCM) is intended to be ON in Low Power mode when the Peripheral Clock (ipg_clk) is turned OFF, thereby enabling the GPT to be operated using the Low Reference Clock in Low Power mode.
High-Frequency Clock (ipg_clk_highfreq)	Provided by the Clock Controller Module (CCM), this high-frequency reference clock is intended to be ON in Normal Power mode when the Peripheral Clock (ipg_clk) is turned OFF, thereby enabling the GPT to be operated using the High Frequency Clock *in Normal Power mode*.
Oscillator Clock (ipg_clk_16M)	This 16-MHz oscillator reference clock is intended to be used against frequency changes of the Peripheral Clock (ipg_clk) to provide a more accurate timer clock for system operation. The CCM provides the 16 MHz Oscillator Clock *without* synchronizing it to the System Bus Clock (ahb_clk) in Normal functional mode. Synchronization is done in GPT module. Before synchronization, the 16 MHz Oscillator Clock is divided by a dedicated prescaler to make sure the clock frequency less than half of System Bus Clock (ahb_clk).
External Clock (GPT_CLK)	The External Clock comes from *outside* the device and can be selected to run the GPT counter. The External Clock frequency is limited to < 1/4 frequency of the Peripheral Clock (ipg_clk) for proper GPT operations. Note that in Low Power modes, *if* the Peripheral Clock (ipg_clk) is not available, then the External Clock *cannot be used* to run the counter.

The clock input source is configured using the clock source field (CLKSRC, in the GPT_CR control register). The clock input to the prescaler can be disabled by programming the CLKSRC bits (of the GPT_CR control register) to 000. **The CLKSRC field value should be changed** *only after disabling the GPT* (by setting the EN bit in the GPT_CR to 0).

The PRESCALER field selects the divide ratio of the input clock that drives the main counter. The prescaler can divide the input clock by a value (from 1 to 4096) and can be changed *at any time*. A change in the value of the PRESCALER field *immediately affects* the output clock frequency.

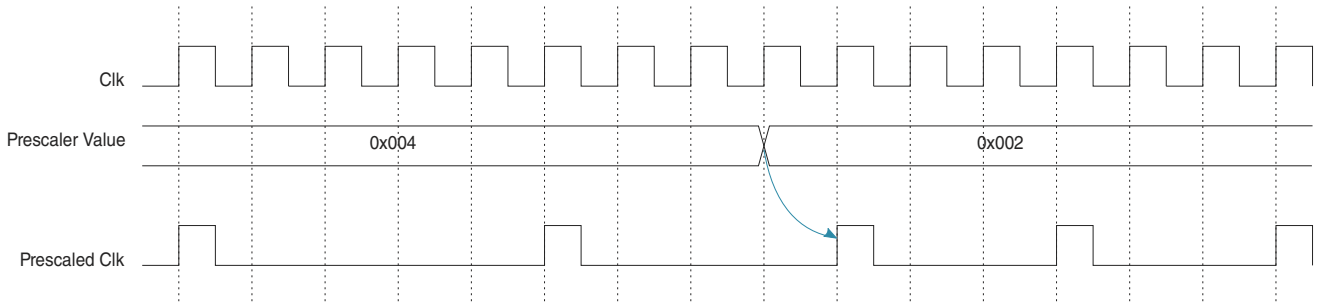

Figure 74-3. Prescaler Value Change Timing Diagram

74.5 Functional Description

This section provides a complete functional description of the GPT.

74.5.1 Operating Modes

The GPT counter can be programmed to work in either of two modes: Restart mode or Free-Run mode.

74.5.1.1 Restart Mode

In Restart mode (selectable through the GPT Control Register GPT_CR), when the counter reaches the compared value, the counter resets and starts again from 0x00000000. The Restart feature is associated only with Compare Channel 1.

Any write access to the Compare register of Channel 1 will reset the GPT counter. This is done to avoid possibly missing a compare event when compare value is changed from a higher value to lower value while counting is proceeding.

For the other two compare channels, when the compare event occurs the counter is *not reset*.

74.5.1.2 Free-Run Mode

In Free-Run mode, when compare events occur for all 3 channels, the counter is *not reset*; instead the counter continues to count until 0xffffffff, and then rolls over (to 0x00000000).

74.5.2 Operation

The General Purpose Timer (GPT) has a single counter (GPT_CNT) that is a 32-bit free-running *up-counter,* which starts counting *after it is enabled by software* (EN=1). The counter's clock source is the output of the prescaler labelled "Prescaler output" in Figure 74-1.

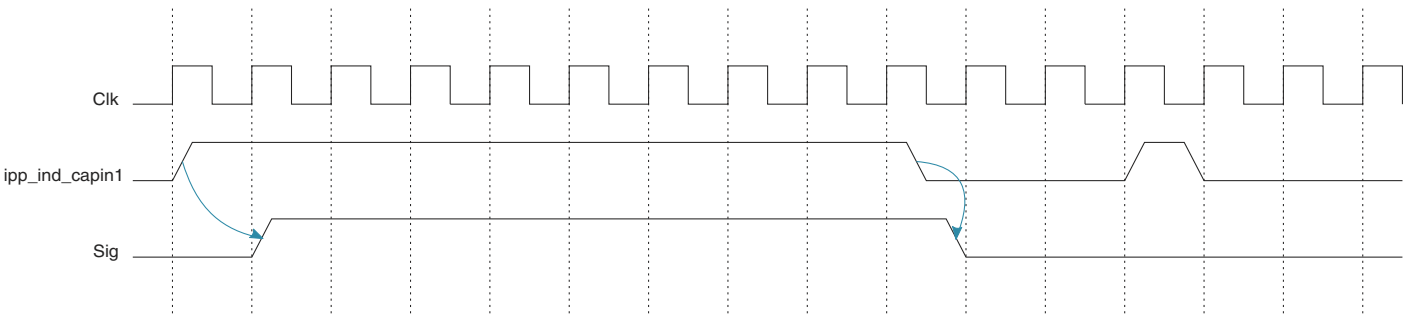
- If the GPT timer is disabled (EN=0), then the Main Counter *and* Prescaler Counter freeze their current count values. The ENMOD bit determines the value of the GPT counter when the EN bit is set and the Counter is enabled again.
  - If the ENMOD bit is set (=1), then the Main Counter and Prescaler Counter values are reset to 0, when GPT is enabled (EN=1).
  - If ENMOD bit is programmed to 0, then the Main Counter and Prescaler Counter restart counting from their frozen values, when GPT is enabled again (EN=1).
- If GPT is programmed to be disabled in a low power mode (STOP/WAIT), then the Main Counter and Prescaler Counter freeze at their current count values *when* GPT enters low power mode. When GPT exits a low power mode, the Main Counter and Prescaler Counter start counting from their frozen values *regardless* of the ENMOD bit value. Note that the GPT_CNT can be read *at any time* by the processor, and that *both* Input Capture Channels use the *same* counter (GPT_CNT).
- A hardware reset resets all the GPT registers to their respective reset values. All registers except the Output Compare Registers (OCR1, OCR2, OCR3) obtain a value of 0x0. The Compare registers are reset to 0xFFFF_FFFF.
- The software reset (SWR bit in the GPT_CR control register) resets *all* of the register bits *except* the EN, ENMOD, STOPEN, WAITEN, and DBGEN bits. The state of these bits is not affected by a software reset. Note that a software reset can be given *while the GPT is disabled*.

74.5.2.1 Input Capture

There are two Input Capture Channels, and each Input Capture Channel has a dedicated capture pin, capture register and input edge detection/selection logic. Each input capture function has an associated status flag, and can cause the processor to make an interrupt service request.

When a selected edge transition occurs on an Input Capture pin, the contents of the GPT_CNT is captured on the corresponding capture register and the appropriate interrupt status flag is set. An interrupt request can be generated when the transition is detected *if* its corresponding enable bit is set (in the Interrupt Register). The capture can be programmed to occur on the input pin's rising edge, falling edge, on both rising and

falling edges, or the capture can be disabled. The events are synchronized with the clock that was selected to run the counter. Only those transitions that occur at least one clock cycle (clock selected to run the counter) *after* the previous recorded transition will be guaranteed to trigger a capture event. There can be up to one clock cycle of uncertainty in the latching of the input transition. The Input Capture registers can be read *at any time* without affecting their values.



Clk = The clock selected from CLKSRC bit field setting

ipp_ind_capin1 = Pad signal for capture channel 1

Sig = Capture signal as sensed by the module

Figure 74-4. Input Capture Event Timing

74.5.2.2 Output Compare

The three Output Compare Channels *use the same counter* (GPT_CNT) as the Input Capture Channels. When the programmed content of an Output Compare register matches the value in GPT_CNT, an output compare status flag is set and an interrupt is generated (if the corresponding bit is set in the interrupt register). Consequently, the Output Compare timer pin is set, cleared, toggled, not affected at all or provide an active-low pulse for one input clock period according to the Output Compare Operating Mode bits in the Control Register (CR[OM*n*]).

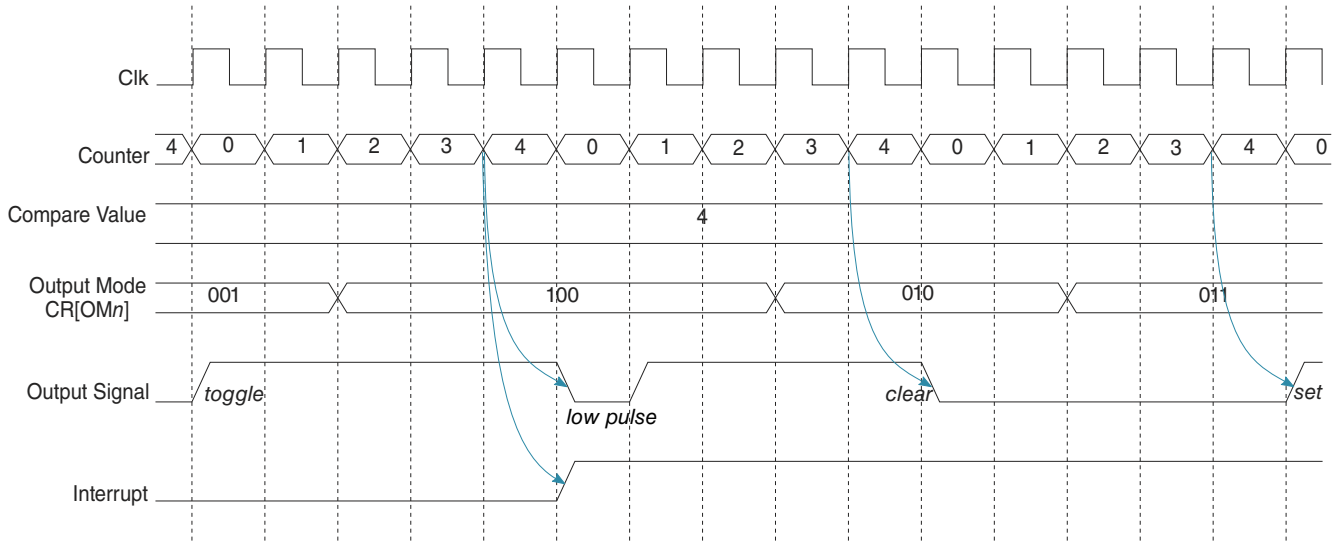


Figure 74-5. Output Compare and Interrupt Timing

There is also a "forced-compare" feature that allows the software to generate a compare event when required, *without the condition of the counter value that is equal to the compare value*. The action taken as a result of a forced compare is the same as when an output compare match occurs, *except that the status flags are not set and no interrupt can be generated*. Forced channels take programmed action immediately after the write to the force-compare bits. These bits are self-negating and always read as zeros.

74.5.2.3 Interrupts

There are 6 different interrupts that are generated by the GPT. If the selected clock for running the counter is available, then *all interrupts can be generated in Low Power and Debug modes*.

- Rollover Interrupt

  The Rollover Interrupt is generated when the GPT counter reaches 0xffffffff, then resets to 0x00000000 and continues counting. The Rollover Interrupt is enabled by the ROVIE bit in the GPT_IR register; the associated status bit is the ROV bit in the GPT_SR register.

- Input Capture Interrupt 1, 2

  After a capture event occurs, the associated Input Capture Channel generates an interrupt. The "capture event" interrupts are enabled by the IF2IE and IF1IE bits (in the GPT_IR register); the associated status bits are IF2 and IF1 (in the GPT_SR register). The capture of the counter value because of a capture event is *not affected*

by a pending capture interrupt. The Capture register is updated with a new counter value when a capture event occurs, regardless of whether that Capture Channels' interrupt has been serviced or not.

- Output Compare Interrupt 1, 2, 3

  After a compare event occurs, the associated Output Compare Channel generates an interrupt. The "compare event" interrupts are enabled by the OF3IE, OF2IE, and OF1IE bits (in the GPT_IR register); the associated status bits are OF3, OF2, and OF1 (in the GPT_SR register). A "forced compare" does not generate an interrupt.

A *cumulative* interrupt line is also present, which is asserted whenever any of the above interrupts are posted. The cumulative interrupt line has *no* associated enables or status bits.

74.5.2.4 Low Power Mode Behavior

In Low Power modes, if the clock from the selected clock source is available (except for the External Clock (GPT_CLK), which can be used *only if* the Peripheral Clock (ipg_clk) is available), the counter will continue to run depending on whether the control bit for that mode is set. If the clock is not present or if the corresponding low power bit in the GPT_CR control register is 0, the Main Counter and the Prescaler Counter freeze at their current values and resume counting (from their frozen values) when the Low Power mode is exited.

74.5.2.5 Debug Mode Behavior

In Debug mode, the modules in the device have the option of continuing to run or be halted.

- If the DBGEN bit is set, then the GPT timer will continue to run in Debug mode.
- If the DBGEN bit is not set (in the GPT_CR control register), then the GPT timer is halted.

74.6 Initialization/ Application Information

74.6.1 Selecting the Clock Source

The Clock Source field in the Control Register (CR[CLKSRC]) selects the clock source. CLKSRC should be changed only after disabling the GPT (CR[EN]=0). To change the clock source, follow this sequence:

1. Disable the GPT: CR[EN]=0
2. Disable GPT interrupts: Clear the Interrupt Register (IR)
3. Configure the Output Mode to unconnected/ disconnected for all channels: CR[OM*n*]=0
4. Disable the Input Capture Modes: CR[IM*n*]=0
5. Change the clock source CR[CLKSRC] to the desired value.
6. Assert a GPT software reset: CR[SWR]=1
7. Clear the flags in the GPT Status Register (SR) by writing 1s to them.
8. Reset the GPT counter to zero: CR[ENMOD]=1
9. Enable the GPT: CR[EN]=1
10. Enable GPT interrupts: For the desired interrupts, write 1s to their enable bits in IR.

74.7 Memory map/register definition

74.7.1 GPT register descriptions

The GPT has 10 user-accessible 32-bit registers used to configure, operate and monitor the GPT.

A write access to the GPT Status Registers (Read-only registers ICR1, ICR2, CNT) generates a bus exception.

74.7.1.1 GPT memory map

GPT1 base address: 400E_C000h

GPT2 base address: 400F_0000h

GPT3 base address: 400F_4000h

GPT4 base address: 400F_8000h

GPT5 base address: 400F_C000h

GPT6 base address: 4010_0000h

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)
0	GPT Control Register (CR)	32	RW	0000_0000
4	GPT Prescaler Register (PR)	32	RW	0000_0000
8	GPT Status Register (SR)	32	W1C	0000_0000
C	GPT Interrupt Register (IR)	32	RW	0000_0000
10 - 18	GPT Output Compare Register (OCR1 - OCR3)	32	RW	FFFF_FFFF
1C - 20	GPT Input Capture Register (ICR1 - ICR2)	32	RO	0000_0000
24	GPT Counter Register (CNT)	32	RO	0000_0000

74.7.1.2 GPT Control Register (CR)

The GPT Control Register (CR) contains configuration options for GPT operations, such as selecting the clock source for the counter and selecting a channel's output pin response when a compare event occurs. The CR register also includes the control bit (SWR) to trigger a software reset.

NOTE

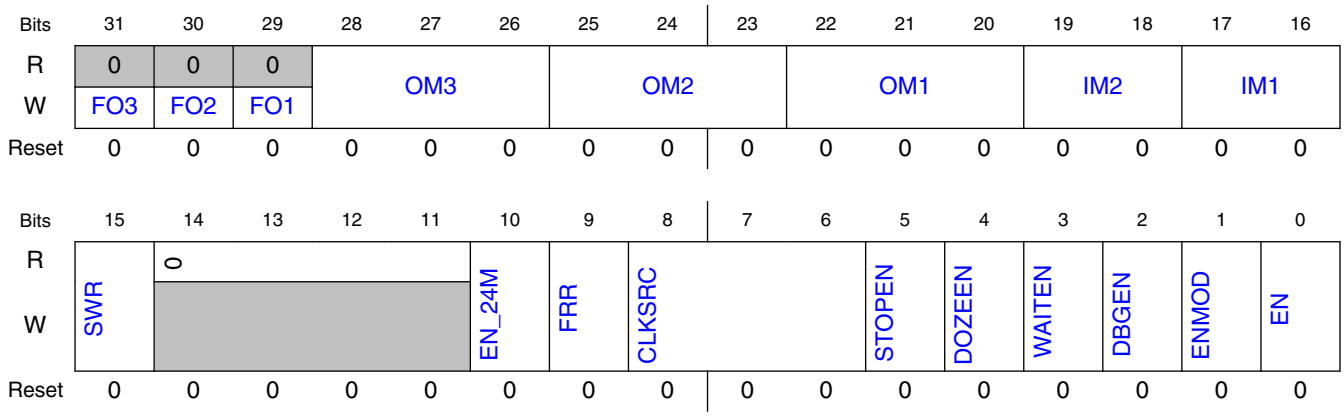
Setting the SWR bit resets **all of the GPT registers** to their default reset values except for the EN, ENMOD, STOPEN, DOZEEN, WAITEN, and DBGEN bits in this register.

For applications where precise timing is critical, be aware that writes to the CR register take effect after one cycle of the module's register bus clock (1 wait state of latency). Reads to the register occur immediately (0 wait states).

74.7.1.2.1 Offset

Register	Offset
CR	0h

74.7.1.2.2 Diagram



74.7.1.2.3 Fields

Field	Description
31-29 FOn	Force Output Compare for Channel n By setting the FO*n* bit, software can force the timer Output Compare *n* pin to respond according to the pin action programmed in the OM*n* bits (in this register). This bit is self-clearing and always reads as zero. **NOTE:** The OF*n* flag in the Status register (SR) is not set. 0 - No effect 1 - Trigger the programmed response on the pin.
28-26: OM3 25-23: OM2 22-20: OM1	Output Compare Operating Mode for Channel n Selects the response on the output pin when a compare event occurs. 000 - Output disabled. No response on pin. 001 - Toggle output pin 010 - Clear output pin 011 - Set output pin 1xx - Generate a low pulse that is one input clock cycle wide on the output pin. When OMn is first programmed as 1xx, the output pin is set to one immediately on the next input clock (if it was not one already). "Input clock" here refers to the clock selected by the CLKSRC field of this register.
19-18: IM2 17-16: IM1	Input Capture Operating Mode for Channel n Selects what transition on the input pin triggers a capture event. 00 - Capture disabled 01 - Capture on rising edge only 10 - Capture on falling edge only 11 - Capture on both edges
15 SWR	Software Reset Setting SWR resets **all of the registers** to their default reset values except for the DOZEEN, EN, ENMOD, STOPEN, WAITEN, and DBGEN bits in this register.

Table continues on the next page...

Field	Description
	The SWR bit remains set while the module is resetting. The SWR bit automatically clears when the reset procedure finishes. 0 - GPT is not in software reset state 1 - GPT is in software reset state
14-11 —	Reserved Software should write 0s to this reserved field. This field always reads as zero.
10 EN_24M	Enable Oscillator Clock Input Enables the 16-MHz clock input from an oscillator. 0 - Disable 1 - Enable
9 FRR	Free-Run or Restart Mode Selects the behavior of the GPT when a compare event in channel 1 occurs. 0 - Restart mode. After a compare event, the counter resets to 0x0000_0000 and resumes counting. 1 - Free-Run mode. After a compare event, the counter continues counting until 0xFFFF_FFFF and then rolls over to 0.
8-6 CLKSRC	Clock Source Select Selects which clock goes to the prescaler and subsequently runs the GPT counter. **NOTE:** The CLKSRC field value should be changed only after disabling the GPT (EN=0). For other programming requirements when changing the clock source, see section Selecting the Clock Source. 000 - No clock 001 - Peripheral Clock (ipg_clk) 010 - High Frequency Reference Clock (ipg_clk_highfreq) 011 - External Clock 100 - Low Frequency Reference Clock (ipg_clk_32k) 101 - Oscillator as Reference Clock (ipg_clk_16M)
5 STOPEN	GPT Stop Mode Enable Enables GPT operation *during Stop mode*. 0 - GPT is disabled in Stop mode. 1 - GPT is enabled in Stop mode.
4 DOZEEN	GPT Doze Mode Enable Enables GPT operation *during Doze mode*. 0 - GPT is disabled in Doze mode. 1 - GPT is enabled in Doze mode.
3 WAITEN	GPT Wait Mode Enable Enables GPT operation *during Wait mode*. 0 - GPT is disabled in Wait mode. 1 - GPT is enabled in Wait mode.
2 DBGEN	GPT Debug Mode Enable Enables GPT operation *during Debug mode*.

Table continues on the next page...

Field	Description
	0 - GPT is disabled in Debug mode. 1 - GPT is enabled in Debug mode.
1 ENMOD	GPT Enable Mode When the GPT is disabled (EN=0), both the Main Counter and Prescaler Counter *freeze their current count values*. The ENMOD bit selects the value of the GPT counter when GPT is enabled again (EN=1). **NOTE:** If GPT is programmed to be disabled in a low power mode (STOP/WAIT), the Main Counter and Prescaler Counter *freeze at their current count values* when the GPT enters low power mode. When GPT exits low power mode, the Main Counter and Prescaler Counter start counting from their frozen values, regardless of the ENMOD bit value. **NOTE:** A software reset (SWR=1) clears the Main Counter and Prescaler Counter values, regardless of the value of EN or ENMOD bits. 0 - The Main Counter and Prescaler Counter restart counting from their frozen values after GPT is enabled (EN=1). 1 - The Main Counter and Prescaler Counter values are reset to 0 after GPT is enabled (EN=1).
0 EN	GPT Enable Enables the GPT module. **NOTE:** Before setting the EN bit, *all registers should be properly programmed*. 0 - GPT is disabled. 1 - GPT is enabled.

74.7.1.3 GPT Prescaler Register (PR)

The GPT Prescaler Register (PR) contains the *divide value* of the clock that runs the counter.

74.7.1.3.1 Offset

Register	Offset
PR	4h

5 ROVIE	Rollover Interrupt Enable Enables the Rollover interrupt. 0 - Disable 1 - Enable
4-3 IFnIE	Input Capture Flag for Channel n Interrupt Enable Enables the Input Capture Flag for Channel *n* interrupt. 0 - Disable 1 - Enable
2-0	Output Compare Flag for Channel n Interrupt Enable

Field	Description
OFnIE	Enables the Output Compare Flag for Channel *n* interrupt. 0 - Disable 1 - Enable

74.7.1.6 GPT Output Compare Register (OCR1 - OCR3)

The GPT Output Compare Register *n* (OCR*n*) holds the value that determines when a compare event is generated on the corresponding Output Compare Channel *n*.

NOTE

The behavior of OCR1 is different compared with OCR2 and OCR3:

- A write access to OCR1 while in Restart mode (CR[FRR]=0) resets the GPT counter.
- Writes to OCR1 take effect after one cycle of the module's register bus clock (1 wait state of latency). Reads to the register occur immediately (0 wait states).

Periodic Interrupt Timer (PIT)

75.1 Chip-specific PIT information

Table 75-1. Reference links to related information

Topic	Related module(s)	Reference
System memory map	-	System Memory Map
Clocking	CCM	Clock Management Clock Control Module (CCM)
Power management	PMU	Power Management Power Management Unit
Signal multiplexing	IOMUX	External Signals and Pin Multiplexing IOMUX
Interrupts, DMA Events and XBAR Assignments	-	Interrupts, DMA Events and XBAR Assignments
PIT channel to DMA channel correspondence	-	PIT Channel Assignments For Periodic DMA Triggering

There are 4 PIT channels in this device.

75.2 Introduction

PIT includes an array of timers that can be used to raise interrupts and trigger DMA channels. Some of the registers listed in PIT register descriptions are used to configure these timers, and after the expiry of a timer, the respective registers indicate a timeout status, which can be used to raise interrupts and triggers.

75.2.1 Block diagram

The following figure shows the block diagram of PIT module.

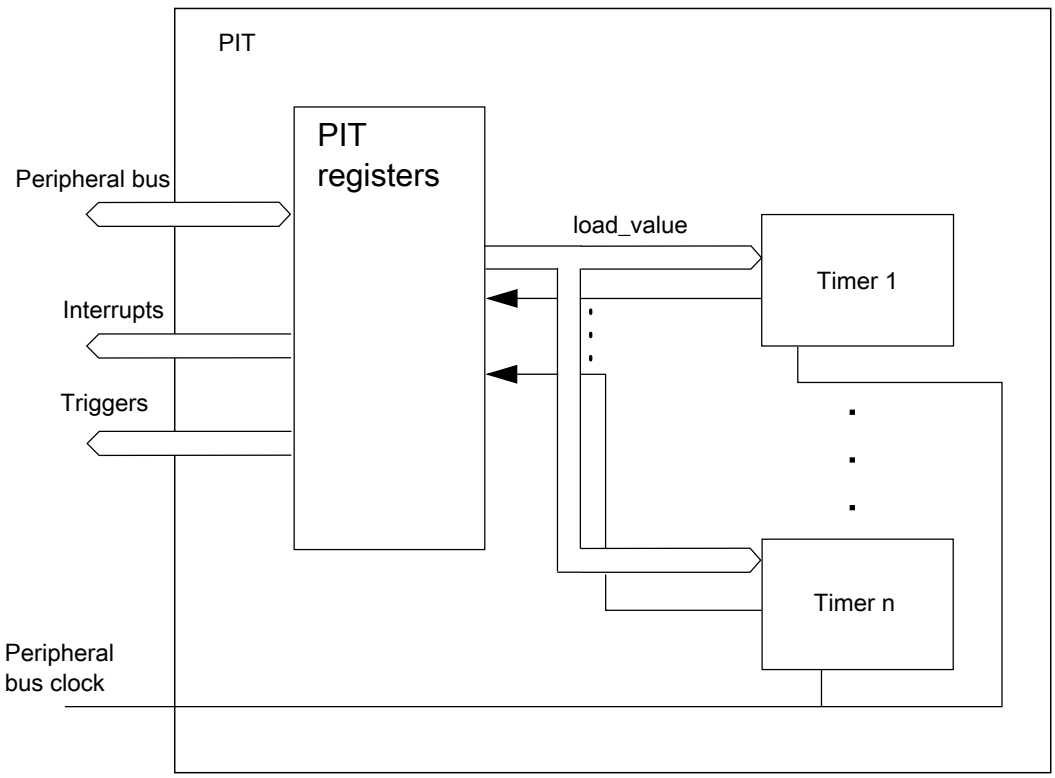

Figure 75-1. Block diagram of PIT

75.2.2 Features

The key features of the module are these:

- Ability of timers to generate DMA trigger pulses
- Ability of timers to generate interrupts
- Maskable interrupts
- Independent timeout periods for each timer
- All the timers use a downcounter

75.3 Modes of operation

This subsection briefly describes all operating modes supported by PIT.

- Run mode

  All functional parts of the PIT are running during normal Run mode.

- Stop mode

75.4 Functional description

This section provides the functional description of the module.

75.4.1 General operation

This section provides detailed information on the internal operation of the module. Each timer can be used to generate trigger pulses and interrupts, and each interrupt is available on a separate interrupt line.

75.4.1.1 Timers

The timers generate triggers at periodic intervals, when enabled. The timers load the start values as specified in their LDVAL registers, count down to 0 and then load the respective start values again. Each time a timer reaches 0, it generates a trigger pulse and sets the interrupt flag.

All interrupts can be enabled or masked by setting TCTRLn[TIE]. A new interrupt can be generated only after the previous one is cleared.

If desired, the current counter value of the timer can be read via the CVAL registers.

The counter period can be restarted by first disabling and then enabling the timer with TCTRLn[TEN]. See the following figure.

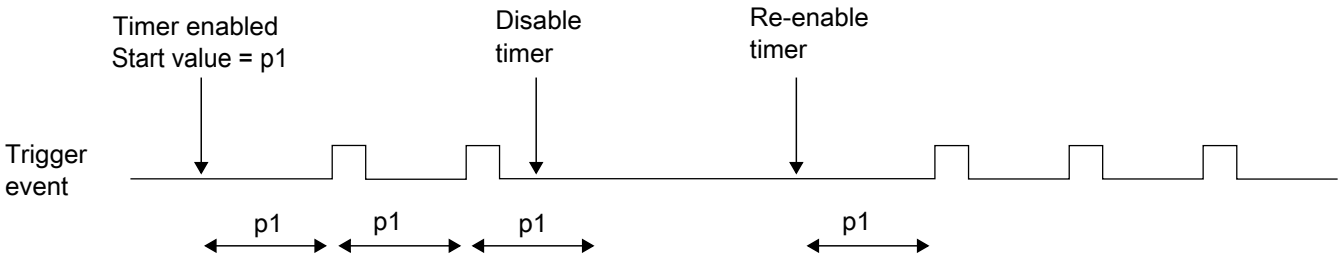

Figure 75-2. Stopping and starting a timer

The counter period of a running timer can be modified by first disabling the timer, setting a new load value, and then enabling the timer again. See the following figure.

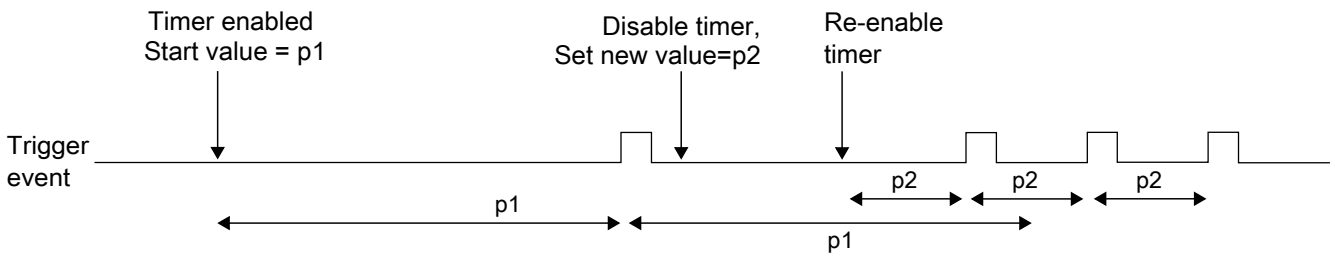

Figure 75-3. Modifying running timer period

It is also possible to change the counter period without restarting the timer, by writing LDVAL with the new load value. This value then loads after the next trigger event. See the following figure.

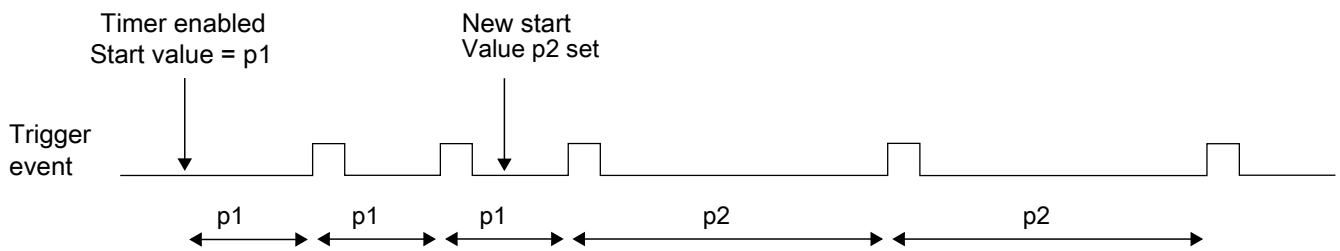

Figure 75-4. Dynamically setting a new load value

NOTE

- If MCR[FRZ] is written as 1 and when the timer is nearing 0 (CVALn =0x0), the debug mode command may not make it to the IP before the timer expires and generates a trigger.

- Debug Mode will be ignored if CVALn =0x0, but the trigger will remain asserted until the mode is removed. The user is recommended to exit Debug mode and then clear the interrupt TFLGn[TIF].
- If the timers are to be freezed for debug, sufficient time must be ensured for the IP to react.

75.4.1.2 Debug mode

In the Debug mode, the timers are frozen based on MCR[FRZ]. This is intended to aid software development, allowing the developer to halt the processor, investigate the current state of the system, for example, the timer values, and then continue the operation.

75.4.2 Interrupts

All the timers support interrupt generation.

Timer interrupts can be enabled by setting TCTRLn[TIE].

TFLGn[TIF] are set to 1 when a timeout occurs on the associated timer, and are cleared to 0 by writing a 1 to the corresponding TFLGn[TIF].

75.4.3 Chained timers

When a timer has chain mode enabled, it counts after the previous timer has expired. So if timer n-1 counts down to 0, counter n decrements the value by one. This allows to chain some of the timers together to form a longer timer. The first timer (timer 0) cannot be chained to any other timer.

See Example configuration for chained timers.

75.4.4 Example configuration for chained timers

In the example configuration:

- The PIT clock has a frequency of 100 MHz.

- Timers 1 and 2 are available.
- An interrupt is raised every 1 minute.

The PIT module needs to be activated by writing a 0 to MCR[MDIS].

The 100 MHz clock frequency equates to a clock period of 10 ns, so the PIT needs to count for 6000 million cycles, which is more than a single timer can do. So, Timer 1 is set up to trigger every 6 s (600 million cycles). Timer 2 is chained to Timer 1 and programmed to trigger 10 times.

The value for the LDVAL register trigger is calculated as number of cycles-1, so LDVAL1 receives the value 0x23C345FF and LDVAL2 receives the value 0x00000009.

The interrupt for Timer 2 is enabled by setting TCTRL2[TIE], the Chain mode is activated by setting TCTRL2[CHN], and the timer is started by writing a 1 to TCTRL2[TEN].

TCTRL1[TEN] needs to be set, and TCTRL1[CHN] and TCTRL1[TIE] are cleared.

The following example code matches the described setup:

```
// turn on PIT
PIT_MCR = 0x00;

// Timer 2
PIT_LDVAL2 = 0x00000009; // setup Timer 2 for 10 counts
PIT_TCTRL2 = TIE; // enable Timer 2 interrupt
PIT_TCTRL2 |= CHN; // chain Timer 2 to Timer 1
PIT_TCTRL2 |= TEN; // start Timer 2

// Timer 1
PIT_LDVAL1 = 0x23C345FF; // setup Timer 1 for 600 000 000 cycles
PIT_TCTRL1 = TEN; // start Timer 1
```

75.4.5 Example configuration for the Lifetime Timer

To configure the Lifetime Timer, channels 0 and 1 need to be chained together.

First, the PIT module needs to be activated by writing a 0 to the MDIS bit in the CTRL register, and then the LDVAL registers need to be set to the maximum value.

The following example code matches the described setup:

```
// turn on PIT
PIT_MCR = 0x00;

// Timer 1
```

```
PIT_LDVAL1 = 0xFFFFFFFF; // setup timer 1 for maximum counting period
PIT_TCTRL1 = 0x0; // disable timer 1 interrupts
PIT_TCTRL1 |= CHN; // chain timer 1 to timer 0
PIT_TCTRL1 |= TEN; // start timer 1

// Timer 0
PIT_LDVAL0 = 0xFFFFFFFF; // setup timer 0 for maximum counting period
PIT_TCTRL0 = TEN; // start timer 0
```

To access the Lifetime Timer, read first LTMR64H and then LTMR64L.

```
current_uptime = PIT_LTMR64H<<32;
current_uptime = current_uptime + PIT_LTMR64L;
```

75.5 Initialization and application information

In the example configuration:

- The PIT clock has a frequency of 50 MHz.
- Timer 1 creates an interrupt every 5.12 ms.
- Timer 3 creates a trigger event every 30 ms.

The PIT module must be activated by writing a 0 to MCR[MDIS].

The 50 MHz clock frequency equates to a clock period of 20 ns. Timer 1 needs to trigger every 5.12 ms/20 ns = 256,000 cycles and Timer 3 every 30 ms/20 ns = 1,500,000 cycles. The value for the LDVAL register trigger is calculated as:

LDVAL trigger = (period / clock period) -1

This means LDVAL1 and LDVAL3 must be written with 0x0003E7FF and 0x0016E35F, respectively.

The interrupt for Timer 1 is enabled by setting TCTRL1[TIE]. The timer is started by writing 1 to TCTRL1[TEN].

Timer 3 shall be used only for triggering. Therefore, Timer 3 is started by writing a 1 to TCTRL3[TEN]. Also, TCTRL3[TIE] stays at 0.

The following example code matches the described setup:

```
// turn on PIT
PIT_MCR = 0x00;

// Timer 1
PIT_LDVAL1 = 0x0003E7FF; // setup timer 1 for 256000 cycles
PIT_TCTRL1 = TIE; // enable Timer 1 interrupts
PIT_TCTRL1 |= TEN; // start Timer 1
```

```
// Timer 3
PIT_LDVAL3 = 0x0016E35F; // setup timer 3 for 1500000 cycles
PIT_TCTRL3 |= TEN; // start Timer 3
```

75.6 Memory Map and Registers

75.6.1 PIT register descriptions

This section provides a detailed description of all registers accessible in the PIT module.

- See the chip-specific PIT information for the number of PIT channels used in this MCU.

75.6.1.1 PIT memory map

PIT1 base address: 400D_8000h

PIT2 base address: 40CB_0000h

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)
0	PIT Module Control Register (MCR)	32	RW	0000_0002
E0	PIT Upper Lifetime Timer Register (LTMR64H)	32	RO	0000_0000
E4	PIT Lower Lifetime Timer Register (LTMR64L)	32	RO	0000_0000
100	Timer Load Value Register (LDVAL0)	32	RW	0000_0000
104	Current Timer Value Register (CVAL0)	32	RO	0000_0000
108	Timer Control Register (TCTRL0)	32	RW	0000_0000

128	Timer Control Register (TCTRL2)	32	RW	0000_0000
12C	Timer Flag Register (TFLG2)	32	W1C	0000_0000
130	Timer Load Value Register (LDVAL3)	32	RW	0000_0000
134	Current Timer Value Register (CVAL3)	32	RO	0000_0000
138	Timer Control Register (TCTRL3)	32	RW	0000_0000
13C	Timer Flag Register (TFLG3)	32	W1C	0000_0000

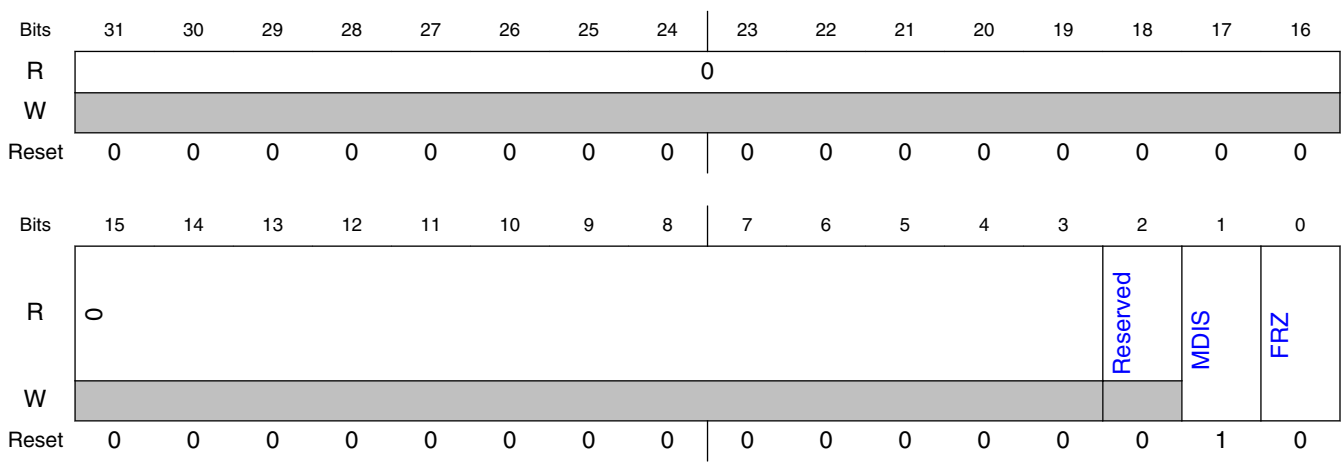
75.6.1.2 PIT Module Control Register (MCR)

This register enables or disables the PIT timer clocks and controls the timers when the PIT enters the Debug mode.

75.6.1.2.1 Offset

Register	Offset
MCR	0h

75.6.1.2.2 Diagram



75.6.1.2.3 Fields

Field	Description
31-3 —	Reserved
2 —	Reserved
1 MDIS	Module Disable for PIT Disables the standard timers. You must write 1 to this field before setting up anything. 0 - Clock for standard PIT timers is enabled.

Table continues on the next page...

Field	Description
	1 - Clock for standard PIT timers is disabled.
0 FRZ	Freeze Allows the timers to be stopped when the device enters the Debug mode. 0 - Timers continue to run in Debug mode. 1 - Timers are stopped in Debug mode.

75.6.1.3 PIT Upper Lifetime Timer Register (LTMR64H)

This register is intended for applications that chain timer 0 and timer 1 to build a 64-bit Lifetime Timer.

75.6.1.3.1 Offset

Register	Offset
LTMR64H	E0h

75.6.1.3.2 Diagram

75.6.1.3.3 Fields

Field	Description
31-0 LTH	Life Timer value Shows the timer value of timer 1. If this register is read at a time t1, LTMR64L shows the value of timer 0 at time t1.

75.6.1.4 PIT Lower Lifetime Timer Register (LTMR64L)

This register is intended for applications that chain timer 0 and timer 1 to build a 64-bit Lifetime Timer.

To use LTMR64H and LTMR64L, timer 0 and timer 1 need to be chained. To obtain the correct value, first read LTMR64H and then LTMR64L. The value for the LTMR64H register is set to CVAL1 register at the time of the first access and the value of the LTMR64L register is set to CVAL0 register at first access. Therefore, the application is not affected by the carry-over effects of the running counter.

75.6.1.4.1 Offset

Register	Offset
LTMR64L	E4h

75.6.1.4.2 Diagram

75.6.1.5.3 Fields

Field	Description
31-0 TSV	Timer Start Value Sets the timer start value. The timer counts down until it reaches 0, then generates an interrupt and loads this register value again. Writing a new value to this register does not restart the timer; instead the value is loaded after the timer expires. To abort the current cycle and start a timer period with the new value, the timer must be disabled and enabled again.

75.6.1.6 Current Timer Value Register (CVAL0 - CVAL3)

These registers indicate the current timer position.

75.6.1.6.1 Offset

Register	Offset
CVAL0	104h
CVAL1	114h
CVAL2	124h
CVAL3	134h

75.6.1.6.3 Fields

Field	Description
31-0	Current Timer Value
TVL	Represents the current timer value, if the timer is enabled. **NOTE:** • If the timer is disabled, do not use this field because its value is unreliable. • The timer uses a downcounter. The timer values are frozen in the Debug mode if MCR[FRZ] is set.

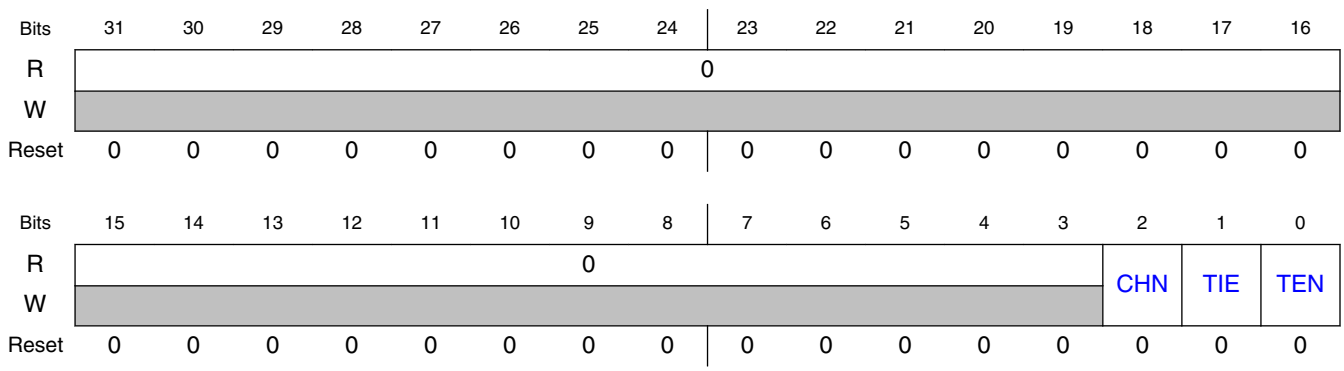
75.6.1.7 Timer Control Register (TCTRL0 - TCTRL3)

These registers contain the control bits for each timer.

75.6.1.7.1 Offset

Register	Offset
TCTRL0	108h
TCTRL1	118h
TCTRL2	128h
TCTRL3	138h

75.6.1.7.2 Diagram



75.6.1.7.3 Fields

Field	Description
31-3 —	Reserved
2 CHN	Chain Mode When activated, timer n-1 needs to expire before timer n (n is > 0) can decrement by 1. Timer 0 cannot be chained. 0 - Timer is not chained. 1 - Timer is chained to a previous timer. For example, for channel 2, if this field is set, Timer 2 is chained to Timer 1.
1 TIE	Timer Interrupt Enable When an interrupt is pending, or if TFLGn[TIF] is set, enabling the interrupt causes an interrupt event. To avoid this, the associated TFLGn[TIF] must be cleared first. 0 - Interrupt requests from Timer n are disabled. 1 - Interrupt is requested whenever TIF is set.
0 TEN	Timer Enable Enables or disables the timer. 0 - Timer n is disabled. 1 - Timer n is enabled.

75.6.1.8 Timer Flag Register (TFLG0 - TFLG3)

These registers hold the PIT interrupt flags.

75.6.1.8.1 Offset

Register	Offset
TFLG0	10Ch
TFLG1	11Ch
TFLG2	12Ch
TFLG3	13Ch

76.2 Overview

Each timer module (TMR) contains four identical counter/timer groups. Each 16-bit counter/timer group contains a prescaler, a counter, a load register, a hold register, a capture register, two compare registers, two status and control registers, and one control register. All of the registers except the prescaler are read/writable.

NOTE

This document uses the terms "Timer" and "Counter" interchangeably because the counter/timers may perform either or both tasks.

The load register provides the initialization value to the counter when the counter's terminal value has been reached.

The hold register captures the counter's value when other counters are being read. This feature supports the reading of cascaded counters.

The capture register enables an external signal to take a "snap shot" of the counter's current value.

The COMP1 and COMP2 registers provide the values to which the counter is compared. If a match occurs, the OFLAG (TMR Output signal) can be set, cleared, or toggled. At match time, an interrupt is generated if enabled, and the new compare value is loaded into the COMP1 or COMP2 registers from CMPLD1 and CMPLD2 if enabled.

The prescaler provides different time bases useful for clocking the counter/timer.

The counter provides the ability to count internal or external events.

Within a timer module (set of four timer/counters), the four inputs are shared by the four counters, but the four outputs are dedicated to each counter.

76.2.1 Block Diagram

Each of the timer/counter groups within the quad-timer are shown in this figure.

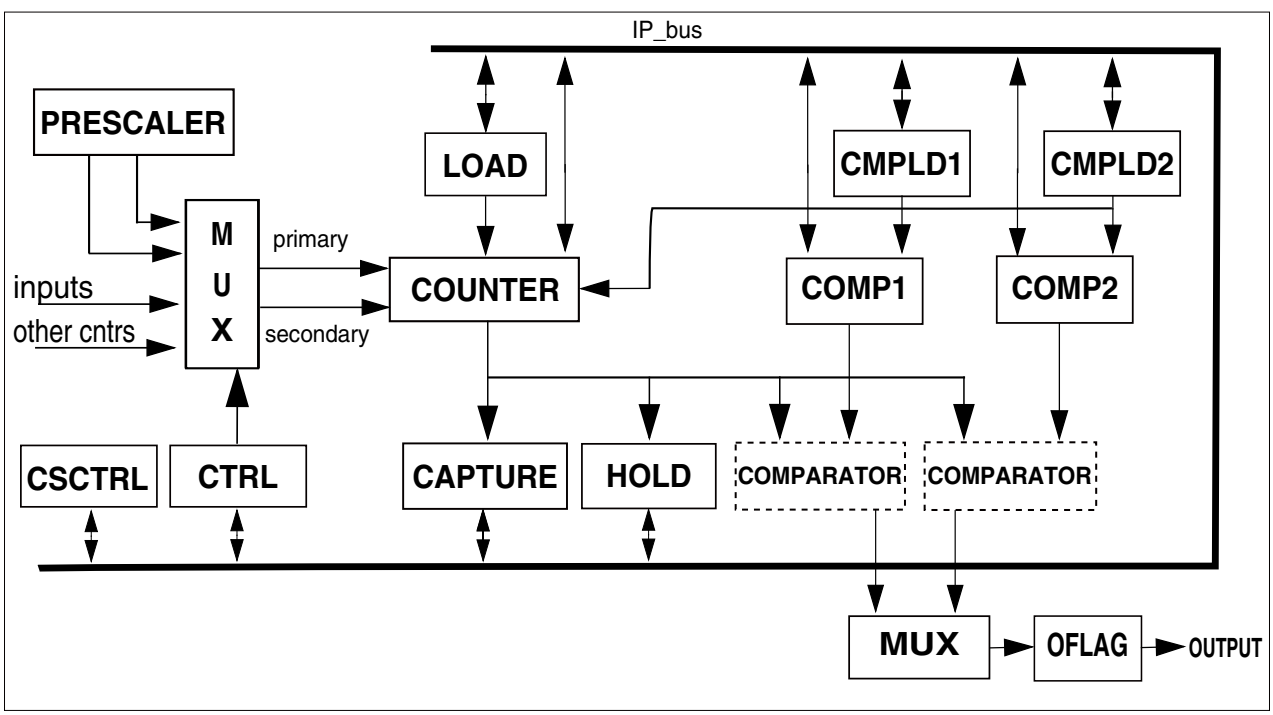

Figure 76-1. Quad Timer Block Diagram

76.2.2 Features

The TMR module design includes these distinctive features:

- Four 16-bit counters/timers
- Count up/down
- Counters are cascadable
- Programmable count modulo
- Max count rate equals BUS_CLOCK_ROOT/2 for external clocks
- Max count rate equals BUS_CLOCK_ROOT for internal clocks
- Count once or repeatedly
- Counters are preloadable
- Compare registers are preloadable (available with compare load feature)
- Counters can share available input pins
- Separate prescaler for each counter
- Each counter has capture and compare capability
- Programmable operation during debug mode
- Inputs may act as fault inputs
- Programmable input filter
- Counting start can be synchronized across counters

76.3 Modes of Operation

The TMR module design operates in only a single mode of operation: Functional Mode. The various counting modes are detailed in the Functional Description.

76.4 Functional Description

76.4.1 General

The counter/timer has two basic modes of operation: it can count internal or external events, or it can count an internal clock source while an external input signal is asserted, thus timing the width of the external input signal.

- The counter can count the rising, falling, or both edges of the selected input pin.
- The counter can decode and count quadrature encoded input signals.
- The counter can count up and down using dual inputs in a "count with direction" format.
- The counter's terminal count value (modulo) is programmable.
    - The value that is loaded into the counter after reaching its terminal count is programmable.
- The counter can count repeatedly, or it can stop after completing one count cycle.
- The counter can be programmed to count to a programmed value and then immediately reinitialize, or it can count through the compare value until the count "rolls over" to zero.

The external inputs to each counter/timer are shareable among each of the four counter/timers within the module. The external inputs can be used as:

- Count commands
- Timer commands
- They can trigger the current counter value to be "captured"
- They can be used to generate interrupt requests

The polarity of the external inputs are selectable.

The primary output of each timer/counter is the output signal OFLAG. The OFLAG output signal can be:

- Set, cleared, or toggled when the counter reaches the programmed value.
- The OFLAG output signal may be output to an external pin instead of having that pin serve as a timer input.
- The OFLAG output signal enables each counter to generate square waves, PWM, or pulse stream outputs.
- The polarity of the OFLAG output signal is selectable.

Any counter/timer can be assigned as a master. A master's compare signal can be broadcast to the other counter/timers within the module. The other counters can be configured to reinitialize their counters and/or force their OFLAG output signals to predetermined values when a master's counter/timer compare event occurs.

76.4.2 Usage of Compare Registers

The dual compare registers (COMP1 and COMP2) provide a bidirectional modulo count capability. The COMP1 register is used when the counter is *counting up*, and the COMP2 register is used when the counter is *counting down*. Alternating compare mode is the only exception.

The COMP1 register should be set to the desired maximum count value or FFFFh to indicate the maximum unsigned value prior to roll-over, and the COMP2 register should be set to the minimum count value or 0000h to indicate the minimum unsigned value prior to roll-under.

If CTRL[OUTMODE] is set to 100, the OFLAG will toggle while using alternating compare registers. In this variable frequency PWM mode, the COMP2 value defines the desired pulse width of the on time, and the COMP1 register defines the off time.

Use caution when changing COMP1 and COMP2 while the counter is active. If the counter has already passed the new value, it will count to FFFFh or 0000h, roll over, then begin counting toward the new value. The check is: Count=CMPx, *not* Count > COMP1 or Count < COMP2.

The use of the CMPLD1 and CMPLD2 registers to compare values will help to minimize this problem.

76.4.3 Usage of Compare Load Registers

The CMPLD1, CMPLD2, and CSCTRL registers offer a high degree of flexibility for loading compare registers with user-defined values on different compare events. To ensure correct functionality while using these registers we strongly suggest using the following method described in this section.

The purpose of the compare load feature is to allow quicker updating of the compare registers. In the past, a compare register could be updated using interrupts. However, because of the latency between an interrupt event occurring and the service of that interrupt, there was the possibility that the counter may have already counted past the

new compare value by the time the compare register was updated by the interrupt service routine. The counter would then continue counting until it rolled over and reached the new compare value.

To address this, the compare registers are now updated in hardware in the same way the counter register is re-initialized to the value stored in the load register. The compare load feature allows the user to calculate new compare values and store them in to the comparator load registers. When a compare event occurs, the new compare values in the comparator load registers are written to the compare registers eliminating the use of software to do this.

The compare load feature is intended to be used in variable frequency PWM mode. The COMP1 register determines the pulse width for the logic low part of OFLAG and COMP2 determines the pulse width for the logic high part of OFLAG. The period of the waveform is determined by the COMP1 and COMP2 values and the frequency of the primary clock source. See the following figure.

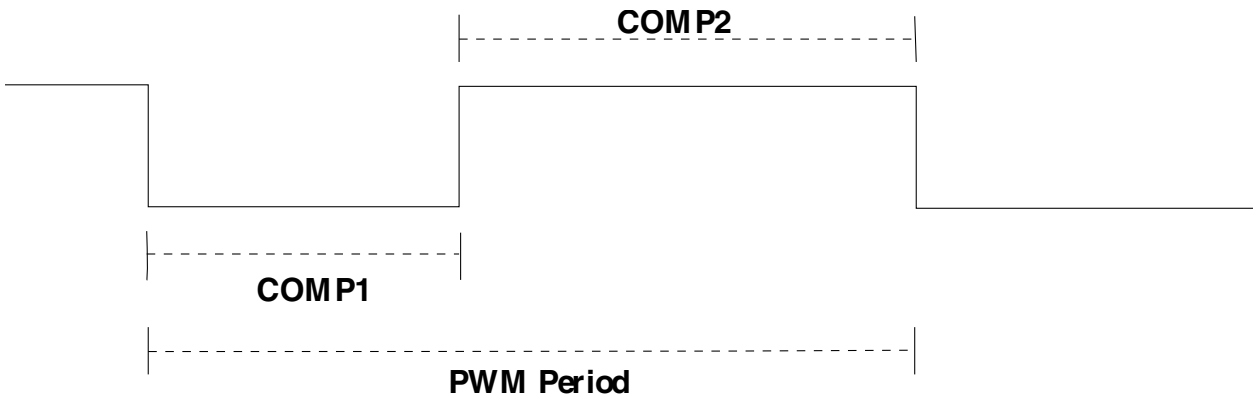

Figure 76-2. Variable PWM Waveform

Should we desire to update the duty cycle or period of the above waveform, we would need to update the COMP1 and COMP2 values using the compare load feature.

76.4.4 Usage of the Capture Register

The capture register stores a copy of the counter's value when an input edge (positive, negative, or both) is detected. After a capture event occurs, no further updating of the capture register will occur until the SCTRL[IEF] (input edge flag) is cleared by writing a zero to the SCTRL[IEF].

76.4.5 Functional Modes

The selected external count signals are sampled at the TMR's base clock rate and then run through a transition detector. The maximum count rate is one-half of the TMR's base clock rate. Internal clock sources can be used to clock the counters at the TMR's base clock rate.

If a counter is programmed to count to a specific value and then stop, the CTRL[CM] field is cleared when the count terminates.

76.4.5.1 Stop Mode

If CTRL[CM] is set to '000', the counter is inert. No counting will occur. Stop mode will also disable the interrupts caused by input transitions on a selected input pin.

76.4.5.2 Count Mode

If CTRL[CM] is set to '001', the counter will count the rising edges of the selected clock source. This mode is useful for generating periodic interrupts for timing purposes, or counting external events such as "widgets" on a conveyor belt passing a sensor. If the selected input is inverted by setting SCTRL[IPS] (input polarity select), then the negative edge of the selected external input signal is counted.

Example: 76.4.5.2.1 Count Pulses from External Source

```
//    This example uses TMR1 to count pulse (actually counts rising edges of the pulse)
//      from an external source (QT3).
//
void Pulse_Init(void)
{
  /* TMR1_CTRL: CM=0,PCS=3,SCS=0,ONCE=0,LENGTH=0,DIR=0,COINIT=0,OUTMODE=0 */
  setReg(TMR1_CTRL,0x0600);           /* Set up mode */
  /* TMR1_SCTRL: TCF=0,TCFIE=0,TOF=0,TOFIE=0,IEF=0,IEFIE=0,IPS=0,INPUT=0,
                 Capture_Mode=0,MSTR=0,EEOF=0,VAL=0,FORCE=0,OPS=0,OEN=0 */
  setReg(TMR1_SCTRL,0x00);
  setReg(TMR1_CNTR,0x00);             /* Reset counter register */
  setReg(TMR1_LOAD,0x00);             /* Reset load register */
  setRegBitGroup(TMR1_CTRL,CM,0x01);  /* Run counter */
}
```

Example: 76.4.5.2.2 Generate Periodic Interrupt By Counting Internal Clocks

```
//   This example generates an interrupt every 100ms,
//     assuming the chip is operating at 60 MHz.
//
```

```
// It does this by using the IP_bus_clk divided by 128 as the counter clock source.
// The counter then counts to 46874 where it matches the COMP1 value.
// At that time an interrupt is generated, the counter is reloaded and
// the next COMP1 value is loaded from CMPLD1.
//
void TimerInt_Init(void)
{
  /* TMR0_CTRL: CM=0,PCS=0,SCS=0,ONCE=0,LENGTH=1,DIR=0,COINIT=0,OUTMODE=0 */
  setReg(TMR0_CTRL,0x20);              /* Stop all functions of the timer */
  /* TMR0_SCTRL: TCF=0,TCFIE=0,TOF=0,TOFIE=0,IEF=0,IEFIE=0,IPS=0,INPUT=0,
                 Capture_Mode=0,MSTR=0,EEOF=0,VAL=0,FORCE=0,OPS=0,OEN=0 */
  setReg(TMR0_SCTRL,0x00);
  setReg(TMR0_LOAD,0x00);             /* Reset load register */
  setReg(TMR0_COMP1,46874);           /* Set up compare 1 register */
  setReg(TMR0_CMPLD1,46874);          /* Also set the compare preload register */
  /* TMR0_CSCTRL: DBG_EN=0,FAULT=0,ALT_LOAD=0,ROC=0,TCI=0,UP=0,OFLAG=0,TCF2EN=0,TCF1EN=1,
                  TCF2=0,TCF1=0,CL2=0,CL1=1 */
  setReg(TMR0_CSCTRL,0x41);           /* Enable compare 1 interrupt and */
                                       /*   compare 1 preload */
  setRegBitGroup(TMR0_CTRL,PCS,0xF); /* Primary Count Source to IP_bus_clk / 128 */
  setReg(TMR0_CNTR,0x00);             /* Reset counter register */
  setRegBitGroup(TMR0_CTRL,CM,0x01); /* Run counter */
}
```

76.4.5.3 Edge-Count Mode

If CTRL[CM] is set to '010', the counter will count both edges of the selected external clock source. This mode is useful for counting the changes in the external environment, such as a simple encoder wheel.

Example: 76.4.5.3.1 Count Both Edges of External Source Signal

```
//  This example uses TMR1 to count pulse (actually counts both edges of the pulse)
//    from an external source (QT3).
//
void Pulse_Init(void)
{
  /* TMR1_CTRL: CM=0,PCS=3,SCS=0,ONCE=0,LENGTH=0,DIR=0,COINIT=0,OUTMODE=0 */
  setReg(TMR1_CTRL,0x0600);           /* Set up mode */
  /* TMR1_SCTRL: TCF=0,TCFIE=0,TOF=0,TOFIE=0,IEF=0,IEFIE=0,IPS=0,INPUT=0,
                 Capture_Mode=0,MSTR=0,EEOF=0,VAL=0,FORCE=0,OPS=0,OEN=0 */
  setReg(TMR1_SCTRL,0x00);
  setReg(TMR1_CNTR,0x00);             /* Reset counter register */
  setReg(TMR1_LOAD,0x00);             /* Reset load register */
  setRegBitGroup(TMR1_CTRL,CM,0x02);  /* Run counter */
}
```

76.4.5.4 Gated-Count Mode

If CTRL[CM] is set to '011', the counter will count while the selected secondary input signal is high. This mode is used to time the duration of external events. If the selected input is inverted by setting SCTRL[IPS] (input polarity select), then the counter will count while the selected secondary input is low.

Example: 76.4.5.4.1 Capture Duration of External Pulse

```
//   This example uses TMR1 to determine the duration of an external pulse.
//
//   The IP_bus clock is used as the primary counter. If the duration of the
//     external pulse is longer than 0.001 seconds one of the other IP_bus clock
//     dividers can be used. If the pulse duration is longer than 0.128 seconds
//     an external clock source will have to be used as the primary clock source.
//
void Pulse1_Init(void)
{
  /* TMR1_CTRL: CM=0,PCS=8,SCS=1,ONCE=0,LENGTH=0,DIR=0,COINIT=0,OUTMODE=0 */
  setReg(TMR1_CTRL,0x1080);             /* Set up mode */
  /* TMR1_SCTRL: TCF=0,TCFIE=0,TOF=0,TOFIE=0,IEF=0,IEFIE=0,IPS=0,INPUT=0,
                 Capture_Mode=0,MSTR=0,EEOF=0,VAL=0,FORCE=0,OPS=0,OEN=0 */
  setReg(TMR1_SCTRL,0x00);
  setReg(TMR1_CNTR,0x00);              /* Reset counter register */
  setReg(TMR1_LOAD,0x00);              /* Reset load register */
  setRegBitGroup(TMR1_CTRL,CM,0x03);  /* Run counter */
}
```

76.4.5.5 Quadrature-Count Mode

If CTRL[CM] is set to '100', the counter will decode the primary and secondary external inputs as quadrature encoded signals. Quadrature signals are usually generated by rotary or linear sensors used to monitor movement of motor shafts or mechanical equipment. The quadrature signals are square waves that are 90 degrees out of phase. The decoding of quadrature signal provides both count and direction information.

This figure shows a timing diagram illustrating the basic operation of a quadrature incremental position encoder.

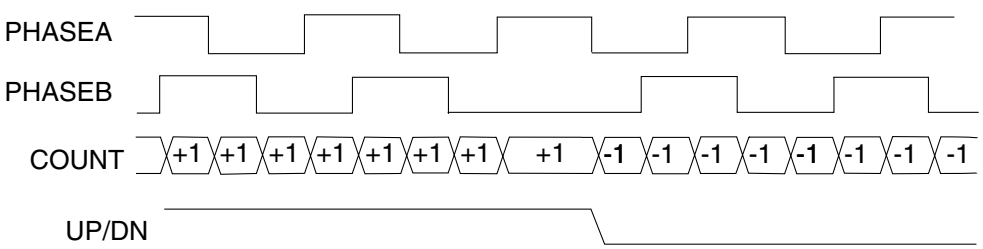

Figure 76-3. Quadrature Incremental Position Encoder

Example: 76.4.5.5.1 Quadrature Count Mode Example

```
//  This example uses TMR0 for counting states of a quadrature position encoder.
//
//  Timer input 0 is used as the primary count source (PHASEA).
//  Timer input 1 is used as the secondary count source (PHASEB).
//
void Pulse_Init(void)
{
  /* TMR0_CTRL: CM=0,PCS=0,SCS=1,ONCE=0,LENGTH=0,DIR=0,COINIT=0,OUTMODE=0 */
```

```
  setReg(TMRC0_CTRL,0x80);              /* Set up mode */
  /* TMR0_SCTRL: TCF=0,TCFIE=0,TOF=0,TOFIE=0,IEF=0,IEFIE=0,IPS=0,INPUT=0,
                 Capture_Mode=0,MSTR=0,EEOF=0,VAL=0,FORCE=0,OPS=0,OEN=1 */
  setReg(TMR0_SCTRL,0x00);
  setReg(TMR0_CNTR,0x00);             /* Reset counter register */
  setReg(TMR0_LOAD,0x00);             /* Reset load register */
  setReg(TMR0_COMP1,0xFFFF);           /* Set up compare 1 register */
  setReg(TMR0_COMP2,0x00);             /* Set up compare 2 register */
  /* TMR0_CSCTRL: DBG_EN=0,FAULT=0,ALT_LOAD=0,ROC=0,TCI=0,UP=0,OFLAG=0,
                  TCF2EN=0,TCF1EN=0,TCF2=0,TCF1=0,CL2=0,CL1=0 */
  setReg(TMR0_CSCTRL,0x00);
  setRegBitGroup(TMR0_CTRL,CM,0x04);  /* Run counter */
}
```

76.4.5.6 Quadrature-Count Mode with Index Input

As an extension to the quadrature count mode discussed in the previous paragraph, some rotary shafts have a HOME or INDEX indicator. This would be a third input to the timer that is used to reset the timer's counter.

In this example, channel 0 is used to decode the quadrature inputs, but it doesn't actually count. Because its upper and lower limits are both set to 0, its output is cascaded count up and count down signals each time the quadrature inputs indicate a change in count. Channel 1 works in cascaded count mode receiving its counting instructions from channel 0. When an input capture event occurs, channel 1 is programmed to reset its counter value. The channel 1 counter contains the position value for the shaft.

Example: 76.4.5.6.1 Quadrature Count Mode with Index Input Example

```
//  This example uses TMR0and TMR1 for counting states of a quadrature position encoder.
//
// Timer input 0 is used as the primary count source (PHASEA).
// Timer input 1 is used as the secondary count source (PHASEB).
// Timer input 2 is used as the index input source (INDEX).
//
void Pulse_Init(void)
{
  /* TMR0_CTRL: CM=0,PCS=0,SCS=1,ONCE=0,LENGTH=1,DIR=0,COINIT=0,OUTMODE=0 */
  setReg(TMR0_CTRL,0xA0);              /* Set up mode */
  /* TMR0_SCTRL: TCF=0,TCFIE=0,TOF=0,TOFIE=0,IEF=0,IEFIE=0,IPS=0,INPUT=0,
                 Capture_Mode=0,MSTR=0,EEOF=0,VAL=0,FORCE=0,OPS=0,OEN=0 */
  setReg(TMR0_SCTRL,0x00);
  setReg(TMR0_CNTR,0x00);             /* Reset counter register */
  setReg(TMR0_LOAD,0x00);             /* Reset load register */
  setReg(TMR0_COMP1,0x00);           /* Set up compare 1 register */
  setReg(TMR0_COMP2,0x00);             /* Set up compare 2 register */
  /* TMR0_CSCTRL: DBG_EN=0,FAULT=0,ALT_LOAD=0,ROC=0,TCI=0,UP=0,OFLAG=0,
                  TCF2EN=0,TCF1EN=0,TCF2=0,TCF1=0,CL2=0,CL1=0 */
  setReg(TMR0_CSCTRL,0x00);
/* TMR1_CTRL: CM=7,PCS=100,SCS=2,ONCE=0,LENGTH=0,DIR=0,COINIT=0,OUTMODE=0 */
  setReg(TMR1_CTRL,0xEA00);            /* Set up capture edge */
/* TMR1_SCTRL: Capture_Mode=10 */
  setReg(TMR1_SCTRL,0x0080);
/* TMR1_CSTRL: ROC=1 */
  setReg(TMR1_CTRL,0x0800);            /* Set up reload on capture */
setRegBitGroup(TMR0_CTRL,CM,0x04);  /* Run counter */
}
```

76.4.5.7 Signed-Count Mode

If CTRL[CM] is set to '101', the counter counts the primary clock source while the selected secondary source provides the selected count direction (up/down).

Example: 76.4.5.7.1 Signed Count Mode Example

```
//  This example uses TMR0 for signed mode counting.
//
//  Timer input 2 is used as the primary count source.
//  Timer input 1 is used to determine the count direction.
//
void Pulse_Init(void)
{
  /* TMR0_CTRL: CM=0,PCS=2,SCS=1,ONCE=0,LENGTH=0,DIR=0,COINIT=0,OUTMODE=0 */
  setReg(TMR0_CTRL,0x0480);              /* Set up mode */
  /* TMR0_SCTRL: TCF=0,TCFIE=0,TOF=0,TOFIE=1,IEF=0,IEFIE=0,IPS=0,INPUT=0,
                 Capture_Mode=0,MSTR=0,EEOF=0,VAL=0,FORCE=0,OPS=0,OEN=0 */
  setReg(TMR0_SCTRL,0x1000);
  setReg(TMR0_CNTR,0x00);              /* Reset counter register */
  setReg(TMR0_LOAD,0x00);              /* Reset load register */
  setRegBitGroup(TMR0_CTRL,CM,0x05);  /* Run counter */
}
```

76.4.5.8 Triggered-Count Mode 1

If CSCTRL[TCI] is clear and CTRL[CM] is set to '110', the counter will begin counting the primary clock source after a positive transition (negative edge if SCTRL[IPS]=1) of the secondary input occurs. The counting will continue until a compare event occurs or another positive input transition is detected. If a second input transition occurs before a terminal count is reached, counting will stop and SCTRL[TCF] (timer compare flag) will be set. Subsequent secondary input transitions will continue to restart and stop the counting until a compare event occurs.

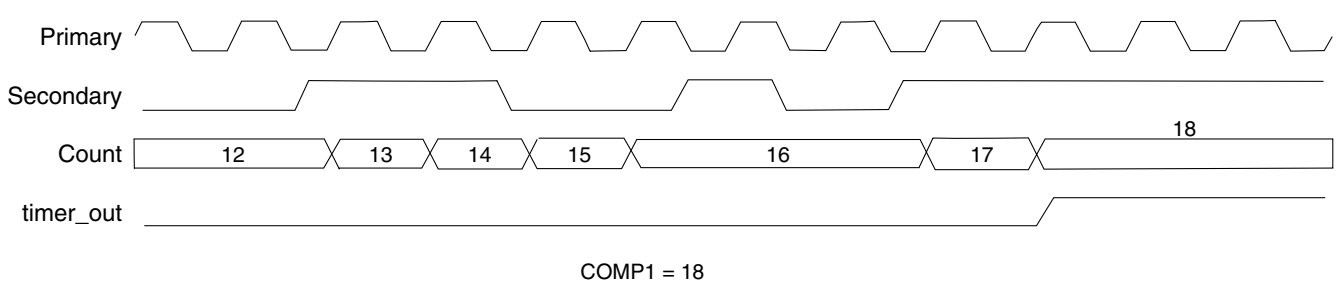

Figure 76-4. Triggered Count Mode 1 (CTRL[LENGTH]=0)

Example: 76.4.5.8.1 Triggered Count Mode 1 Example

```
//   This example uses TMR1 for triggered mode counting.
//
//   Timer input 3 is used as the primary count source.
//   Timer input 2 is used for the trigger input.
//
void Pulse_Init(void)
{
  /* TMR1_CTRL: CM=0,PCS=3,SCS=2,ONCE=0,LENGTH=0,DIR=0,COINIT=0,OUTMODE=0 */
  setReg(TMR1_CTRL,0x0700);             /* Set up mode */
  /* TMR1_SCTRL: TCF=0,TCFIE=0,TOF=0,TOFIE=1,IEF=0,IEFIE=0,IPS=0,INPUT=0,
                 Capture_Mode=0,MSTR=0,EEOF=0,VAL=0,FORCE=0,OPS=0,OEN=0 */
  setReg(TMR1_SCTRL,0x1000);
  setReg(TMR1_CNTR,0x00);               /* Reset counter register */
  setReg(TMR1_LOAD,0x00);               /* Reset load register */
  setReg(TMR1_COMP1,0x0012);             /* Set up compare 1 register */
  /* TMR1_CSCTRL: DBG_EN=0,FAULT=0,ALT_LOAD=0,ROC=0,TCI=0,UP=0,OFLAG=0,
                  TCF2EN=0,TCF1EN=0,TCF2=0,TCF1=0,CL2=0,CL1=0 */
  setReg(TMR1_CSCTRL,0x00);
  setRegBitGroup(TMR1_CTRL,CM,0x06);    /* Run counter */
}
```

76.4.5.9 Triggered-Count Mode 2

If CSCTRL[TCI] is set and CTRL[CM] is set to '110', the counter will begin counting the primary clock source after a positive transition (negative edge if SCTRL[IPS]=1) of the secondary input occurs. The counting will continue until a compare event occurs or another positive input transition is detected. If a second input transition occurs before a terminal count was reached, the counter will reload and continue counting. When CSCTRL[TCI] is set, the OFLAG output mode, CTRL[OUTMODE], should probably be set to '101' (cleared on init, set on compare) to ensure the output will be in a known state after the second input transition and subsequent reload takes place.

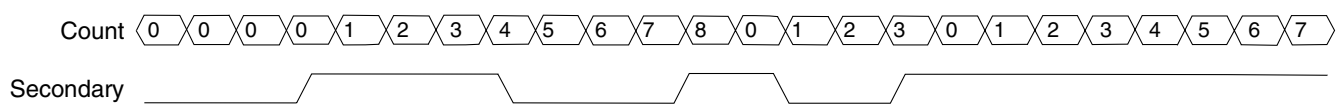

Figure 76-5. Triggered Count Mode 2 (CTRL[LENGTH]=0)

Example: 76.4.5.9.1 Triggered Count Mode 2Example

```
//   This example uses TMR1 for triggered mode counting.
//
//   Timer input 3 is used as the primary count source.
//   Timer input 2 is used for the trigger input.
//
void Pulse_Init(void)
{
  /* TMR1_CTRL: CM=0,PCS=3,SCS=2,ONCE=0,LENGTH=0,DIR=0,COINIT=0,OUTMODE=0 */
  setReg(TMR1_CTRL,0x0700);            /* Set up mode */
  /* TMR1_SCTRL: TCF=0,TCFIE=0,TOF=0,TOFIE=1,IEF=0,IEFIE=0,IPS=0,INPUT=0,
                 Capture_Mode=0,MSTR=0,EEOF=0,VAL=0,FORCE=0,OPS=0,OEN=0 */
  setReg(TMR1_SCTRL,0x1000);

  setReg(TMR1_CNTR,0x00);              /* Reset counter register */
```

```
  setReg(TMR1_LOAD,0x00);             /* Reset load register */
  setReg(TMR1_COMP1,0x0012);           /* Set up compare 1 register */
  /* TMR1_CSCTRL: DBG_EN=0,FAULT=0,ALT_LOAD=0,ROC=0,TCI=0,UP=0,OFLAG=0,
                  TCF2EN=0,TCF1EN=0,TCF2=0,TCF1=0,CL2=0,CL1=0 */
  setReg(TMR1_CSCTRL,0x00);
  setRegBitGroup(TMR1_CTRL,CM,0x06); /* Run counter */
}
```

76.4.5.10 One-Shot Mode

If CTRL[CM] is set to '110', and the counter is set to reinitialize at a compare event (CTRL[LENGTH]=1),and CTRL[OUTMODE] is set to '101' (cleared on init, set on compare), the counter works in a one-shot mode. An external event causes the counter to count, and when the terminal count is reached, the output is asserted. This delayed output can be used to provide timing delays.

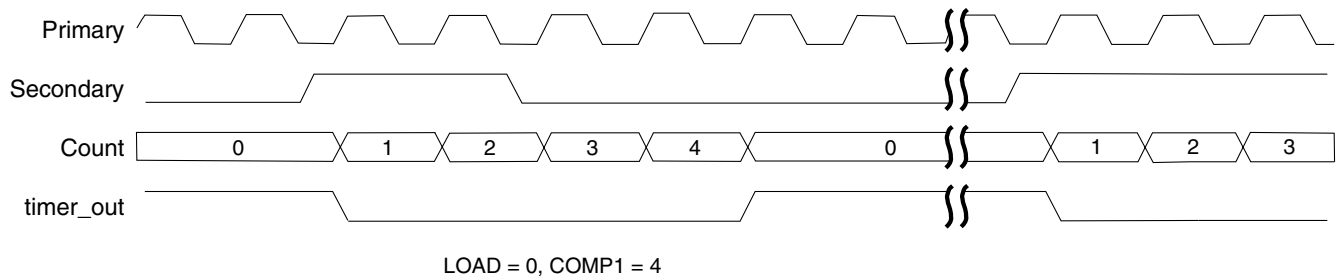

Figure 76-6. One-Shot Mode (CTRL[LENGTH]=1)

Example: 76.4.5.10.1 One-Shot Mode Example

```
//  This example uses TMR1 for one-shot mode counting.
//
//  Timer input 3 is used as the primary count source.
//  Timer input 2 is used for the trigger input.
//
void Pulse_Init(void)
{
  /* TMR1_CTRL: CM=0,PCS=3,SCS=2,ONCE=0,LENGTH=0,DIR=0,COINIT=0,OUTMODE=5 */
  setReg(TMR1_CTRL,0x0725);           /* Set up mode */
  /* TMR1_SCTRL: TCF=0,TCFIE=0,TOF=0,TOFIE=1,IEF=0,IEFIE=0,IPS=0,INPUT=0,
              Capture_Mode=0,MSTR=0,EEOF=0,VAL=0,FORCE=0,OPS=0,OEN=0 */
  setReg(TMR1_SCTRL,0x1000);
  setReg(TMR1_CNTR,0x00);             /* Reset counter register */
  setReg(TMR1_LOAD,0x00);             /* Reset load register */
  setReg(TMR1_COMP1,0x0004);           /* Set up compare 1 register */
  /* TMR1_CSCTRL: DBG_EN=0,FAULT=0,ALT_LOAD=0,ROC=0,TCI=0,UP=0,OFLAG=0,
                  TCF2EN=0,TCF1EN=0,TCF2=0,TCF1=0,CL2=0,CL1=0 */
  setReg(TMR1_CSCTRL,0x00);
  setRegBitGroup(TMR1_CTRL,CM,0x06);  /* Run counter */
}
```

76.4.5.11 Cascade-Count Mode

If CTRL[CM] is set to '111', the counter's input is connected to the output of another selected counter. The counter will count up and down as compare events occur in the selected source counter. This cascade or daisy-chained mode enables multiple counters to be cascaded to yield longer counter lengths. When operating in cascade mode, a special high-speed signal path is used between modules rather than the OFLAG output signal. If the selected source counter is counting up and it experiences a compare event, the counter will be incremented. If the selected source counter is counting down and it experiences a compare event, the counter will be decremented.

Up to four counters may be cascaded to create a 64-bit wide synchronous counter. Check the data sheet to see if there are any frequency limits for cascaded counting mode.

Whenever any counter is read within a counter module, all of the counters' values within the module are captured in their respective hold registers. This action supports the reading of a cascaded counter chain. First read any counter of a cascaded counter chain, then read the hold registers of the other counters in the chain. The cascaded counter mode is synchronous.

Note

It is possible to connect counters together by using the other (non-cascade) counter modes and selecting the outputs of other counters as a clock source. In this case, the counters are operating in a ripple mode, where higher order counters will transition a clock later than a purely synchronous design.

Example: 76.4.5.11.1 Generate Periodic Interrupt Cascading Two Counters

```
// This example generates an interrupt every 30 seconds,
//    assuming the chip is operating at 60 MHz.
//
// To do this, counter 2 is used to count 60,000 IP_bus clocks, which means it
//    will compare and reload every 0.001 seconds.
// Counter 3 is cascaded and used to count the 0.001 second ticks and
//    generate the desired interrupt interval.
//
void TimerInt_Init(void)
{
  // Set counter 2 to count IP_bus clocks
  /* TMR2_CTRL: CM=0,PCS=8,SCS=0,ONCE=0,LENGTH=1,DIR=0,COINIT=0,OUTMODE=0 */
  setReg(TMR2_CTRL,0x1020);           /* Stop all functions of the timer */
  // Set counter 3 as cascaded and to count counter 2 outputs
  /* TMR3_CTRL: CM=7,PCS=6,SCS=0,ONCE=0,LENGTH=1,DIR=0,COINIT=0,OUTMODE=0 */
  setReg(TMR3_CTRL,0xEC20);            /* Set up cascade counter mode */
  /* TMR3_SCTRL: TCF=0,TCFIE=0,TOF=0,TOFIE=0,IEF=0,IEFIE=0,IPS=0,INPUT=0,
                 Capture_Mode=0,MSTR=0,EEOF=0,VAL=0,FORCE=0,OPS=0,OEN=0 */
  setReg(TMR3_SCTRL,0x00);
  /* TMR2_SCTRL: TCF=0,TCFIE=0,TOF=0,TOFIE=0,IEF=0,IEFIE=0,IPS=0,INPUT=0,
                 Capture_Mode=0,MSTR=0,EEOF=0,VAL=0,FORCE=0,OPS=0,OEN=0 */
  setReg(TMR2_SCTRL,0x00);
```

```
  setReg(TMR3_CNTR,0x00);             /* Reset counter register */
  setReg(TMR2_CNTR,0x00);
  setReg(TMR3_LOAD,0x00);             /* Reset load register */
  setReg(TMR2_LOAD,0x00);
  setReg(TMR3_COMP1, 30000-1);        /* milliseconds in 30 seconds */
  setReg(TMR3_CMPLD1,30000-1);
  setReg(TMR2_COMP1, 60000-1);        /* Set to cycle every milisecond */
  setReg(TMR2_CMPLD1,60000-1);
  /* TMR3_CSCTRL: DBG_EN=0,FAULT=0,ALT_LOAD=0,ROC=0,TCI=0,UP=0,OFLAG=0,
                  TCF2EN=0,TCF1EN=1,TCF2=0,TCF1=0,CL2=0,CL1=1 */
  setReg(TMR3_CSCTRL,0x41);           /* Enable compare 1 interrupt and */
                                      /* compare 1 preload              */
  /* TMR2_CSCTRL: DBG_EN=0,FAULT=0,ALT_LOAD=0,ROC=0,TCI=0,UP=0,OFLAG=0,
                  TCF2EN=0,TCF1EN=0,TCF2=0,TCF1=0,CL2=0,CL1=1 */
  setReg(TMR2_CSCTRL,0x01);           /* Enable Compare 1 preload */
  setRegBitGroup(TMR2_CTRL,CM,0x01);  /* Run counter */
}
```

76.4.5.12 Pulse-Output Mode

If CTRL[CM]=001, and CTRL[OUTMODE] is set to 111' (gated clock output), and CTRL[ONCE] is set, then the counter will output a pulse stream of pulses that has the same frequency of the selected clock source, and the number of output pulses is equal to the compare value minus the init value. This mode is useful for driving step motor systems.

Note

This does not work if CTRL[PCS] is set to 1000 (IP_bus/1).

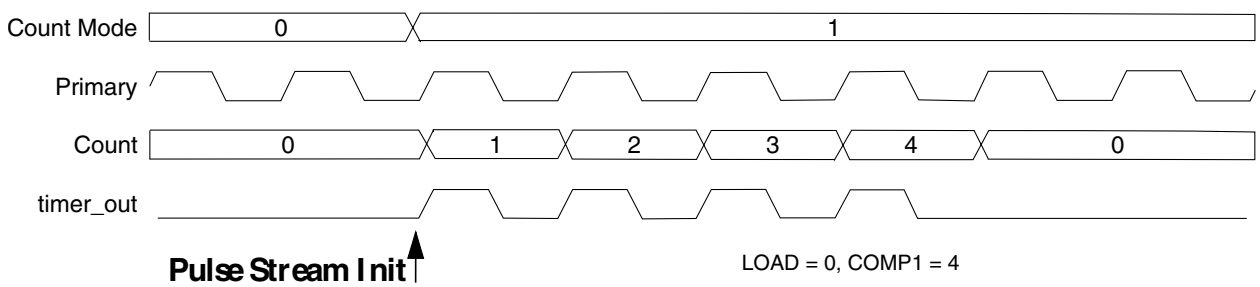

Figure 76-7. Pulse Output Mode

Example: 76.4.5.12.1 Pulse Outputs Using Two Counters

```
// This example generates six 10ms pulses, from QT1 output.
// Assuming the chip is operating at 60 MHz.
//
// To do this, timer 3 is used to generate a clock with a period of 10ms.
//
// Timer 1 is used to gate these clocks and count the number of pulses that have
//  been generated.
//
void PulseStream_Init(void)
{
// Select IP_bus_clk/16 as the clock source for Timer 3
```

```
  /* TMR3_CTRL: CM=0,PCS=0x0C,SCS=0,ONCE=0,LENGTH=1,DIR=0,COINIT=0,OUTMODE=3 */
   setReg(TMR3_CTRL,0x1823);             /* Set up mode */
  /* TMR3_SCTRL: TCF=0,TCFIE=0,TOF=0,TOFIE=0,IEF=0,IEFIE=0,IPS=0,INPUT=0,
                 Capture_Mode=0,MSTR=0,EEOF=0,VAL=0,FORCE=0,OPS=0,OEN=0 */
   setReg(TMR3_SCTRL,0x00);
   setReg(TMR3_LOAD,0x00);              /* Reset load register */
   setReg(TMR3_COMP1,37500-1);          /* (16 * 37500 ) / 60e6 = 0.01 sec */
 /* TMR3_CSCTRL: DBG_EN=0,FAULT=0,ALT_LOAD=0,ROC=0,TCI=0,UP=0,OFLAG=0,
                   TCF2EN=0,TCF1EN=0,TCF2=0,TCF1=0,CL2=0,CL1=0 */
  setReg(TMR3_CSCTRL,0x00);             /* Set up comparator control register */

// Timer 3 output is the clock source for this timer.
  /* TMR1_CTRL: CM=0,PCS=7,SCS=0,ONCE=1,LENGTH=1,DIR=0,COINIT=0,OUTMODE=7 */
  setReg(TMR1_CTRL,0x0E67);             /* Set up mode */
  /* TMR1_SCTRL: TCF=0,TCFIE=0,TOF=0,TOFIE=0,IEF=0,IEFIE=0,IPS=0,INPUT=0,
                 Capture_Mode=0,MSTR=0,EEOF=0,VAL=0,FORCE=0,OPS=0,OEN=1 */
   setReg(TMR1_SCTRL,0x01);
   setReg(TMR1_CNTR,0x00);              /* Reset counter register */
   setReg(TMR1_LOAD,0x00);              /* Reset load register */
   setReg(TMR1_COMP1,0x04);             /* Set up compare 1 register */

// set to interrupt after the last pulse
  /* TMR1_CSCTRL: DBG_EN=0,FAULT=0,ALT_LOAD=0,ROC=0,TCI=0,UP=0,OFLAG=0,
                  TCF2EN=0,TCF1EN=1,TCF2=0,TCF1=0,CL2=0,CL1=0 */
  setReg(TMR1_CSCTRL,0x40);             /* Set up comparator control register */
// Finally, start the counters running
  setReg(TMR3_CNTR,0);                  /* Reset counter */
  setRegBitGroup(TMR3_CTRL,CM,0x01);    /* Run source clock counter */
  setRegBitGroup(TMR1_CTRL,CM,0x01);    /* Run counter */
}
```

76.4.5.13 Fixed-Frequency PWM Mode

If CTRL[CM]=001, count through roll-over (CTRL[LENGTH]=0), continuous count (CTRL[ONCE]=0) and CTRL[OUTMODE] is '110' (set on compare, cleared on counter roll-over), then the counter output yields a pulse-width modulated (PWM) signal with a frequency equal to the count clock frequency divided by 65,536 and a pulse-width duty cycle equal to the compare value divided by 65,536. This mode of operation is often used to drive PWM amplifiers used to power motors and inverters.

Example: 76.4.5.13.1 Fixed-Frequency PWM Mode Example

```
// This example uses TMR0 for Fixed-Frequency PWM mode timing.
//
// The timer will count IP_bus clocks continuously until it rolls over.
// This results in a PWM period of 65536 / 60e6 = 1092.267 usec
//
// Initially, an output pulse width of 25 usec is generated ( 1500 / 60e6 )
//   giving a PWM ratio of 1500 / 65536 = 2.289%
// This pulse width can be changed by changing the COMP1 register value (using CMPLD1).
//
void PWM1_Init(void)
{
  setReg(TMR0_CNTR,0);           /* Reset counter */
  /* TMR0_SCTRL: TCF=0,TCFIE=0,TOF=0,TOFIE=0,IEF=0,IEFIE=0,IPS=0,INPUT=0,
                 Capture_Mode=0,MSTR=0,EEOF=0,VAL=0,FORCE=1,OPS=0,OEN=1 */
```

```
  setReg(TMR0_SCTRL,0x05);       /* Enable output */
  setReg(TMR0_COMP1,1500-1);     /* Store initial value to the duty-compare register */
  /* TMR0_CTRL: CM=1,PCS=8,SCS=0,ONCE=0,LENGTH=0,DIR=0,COINIT=0,OUTMODE=6 */
  setReg(TMR0_CTRL,0x3006);      /* Run counter */
}
```

76.4.5.14 Variable-Frequency PWM Mode

If CTRL[CM]=001, count until compare (CTRL[LENGTH]=1), continuous count (CTRL[ONCE] = 0) and CTRL[OUTMODE] is '100' (toggle OFLAG and alternate compare registers), then the counter output yields a pulse-width modulated (PWM) signal whose frequency and pulse width is determined by the values programmed into the COMP1 and COMP2 registers, and the input clock frequency. This method of PWM generation has the advantage of allowing almost any desired PWM frequency and/or constant on or off periods. This mode of operation is often used to drive PWM amplifiers used to power motors and inverters. The CMPLD1 and CMPLD2 registers are especially useful for this mode, as they allow the programmer time to calculate values for the next PWM cycle while the PWM current cycle is underway.

To set up the TMR to run in variable frequency PWM mode with compare preload please use the following setup for the specific counter you would like to use. When performing the setup, update the TMR_CTRL register last because the counter will start counting if the count mode is changed to any value other than 000 (assuming the primary count source is already active).

Timer Control Register (CTRL)

- CM=001 (count rising edges of primary source)
- PCS=1000 (IP bus clock for best granularity for waveform timing)
- SCS=Any (ignored in this mode)
- ONCE=0 (want to count repeatedly)
- LENGTH=1 (want to count until compare value is reached and re-initialize counter register)
- DIR=Any (user's choice. The compare register values must be chosen carefully to account for things like roll-under, etc.)
- COINIT=0 (user can set this if they need this function)
- OUTMODE=100 (toggle OFLAG output using alternating compare registers)

Timer Status and Control Register (SCTRL)

- OEN = 1 (output enable to allow OFLAG output to be put on an external pin. Set this bit as needed.)
- OPS = Any (user's choice)
- Make sure the rest of the bits are cleared for this register. We will enable interrupts in the comparator status and control register instead of in this register.

Comparator Status and Control Register (CSCTRL)

- TCF2EN=1 (allow interrupt to be issued when CSCTRL[TCF2] is set)
- TCF1EN=0 (do not allow interrupt to be issued when CSCTRL[TCF1] is set)
- TCF1=0 (clear timer compare 1 interrupt source flag. This is set when counter register equals compare register 1 value and OFLAG is low)
- TCF2=0 (clear timer compare 2 interrupt source flag. This is set when counter register equals compare register 2 value and OFLAG is high)
- CL1=10 (load compare register when CSCTRL[TCF2] is asserted)
- CL2=01 (load compare register when CSCTRL[TCF1] is asserted)

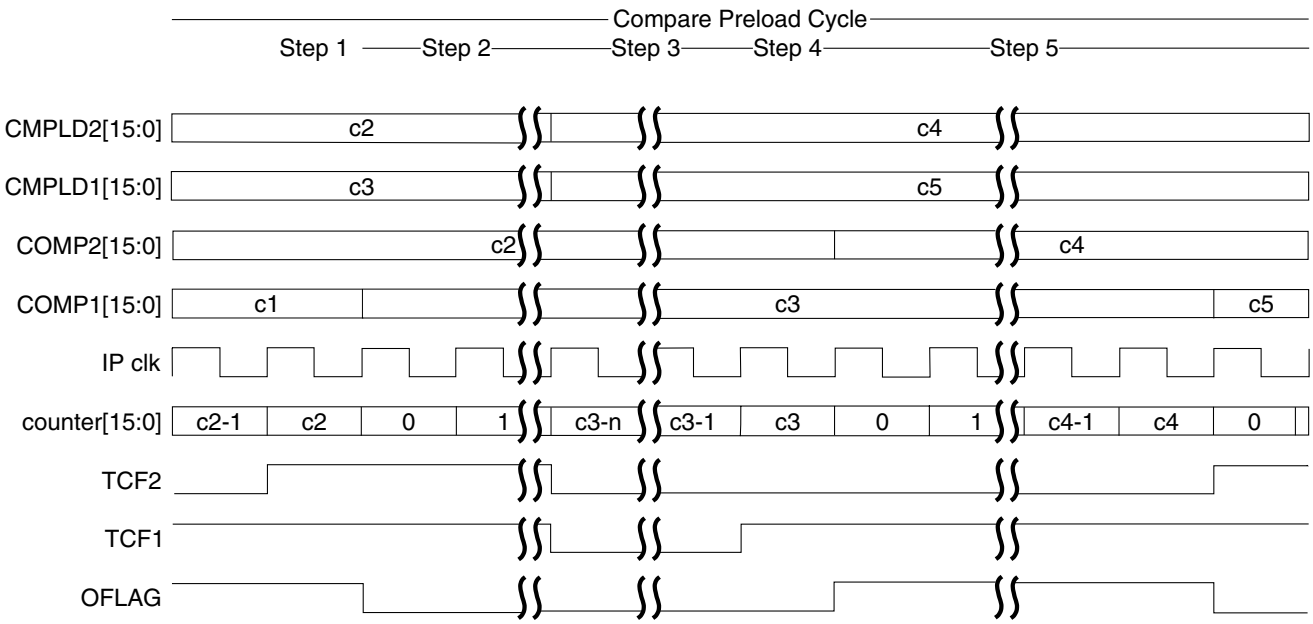
Interrupt Service Routines

To service the CSCTRL[TCF2] interrupts generated by the timer, the interrupt controller must be configured to enable the interrupts for the particular timer being used. Additionally the user will need to write an interrupt service routine to do at a minimum the following:

- Clear CSCTRL[TCF2] and CSCTRL[TCF1] flags.
- Calculate and write new values for both CMPLD1 and CMPLD2.

Timing

This figure contains the timing for using the compare preload feature. The compare preload cycle begins with a compare event on COMP2 causing CSCTRL[TCF2] to be asserted. COMP1 is loaded with the value in the CMPLD1 (c3) one IP bus clock later. In addition an interrupt is asserted by the timer and the interrupt service routine is executed during which both comparator load registers are updated with new values (c4 and c5). When CSCTRL[TCF1] is asserted, COMP2 is loaded with the value in CMPLD2 (c4). And on the subsequent CSCTRL[TCF2] event, COMP1 is loaded with the value in CMPLD1 (c5). The cycle starts over again as an interrupt is asserted and the interrupt service routine clears CSCTRL[TCF1] and CSCTRL[TCF2] and calculates new values for CMPLD1 and CMPLD2.



Step 1-- CNTR matches COMP2 value. CSCTRL[TCF2] is asserted and an interrupt request is generated.

Step 2-- One clock later, OFLAG toggles, CMPLD1 is copied to COMP1, LOAD is copied to CNTR, the counter starts counting.

Step 3-- The interrupt service routine clears CSCTRL[TCF1] and CSCTRL[TCF2] and the ISR loads CMPLD1 and CMPLD2 with the values for the next cycle. The counter continues counting until CNTR matches COMP1.

Step 4-- CSCTRL[TCF1] is asserted. One clock later, OFLAG toggles, CMPLD2 is copied to COMP2, LOAD is copied to CNTR and the counter starts counting.

Step 5--The counter continues counting until CNTR matches COMP2.

Figure 76-8. Compare Load Timing

Example: 76.4.5.14.1 Variable Frequency PWM Mode

```
// This example starts with an 11 msec with a 31 msec cycle.
// Assuming the chip is operating at 60 MHz, the timer use IP_bus_clk/32 as its
//   clock source.
//
// Initial pulse period: 60e6/32 clocks/sec * 31 ms = 58125 total clocks in period
// Initial pulse width: 60e6/32 clocks/sec * 11 ms = 20625 clocks in pulse
//
//
// Once the initial values of COMP1/CMPLD1 and COMP2/CMPLD2 are set the pulse width
//   can be varied by load new values of CMPLD1 and CMPLD2 on each compare interrupt.
//    (See Usage of Compare Load Registers.)
//
void PPG1_Init(void)
{
  setReg(TMR0_LOAD,0);                /* Clear load register */
  setReg(TMR0_CNTR,0);                /* Clear counter */
```

```
  /* TMR0_SCTRL: TCF=0,TCFIE=0,TOF=0,TOFIE=0,IEF=0,IEFIE=0,IPS=0,INPUT=0,
                 Capture_Mode=0,MSTR=0,EEOF=0,VAL=0,FORCE=1,OPS=0,OEN=1 */
  setReg(TMR0_SCTRL,5);                /* Set Status and Control Register */
  // Set compare preload operation and enable an interrupt on compare2 events.
  /* TMR0_CSCTRL: TCF2EN=1,TCF1EN=0,TCF2=0,TCF1=0,CL21=0,CL20=1,CL11=1,CL10=0 */
  setReg(TMR0_CSCTRL,0x86);            /* Set Comparator Status and Control Register */

  setReg(TMR0_COMP1, 20625-1);         /* Set the pulse width of the off time */
  setReg(TMR0_CMPLD1,20625-1);         /* Set the pulse width of the off time */
  setReg(TMR0_COMP2, 58125-20625-1);   /* Set the pulse width of the on time */
  setReg(TMR0_CMPLD2,58125-20625-1);   /* Set the pulse width of the on time */
  /* TMR0_CTRL: CM=1,PCS=0xD,SCS=0,ONCE=0,LENGTH=1,DIR=0,COINIT=0,OUTMODE=4 */
  setRegBits(TMR0_CTRL,0x3A24);        /* Set variable PWM mode and run counter */
}
```

76.4.6 Low Speed Operation

Some applications require that the TMR operate at a very low speed using a clock that is of lower frequency that the system clock frequency. This difference in clock speeds means that the CPU can't access the TMR registers. To accommodate this application the TMR has an input signal called tmr_cnts_freeze that can be used to reload the counter with the contents of the LOAD register and to reset the OFLAG. The software would first set the TMR control registers while the TMR is operating at the system clock speed and then would assert this signal prior to changing the clocks to the TMR. Once the TMR is operating off of a slower clock the tmr_cnts_freeze signal would be de-asserted and the TMR would start counting from a known state using a low speed clock.

76.5 Resets

76.5.1 General

The TMR module can be reset only by the RST_B signal. This forces all registers to their reset state and clears the OFLAG signal if it is asserted. The counter will be turned off until the settings in the control register are changed.

Table 76-2. Reset Summary

Reset	Priority	Source	Characteristics
RST_B	n/a	Hardware Reset	Full System Reset

76.6 Clocks

76.6.1 General

The timer only receives BUS_CLK_ROOT .

76.7 Interrupts

76.7.1 General

The TMR module can generate 20 interrupts, Five for each of the four counters/channels.

Table 76-3. Interrupt Summary

Core Interrupt	Interrupt	Description
TMR Channel 0	TMR0_COMP_IRQ_B	Compare Interrupt Request for Timer Channel 0
	TMR0_COMP1_IRQ_B	Compare 1 Interrupt Request for Timer Channel 0
	TMR0_COMP2_IRQ_B	Compare 2 Interrupt Request for Timer Channel 0
	TMR0_OVF_IRQ_B	Overflow Interrupt Request for Timer Channel 0
	TMR0_EDGE_IRQ_B	Input Edge Interrupt Request for Timer Channel 0
TMR Channel 1	TMR1_COMP_IRQ_B	Compare Interrupt Request for Timer Channel 1
	TMR1_COMP1_IRQ_B	Compare 1 Interrupt Request for Timer Channel 1
	TMR1_COMP2_IRQ_B	Compare 2 Interrupt Request for Timer Channel 1
	TMR1_OVF_IRQ_B	Overflow Interrupt Request for Timer Channel 1
	TMR1_EDGE_IRQ_B	Input Edge Interrupt Request for Timer Channel 1
TMR Channel 2	TMR2_COMP_IRQ_B	Compare Interrupt Request for Timer Channel 2
	TMR2_COMP1_IRQ_B	Compare 1 Interrupt Request for Timer Channel 2
	TMR2_COMP2_IRQ_B	Compare 2 Interrupt Request for Timer Channel 2
	TMR2_OVF_IRQ_B	Overflow Interrupt Request for Timer Channel 2
	TMR2_EDGE_IRQ_B	Input Edge Interrupt Request for Timer Channel 2
TMR Channel 3	TMR3_COMP_IRQ_B	Compare Interrupt Request for Timer Channel 3
	TMR3_COMP1_IRQ_B	Compare 1 Interrupt Request for Timer Channel 3
	TMR3_COMP2_IRQ_B	Compare 2 Interrupt Request for Timer Channel 3
	TMR3_OVF_IRQ_B	Overflow Interrupt Request for Timer Channel 3
	TMR3_EDGE_IRQ_B	Input Edge Interrupt Request for Timer Channel 3

76.7.2 Description of Interrupt Operation

76.7.2.1 Timer Compare Interrupts

These interrupts are generated when a successful compare occurs between a counter and it's compare registers while SCTRL[TCFIE] is set. These interrupts are cleared by writing a zero to the appropriate SCTRL[TCF].

When a timer compare interrupt is set in TMR_SCTRL and the Compare Load registers are available, one of the following two interrupts will also be asserted.

76.7.2.1.1 Timer Compare 1 Interrupts (Available with Compare Load Feature)

These interrupts are generated when a successful compare occurs between a counter and its COMP1 register while CSCTRL[TCF1EN] is set. These interrupts are cleared by writing a zero to the appropriate CSCTRL[TCF1].

76.7.2.1.2 Timer Compare 2 Interrupts (Available with Compare Load Feature)

These interrupts are generated when a successful compare occurs between a counter and its COMP2 register while CSCTRL[TCF2EN] is set. These interrupts are cleared by writing a zero to the appropriate CSCTRL[TCF2].

76.7.2.2 Timer Overflow Interrupts

These interrupts are generated when a counter rolls over its maximum value while SCTRL[TOFIE] is set. These interrupts are cleared by writing zero to the appropriate SCTRL[TOF].

76.7.2.3 Timer Input Edge Interrupts

These interrupts are generated by a transition of the input signal (either positive or negative depending on IPS setting) while SCTRL[IEFIE] is set. These interrupts are cleared by writing a zero to the appropriate SCTRL[IEF].

76.8 DMA

The TMR module can generate twelve DMA requests: three for each of the four counters/channels. Refer to the following table.

Table 76-4. DMA Summary

DMA Request	DMA Enable	Description
Channels 0-3	DMA[IEFDE]	CAPT contains a value
	DMA[CMPLD1DE]	CMPLD1 needs an update
	DMA[CMPLD2DE]	CMPLD2 needs an update

76.9 Memory map/register definition

76.9.1 TMR register descriptions

The address of a register is the sum of a base address and an address offset. The base address is defined at the chip level and the address offset is defined at the module level. Make certain to check which quad timer is available on the chip being used, and which timer channels have external I/O.

76.9.1.1 TMR memory map

TMR1 base address: 4015_C000h

TMR2 base address: 4016_0000h

TMR3 base address: 4016_4000h

TMR4 base address: 4016_8000h

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)
0	Timer Channel Compare Register 1 (COMP10)	16	RW	0000
1	Timer Channel Compare Register 2 (COMP20)	16	RW	0000

76.9.1.8.3 Fields

Field	Description
15-13 CM	Count Mode These bits control the basic counting and behavior of the counter. 000 - No operation 001 - Count rising edges of primary source[1] 010 - Count rising and falling edges of primary source[2] 011 - Count rising edges of primary source while secondary input high active 100 - Quadrature count mode, uses primary and secondary sources 101 - Count rising edges of primary source; secondary source specifies direction[3] 110 - Edge of secondary source triggers primary count until compare 111 - Cascaded counter mode (up/down)[4]
12-9 PCS	Primary Count Source These bits select the primary count source. **NOTE:** A timer selecting its own output for input is not a legal choice. The result is no counting. 0000 - Counter 0 input pin 0001 - Counter 1 input pin 0010 - Counter 2 input pin 0011 - Counter 3 input pin

Table continues on the next page...

Field	Description
	0100 - Counter 0 output 0101 - Counter 1 output 0110 - Counter 2 output 0111 - Counter 3 output 1000 - IP bus clock divide by 1 prescaler 1001 - IP bus clock divide by 2 prescaler 1010 - IP bus clock divide by 4 prescaler 1011 - IP bus clock divide by 8 prescaler 1100 - IP bus clock divide by 16 prescaler 1101 - IP bus clock divide by 32 prescaler 1110 - IP bus clock divide by 64 prescaler 1111 - IP bus clock divide by 128 prescaler
8-7 SCS	Secondary Count Source These bits identify the external input pin to be used as a count command or timer command. The selected input can trigger the timer to capture the current value of CNTR . The selected input can also be used to specify the count direction. The selected signal can also be used as a fault input when CSCTRL[FAULT] is set. The polarity of the signal can be inverted by SCTRL[IPS]. 00 - Counter 0 input pin 01 - Counter 1 input pin 10 - Counter 2 input pin 11 - Counter 3 input pin
6 ONCE	Count Once This bit selects continuous or one shot counting mode. 0 - Count repeatedly. 1 - Count until compare and then stop. If counting up, a successful compare occurs when the counter reaches a COMP1 value. If counting down, a successful compare occurs when the counter reaches a COMP2 value. When output mode $4 is used, the counter re-initializes after reaching the COMP1 value, continues to count to the COMP2 value, and then stops.
5 LENGTH	Count Length This bit determines whether the counter: • counts to the compare value and then re-initializes itself to the value specified in the LOAD (or CMPLD2) register, or • continues counting past the compare value to the binary roll over. 0 - Count until roll over at $FFFF and then continue by re-initializing the counter from the LOAD register. 1 - Count until compare, then re-initialize using the LOAD register. If counting up, a successful compare occurs when the counter reaches a COMP1 value. If counting down, a successful compare occurs when the counter reaches a COMP2 value. When output mode $4 is used, alternating values of COMP1 and COMP2 are used to generate successful comparisons. For example, the counter counts until a COMP1 value is reached, re-initializes, counts until COMP2 value is reached, re-initializes, counts until COMP1 value is reached, and so on.
4 DIR	Count Direction This bit selects either the normal count direction up, or the reverse direction, down. 0 - Count up.

Table continues on the next page...

Field	Description
	1 - Count down.
3 COINIT	Co-Channel Initialization This bit enables another counter/timer within the module to force the re-initialization of this counter/timer when it has an active compare event. 0 - Co-channel counter/timers cannot force a re-initialization of this counter/timer 1 - Co-channel counter/timers may force a re-initialization of this counter/timer
2-0 OUTMODE	Output Mode These bits determine the mode of operation for the OFLAG output signal. 000 - Asserted while counter is active 001 - Clear OFLAG output on successful compare 010 - Set OFLAG output on successful compare 011 - Toggle OFLAG output on successful compare 100 - Toggle OFLAG output using alternating compare registers 101 - Set on compare, cleared on secondary source input edge 110 - Set on compare, cleared on counter rollover 111 - Enable gated clock output while counter is active

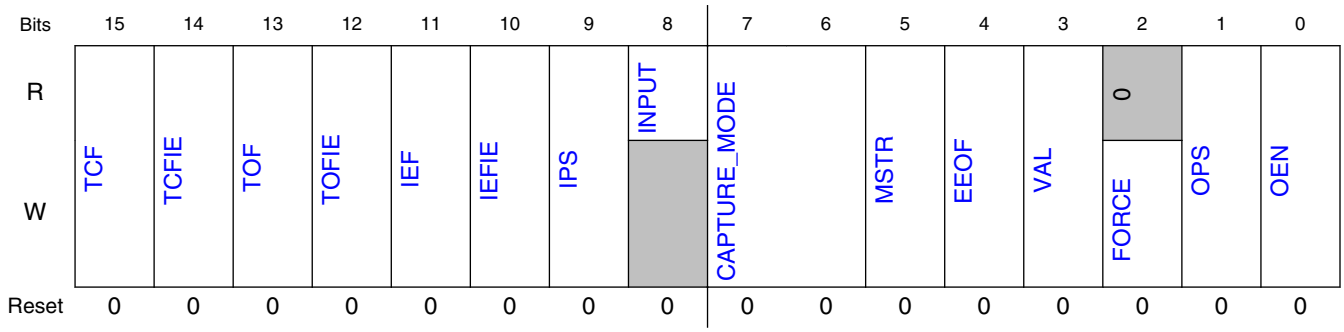
1. Rising edges are counted only when SCTRL[IPS] = 0. Falling edges are counted when SCTRL[IPS] = 1. If the primary count source is IP bus clock divide by 1, only rising edges are counted regardless of the value of SCTRL[IPS].
2. IP bus clock divide by 1 cannot be used as a primary count source in edge count mode.
3. Rising edges are counted only when SCTRL[IPS] = 0. Falling edges are counted when SCTRL[IPS] = 1.
4. The primary count source must be set to one of the counter outputs.

76.9.1.9 Timer Channel Status and Control Register (SCTRL0 - SCTRL3)

76.9.1.9.1 Offset

Register	Offset
SCTRL0	7h
SCTRL1	17h
SCTRL2	27h
SCTRL3	37h

76.9.1.9.2 Diagram



76.9.1.9.3 Fields

Field	Description
15 TCF	Timer Compare Flag This bit is set when a successful compare occurs. This bit is cleared by writing a zero to this bit location.
14 TCFIE	Timer Compare Flag Interrupt Enable This bit (when set) enables interrupts when TCF is set.
13 TOF	Timer Overflow Flag This bit is set when the counter rolls over its maximum value $FFFF or $0000 (depending on count direction). This bit is cleared by writing a zero to this bit location.
12 TOFIE	Timer Overflow Flag Interrupt Enable This bit (when set) enables interrupts when TOF is set.
11 IEF	Input Edge Flag This bit is set when CAPTMODE is enabled and a proper input transition occurs (on an input selected as a secondary count source) while the count mode does not equal 000. This bit is cleared by writing a zero to this bit position. This bit can also be cleared automatically by a read of CAPT when DMA[IEFDE] is set. **NOTE:** Setting the input polarity select bit (IPS) changes the edge to be detected. Also, the control register's secondary count source determines which external input pin is monitored by the detection circuitry.
10 IEFIE	Input Edge Flag Interrupt Enable This bit (when set) enables interrupts when IEF is set. **Restriction:** Do not set both this bit and DMA[IEFDE].
9 IPS	Input Polarity Select This bit (when set) inverts the input signal polarity.
8 INPUT	External Input Signal This read-only bit reflects the current state of the external input pin selected via the secondary count source after application of IPS and filtering.
7-6 CAPTURE_MODE	Input Capture Mode These bits specify the operation of the capture register as well as the operation of the input edge flag. The input source is the secondary count source. 00 - Capture function is disabled

Table continues on the next page...

Field	Description
	01 - Load capture register on rising edge (when IPS=0) or falling edge (when IPS=1) of input 10 - Load capture register on falling edge (when IPS=0) or rising edge (when IPS=1) of input 11 - Load capture register on both edges of input
5 MSTR	Master Mode This bit (when set) enables the compare function's output to be broadcasted to the other counters/timers in the module. This signal then can be used to re-initialize the other counters and/or force their OFLAG signal outputs.
4 EEOF	Enable External OFLAG Force This bit (when set) enables the compare from another counter/timer within the same module to force the state of this counter's OFLAG output signal.
3 VAL	Forced OFLAG Value This bit determines the value of the OFLAG output signal when software triggers a FORCE command.
2 FORCE	Force OFLAG Output This write only bit forces the current value of VAL to be written to the OFLAG output. This bit always reads as a zero. VAL and FORCE can be written simultaneously in a single write operation. Write to FORCE only if the counter is disabled. Setting this bit while the counter is enabled may yield unpredictable results.
1 OPS	Output Polarity Select This bit determines the polarity of the OFLAG output signal. 0 - True polarity. 1 - Inverted polarity.
0 OEN	Output Enable This bit determines the direction of the external pin. 0 - The external pin is configured as an input. 1 - The OFLAG output signal is driven on the external pin. Other timer groups using this external pin as their input see the driven value. The polarity of the signal is determined by OPS.

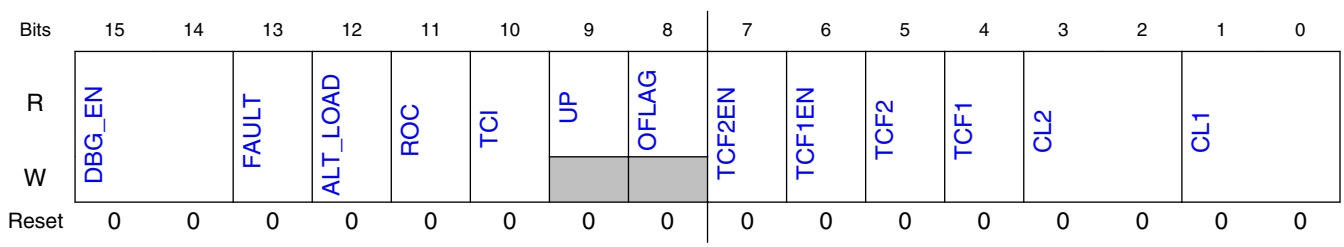
76.9.1.12.2 Diagram



76.9.1.12.3 Fields

Field	Description
15-14 DBG_EN	Debug Actions Enable These bits allow the TMR module to perform certain actions in response to the chip entering debug mode. 00 - Continue with normal operation during debug mode. (default) 01 - Halt TMR counter during debug mode. 10 - Force TMR output to logic 0 (prior to consideration of SCTRL[OPS]).

Table continues on the next page...

Field	Description
	11 - Both halt counter and force output to 0 during debug mode.
13 FAULT	Fault Enable The selected secondary input acts as a fault signal so that the timer OFLAG is cleared when the secondary input is set. When the secondary input is used in this mode, there is no resynchronization of the input so that there is a combinational path to clear the OFLAG. Fault inputs less than two clock periods wide will not be latched. Latched faults will be cleared the next time that the counter logic sets the OFLAG. 0 - Fault function disabled. 1 - Fault function enabled.
12 ALT_LOAD	Alternative Load Enable This bit allows for an alternative method for loading the counter during modulo counting. Normally, the counter can be loaded only with the value from the LOAD register. When this bit is set, the counter is loaded from the LOAD register when counting up and a match with COMP1 occurs, or the counter is loaded from the CMPLD2 register when counting down and a match with COMP2 occurs. 0 - Counter can be re-initialized only with the LOAD register. 1 - Counter can be re-initialized with the LOAD or CMPLD2 registers depending on count direction.
11 ROC	Reload on Capture This bit enables the capture function to cause the counter to be reloaded from the LOAD register. 0 - Do not reload the counter on a capture event. 1 - Reload the counter on a capture event.
10 TCI	Triggered Count Initialization Control This bit is used during triggered count mode, CTRL[CM] = 110, to enable the counter to be re-initialized when a second trigger occurs while the counter is still counting. Normally, the second trigger causes the counting to stop/pause until a third trigger occurs. With this bit set, a second trigger event causes the counter to re-initialize and continue counting. 0 - Stop counter upon receiving a second trigger event while still counting from the first trigger event. 1 - Reload the counter upon receiving a second trigger event while still counting from the first trigger event.
9 UP	Counting Direction Indicator This read-only bit is used during quadrature count mode, CTRL[CM] = 100, to read the direction of the last count. CTRL[DIR] reverses the sense of this bit. 0 - The last count was in the DOWN direction. 1 - The last count was in the UP direction.
8 OFLAG	Output flag This read only bit shows the state of the Timer's internal OFLAG signal prior to consideration of polarity or debug mode.
7 TCF2EN	Timer Compare 2 Interrupt Enable An interrupt is issued when both this bit and TCF2 are set.
6 TCF1EN	Timer Compare 1 Interrupt Enable An interrupt is issued when both this bit and TCF1 are set.
5 TCF2	Timer Compare 2 Interrupt Flag When set, this bit indicates a successful comparison of the timer and the the COMP2 register has occurred. This bit is sticky, and will remain set until explicitly cleared by writing a zero to this bit location.
4	Timer Compare 1 Interrupt Flag

Table continues on the next page...

Field	Description
TCF1	When set, this bit indicates a successful comparison of the timer and the the COMP1 register has occurred. This bit is sticky, and will remain set until explicitly cleared by writing a zero to this bit location.
3-2 CL2	Compare Load Control 2 These bits control when COMP2 is preloaded with the value from CMPLD2. 00 - Never preload 01 - Load upon successful compare with the value in COMP1 10 - Load upon successful compare with the value in COMP2 11 - Reserved
1-0 CL1	Compare Load Control 1 These bits control when COMP1 is preloaded with the value from CMPLD1. 00 - Never preload 01 - Load upon successful compare with the value in COMP1 10 - Load upon successful compare with the value in COMP2 11 - Reserved

76.9.1.13 Timer Channel Input Filter Register (FILT0 - FILT3)

The FILT register programs the values for the filtering of the corresponding input without regard for the fact that any timer channel can use the input as a count source.

Input filter considerations:

- Set the FILT_PER value such that the sampling period is larger than the period of the expected noise. In this way, a noise spike will corrupt only one sample. Choose the FILT_CNT value to reduce the probability that noisy samples cause an incorrect transition to be recognized. The probability of an incorrect transistion is defined as the probability of an incorrect sample raised to the power of (FILT_CNT + 3).
- The values of FILT_PER and FILT_CNT must also be balanced against the desire for minimal latency in recognizing input transitions. Turning on the input filter (setting FILT_PER to a non-zero value) introduces a latency of (((FILT_CNT + 3) x FILT_PER) + 2) IP bus clock periods.

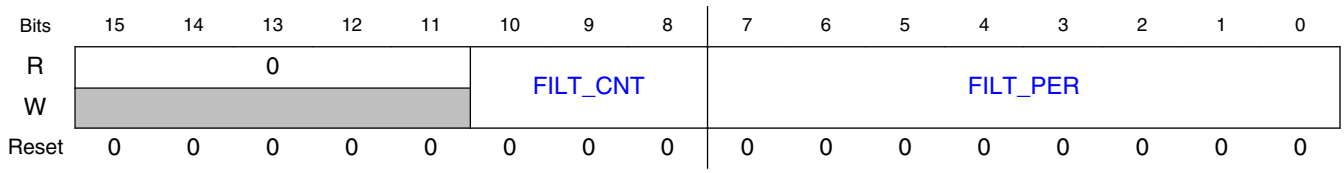
76.9.1.13.1 Offset

Register	Offset
FILT0	Bh
FILT1	1Bh

Table continues on the next page...

Register	Offset
FILT2	2Bh
FILT3	3Bh

76.9.1.13.2 Diagram



76.9.1.13.3 Fields

Field	Description
15-11 —	RESERVED
10-8 FILT_CNT	Input Filter Sample Count These bits represent the number of consecutive samples that must agree prior to the input filter accepting an input transition. A value of 0x0 represents 3 samples. A value of 0x7 represents 10 samples. The value of FILT_CNT affects the input latency.
7-0 FILT_PER	Input Filter Sample Period These bits represent the sampling period (in IP bus clock cycles) of the TMR input signals. Each input is sampled multiple times at the rate specified by this field. If FILT_PER is 0x00 (default), then the input filter is bypassed. The value of FILT_PER affects the input latency. When changing values for FILT_PER from one non-zero value to another non-zero value, write a value of zero first to clear the filter.

76.9.1.14 Timer Channel DMA Enable Register (DMA0 - DMA3)

76.9.1.14.1 Offset

Power management	PMU	Power Management Power Management Unit
Signal multiplexing	IOMUX	External Signals and Pin Multiplexing IOMUX
Interrupts, DMA Events and XBAR Assignments	-	Interrupts, DMA Events and XBAR Assignments

77.2 Overview

QDC interfaces to position and speed sensors used in industrial motor control applications. QDC uses the following five input signals from those position and speed sensors to decode shaft position, revolution count, and speed:

- PHASEA
- PHASEB
- INDEX
- TRIGGER
- HOME

77.2.1 Block diagram

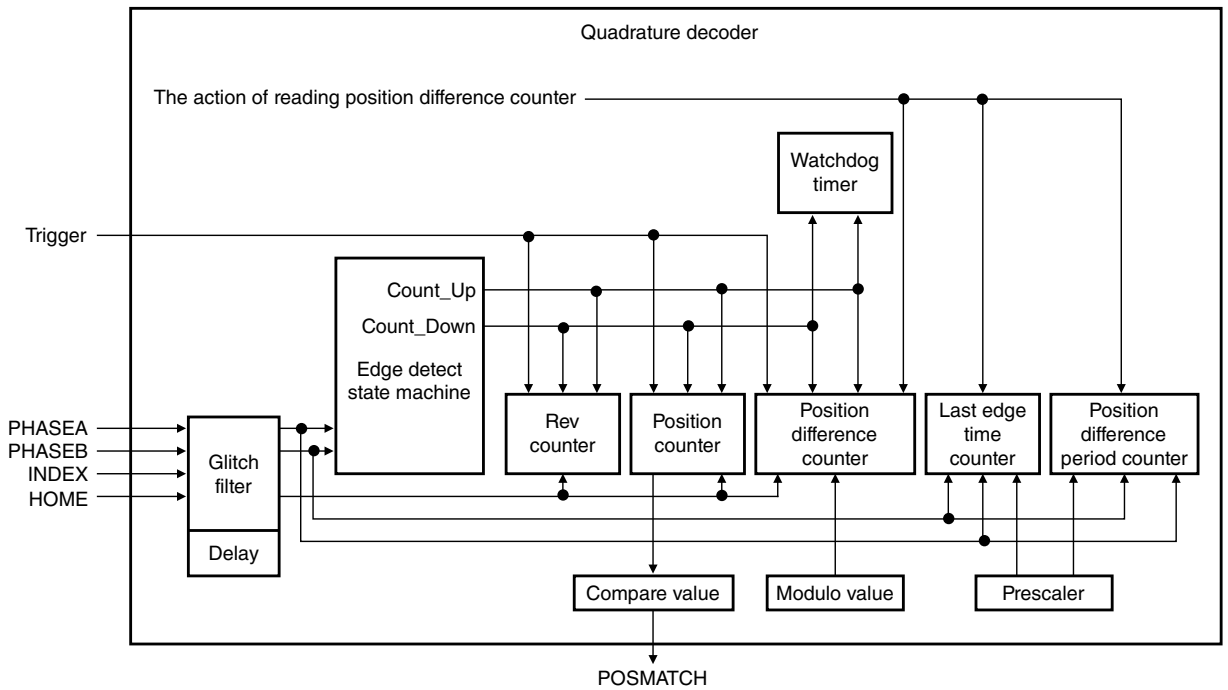

Figure 77-1. QDC block diagram

77.2.2 Features

- Logic to decode quadrature signals
- Inputs that you could connect to a general purpose timer to perform low-speed velocity measurements
- Digital filter for inputs that you could configure according to your requirements
- Quadrature decoder filter that can be bypassed
- 32-bit position counter capable of modulo counting
- Position counter that you, or external events, could initialize
- 16-bit position difference register
- Compare function to indicate when the shaft has reached a defined position
- Watchdog timer to detect a non-rotating shaft condition
- 16-bit revolution counter that could be preloaded
- Maximum count frequency that equals the peripheral clock rate
- Availability of an optional interrupt when both PHASEA and PHASEB inputs change in the same cycle

77.2.3 Decoder Block Diagram

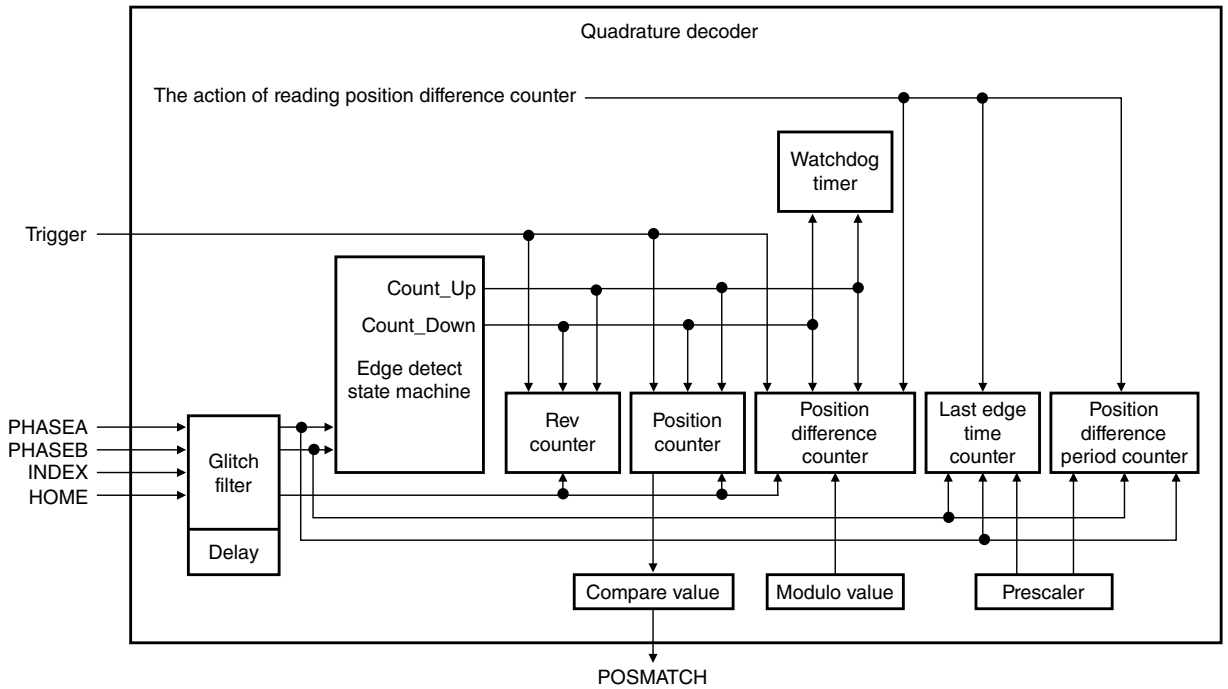

Figure 77-2. Quadrature Decoder Block Diagram

77.2.3.1 Glitch filter

The quadrature decoder logic must sense signal transitions, and the signal inputs first run through a glitch filter. This glitch filter has a digital delay line, which samples multiple time points on the signal and verifies a stable new signal state before outputting this new signal state to the internal quadrature decoder logic. To adapt to a variety of signal bandwidths, the sample rate of this delay line is programmable.

77.2.3.2 Edge detect state machine

The edge detect state machine looks for changes in the four possible states of the filtered PHASEA and PHASEB inputs, which calculates the direction of motion. Format this information as Count_Up and Count_Down signals. Each counter includes its hold register. These signals route into up to three up/down counters:

- Position counter
- Revolution counter
- Position difference counter

77.2.3.3 Position counter

The 32-bit position counter calculates up or down on every count pulse, which the difference between PHASEA and PHASEB generates. The position counter acts as integration information, whose count value is proportional to position. Count_Up and Count_Down signals determine the direction of the count. You may initialize the position counters to a predetermined value by one of 4 different methods:

- Software-triggered event
- INDEX signal transition
- HOME signal transition
- Rising edge of a trigger event

You can program the INDEX and HOME signals to interrupt the processor. Whenever you read the position counters (Upper Position Counter (UPOS) or Lower Position Counter (LPOS)), a snapshot of the following counters are placed into their respective hold registers:

- Position counter
- Position difference counter (only if CTRL3[PMEN] is 0)
- Revolution counter

77.2.3.4 Position difference counter

The 16-bit position difference counter contains the position difference value occurring between each read of the position register. The position register counts up or down on every count pulse. The position difference counter acts as a differentiator whose count value is proportional to the change in position since the last time the position counter was read.

When you read the position registers, the position difference counter, or the revolution counter, the contents of Position Difference Counter (POSD) are copied into Position Difference Hold (POSDH), and the position difference counter becomes 0.

If CTRL3[PMEN] is 1, a read of the position difference counter, and not a read of the revolution counter or position counters, updates the position difference counter and its hold register.

77.2.3.5 Position difference counter hold

Position Difference Hold (POSDH) stores a copy of the position difference counter when you read the position register. When you read the position register, the position difference counter, or the revolution counter, the position difference counter's contents are copied into Position Difference Hold (POSDH), and the position difference counter becomes 0.

If CTRL3[PMEN] is 1, a read of the position difference counter, and not a read of the revolution counter or position counters, updates Position Difference Hold (POSDH).

77.2.3.6 Revolution counter

The 16-bit up/down revolution counter counts or integrate revolutions by counting index pulses. Determine the direction of the count by the Count_Up and Count_Down signals, determined by the Phase A and B inputs. A different count direction on the rising and falling edges of the index pulse indicates that the quad encoder changed direction on the index pulse.

77.2.3.7 Watchdog timer

The watchdog timer ensures that the algorithm indicates motion in the shaft. Two successive counts indicate proper operation and reset the timer.

- The timeout value is programmable.
- When a timeout occurs, you can generate an interrupt to the processor.

77.2.3.8 Pulse accumulator functionality

You can program the logic to integrate only selected transitions of the PHASEA signal. This way, you can use the position counter as a pulse accumulator.

- The count direction is up.
- The INDEX input can optionally initialize the pulse accumulator.

77.2.3.9 Last edge time counter

The 16-bit last edge time counter contains the time since the last edge on PHASEA or PHASEB. The last edge time counter counts up on every prescaled clock pulse.

When you read the position difference counter, copy the content of LASTEDGE[LASTEDGE] into Last Edge Time Hold (LASTEDGEH).

77.2.3.10 Position difference period counter

The position difference period counter:

- Contains the accumulated time from the last time you read the position difference counter.

- Counts up on every prescaled clock pulse.
- Loads from the last edge time counter whenever you read the position difference register.

77.3 Functional description

The following timing diagram shows the basic operation of an incremental position QDC.

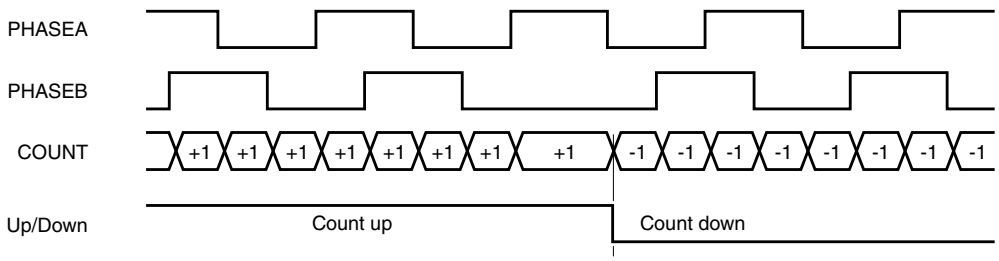

Figure 77-3. QDC signals

77.3.1 Positive versus negative direction

A typical quad encoder has three outputs: PHASEA signal, PHASEB signal, and INDEX pulse (not shown).

- If PHASEA leads PHASEB, then motion is in the positive direction.
- If PHASEA trails PHASEB, then motion is in the negative direction.

You can integrate the transitions on these phases to yield position or differentiate to yield velocity. Design the QDC to perform these functions in hardware.

77.3.2 Holding Registers and Initializing Registers

Hold registers are associated with 3 types of counters:

- Position
- Position difference
- Revolution

When any of the counter registers are read, the contents of each counter register is written to the corresponding hold register. Taking a snapshot of the counters' values allows a consistent view of a system's position and the velocity to be attained. If CTRL3[PMEN] is set, then the POSDH register will only be updated when the POSD counter is read and not when other counters are read. To capture a time stamp of when these registers are read, use the POSMATCH output with a timer channel.

The position counter is 32 bits wide. To ensure that the position counter can be reliably initialized with two 16-bit accesses, two registers (an upper and a lower initialization register) are provided. The upper initialization register (UINIT) and lower initialization register (LINIT) should be loaded with the desired value. Next, the position counter can be loaded by writing 1 to the Software-Triggered Initialization of Position Counters UPOS and LPOS bit (CTRL[SWIP]). Alternatively, either the INDEX-Triggered Initialization of Position Counters UPOS and LPOS bit (CTRL[XIP]) or the Enable HOME to Initialize Position Counters UPOS and LPOS bit (CTRL[HIP]) can enable the position counter to be initialized in response to a HOME or INDEX signal transition.

77.3.3 Speed measurement method

This section explains the speed measurement method. It includes a speed measurement algorithm.

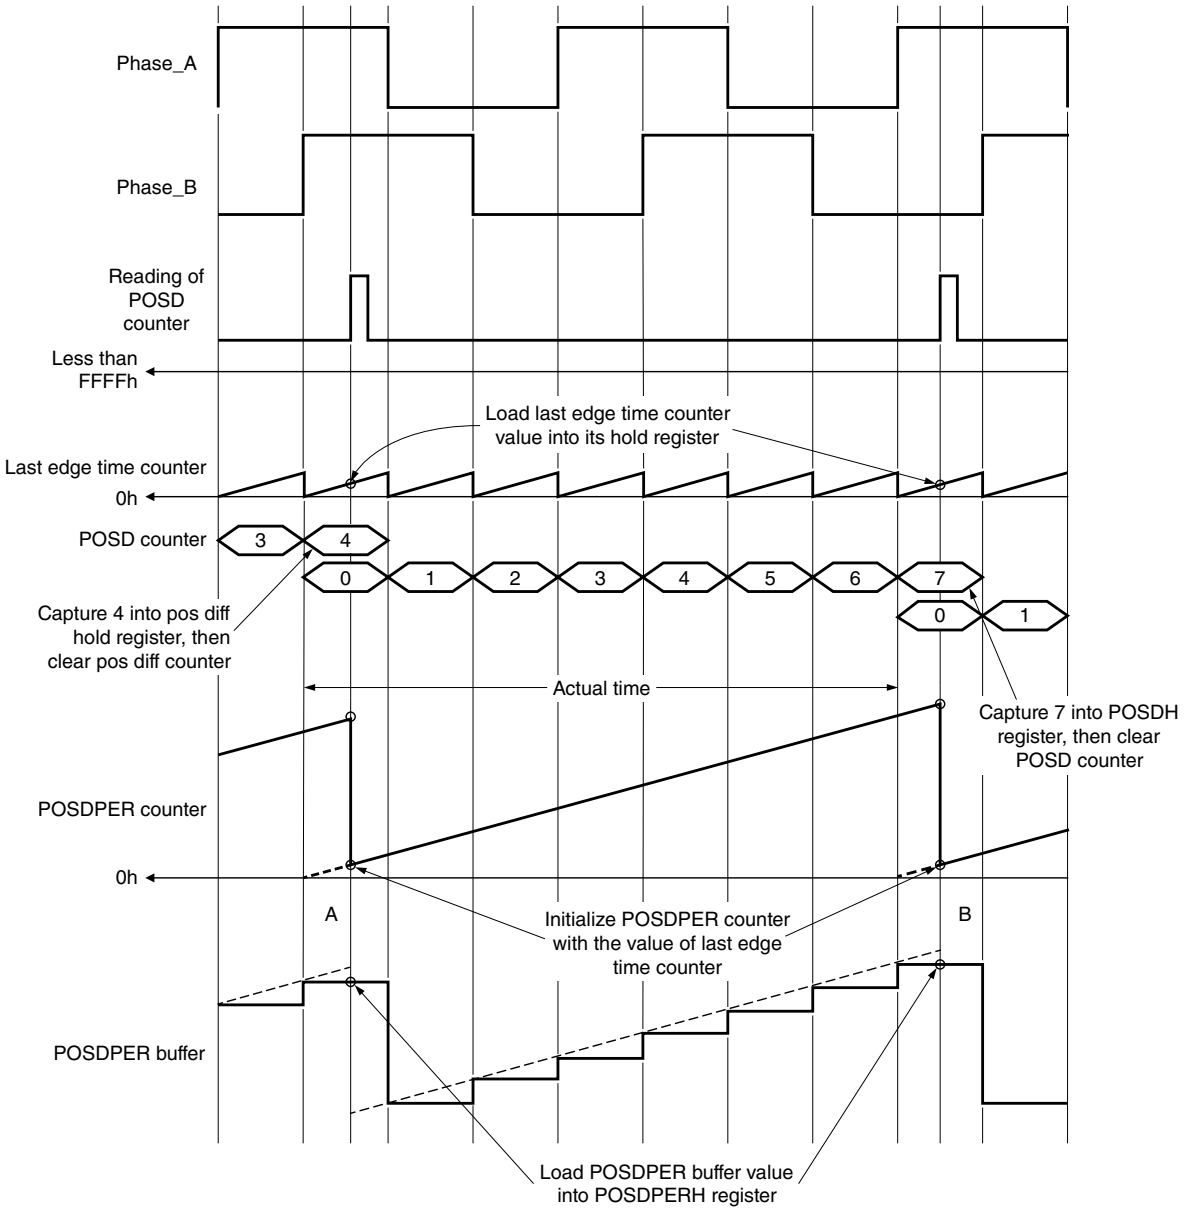

Figure 77-4. Counters behavior and updating mechanism

Reading of Position Difference Counter (POSD) occurs at time point A and time point B. “Actual time” represents the time duration between the first phase_a/b edges right before time points A and B. At time point B, after reading Position Difference Counter (POSD), Position Difference Period Hold (POSDPERH) contains the time length of “Actual time” and Position Difference Hold (POSDH) includes the value of phase_a/b pulses within that “Actual time”. You can calculate the speed based on Position Difference Period Hold (POSDPERH) and Position Difference Hold (POSDH). The following figure shows a visualized explanation of speed measurement with this method:

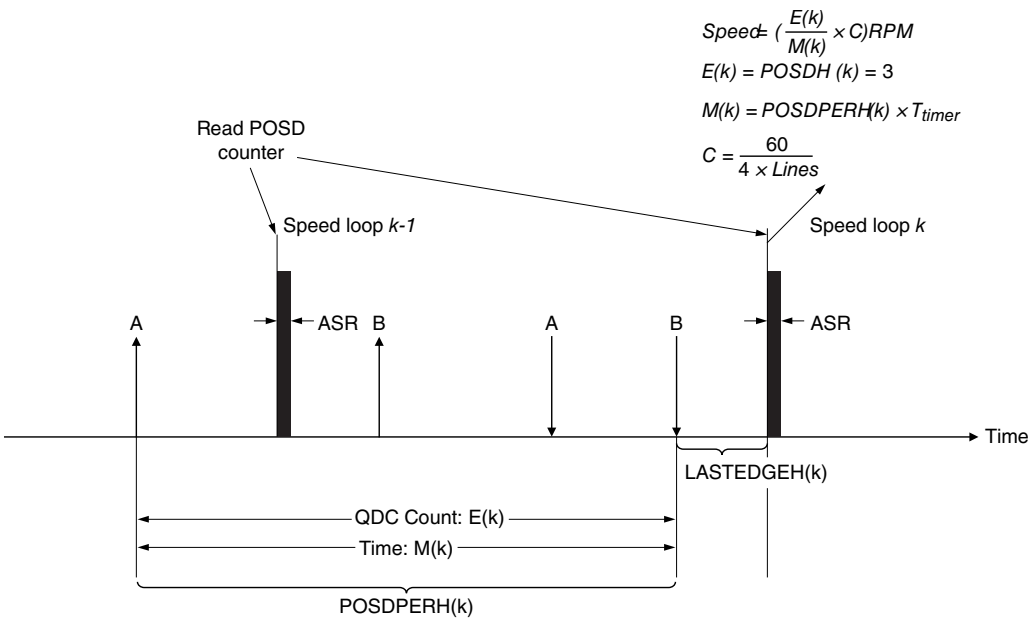

Figure 77-5. High speed measurement with method

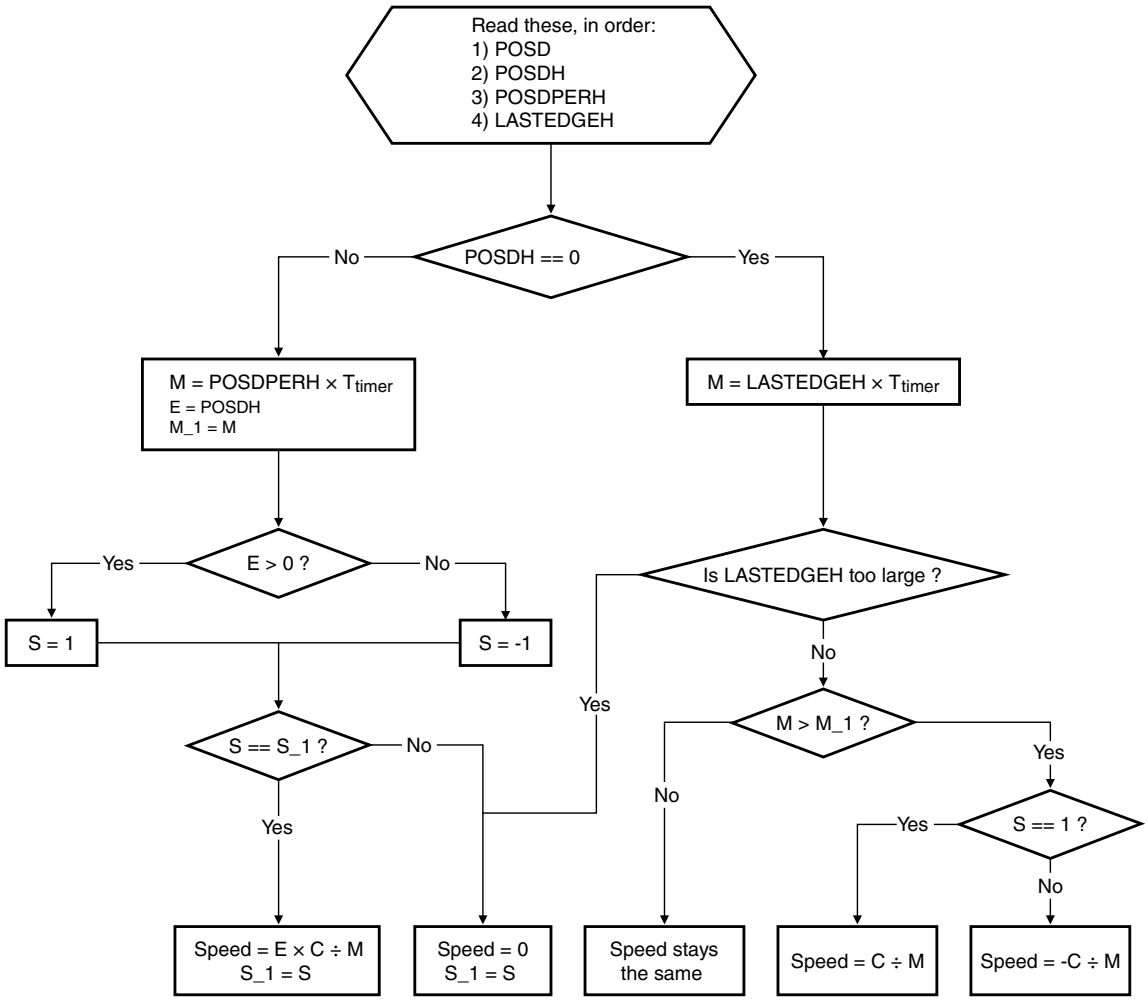
77.3.3.1 Speed calculation algorithm

However, to cover all the cases in real applications, a simple speed measurement algorithm is necessary. The following figure shows the speed measurement algorithm.



S: Indicates whether E = 0 in this POSD reading operation. If E = 0, then S = -1. If E > 0, then S = 1.
S_1: Indicates whether E = 0 in the previous POSD reading operation. If E=0, then S = -1. If E > 0, then S=1.
M: Indicates the M value in this POSD reading operation.
M_1: Indicates the M value in the previous POSD reading operation.

77.4 Memory map and registers

This section describes the module memory map and registers.

77.4.1 QDC register descriptions

The address of a register is the sum of a base address and an address offset.

- Base address is defined at the MCU level
- Address offset is defined at the module level

For the base address, see the chip-specific documentation. All memory locations base and offsets are given in hex.

77.4.1.1 QDC memory map

ENC1 base address: 4017_4000h

ENC2 base address: 4017_8000h

ENC3 base address: 4017_C000h

ENC4 base address: 4018_0000h

Offset	Register	Width (In bits)	Access	Reset value

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

77.4.1.2.4 Fields

Field	Function
15 HIRQ	HOME Signal Transition Interrupt Request Specifies whether a transition has occurred on the HOME signal. This field becomes 1 when a HOME signal transitions, according to CTRL[HNE]. If this field and CTRL[HIE] are 1, then a HOME interrupt occurs. 0b - Not occurred 1b - Occurred
14 HIE	HOME Interrupt Enable Enables or disables HOME signal interrupts. 0b - Disable 1b - Enable
13 HIP	Enable HOME to Initialize Position Counters UPOS and LPOS Enables the position counter, which the HOME signal initializes. 0b - No action 1b - HOME signal initializes the position counter
12 HNE	Use Negative Edge of HOME Input Selects using the positive and negative edge of the HOME input. 0b - Use positive-going edge-to-trigger initialization of position counters UPOS and LPOS 1b - Use negative-going edge-to-trigger initialization of position counters UPOS and LPOS
11 SWIP	Software-Triggered Initialization of Position Counters UPOS and LPOS Specifies that writing 1 to this field transfers the Upper Initialization (UINIT) and Lower Initialization (LINIT) contents to Upper Position Counter (UPOS) and Lower Position Counter (LPOS) (thereby initializing those counters). 0b - No action 1b - Initialize position counter
10 REV	Enable Reverse Direction Counting Selects the direction of the count (how you interpret the quadrature signal). 0b - Counts normally 1b - Counts in the reverse direction
9 PH1	Enable Signal Phase Count Mode Bypasses or uses the quadrature decoder logic. 0b - Uses the standard quadrature decoder, where PHASEA and PHASEB represent a two-phase quadrature signal.

Table continues on the next page...

Field	Function
	1b - Bypasses the quadrature decoder. A positive transition of the PHASEA input generates a count signal. PHASEB input and CTRL[REV] controls the counter direction. If the value of CTRL[REV] and PHASEB are identical; then count is up. If the value of CTRL[REV] and PHASEB is different, then count is down.
8 XIRQ	INDEX Pulse Interrupt Request Specifies whether the INDEX pulse has occurred. This field becomes 1 when a transition on the INDEX signal occurs, according to the use negative edge of CTRL[XNE]. If this field and CTRL[XIE] become 1, then an INDEX interrupt occurs. 0b - Not occurred 1b - Occurred
7 XIE	INDEX Pulse Interrupt Enable Enables or disables INDEX pulse interrupts. 0b - Disable 1b - Enable
6 XIP	INDEX Triggered Initialization of Position Counters UPOS and LPOS Enables or disables the position counter that the INDEX pulse initializes. 0b - Does not initialize 1b - Initializes
5 XNE	Select Positive and Negative Edge of INDEX Pulse Selects the positive and negative edge of the INDEX pulse. 0b - Use positive edge 1b - Use negative edge
4 DIRQ	Watchdog Timeout Interrupt Request Specifies whether the watchdog timeout interrupt has occurred. This field also becomes 0 when CTRL[WDE] = 0. 0b - Not occurred 1b - Occurred
3 DIE	Watchdog Timeout Interrupt Enable Enables or disables the watchdog timeout interrupts. 0b - Disable 1b - Enable
2 WDE	Watchdog Enable Enables or disables the watchdog timer that monitors the PHASEA and PHASEB inputs for motor movement. 0b - Disable 1b - Enable
1 CMPIRQ	Compare Interrupt Request Specifies whether the COMP match has occurred. This field becomes 1 when the counter matches the COMP value. 0b - No match has occurred 1b - COMP match has occurred
0 CMPIE	Compare Interrupt Enable Enables the compare interrupt. 0b - Disable 1b - Enable

77.4.1.3 Input Filter (FILT)

77.4.1.3.1 Offset

Register	Offset
FILT	1h

77.4.1.3.2 Function

Specifies:

- The input filter sample period.
- The filter sample count.

Choose FILT[FILT_PER] such that the sampling period is larger than the period of the expected noise. Doing this means that a noise spike will only corrupt one sample.

Choose FILT[FILT_CNT] to reduce the probability of noisy samples causing an incorrect transition to be recognized. The probability of an incorrect transition is defined as the probability of an incorrect sample raised to the power of FILT_CNT+3.

You must also trade off the values of FILT[FILT_PER] and FILT[FILT_CNT] against the need for minimal latency in recognizing valid input transitions. Turning on the input filter (write a non-zero value to FILT[FILT_PER]) introduces a latency of ((FILT[FILT_CNT] + 3)×FILT[FILT_PER]) FILT clock cycles + 2 IPBus clock periods.

You can measure the filter latency:

- Drive the quadrature decoder inputs (PHASEA, PHASEB, INDEX, HOME).
- Monitor the filtered output in Input Monitor (IMR).
- Determine how many IPBus clock cycles it takes before the output shows up, using the following equations, where f is FILT[FILT_PER], and s is FILT[FILT_CNT].
  - DELAY = f×(s+3)(FILT clock cycles) + 1 (IPBus clock cycles)(to read the filtered output)
  - DELAY = f×(s+3)(FILT clock cycles) + 2 (IPBus clock cycles) (to monitor the output in the IMR)

One additional IPBus clock cycle is required to read the filtered output, and two more IPBus clock cycles are required to monitor the filtered output in Input Monitor (IMR). The sample rate sets when it reaches the number f. The following examples use the preceding equations:

- Example: when f = 0, the filter is bypassed: DELAY = 1 or 2 clock cycles.
- Example: when f = 5 and s = 2: DELAY = 5×(2+3) FILT clock cycles + (1 or 2) IPBus clock cycles

77.4.1.3.3 Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	0			0		FILT_CNT			FILT_PER							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

77.4.1.3.4 Fields

Field	Function
15-13	Reserved
12-11 —	Reserved
10-8 FILT_CNT	Input Filter Sample Count Represents the number of consecutive samples that must agree, before the input filter accepts an input transition. • A value of 0h represents three samples • A value of 7h represents ten samples The value of this field affects the input latency.
7-0 FILT_PER	Input Filter Sample Period Represents the decoder input signals' sampling period (in IPBus clock cycles). Sample each input multiple times at the rate this field specifies. • If FILT_PER is 00h, then the input filter is bypassed. Bypassing the digital filter enables the position/position difference counters to operate with count rates up to the IPBus frequency. • The value of this field affects the input latency. • When you change the value of this field from a non-zero value to another non-zero value, write 0 first to clear the filter.

77.4.1.4 Watchdog Timeout (WTR)

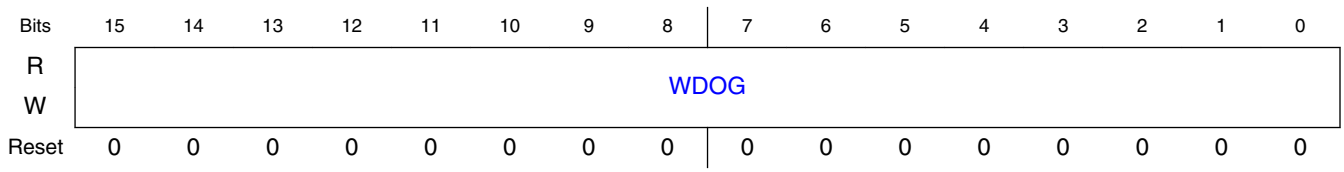
77.4.1.4.1 Offset

Register	Offset
WTR	2h

77.4.1.4.2 Function

Stores the timeout count for the quadrature decoder module watchdog timer. This quadrature decoder module watchdog timer is different from any other watchdog timer(s) that may also be present in the chip.

77.4.1.4.3 Diagram



77.4.1.4.4 Fields

Field	Function
15-0 WDOG	WDOG Represents the number of clock cycles, plus one clock cycle that the watchdog timer counts before timing out (and optionally generating an interrupt).

77.4.1.5 Position Difference Counter (POSD)

77.4.1.5.1 Offset

Register	Offset
POSD	3h

77.4.1.5.2 Function

Contains the position change in value occurring between each read of the position register. You can use the value of this register to calculate velocity.

- This register computes up or down on every count pulse.
- This register acts as a differentiator, whose count value is proportional to the change in position since the last time you read the position counter.
- When you read this register, its contents are copied into Position Difference Hold (POSDH) and this register becomes 0.

77.4.1.5.3 Diagram

77.4.1.14.4 Fields

Field	Function
15-0 INIT	INIT Contains the value to initialize Lower Position Counter (LPOS).

77.4.1.15 Input Monitor (IMR)

77.4.1.15.1 Offset

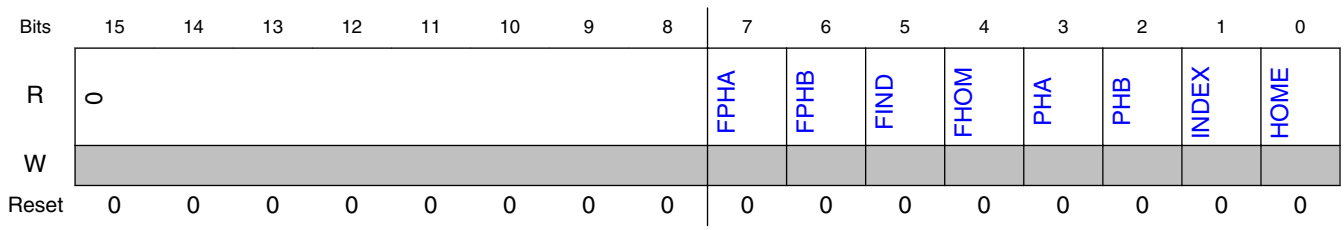
Register	Offset
IMR	Dh

77.4.1.15.2 Function

Contains the values of the raw and filtered PHASEA, PHASEB, INDEX, and HOME input signals. The reset value depends on the values of the raw and filtered values of PHASEA, PHASEB, INDEX, and HOME input signals:

- If you connect these input pins to a pullup, then bits 0–7 of this register are all ones.
- If you connect these input pins to a pulldown device, then bits 0–7 of this register are all zeros.

77.4.1.15.3 Diagram



77.4.1.15.4 Fields

Field	Function
15-8 —	Reserved
7 FPHA	FPHA Specifies the filtered version of PHASEA input.
6 FPHB	FPHB Specifies the filtered version of PHASEB input.
5 FIND	FIND Specifies the filtered version of INDEX input.
4 FHOM	FHOM Specifies the filtered version of HOME input.
3 PHA	PHA Specifies the raw PHASEA input.
2 PHB	PHB Specifies the raw PHASEB input.
1 INDEX	INDEX Specifies the raw INDEX input.
0 HOME	HOME Specifies the raw HOME input.

77.4.1.16 Test (TST)

77.4.1.16.1 Offset

Register	Offset
TST	Eh

77.4.1.16.2 Function

Controls and sets the frequency of a quadrature signal generator; it provides a quadrature test signal to the inputs of the quadrature decoder module.

- The TEST_COUNT value is counted down to zero when TST[TEN] and TST[TCE] are 1.
- Each count value of one represents a single quadrature cycle, which the position counter (Upper Position Counter (UPOS) and Lower Position Counter (LPOS)) interprets as a count of one if enabled (TST[TEN] and TST[TCE] are 1).
- Repeated writing of new values to TEST_COUNT can cause an extra phase transition and, therefore an extra count by the Position Counter.
- The period field determines each quadrature cycle phase's length (in IPBus clock cycles).

This register is a factory test feature; however, you may find it helpful during your software development and testing.

77.4.1.16.3 Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	TEN	TCE	QDN	TEST_PERIOD					TEST_COUNT

77.4.1.16.4 Fields

Field	Function
15 TEN	Test Mode Enable Connects the test module to inputs of the quadrature decoder module. 0b - Disable 1b - Enable

Table continues on the next page...

Field	Function
14 TCE	Test Counter Enable Connects the test counter to inputs of the quadrature decoder module. 0b - Disable 1b - Enable
13 QDN	Quadrature Decoder Negative Signal Selects whether a negative or positive quadrature decoder signal is generated. 0b - Positive quadrature decoder signal 1b - Negative quadrature decoder signal
12-8 TEST_PERIOD	TEST_PERIOD Specifies the period of the quadrature phase in IPBus clock cycles.
7-0 TEST_COUNT	TEST_COUNT Specifies the number of quadrature advances to generate.

77.4.1.17 Control 2 (CTRL2)

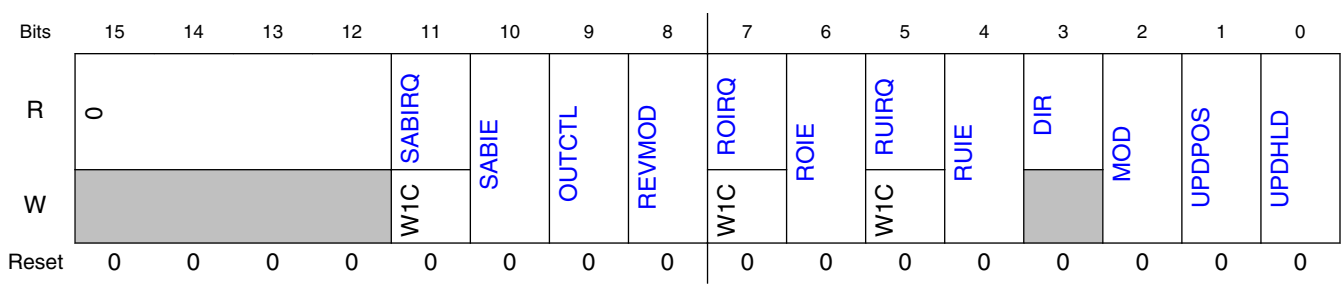
77.4.1.17.1 Offset

Register	Offset
CTRL2	Fh

77.4.1.17.2 Function

Specifies the status of interrupts, interrupt enable, and part of basic functions.

77.4.1.17.3 Diagram



77.4.1.17.4 Fields

Field	Function
15-12 —	Reserved
11 SABIRQ	Simultaneous PHASEA and PHASEB Change Interrupt Request Indicates that the PHASEA and PHASEB inputs changed simultaneously (within a single clock period). This event typically indicates an error condition, because quadrature coding requires only one of these inputs to change at a time. 0b - No simultaneous change has occurred 1b - A simultaneous change has occurred
10 SABIE	Simultaneous PHASEA and PHASEB Change Interrupt Enable Enables simultaneous PHASEA and PHASEB change interrupts when CTRL2[SABIRQ] becomes 1. 0b - Disable 1b - Enable
9 OUTCTL	Output Control Controls the pulsing of the POSMATCH output signal. This can control when a timer channel captures a timestamp. 0b - POSMATCH pulses when a match occurs between the position counters (POS) and the corresponding compare value (COMP) 1b - POSMATCH pulses when the UPOS, LPOS, REV, or POSD registers are read
8 REVMOD	Revolution Counter Modulus Enable Selects how Revolution Counter (REV) increments or decrements. By default, Revolution Counter (REV) is controlled based on the count direction and the INDEX pulse. As an option, you can control the revolution counter using the roll-over/under detection during modulo counting. 0b - Use INDEX pulse 1b - Use modulus counting roll-over or roll-under
7 ROIRQ	Roll-over Interrupt Request Indicates when the position counter (POS) rolls over from the MOD value to the INIT value or from FFFF_FFFFh to 0000_0000h. 0b - Did not occur 1b - Occurred
6 ROIE	Roll-over Interrupt Enable Enables roll-over interrupts when CTRL2[ROIRQ] is 1. This roll-over interrupt combines with the index interrupt signal. 0b - Disable 1b - Enable
5 RUIRQ	Roll-under Interrupt Request Indicates when the position counter (POS) rolls under from the INIT value to the MOD value or from 0000_0000h to FFFF_FFFFh. 0b - No roll-under has occurred 1b - Roll-under has occurred
4 RUIE	Roll-under Interrupt Enable Enables roll-under interrupts when CTRL2[RUIRQ] is 1. This roll-under interrupt combines with the index interrupt signal. 0b - Disable 1b - Enable
3 DIR	Count Direction Flag Indicates the direction of the last count.

Table continues on the next page...

Field	Function
	0b - Down direction 1b - Up direction

2
MOD
	Enable Modulo Counting
	Has multiple functions:
	• When this field is 1, it allows Upper Position Counter (UPOS) and Lower Position Counter (LPOS) to count in a modulo fashion, using MOD and INIT as the upper and lower bounds of the counting range. During modulo counting:
	  • When you indicate a "count up" and the position counter is equal to MOD, then the position counter reloads with the value of INIT.
	  • When you indicate a "count down" and the position counter is equal to INIT, then the position counter reloads with the value of MOD.
	• When this field is 0, then the values of MOD and INIT are ignored, and the position counter wraps to zero when counting up from FFFF_FFFFh, or wraps to FFFF_FFFFh when counting down from 0.
	
	0b - Disable
	1b - Enable

1 UPDPOS	Update Position Registers Has multiple functions: • When this field is 1, it allows the TRIGGER input to write 0 to Position Difference Counter (POSD), Revolution Counter (REV), Upper Position Counter (UPOS), and Lower Position Counter (LPOS). • When this field is 0, Position Difference Counter (POSD), Revolution Counter (REV), Upper Position Counter (UPOS), and Lower Position Counter (LPOS) ignore the TRIGGER input. Do not write 1 to this field when you use Last Edge Time (LASTEDGE) and Position Difference Period Counter (POSDPER) to measure speed. 0b - No action 1b - Clear
0 UPDHLD	Update Hold Registers Has multiple functions: • When this field is 1, it allows the TRIGGER input to update Position Difference Hold (POSDH), Revolution Hold (REVH), Upper Position Hold (UPOSH), and Lower Position Hold (LPOSH). • When this field is 0, the TRIGGER input does not update the hold registers (Position Difference Hold (POSDH), Revolution Hold (REVH), Upper Position Hold (UPOSH), and Lower Position Hold (LPOSH)). Do not write 1 to this field when you use Last Edge Time (LASTEDGE) and Position Difference Period Counter (POSDPER) to measure speed. Updating Position Difference Hold (POSDH) causes Position Difference Counter (POSD) to become 0. 0b - Disable 1b - Enable

77.4.1.18 Upper Modulus (UMOD)

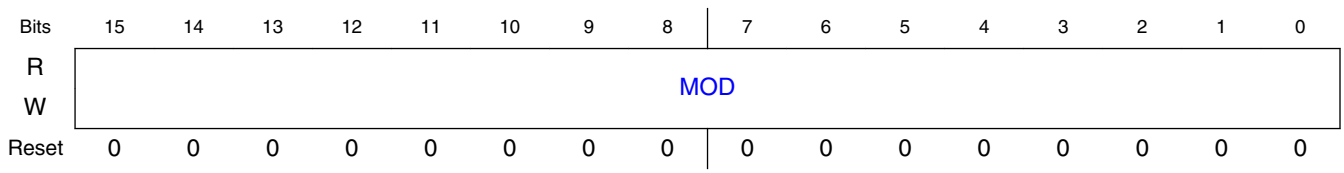
77.4.1.18.1 Offset

Register	Offset
UMOD	10h

77.4.1.18.2 Function

Contains the upper (most significant) half of the modulus register.

77.4.1.18.3 Diagram



77.4.1.18.4 Fields

Field	Function
15-0 MOD	MOD Specifies the upper (most significant) half of the modulus register. This field acts as the upper bound during modulo counting and as the upper reload value when rolling over from the lower bound.

77.4.1.19 Lower Modulus (LMOD)

77.4.1.19.1 Offset

Register	Offset
LMOD	11h

77.4.1.19.2 Function

Contains the lower (least significant) half of the modulus register.

77.4.1.22 Last Edge Time (LASTEDGE)

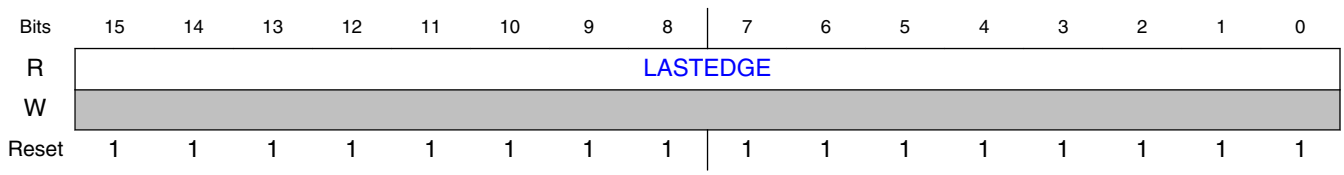
77.4.1.22.1 Offset

Register	Offset
LASTEDGE	14h

77.4.1.22.2 Function

Represents the time after the last edge occurred on PHASEA or PHASEB.

77.4.1.22.3 Diagram



77.4.1.22.4 Fields

Field	Function
15-0 LASTEDGE	Last Edge Time Counter Represents the time after the last edge occurred on PHASEA or PHASEB. This field counts up using the peripheral clock that CTRL3[PRSC] prescales. Any edge on PHASEA or PHASEB resets this field to 0 and starts counting. If the LASTEDGE count reaches FFFFh, the counting stops to prevent an overflow. Counting continues when an edge occurs on PHASEA or PHASEB.

77.4.1.23 Last Edge Time Hold (LASTEDGEH)

77.4.1.23.1 Offset

Register	Offset
LASTEDGEH	15h

77.4.1.23.2 Function

Holds register for the Last Edge Time (LASTEDGE) value.

77.4.1.23.3 Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

77.4.1.23.4 Fields

Field	Function
15-0 LASTEDGEH	Last Edge Time Hold Holds the Last Edge Time (LASTEDGE) value when you read Position Difference Counter (POSD).

77.4.1.24 Position Difference Period Counter (POSDPER)

77.4.1.24.1 Offset

Register	Offset
POSDPER	16h

77.4.1.24.2 Function

Indicates the position-difference period.

77.4.1.24.3 Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	POSDPER															
W																
Reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

77.4.1.24.4 Fields

Field	Function
15-0 POSDPER	Position difference period

Field	Function
	Counts up using the peripheral clock that CTRL3[PRSC] prescales. Reading Position Difference Counter (POSD) loads the value of Last Edge Time (LASTEDGE) into Position Difference Period Counter (POSDPER). If Position Difference Period Counter (POSDPER) count reaches FFFFh, the counting stops to prevent an overflow. Counting continues when an edge occurs on PHASEA or PHASEB.

7-4 PRSC	Prescaler Prescales the peripheral clock that LASTEDGE[LASTEDGE] and POSDPER[POSDPER] use. The resulting prescale clock value is 2^{PRSC}. The prescaler logic can divide the clock by a minimum of 1 and a maximum of 32,768.
3-1 —	Reserved
0 PMEN	Period Measurement Function Enable Specifies that the period-measurement functions of the following registers are used: • Last Edge Time (LASTEDGE) • Last Edge Time Hold (LASTEDGEH) • Position Difference Period Counter (POSDPER) • Position Difference Period Buffer (POSDPERBFR) • Position Difference Period Hold (POSDPERH) If this field is 0, Position Difference Counter (POSD) is loaded to Position Difference Hold (POSDH) and then becomes 0 whenever you read Position Difference Counter (POSD), Upper Position Counter (UPOS), Lower Position Counter (LPOS), or Revolution Counter (REV). If this field is 1, Position Difference Counter (POSD) is loaded to Position Difference Hold (POSDH) and then becomes 0 only when you read Position Difference Counter (POSD). 0b - Not used 1b - Used

Chapter 78
System Watchdog Timer (WDOG 1,2)

78.1 Chip-specific System Watchdog information

Table 78-1. Reference links to related information

Topic	Related module(s)	Reference
System memory map	-	System Memory Map
Clocking	CCM	Clock Management Clock Control Module (CCM)
Power management	PMU	Power Management Power Management Unit
Signal multiplexing	IOMUX	External Signals and Pin Multiplexing IOMUX
Interrupts, DMA Events and XBAR Assignments	-	Interrupts, DMA Events and XBAR Assignments

System WDOG1 services the system reset signal (WDOG_RESET_B_DEB) to System Reset Controller (SRC).

System WDOG2 asserts the interrupt to SNVS to report a Security Violation (SV).

78.2 Overview

The Watchdog Timer (WDOG) protects against system failures by providing a method by which to escape from unexpected events or programming errors.

Once the WDOG is activated, it must be serviced by the software on a periodic basis. If servicing does not take place, the timer times out. Upon timeout, the WDOG asserts the internal system reset signal, WDOG_RESET_B_DEB to the System Reset Controller (SRC).

There is also a provision for WDOG(ipp_wdog) signal assertion by timeout counter expiration. There is an option of programmable interrupt generation before the counter actually times out. The time at which the interrupt needs to be generated prior to counter timeout is programmable. There is a power down counter which is enabled out of any reset (POR, Warm/Cold). This counter has a fixed timeout period of 16 seconds, upon which it asserts the WDOG(ipp_wdog) signal.

Flow diagrams for the timeout counter, power down counter and interrupt operations are are shown in Flow Diagrams.

78.2.1 Block Diagram

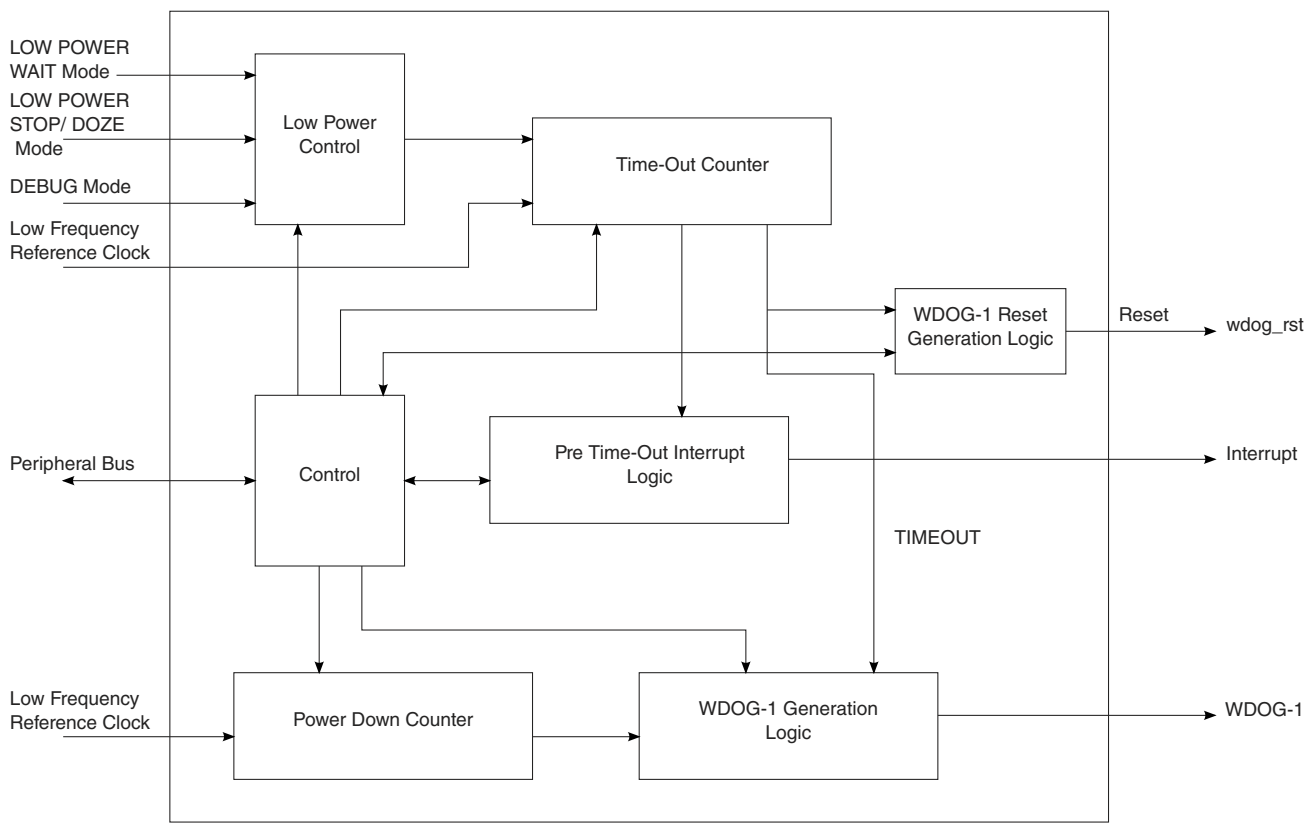

Figure 78-1. WDOG Diagram

78.2.2 Features

The WDOG features are listed below:

- Configurable timeout counter with timeout periods from 0.5 to 128 seconds which, after timeout expiration, result in the assertion of WDOG_RESET_B_DEB reset signal.
- Time resolution of 0.5 seconds
- Configurable timeout counter that can be programmed to run or stop during low-power modes
- Configurable timeout counter that can be programmed to run or stop during DEBUG mode
- Programmable interrupt generation prior to timeout
- The duration between interrupt and timeout events can be programmed from 0 to 127.5 seconds in steps of 0.5 seconds.
- Power down counter with fixed timeout period of 16 seconds, which if not disabled after reset will assert WDOG_B (ipp_wdog) signal low
- Power down counter will be enabled out of any reset (POR, Warm / Cold reset) by default.

78.3 Functional description

This section provides a complete functional description of the block.

78.3.1 Watchdog mechanism and system integration

The modules are disabled by default (after reset). WDOG1 will be configured during boot while WDOG2 is dedicated for secure world purposes and will be activated by TZ software if required. The TZ watchdog (TZ watchdog) module protects against TZ starvation by providing a method of escaping normal mode and forcing a switch to the TZ mode.TZ starvation is a situation where the normal OS prevents switching to the TZ mode. Such a situation is undesirable as it can compromise the system’s security.

Once the TZ WDOG module is activated, it must be serviced by TZ on a periodic basis. If servicing does not take place, the timer times out. Upon a timeout, the TZ WDOG asserts a TZ-mapped interrupt that forces switching to the TZ mode. If it is still not serviced, the TZ WDOG asserts a security violation signal to the CSU. The TZ WDOG module cannot be programmed or de-activated by normal mode software.

The WDOG modules operate as follows:

- If servicing does not take place, the timer times out and the wdog_rst_b signal is activated (low)
- Interrupt can be generated before the counter actually times out

- The wdog_rst_b signal can be activated by software
- There is a power-down counter which gets enabled out of any reset. This counter has a fixed timeout period of 16 seconds upon which it will assert the ipp_wdog_b signal.

78.3.2 Timeout event

The WDOG provides timeout periods from 0.5 to 128 seconds with a time resolution of 0.5 seconds.

The user can determine the timeout period by writing to the WDOG timeout field (WT[7:0]) in the Watchdog Control Register (WCR). The WDOG must be enabled by setting the WDE bit of Watchdog Control Register (WCR) for the timeout counter to start running. After the WDOG is enabled, the counter is activated, loads the timeout value and begins to count down from this programmed value. The timer will time out when the counter reaches zero and the WDOG outputs a system reset signal, WDOG_RESET_B_DEB and asserts WDOG_B (ipp_wdog_b) (WDT bit should be set in Watchdog Control Register (WCR)).

However, the timeout condition can be prevented by reloading the counter with the new timeout value (WT[7:0] of WDOG_WCR) if a service routine (see Servicing WDOG to reload the counter) is performed before the counter reaches zero. If any system errors occur which prevent the software from servicing the Watchdog Service Register (WSR), the timeout condition occurs. By performing the service routine, the WDOG reloads its counter to the timeout value indicated by bits WT[7:0] of the Watchdog Control Register (WCR) and it restarts the countdown.

A system reset will reset the counter and place it in the idle state at any time during the countdown. The counter flow diagram is shown in Flow Diagrams.

NOTE

The timeout value is reloaded to the counter either at the time WDOG is enabled or after the service routine has been performed.

78.3.2.1 Servicing WDOG to reload the counter

To reload a timeout value to the counter, the proper service sequence begins by writing 0x_5555 followed by 0x_AAAA to the Watchdog Service Register (WSR). Any number of instructions can be executed between the two writes. If the WDOG_WSR is not loaded with 0x_5555 prior to writing 0x_AAAA to the WDOG_WSR, the counter is not

reloaded. If any value other than 0x_AAAA is written to the WDOG_WSR after 0x_5555, the counter is not reloaded. This service sequence will reload the counter with the timeout value WT[7:0] of Watchdog Control Register (WCR). The timeout value can be changed at any point; it is reloaded when WDOG is serviced by the core.

78.3.3 Interrupt event

Prior to timeout, the WDOG can generate an interrupt which can be considered a warning that timeout will occur shortly.

The duration between interrupt event and timeout event can be controlled by writing to the WICT field of Watchdog Interrupt Control Register (WICR). It can vary between 0 and 127.5 seconds. If the WDOG is serviced (Servicing WDOG to reload the counter) before the interrupt generation, the counter will be reloaded with the timeout value WT[7:0] of Watchdog Control Register (WCR) and the interrupt will not be triggered.

78.3.4 Power-down counter event

The power-down counter inside WDOG will be enabled out of reset. This counter has a fixed timeout value of 16 seconds, after which it will drive the WDOG_B (ipp_wdog) signal low.

To prevent this, the software must disable this counter by clearing the PDE bit of Watchdog Miscellaneous Control Register (WMCR) within 16 seconds of reset deassertion. Once disabled, this counter can't be enabled again until the next system reset occurs. This feature is intended to prevent the hanging up of cores after reset, as WDOG is not enabled out of reset.

78.3.5 Low power modes

78.3.5.1 STOP and DOZE mode

If the WDOG timer disable bit for low power STOP and DOZE mode (WDZST) bit in the Watchdog Control Register (WCR), is cleared, the WDOG timer continues to operate using the low frequency reference clock. If the low power enable (WDZST) bit is set, the WDOG timer operation will be suspended in low power STOP or DOZE mode. Upon exiting low power STOP or DOZE mode, the WDOG operation returns to what it was prior to entering the STOP or DOZE mode.

78.3.5.2 WAIT mode

If the WDOG timer disable bit for low power WAIT mode (WDW) bit in the Watchdog Control Register (WCR), is cleared, the WDOG timer continues to operate using the low frequency reference clock i.e *ipg_clk_32k* clock (32.768 kHz frequency clock). If the low power WAIT enable (WDW) bit is set, the WDOG timer operation will be suspended. Upon exiting low power WAIT mode, the WDOG operation returns to what it was prior to entering the WAIT mode.

NOTE

The WDOG timer won't be able to detect events that happen for periods shorter than one low frequency reference clock cycle. For example, in repeated WAIT mode entry or exit, if the RUN mode time is less than one low frequency reference clock cycle and if the WDW bit is set, the WDOG timer may never time out, even though the system is in RUN mode for a finite duration; WDOG may not see a low frequency reference clock edge during its wake time.

78.3.6 Debug mode

The WDOG timer can be configured for continual operation, or for suspension during debug mode. If the WDOG debug enable (WDBG) bit is set in the Watchdog Control Register (WCR), the WDOG timer operation is suspended in debug mode. If the WDBG bit is set and the debug mode (*ipg_debug* signal assertion) is entered, WDOG timer operation is suspended after two low frequency reference (*ipg_clk_32k*) clocks. Similarly, WDOG timer operation continues after two low frequency reference clocks of debug mode exit. Register read and write accesses in debug mode continue to function normally. Also, while in debug mode, the WDE bit of Watchdog Control Register (WCR) can be enabled/disabled directly. If the WDOG debug enable (WDBG) bit is cleared then WDOG timer operation is not suspended. The power-down counter is not affected by debug mode entry/exit.

NOTE

If the WDE bit of Watchdog Control Register (WCR) is set/ cleared while in debug mode, it remains set/cleared even after exiting debug mode.

78.3.7 Operations

78.3.7.1 Watchdog reset generation

The WDOG generated reset signal WDOG_RESET_B_DEB is asserted by the following operations:

- A software write to the Software Reset Signal (SRS) bit of the Watchdog Control Register (WCR).
- WDOG timeout. See Timeout event.

The wdog_rst_b will be asserted for one clock cycle of low frequency reference clock for both a timeout condition and a software write occurrence. It remains asserted for 1 clock cycle of low frequency reference clock even if a system reset is asserted in between. Figure 78-3 shows the timing diagram of this signal due to a timeout condition.

78.3.7.2 WDOG_B generation

The WDOG asserts WDOG_B in the following scenarios:

- Software write to WDA bit of Watchdog Control Register (WCR). WDOG_B signal remains asserted as long as the WDA bit is "0".
- WDOG timeout condition, WDT bit of Watchdog Control Register (WCR) must be set for this scenario. A description of the timeout condition can be found in the Timeout event. WDOG_B (ipp_wdog) signal remains asserted until a power-on reset (POR) occurs. It gets cleared after the POR occurs (not due to any other system reset). Figure 78-4 shows the timing diagram of WDOG_B (ipp_wdog) due to timeout condition.
- WDOG power-down counter timeout, PDE bit of Watchdog Miscellaneous Control Register (WMCR) should not be cleared for this scenario. A description of this counter can be found in the Power-down counter event. WDOG_B (ipp_wdog) signal remains asserted for one clock cycle of low frequency reference clock (*ipg_clk_32k*).

Figure 78-2 shows the scenarios under which WDOG_B(ipp_wdog_b) gets asserted.

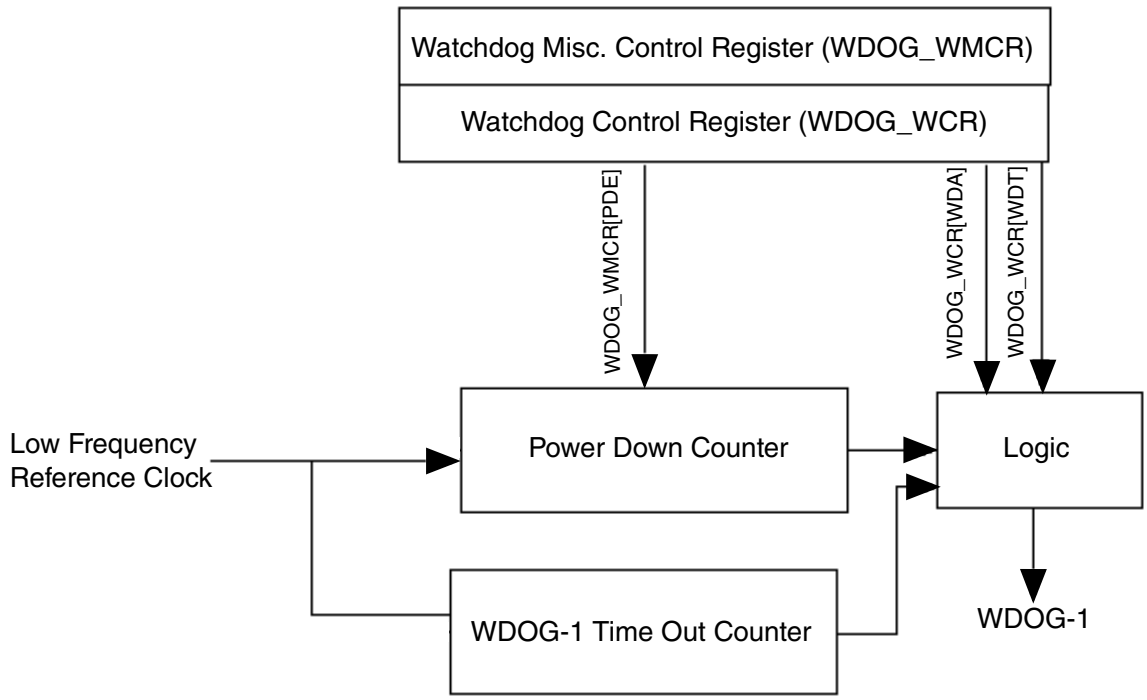

Figure 78-2. WDOG_B (ipp_wdog) generation

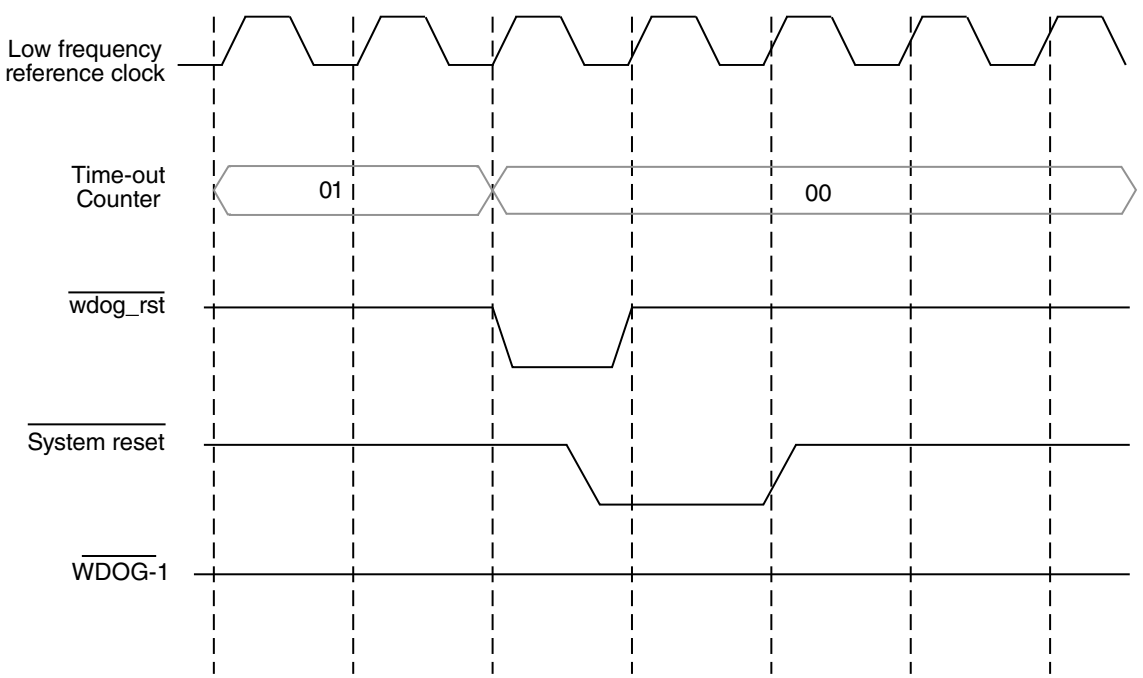

Figure 78-3. WDOG timeout condition/WDT bit is not set

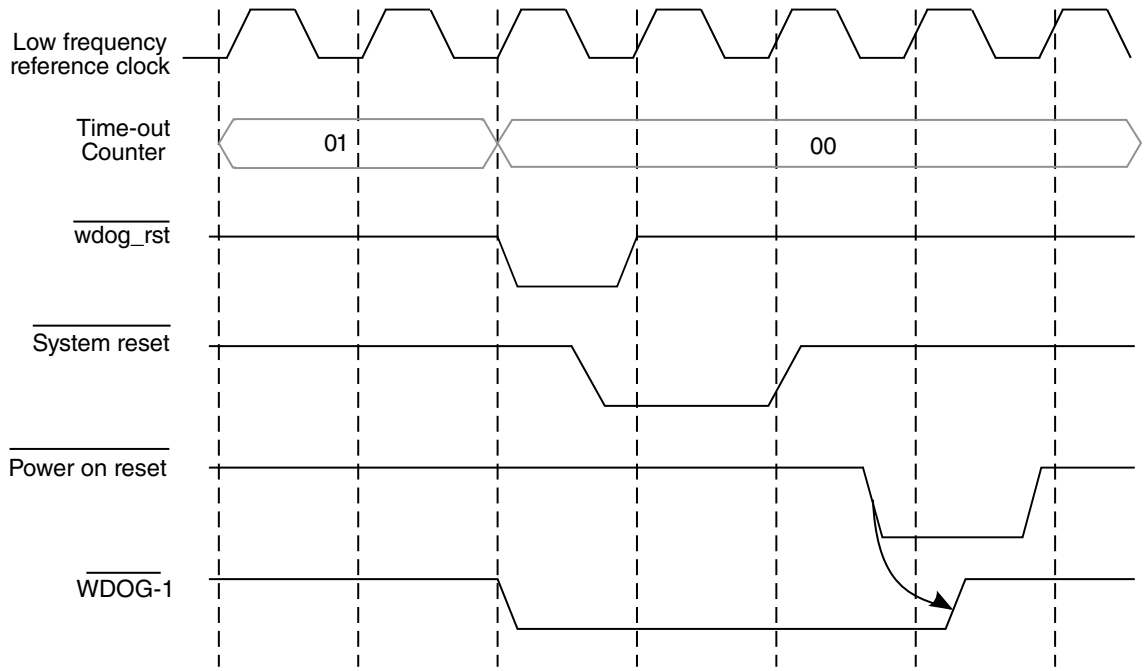

Figure 78-4. WDOG timeout condition/WDT bit is set

78.3.8 Clocks

This section describes clocks and special clocking requirements of the block.

The WDOG uses the low frequency reference clock for its counter and control operations. The peripheral bus clock is used for register read/write operations.

The following table describes the clock sources for WDOG. Please see for clock setting, configuration and gating information.

Table 78-2. WDOG Clocks

Clock name	Clock Root	Description
ipg_clk	ipg_clk_root	IP Global functional clock. All functionality inside the WDOG module is synchronized to this clock.
ipg_clk_s	ipg_clk_root	IP slave bus clock. This clock is synchronized to ipg_clk and is only used for register read/write operations.
ipg_clk_32k	ckil_sync_clk_root	Low frequency (32.768 kHz) clock that continues to run in low-power mode. It is assumed that the Clock Controller will provide this clock signal synchronized to ipg_clk in the normal mode, and switch to a non-synchronized signal in low-power mode when the ipg_clk is off.

78.3.9 Reset

The block is reset by a system reset and the WDOG counter will be disabled. The power-down counter is enabled and starts counting.

78.3.10 Interrupt

The WDOG has the feature of Interrupt generation before timeout.

The interrupt will be generated only if the WIE bit in Watchdog Interrupt Control Register (WICR) is set. The exact time at which the interrupt should occur (prior to timeout) depends on the value of WICT field of Watchdog Interrupt Control Register (WICR). For example, if the WICT field has a value 0x04, then the interrupt will be generated two seconds prior to timeout. Once the interrupt is triggered the WTIS bit in Watchdog Interrupt Control Register (WICR) will be set. The software needs to clear this bit to deassert the interrupt. If the WDOG is serviced before the interrupt generation then the counter will be reloaded with the timeout value WT[7:0] of Watchdog Control Register (WCR) and interrupt would not be triggered.

78.3.11 Flow Diagrams

The flow diagrams for WDOG operation are shown below.

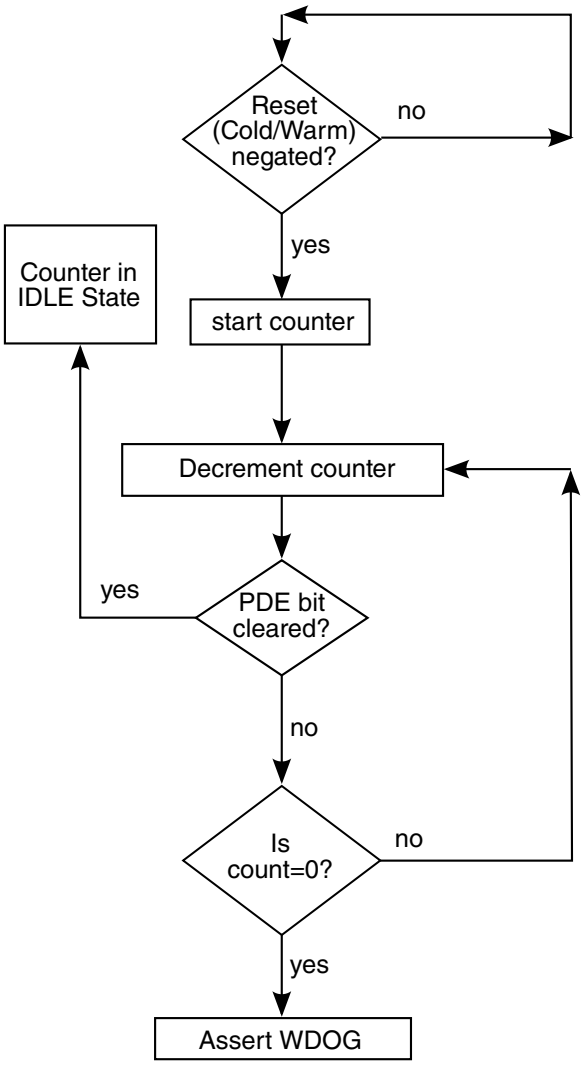

Figure 78-5. Power-Down Counter Flow Diagram

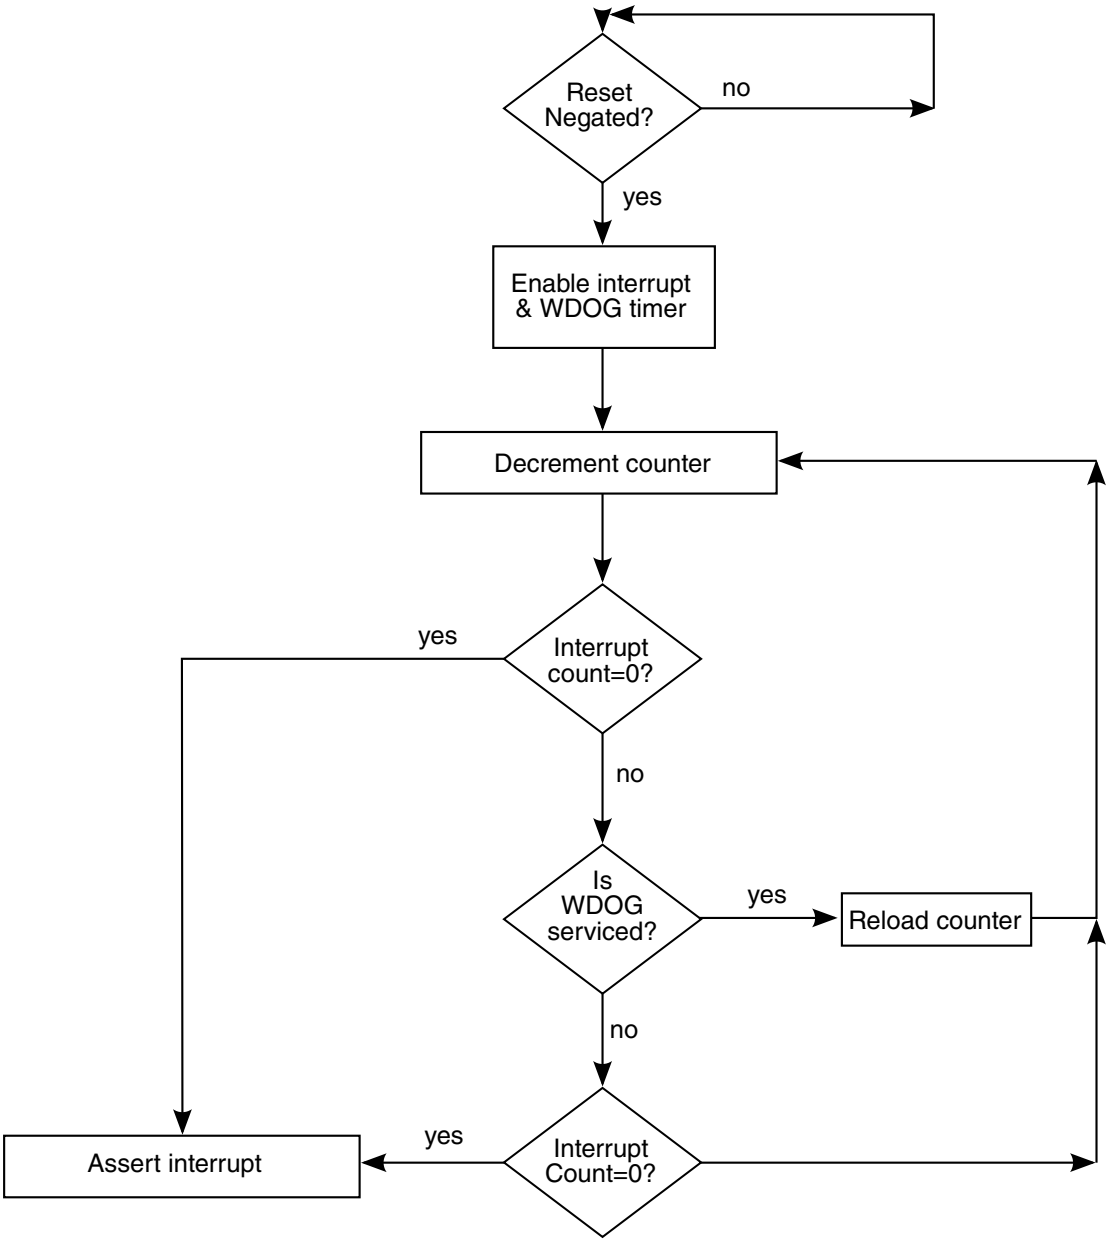

Figure 78-6. Interrupt Generation Flow Diagram

78.4 External signals

Table 78-3. WDOG External Signals

Signal	Description	Direction
WDOG_ANY	Global WDOG signal	IO
WDOG_B	This signal will power down the chip.	IO
WDOG_RESET_B_DEB	This signal is a reset source for the chip.	O

78.5 Initialization

The following sequence should be performed for WDOG initialization.

- PDE bit of Watchdog Miscellaneous Control Register (WMCR) should be cleared to disable the power down counter.
- WT field of Watchdog Control Register (WCR) should be programmed for sufficient timeout value.
- WDOG should be enabled by setting WDE bit of Watchdog Control Register (WCR) so that the timeout counter loads the WT field value of Watchdog Control Register (WCR) and starts counting.

78.6 WDOG Memory Map/Register Definition

78.6.1 WDOG register descriptions

The WDOG has user-accessible, 16-bit registers used to configure, operate, and monitor the state of the Watchdog Timer. Byte operations can be performed on these registers. If a 32-bit access is performed,the WDOG will not generate a peripheral bus error but will behave normally, like a 16-Bit access, making read/write possible. A 32-Bit access should be avoided, as the system may go to an unknown state.

78.6.1.1 WDOG memory map

WDOG1 base address: 4003_0000h

WDOG2 base address: 4003_4000h

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)
0	Watchdog Control Register (WCR)	16	RW	0030
2	Watchdog Service Register (WSR)	16	RW	0000
4	Watchdog Reset Status Register (WRSR)	16	RO	0000
6	Watchdog Interrupt Control Register (WICR)	16	RW	0004
8	Watchdog Miscellaneous Control Register (WMCR)	16	RW	0001

78.6.1.2 Watchdog Control Register (WCR)

The Watchdog Control Register (WDOG_WCR) controls the WDOG operation.

- WDZST, WDBG and WDW are write-once only bits. Once the software does a write access to these bits, they will be locked and cannot be reprogrammed until the next system reset assertion.
- WDE is a write one once only bit. Once software performs a write "1" operation to this bit it cannot be reset/cleared until the next system reset.
- WDT is also a write one once only bit. Once software performs a write "1" operation to this bit it cannot be reset/cleared until the next POR. This bit does not get reset/cleared due to any system reset.

78.6.1.2.1 Offset

Register	Offset
WCR	0h

78.6.1.2.2 Diagram

78.6.1.2.3 Fields

Field	Description
15-8 WT	WT Watchdog Time-out Field. This 8-bit field contains the time-out value that is loaded into the Watchdog counter after the service routine has been performed or after the Watchdog is enabled. After reset, WT[7:0] must have a value written to it before enabling the Watchdog otherwise count value of zero which is 0.5 seconds is loaded into the counter. **NOTE:** The time-out value can be written at any point of time but it is loaded to the counter at the time when WDOG is enabled or after the service routine has been performed. For more information see Timeout event . 00000000 - - 0.5 Seconds (Default).

Table continues on the next page...

Field	Description
	00000001 - - 1.0 Seconds. 00000010 - - 1.5 Seconds. 00000011 - - 2.0 Seconds. 11111111 - - 128 Seconds.
7 WDW	WDW Watchdog Disable for Wait. This bit determines the operation of WDOG during Low Power WAIT mode. This is a write once only bit. 0 - Continue WDOG timer operation (Default). 1 - Suspend WDOG timer operation.
6 SRE	Software Reset Extension, an optional way to generate software reset adopt a new way to generate a more robust software reset. This bit can be set/cleared with IP bus and will be reset with power-on reset . 0 - using original way to generate software reset (default) 1 - using new way to generate software reset.
5 WDA	WDA WDOG_B assertion. Controls the software assertion of the WDOG_B signal. 0 - Assert WDOG_B output. 1 - No effect on system (Default).
4 SRS	SRS Software Reset Signal. Controls the software assertion of the WDOG-generated reset signal WDOG_RESET_B_DEB . This bit automatically resets to "1" after it has been asserted to "0". **NOTE:** This bit does not generate the software reset to the block. 0 - Assert system reset signal. 1 - No effect on the system (Default).
3 WDT	WDT WDOG_B Time-out assertion. Determines if the WDOG_B gets asserted upon a Watchdog Time-out Event. This is a write-one once only bit. **NOTE:** There is no effect on WDOG_RESET_B_DEB (WDOG Reset) upon writing on this bit. WDOG_B gets asserted along with WDOG_RESET_B_DEB if this bit is set. 0 - No effect on WDOG_B (Default). 1 - Assert WDOG_B upon a Watchdog Time-out event.
2 WDE	WDE Watchdog Enable. Enables or disables the WDOG block. This is a write one once only bit. It is not possible to clear this bit by a software write, once the bit is set. **NOTE:** This bit can be set/reset in debug mode (exception). 0 - Disable the Watchdog (Default). 1 - Enable the Watchdog.
1 WDBG	WDBG Watchdog DEBUG Enable. Determines the operation of the WDOG during DEBUG mode. This bit is write once only. 0 - Continue WDOG timer operation (Default).

Table continues on the next page...

Field	Description
	1 - Suspend the watchdog timer.
0 WDZST	WDZST Watchdog Low Power. Determines the operation of the WDOG during low-power modes. This bit is write once-only. **NOTE:** The WDOG can continue/suspend the timer operation in the low-power modes (STOP and DOZE mode). 0 - Continue timer operation (Default). 1 - Suspend the watchdog timer.

78.6.1.3 Watchdog Service Register (WSR)

When enabled, the WDOG requires that a service sequence be written to the Watchdog Service Register (WSR) to prevent the timeout condition.

NOTE

Executing the service sequence will reload the WDOG timeout counter.

78.6.1.3.1 Offset

Register	Offset
WSR	2h

78.6.1.3.2 Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

78.6.1.3.3 Fields

Field	Description
15-0 WSR	WSR

Field	Description
	Watchdog Service Register. This 16-bit field contains the Watchdog service sequence. Both writes must occur in the order listed prior to the time-out, but any number of instructions can be executed between the two writes. The service sequence must be performed as follows: 0101010101010101 - Write to the Watchdog Service Register (WDOG_WSR). 1010101010101010 - Write to the Watchdog Service Register (WDOG_WSR).

78.6.1.4 Watchdog Reset Status Register (WRSR)

The WRSR is a read-only register that records the source of the output reset assertion. It is not cleared by a hard reset. Therefore, only one bit in the WRSR will always be asserted high. The register will always indicate the source of the last reset generated due to WDOG. Read access to this register is with one wait state. Any write performed on this register will generate a Peripheral Bus Error .

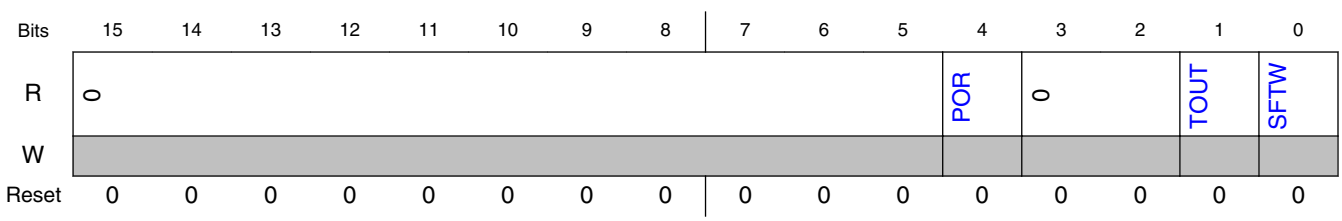
A reset can be generated by the following sources, as listed in priority from highest to lowest:

- Watchdog Time-out
- Software Reset

78.6.1.4.1 Offset

Register	Offset
WRSR	4h

78.6.1.4.2 Diagram



78.6.1.4.3 Fields

Field	Description
15-5 —	Reserved.
4 POR	POR Power On Reset. Indicates whether the reset is the result of a power on reset. 0 - Reset is not the result of a power on reset. 1 - Reset is the result of a power on reset.
3-2 —	Reserved.
1 TOUT	TOUT Timeout. Indicates whether the reset is the result of a WDOG timeout. 0 - Reset is not the result of a WDOG timeout. 1 - Reset is the result of a WDOG timeout.
0 SFTW	SFTW Software Reset. Indicates whether the reset is the result of a WDOG software reset by asserting SRS bit 0 - Reset is not the result of a software reset. 1 - Reset is the result of a software reset.

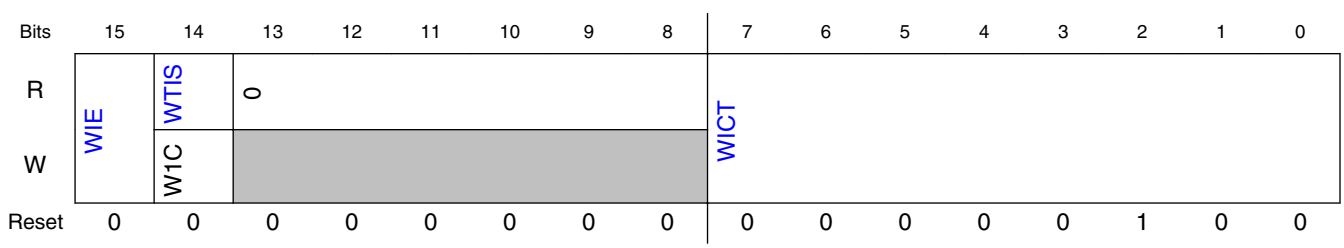
78.6.1.5 Watchdog Interrupt Control Register (WICR)

The WDOG_WICR controls the WDOG interrupt generation.

78.6.1.5.1 Offset

Register	Offset
WICR	6h

78.6.1.5.2 Diagram



78.6.1.5.3 Fields

Field	Description
15 WIE	WIE Watchdog Timer Interrupt enable bit. Reset value is 0. **NOTE:** This bit is a write once only bit. Once the software does a write access to this bit, it will get locked and cannot be reprogrammed until the next system reset assertion 0 - Disable Interrupt (Default). 1 - Enable Interrupt.
14 WTIS	WTIS Watchdog TImer Interrupt Status bit will reflect the timer interrupt status, whether interrupt has occurred or not. Once the interrupt has been triggered software must clear this bit by writing 1 to it. 0 - No interrupt has occurred (Default). 1 - Interrupt has occurred
13-8 —	Reserved.
7-0 WICT	WICT Watchdog Interrupt Count Time-out (WICT) field determines, how long before the counter time-out must the interrupt occur. The reset value is 0x04 implies interrupt will occur 2 seconds before time-out. The maximum value that can be programmed to WICT field is 127.5 seconds with a resolution of 0.5 seconds. **NOTE:** This field is write once only. Once the software does a write access to this field, it will get locked and cannot be reprogrammed until the next system reset assertion. 00000000 - WICT[7:0] = Time duration between interrupt and time-out is 0 seconds. 00000001 - WICT[7:0] = Time duration between interrupt and time-out is 0.5 seconds. 00000100 - WICT[7:0] = Time duration between interrupt and time-out is 2 seconds (Default). 11111111 - WICT[7:0] = Time duration between interrupt and time-out is 127.5 seconds.

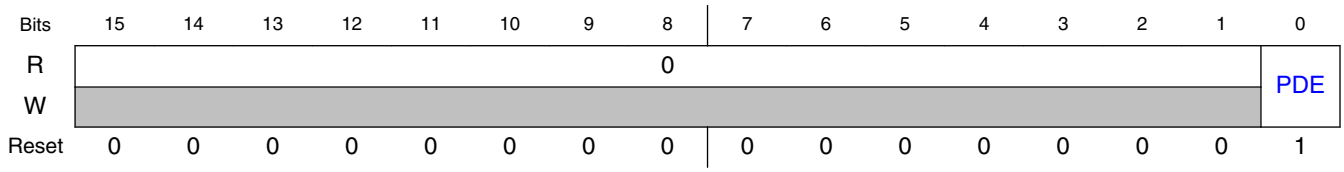
78.6.1.6 Watchdog Miscellaneous Control Register (WMCR)

WDOG_WMCR Controls the Power Down counter operation.

78.6.1.6.1 Offset

Register	Offset
WMCR	8h

78.6.1.6.2 Diagram



78.6.1.6.3 Fields

Field	Description
15-1 —	Reserved.
0 PDE	PDE Power Down Enable bit. Reset value of this bit is 1, which means the power down counter inside the WDOG is enabled after reset. The software must write 0 to this bit to disable the counter within 16 seconds of reset de-assertion. Once disabled this counter cannot be enabled again. See Power-down counter event for operation of this counter. **NOTE:** This bit is write-one once only bit. Once software sets this bit it cannot be reset until the next system reset. 0 - Power Down Counter of WDOG is disabled. 1 - Power Down Counter of WDOG is enabled (Default).

Chapter 79
CPU Watchdog Timer (WDOG 3,4)

79.1 Chip-specific CPU Watchdog information

Table 79-1. Reference links to related information

Topic	Related module(s)	Reference
System memory map	-	System Memory Map

CPU WDOG3 services the CPU reset for the CM7.

CPU WDOG4 services the CPU reset for the CM4.

NOTE

- WDOG 1 and 2 are controlled by the System WDOG. Please see that chapter for more details.
- On this device, both LPO clock and INTCLK are 32 KHz clock generated by 32 KHz XTAL, which could be automatically switched to 32 KHz RCOSC upon XTAL clock loss. ERCLK is 1 MHz RCOSC clock generated by ANATOP.

NOTE

Clock source definition for bit[9:8] in Watchdog Control and Status Register (CS):

```
00b - Bus clock
01b - LPO clock
10b - INTCLK (internal clock)
11b - ERCLK (external reference clock)
```

79.2 Overview

The Watchdog Timer (WDOG) module is an independent timer that is available for system use. It provides a safety feature to ensure that software is executing as planned and that the CPU is not stuck in an infinite loop or executing unintended code. If the WDOG module is not serviced (refreshed) within a certain period, it resets the MCU.

79.2.1 Block diagram

The following figure shows a block diagram of the WDOG module.

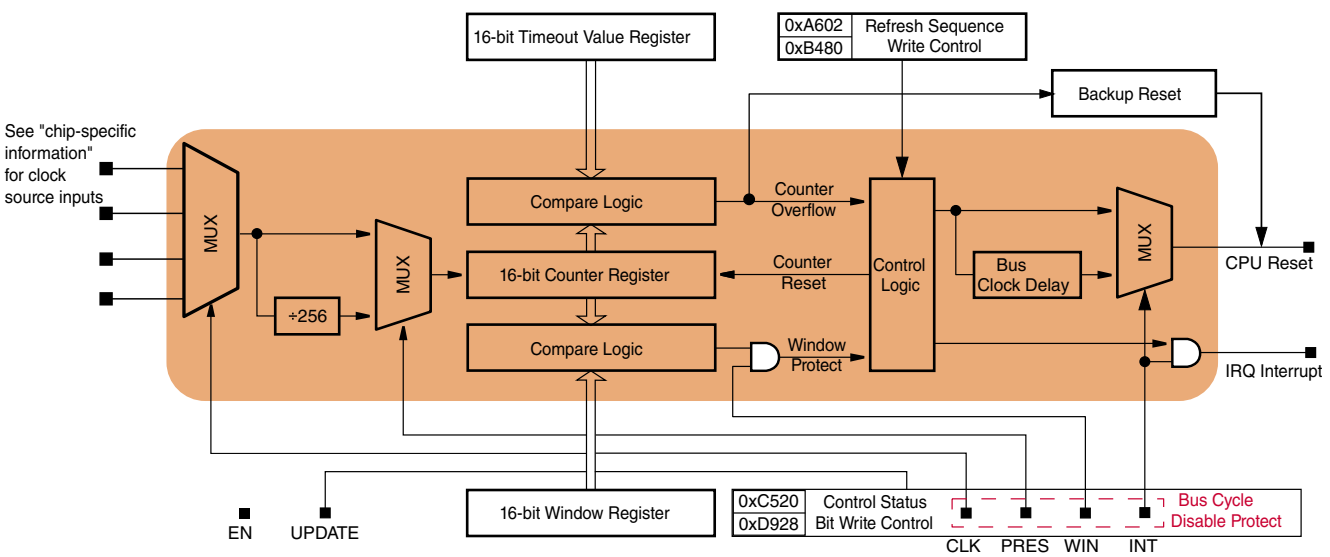

Figure 79-1. WDOG block diagram

79.2.2 Features

Features of the WDOG module include:

- Configurable clock source inputs independent from the bus clock
- Programmable timeout period

    - Programmable 16-bit timeout value
    - Optional fixed 256 clock prescaler when longer timeout periods are needed
- Robust write sequence for counter refresh
    - Refresh sequence of writing 0xA602 and then 0xB480
- Window mode option for the refresh mechanism
    - Programmable 16-bit window value
    - Provides robust check that program flow is faster than expected
    - Early refresh attempts trigger a reset.
- Optional timeout interrupt to allow post-processing diagnostics
    - Interrupt request to CPU with interrupt vector for an interrupt service routine (ISR)
    - Forced reset occurs 255 bus clocks after the interrupt vector fetch.
- Configuration bits are write-once-after-reset to ensure watchdog configuration cannot be mistakenly altered.
- Robust write sequence for unlocking write-once configuration bits
    - Unlock sequence of writing 0xC520 and then 0xD928 for allowing updates to write-once configuration bits
    - Software must make updates within 255 bus clocks after unlocking and before WDOG closing unlock window.

79.3 Functional description

The WDOG module provides a fail safe mechanism to ensure the system can be reset to a known state of operation in case of system failure, such as the CPU clock stopping or there being a run away condition in the software code. The watchdog counter runs continuously off a selectable clock source and expects to be serviced (refreshed) periodically. If it is not, it generates a reset triggering event.

79.3.1 Watchdog refresh mechanism

The watchdog resets the MCU if the watchdog counter is not refreshed. A robust refresh mechanism makes it very unlikely that the watchdog can be refreshed by runaway code.

To refresh the watchdog counter, software must execute a refresh write sequence before the timeout period expires. In addition, if window mode is used, software must not start the refresh sequence until after the time value set in the WIN register. See the following figure.

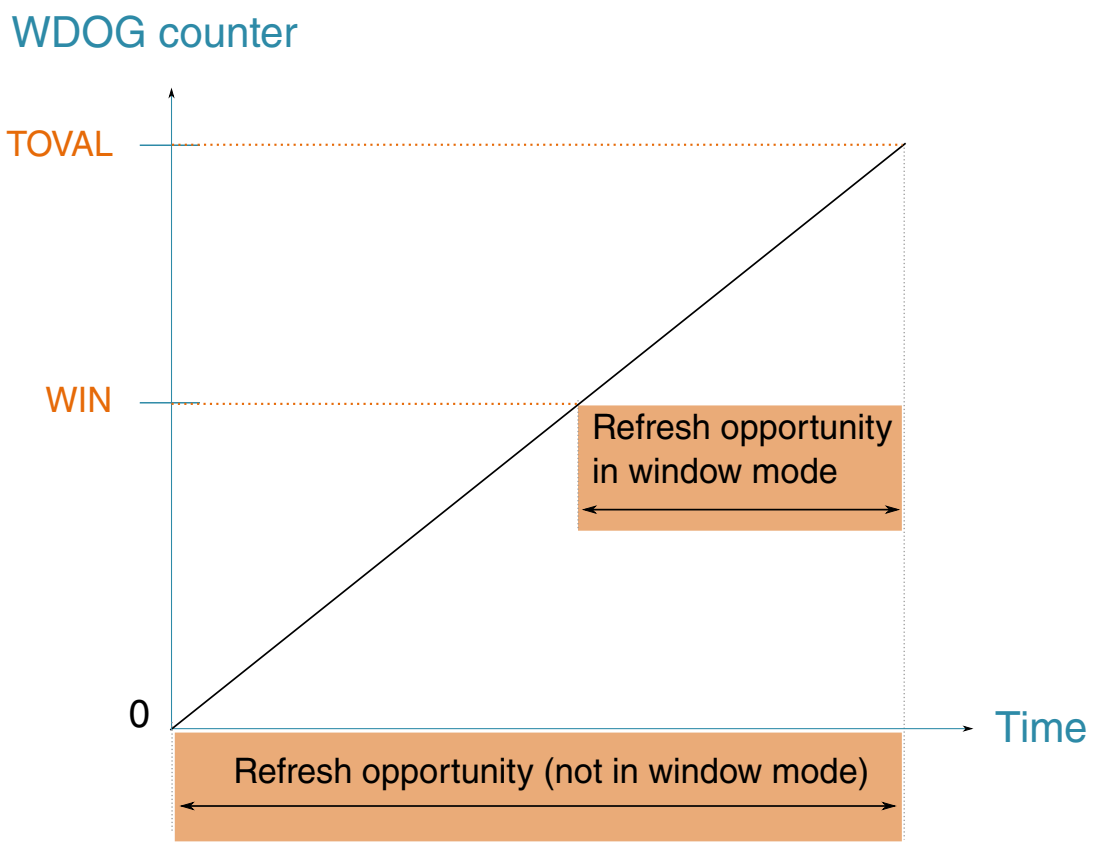

Figure 79-2. Refresh opportunity for the Watchdog counter

79.3.1.1 Window mode

Software finishing its main control loop faster than expected could be an indication of a problem. Depending on the requirements of the application, the WDOG can be programmed to force a reset when refresh attempts are early.

When Window mode is enabled, the watchdog must be refreshed after the counter has reached a minimum expected time value; otherwise, the watchdog resets the MCU. The minimum expected time value is specified in the WIN register. Setting CS[WIN] enables Window mode.

79.3.1.2 Refreshing the Watchdog

The refresh write sequence can be

- either two 16-bit writes (0xA602, 0xB480) or four 8-bit writes (0xA6, 0x02, 0xB4, 0x80) if WDOG_CS[CMD32EN] is 0;
- one 32-bit write (0xB480_A602) if WDOG_CS[CMD32EN] is 1.

to the CNT register. Both methods must occur before the WDG timeout; otherwise, the watchdog resets the MCU.

Note

Before starting the refresh sequence, disable the global interrupts. Otherwise, an interrupt could effectively invalidate the refresh sequence, if the interrupt occurs before the refresh writes finish. After the sequence finishes, restore the global interrupt control state.

The example codes can be found at the end of this chapter.

79.3.2 Configuring the Watchdog

79.3.2.1 Configuring the Watchdog Once

All watchdog control bits, timeout value, and window value are write-once after reset . This means that after a write has occurred they cannot be changed unless a reset occurs. This is guaranteed by the user configuring the window and timeout value first, followed by the other control bits, and ensuring that CS[UPDATE] is also set to 0.

This provides a robust mechanism to configure the watchdog and ensure that a runaway condition cannot mistakenly disable or modify the watchdog configuration after configured.

The new configuration takes effect only after all registers except CNT are written after reset. Otherwise, the WDOG uses the reset values by default. If window mode is not used (CS[WIN] is 0), writing to WIN is not required to make the new configuration take effect.

79.3.2.2 Reconfiguring the Watchdog

In some cases (like when supporting a bootloader function), you may want to reconfigure or disable the watchdog, *without forcing a reset first*.

- By setting CS[UPDATE] to 1 on the initial configuration of the watchdog after a reset, you can reconfigure the watchdog at any time by executing an unlock sequence.
- Conversely, if CS[UPDATE] remains 0, the only way to reconfigure the watchdog is by initiating a reset.

The unlock sequence is similar to the refresh sequence but uses different values.

79.3.2.2.1 Unlocking the Watchdog

The unlock sequence is a write to the CNT register of 0xC520 followed by 0xD928 within 31 bus clocks at any time after the watchdog has been configured. On completing the unlock sequence, the user must reconfigure the watchdog within 255 bus clocks; otherwise, the watchdog closes the unlock window.

NOTE

Due to the 255 bus clocks requirement for reconfiguring the watchdog, some delays must be inserted before executing STOP or WAIT instructions after reconfiguring the watchdog. This ensures that the watchdog's new configuration takes effect before the MCU enters low power mode. Otherwise, the MCU may not be waken up from low power mode.

The example codes can be found at end of this chapter.

79.3.3 Functionality in debug and low-power modes

By default, the watchdog is not functional in Debug mode, Wait mode, or Stop mode. However, the watchdog can remain functional in these modes as follows:

- **For Debug mode,** set CS[DBG]. (This way the watchdog is functional in Debug mode even when the CPU is held by the Debug module.)
- **For Wait mode,** set CS[WAIT].
- **For Stop mode,** set CS[STOP], CS[WAIT], and ensure the clock source is active in Stop mode.

NOTE

The watchdog can generate interrupt in Stop mode.

For Debug mode and Stop mode, in addition to the above configurations, a clock source other than the bus clock must be used as the reference clock for the counter; otherwise, the watchdog cannot function.

79.3.4 Fast testing of the watchdog

Before executing application code in safety critical applications, users are required to test that the watchdog works as expected and resets the MCU. Testing every bit of a 16-bit counter by letting it run to the overflow value takes a relatively long time (64 k clocks).

To help minimize the startup delay for application code after reset, the watchdog has a feature to test the watchdog more quickly by splitting the counter into its constituent byte-wide stages. The low and high bytes are run independently and tested for timeout against the corresponding byte of the timeout value register. (For complete coverage when testing the high byte of the counter, the test feature feeds the input clock via the 8th bit of the low byte, thus ensuring that the overflow connection from the low byte to the high byte is tested.)

Using this test feature reduces the test time to 512 clocks (not including overhead, such as user configuration and reset vector fetches). To further speed testing, use a faster clock (such as the bus clock) for the counter reference.

On a power-on reset, the POR bit in the system reset register is set, indicating the user should perform the WDOG fast test.

79.3.4.1 Testing each byte of the counter

The test procedure follows these steps:

1. Program the preferred watchdog timeout value in the TOVAL register during the watchdog configuration time period.
2. Select a byte of the counter to test using the CS[TST] = 10b for the low byte; CS[TST] = 11b for the high byte.
3. Wait for the watchdog to timeout. Optionally, in the idle loop, increment RAM locations as a parallel software counter for later comparison. Because the RAM is not affected by a watchdog reset, the timeout period of the watchdog counter can be

compared with the software counter to verify the timeout period has occurred as expected.
4. The watchdog counter times out and forces a reset.
5. Confirm the WDOG flag in the system reset register is set, indicating that the watchdog caused the reset. (The POR flag remains clear.)
6. Confirm that CS[TST] shows a test (10b or 11b) was performed.

If confirmed, the count and compare functions work for the selected byte. Repeat the procedure, selecting the other byte in step 2.

NOTE

CS[TST] is cleared by a POR only and not affected by other resets.

79.3.4.2 Entering user mode

After successfully testing the low and high bytes of the watchdog counter, the user can configure CS[TST] to 01b to indicate the watchdog is ready for use in application user mode. Thus if a reset occurs again, software can recognize the reset trigger as a real watchdog reset caused by runaway or faulty application code.

As an ongoing test when using the default clock source, software can periodically read the CNT register to ensure the counter is being incremented.

79.3.5 Clock source

The watchdog counter has the clock source options selected by programming CS[CLK]. See the "chip-specific information" section for available clock inputs and the default option for this device.

The options allow software to select a clock source independent of the bus clock for applications that need to meet more robust safety requirements. Using a clock source other than the bus clock ensures that the watchdog counter continues to run if the bus clock is somehow halted; see Backup reset.

NOTE

The *default* clock source of WDOG should be enabled after its functional reset is deasserted, for the WDOG module to function properly.

An optional fixed prescaler for all clock sources allows for longer timeout periods. When CS[PRES] is set, the clock source is prescaled by 256 before clocking the watchdog counter.

The following table summarizes the different watchdog timeout periods which could be available, as an example.

Table 79-2. Watchdog timeout availability

Reference clock	Prescaler	Watchdog time-out availability
REF_CLK	Pass through	1×RCP to 65535×RCP [1]
	Enable	256×RCP to 16776960×RCP

1. RCP means Reference Clock Period.

NOTE

When the programmer switches clock sources during reconfiguration, the watchdog hardware holds the counter at zero for 2.5 periods of the previous clock source and 2.5 periods of the new clock source after the configuration time period (255 bus clocks) ends. This delay ensures a smooth transition before restarting the counter with the new configuration.

79.3.6 Backup reset

NOTE

A clock source other than the bus clock must be used as the reference clock for the counter; otherwise, the backup reset function is not available.

The backup reset function is a safeguard feature that independently generates a reset in case the main WDOG logic loses its clock (the bus clock) and can no longer monitor the counter. If the watchdog counter overflows twice in succession (without an intervening reset), the backup reset function takes effect and generates a reset.

Backup reset becomes valid when interrupt is enabled and the watchdog clock is from non bus clock. If interrupt is enabled, once the bus clock is cut off before exiting interrupt routine, the normal watchdog reset will be blocked. Under this case, the second overflow will cause backup reset directly.

79.3.7 Using interrupts to delay resets

- **When interrupts are enabled (CS[INT] = 1):** After a reset-triggering event (like a counter timeout or invalid refresh attempt), the watchdog first generates an interrupt request. Next, the watchdog delays 255 bus clocks (from the interrupt vector fetch, not the reset-triggering event) before forcing a reset, to allow the interrupt service routine (ISR) to perform tasks (like analyzing the stack to debug code).
- **When interrupts are disabled (CS[INT] = 0):** the watchdog does not delay before forcing a reset.

79.4 External signals

There are no external signals pinned out for this block.

79.5 Application Information

The watchdog is enabled by default after reset. To disable or reconfigure the watchdog, it is better to be done before the first watchdog timeout. It is suggested to disable or reconfigure the watchdog at the very beginning of the software code, e.g. beginning of the startup or main function.

NOTE

When the watchdog is configured by user, it needs at least 2.5 periods of watchdog clock to take effect. This means interval between two configures by user must be larger than 2.5 clocks.

NOTE

When Chip startup from BOOT ROM then jump to flash, the watchdog would be disabled in the beginning of bootloader, and enabled when bootloader exits. If there is any code in the flash program want to reconfigure the watchdog, it must be run 2.5 watchdog clocks later after the bootloader exits.

To disable or reconfigure the watchdog without forcing a reset, WDOG_CS[UPDATE] bit must be set during the initial configuration of the WDOG module. Then, the unlock sequence can be used at any time within the timeout limit to reconfigure the watchdog.

79.5.1 Disable Watchdog

To disable the watchdog, first do unlock sequence, then unset the WDOG_CS[EN] bit. The code snippet below shows an example for 32-bit write.

```
DisableInterrupts; // disable global interrupt
WDOG_CNT = 0xD928C520; //unlock watchdog
WDOG_CS &= ~WDOG_CS_EN_MASK; //disable watchdog
EnableInterrupts; //enable global interrupt
```

79.5.2 Disable Watchdog after Reset

All of watchdog registers are unlocked by reset. Therefore, unlock sequence is unnecessary, but it needs to write all of watchdog registers to make the new configuration take effect. The code snippet below shows an example of disabling watchdog after reset.

```
DisableInterrupts; // disable global interrupt
WDOG_CS &= ~WDOG_CS_EN_MASK; // disable watchdog
WDOG_TOVAL= 0xFFFF;
while(WDOG_CS[ULK]);  // waiting for lock
while(~WDOG_CS[RCS]); // waiting for new configuration to take effect
EnableInterrupts; // enable global interrupt
```

79.5.3 Configure Watchdog

The watchdog can be configured once by setting the WDOG_CS[UPDATE]=0. After that, the watchdog cannot be reconfigured until a reset. If set WDOG_CS[UPDATE]=1 when configuring the watchdog, the watchdog can be reconfigured without forcing a reset. The following example code shows how to configure the watchdog without window mode, clock source as LPO, interrupt enabled and timeout value to 256 clocks. The code snippet below shows an example for 32-bit write.

Configure once

```
DisableInterrupts; // disable global interrupt
WDOG_CNT = 0xD928C520; //unlock watchdog
while(WDOG_CS[ULK]==0);  //wait until registers are unlocked
WDOG_TOVAL = 256; //set timeout value
WDOG_CS = WDOG_CS_EN(1) | WDOG_CS_CLK(1) | WDOG_CS_INT(1) |
          WDOG_CS_WIN(0) | WDOG_CS_UPDATE(0);
while(WDOG_CS[RCS]==0); //wait until new configuration takes effect
EnableInterrupts; //enable global interrupt
```

Configure for reconfigurable

```
DisableInterrupts; //disable global interrupt
WDOG_CNT = 0xD928C520; //unlock watchdog
while(WDOG_CS[ULK]==0);  //wait until registers are unlocked
WDOG_TOVAL = 256; //set timeout value
WDOG_CS = WDOG_CS_EN(1) | WDOG_CS_CLK(1) | WDOG_CS_INT(1) |
          WDOG_CS_WIN(0) | WDOG_CS_UPDATE(1);
while(WDOG_CS[RCS]==0); //wait until new configuration takes effect
EnableInterrupts; //enable global interrupt
```

79.5.4 Refreshing the Watchdog

To refresh the watchdog and reset the watchdog counter to zero, a refresh sequence is required. The code snippet below shows an example for 32-bit write.

```
DisableInterrupts; // disable global interrupt
WDOG_CNT = 0xB480A602; // refresh watchdog
EnableInterrupts; // enable global interrupt
```

79.6 Memory map and register definition

79.6.1 WDOG register descriptions

79.6.1.1 WDOG memory map

WDOG3 base address: 4003_8000h

WDOG4 base address: 40C1_0000h

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)
0	Watchdog Control and Status Register (CS)	32	RW	0000_2180
4	Watchdog Counter Register (CNT)	32	RW	0000_0000
8	Watchdog Timeout Value Register (TOVAL)	32	RW	0000_7D00
C	Watchdog Window Register (WIN)	32	RW	0000_0000

79.6.1.2 Watchdog Control and Status Register (CS)

This section describes the function of Watchdog Control and Status Register.

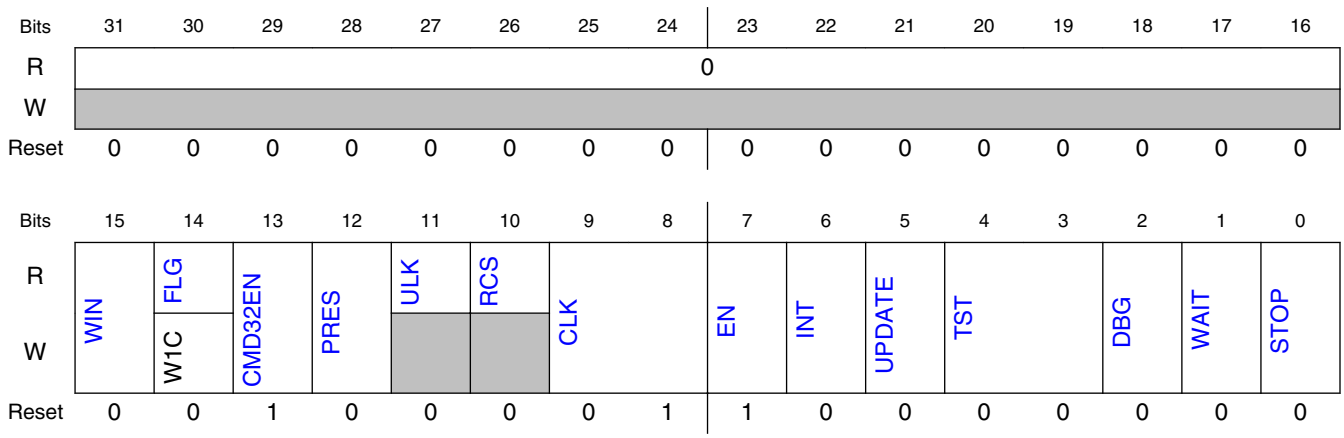
NOTE

TST is cleared (0:0) on POR only. Any other reset does not affect the value of this field.

79.6.1.2.1 Offset

Register	Offset
CS	0h

79.6.1.2.2 Diagram



79.6.1.2.3 Fields

Field	Description
31-16 —	Reserved
15 WIN	Watchdog Window This write-once bit enables window mode. See the Window mode section. 0 - Window mode disabled. 1 - Window mode enabled.
14 FLG	Watchdog Interrupt Flag This bit is an interrupt indicator when INT is set in control and status register 1. Write 1 to clear it. 0 - No interrupt occurred. 1 - An interrupt occurred.
13 CMD32EN	Enables or disables WDOG support for 32-bit (otherwise 16-bit or 8-bit) refresh/unlock command write words This is write-once field, and the user needs to unlock WDOG after writing this field for reconfiguration. 0 - Disables support for 32-bit refresh/unlock command write words. Only 16-bit or 8-bit is supported. 1 - Enables support for 32-bit refresh/unlock command write words. 16-bit or 8-bit is NOT supported.
12 PRES	Watchdog prescaler This write-once bit enables a fixed 256 pre-scaling of watchdog counter reference clock. (The block diagram shows this clock divider option.)

Table continues on the next page...

Field	Description
	0 - 256 prescaler disabled. 1 - 256 prescaler enabled.
11 ULK	Unlock status This read-only bit indicates whether WDOG is unlocked or not. 0 - WDOG is locked. 1 - WDOG is unlocked.
10 RCS	Reconfiguration Success This read-only bit indicates whether the reconfiguration is successful or not. Default reset value is 0.This bit is set when new configuration takes effect, and is cleared by successful unlock command. 0 - Reconfiguring WDOG. 1 - Reconfiguration is successful.
9-8 CLK	Watchdog Clock This write-once field indicates the clock source that feeds the watchdog counter. See the "chip-specific information" section.
7 EN	Watchdog Enable This write-once bit enables the watchdog counter to start counting. 0 - Watchdog disabled. 1 - Watchdog enabled.
6 INT	Watchdog Interrupt This write-once bit configures the watchdog to immediately generate an interrupt request upon a reset-triggering event (timeout or illegal write to the watchdog), before forcing a reset. After the interrupt vector fetch (which comes after the reset-triggering event), the reset occurs after a delay of 255 bus clocks. 0 - Watchdog interrupts are disabled. Watchdog resets are not delayed. 1 - Watchdog interrupts are enabled. Watchdog resets are delayed by 255 bus clocks from the interrupt vector fetch.
5 UPDATE	Allow updates This write-once bit allows software to reconfigure the watchdog without a reset. 0 - Updates not allowed. After the initial configuration, the watchdog cannot be later modified without forcing a reset. 1 - Updates allowed. Software can modify the watchdog configuration registers within 255 bus clocks after performing the unlock write sequence.
4-3 TST	Watchdog Test Enables the fast test mode. The test mode allows software to exercise all bits of the counter to demonstrate that the watchdog is functioning properly. See the Fast testing of the watchdog section. This write-once field is cleared (0:0) on POR only. Any other reset does not affect the value of this field. 00 - Watchdog test mode disabled. 01 - Watchdog user mode enabled. (Watchdog test mode disabled.) After testing the watchdog, software should use this setting to indicate that the watchdog is functioning normally in user mode. 10 - Watchdog test mode enabled, only the low byte is used. CNT[CNTLOW] is compared with TOVAL[TOVALLOW]. 11 - Watchdog test mode enabled, only the high byte is used. CNT[CNTHIGH] is compared with TOVAL[TOVALHIGH].
2	Debug Enable

Table continues on the next page...

Field	Description
DBG	This write-once bit enables the watchdog to operate when the chip is in debug mode. 0 - Watchdog disabled in chip debug mode. 1 - Watchdog enabled in chip debug mode.
1 WAIT	Wait Enable This write-once bit enables the watchdog to operate when the chip is in wait mode. 0 - Watchdog disabled in chip wait mode. 1 - Watchdog enabled in chip wait mode.
0 STOP	Stop Enable This write-once bit enables the watchdog to operate when the chip is in stop mode. 0 - Watchdog disabled in chip stop mode. 1 - Watchdog enabled in chip stop mode.

79.6.1.3 Watchdog Counter Register (CNT)

This section describes the watchdog counter register.

The watchdog counter register provides access to the value of the free-running watchdog counter. Software can read the counter register at any time.

Software cannot write directly to the watchdog counter; however, two write sequences to these registers have special functions:

1. The *refresh sequence* resets the watchdog counter to 0x0000. See the "Refreshing the Watchdog" section.
2. The *unlock sequence* allows the watchdog to be reconfigured without forcing a reset (when CS[UPDATE] = 1). See the "Configure for reconfigurable" section.

NOTE

All other writes to this register are illegal and force a reset.

79.6.1.3.1 Offset

Register	Offset
CNT	4h

31-16 —	Reserved
15-8 CNTHIGH	High byte of the Watchdog Counter
7-0 CNTLOW	Low byte of the Watchdog Counter

79.6.1.4 Watchdog Timeout Value Register (TOVAL)

This section describes the watchdog timeout value register. TOVAL contains the 16-bit value used to set the timeout period of the watchdog.

The watchdog counter (CNT) is continuously compared with the timeout value (TOVAL). If the counter reaches the timeout value, the watchdog forces a reset triggering event.

NOTE

Do not write 0 to the TOVAL register (if CS[TST]=11b, then TOVALHIGH cannot be written as 0; if CS[TST]=10b, then TOVALLOW cannot be 0); otherwise, the watchdog always generates a reset.

79.6.1.4.1 Offset

80.2 Overview

For safety, a redundant watchdog system, External Watchdog Monitor (EWM), is designed to monitor external circuits, as well as the MCU software flow. This provides a back-up mechanism to the internal watchdog that resets the MCU's CPU and peripherals.

The watchdog is generally used to monitor the flow and execution of embedded software within an MCU. The watchdog consists of a counter that if allowed to overflow, forces an internal reset (asynchronous) to all on-chip peripherals and optionally asserts the RESET_B pin to reset external devices/circuits. The overflow of the watchdog counter must not occur if the software code works well and services the watchdog to re-start the actual counter.

The EWM differs from the internal watchdog in that it does not reset the MCU's CPU and peripherals. The EWM provides an independent EWM_OUT_b signal that when asserted resets or places an external circuit into a safe mode. The EWM_OUT_b signal is asserted upon the EWM counter time-out. An optional external input EWM_in is provided to allow additional control of the assertion of EWM_OUT_b signal.

80.2.1 Block Diagram

This figure shows the EWM block diagram.

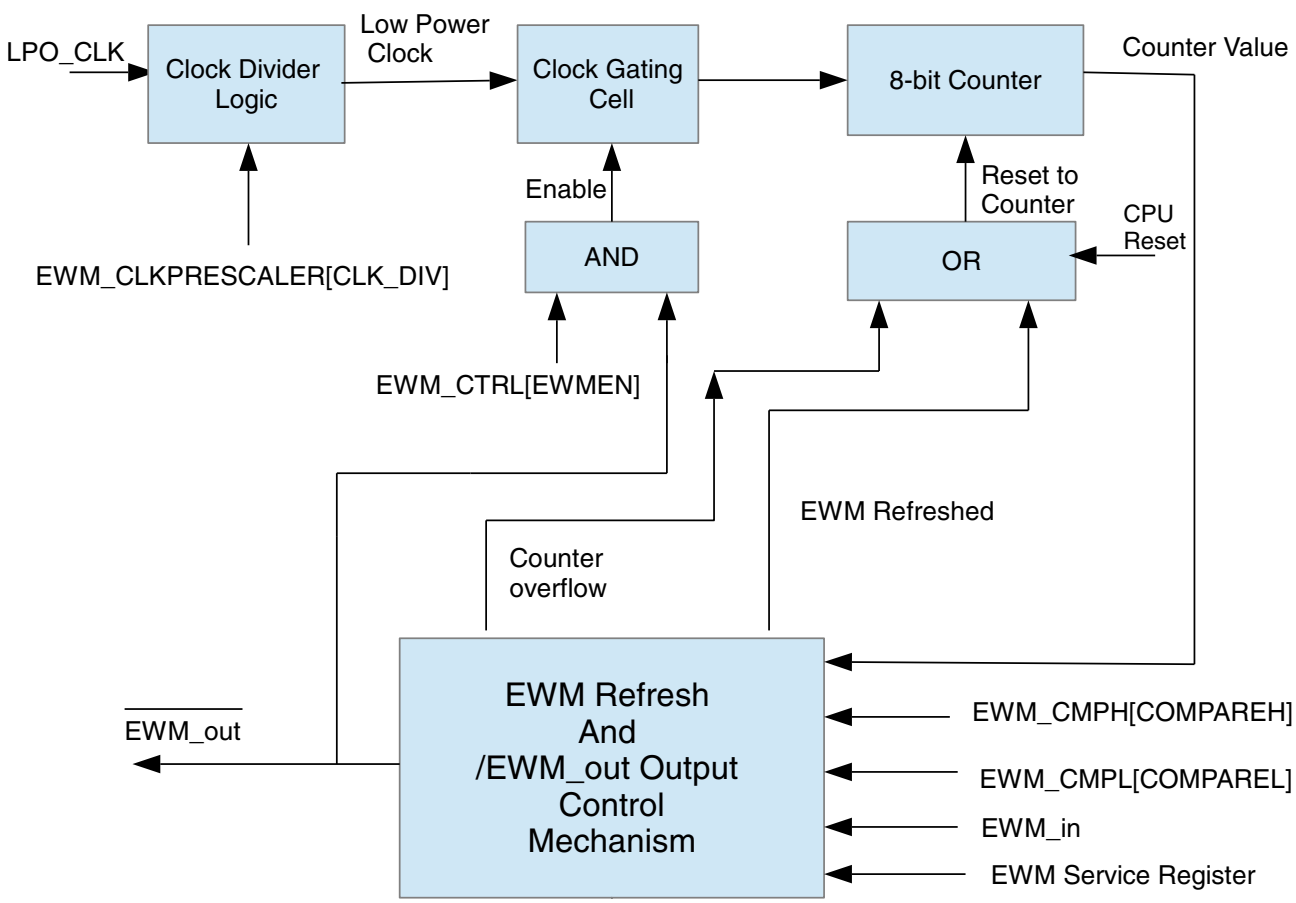

Figure 80-1. EWM Block Diagram

80.2.2 Features

Features of EWM module include:

- Independent LPO_CLK clock source
- Programmable time-out period specified in terms of number of EWM LPO_CLK clock cycles.
- Windowed refresh option
  - Provides robust check that program flow is faster than expected.
  - Programmable window.
  - Refresh outside window leads to assertion of EWM_OUT_b.
- Robust refresh mechanism
  - Write values of 0xB4 and 0x2C to EWM Refresh Register within 63 peripheral bus clock cycles.
- One output port, EWM_OUT_b, when asserted is used to reset or place the external circuit into safe mode.
- One Input port, EWM_in, allows an external circuit to control the assertion of the EWM_OUT_b signal.

80.3 Functional Description

The following sections describe functional details of the EWM module.

NOTE

When the BUS_CLK is lost, then EWM module doesn't generate the EWM_OUT_b signal and no refresh operation is possible

80.3.1 Modes of Operation

This section describes the module's operating modes.

80.3.1.1 Stop Mode

When the EWM is in stop mode, the CPU refreshes to the EWM cannot occur. On entry to stop mode, the EWM's counter freezes.

There are two possible ways to exit from Stop mode:

- On exit from stop mode through a reset, the EWM remains disabled.
- On exit from stop mode by an interrupt, the EWM is re-enabled, and the counter continues to be clocked from the same value prior to entry to stop mode.

Note the following if the EWM enters the stop mode during CPU refresh mechanism: At the exit from stop mode by an interrupt, refresh mechanism state machine starts from the previous state which means, if first refresh command is written correctly and EWM enters the stop mode immediately, the next command has to be written within the next *63* peripheral bus clocks after exiting from stop mode. User must mask all interrupts prior to executing EWM refresh instructions.

80.3.1.2 Wait Mode

The EWM module treats the stop and wait modes as the same. EWM functionality remains the same in both of these modes.

80.3.1.3 Debug Mode

Entry to debug mode has no effect on the EWM.

- If the EWM is enabled prior to entry of debug mode, it remains enabled.
- If the EWM is disabled prior to entry of debug mode, it remains disabled.

80.3.2 The EWM_OUT_b Signal

The EWM_OUT_b is a digital output signal used to gate an external circuit (application specific) that controls critical safety functions. For example, the EWM_OUT_b could be connected to the high voltage transistors circuits that control an AC motor in a large appliance.

The EWM_OUT_b signal remains deasserted when the EWM is being regularly refreshed by the CPU within the programmable refresh window, indicating that the application code is executed as expected.

The EWM_OUT_b signal is asserted in any of the following conditions:

- The EWM refresh occurs when the counter value is less than CMPL value.
- The EWM counter value reaches the CMPH value, and no EWM refresh has occurred.
- If functionality of EWM_in pin is enabled and EWM_in pin is asserted while refreshing the EWM.
- After any reset (by the virtue of the external pull-down mechanism on the EWM_OUT_b pin)

The EWM_OUT_b is asserted after any reset by the virtue of the external pull-down mechanism on the EWM_OUT_b signal. Then, to deassert the EWM_OUT_b signal, set EWMEN bit in the CTRL register to enable the EWM.

If the EWM_OUT_b signal shares its pad with a digital I/O pin, on reset this actual pad defers to being an input signal. The pad state is controlled by the EWM_OUT_b signal only after the EWM is enabled by the EWMEN bit in the CTRL register.

Note

EWM_OUT_b pad must be in pull down state when EWM functionality is used and when EWM is under Reset.

80.3.3 EWM_OUT_b pin state in low power modes

During Wait, Stop and Power Down modes the EWM_OUT_b pin enters a high-impedance state. A user has the option to control the logic state of the pin using an external pull device or by configuring the internal pull device. When the CPU enters a Run mode from Wait or Stop recovery, the pin resumes its previous state before entering Wait or Stop mode. When the CPU enters Run mode from Power Down, the pin returns to its reset state.

80.3.4 The EWM_in Signal

The EWM_in is a digital input signal for safety status of external safety circuits, that allows an external circuit to control the assertion of the EWM_OUT_b signal. For example, in the application, an external circuit monitors a critical safety function, and if there is fault with safety function, the external circuit can then actively initiate the EWM_OUT_b signal that controls the gating circuit.

The EWM_in signal is ignored if the EWM is disabled, or if INEN bit of CTRL register is cleared, as after any reset.

On enabling the EWM (setting the CTRL[EWMEN] bit) and enabling EWM_in functionality (setting the CTRL[INEN] bit), the EWM_in signal must be in the deasserted state prior to the CPU start refreshing the EWM. This ensures that the EWM_OUT_b stays in the deasserted state; otherwise, the EWM_OUT_b output signal is asserted.

Note

The user must update the CMPH and CMPL registers prior to enabling the EWM. After enabling the EWM, the counter resets to zero, therefore the user shall provide a reasonable time after a power-on reset for the external monitoring circuit to stabilize. The user shall also ensure that the EWM_in pin is deasserted.

80.3.5 EWM Counter

It is an 8-bit ripple counter fed from a clock source that is independent of the peripheral bus clock source. As the preferred time-out is between 1 ms and 100 ms the actual clock source should be in the kHz range.

The counter is reset to zero after the CPU reset, or when EWM refresh action completes, or at counter overflow. The counter value is not accessible to the CPU.

80.3.6 EWM Compare Registers

The compare registers CMPL and CMPH are write-once after a CPU reset and cannot be modified until another CPU reset occurs.

The EWM compare registers are used to create a refresh window to refresh the EWM module.

It is illegal to program CMPL and CMPH with same value. In this case, as soon as counter reaches (CMPL + 1), EWM_OUT_b is asserted.

80.3.7 EWM Refresh Mechanism

Other than the initial configuration of the EWM, the CPU can only access the EWM by the EWM Service Register. The CPU must access the EWM service register with correct write of unique data within the windowed time frame as determined by the CMPL and CMPH registers for correct EWM refresh operation. Therefore, three possible conditions can occur:

Table 80-2. EWM Refresh Mechanisms

Condition	Mechanism
An EWM refresh action completes when: CMPL < Counter < CMPH.	The software behaves as expected and the EWM counter is reset to zero. The EWM_OUT_b output signal remains in the deasserted state if, during the EWM refresh action, the EWM_in input has been in deasserted state.
An EWM refresh action completes when Counter < CMPL	The software refreshes the EWM before the windowed time frame, the counter is reset to zero and the EWM_OUT_b output signal is asserted irrespective of the input EWM_in signal.
Counter value reaches CMPH prior to completion of EWM refresh action.	Software has not refreshed the EWM. The EWM counter is reset to zero and the EWM_OUT_b output signal is asserted irrespective of the input EWM_in signal.

80.3.8 EWM Interrupt

When EWM_OUT_b is asserted, an interrupt request is generated to indicate the assertion of the EWM reset out signal. This interrupt is enabled when CTRL[INTEN] is set. Clearing this bit clears the interrupt request but does not affect EWM_OUT_b. The EWM_OUT_b signal can be deasserted only by forcing a system reset.

80.3.9 Selecting the EWM counter clock

There are four possible low power clock sources for the EWM counter. Select one of the available clock sources by programming CLKCTRL[CLKSEL].

80.3.10 Counter clock prescaler

The EWM counter clock source can be prescaled by a clock divider, by programming CLKPRESCALER[CLK_DIV]. This divided clock is used to run the EWM counter.

NOTE

The divided clock used to run the EWM counter must be no more than half the frequency of the bus clock.

80.4 EWM Signal Descriptions

The EWM has two external signals and internal options for the counter clock sources, as shown in the following table.

NOTE

All active-low signals are now represented with the suffix "_b" throughout the chapter.

Table 80-3. EWM Signal Descriptions

Signal	Description	I/O
EWM_in	EWM input for safety status of external safety circuits. The polarity of EWM_in is programmable using the EWM_CTRL[ASSIN] bit. The default polarity is active low.	I
EWM_OUT_b	EWM reset out signal	O
lpo_clk[3:0]	Low power clock sources for running counter	I

80.5 Memory Map/Register Definition

This section contains the module memory map and registers.

NOTE

EWM only supports 8-bit register access. 16-bit and 32-bit access are not possible.

80.5.1 EWM register descriptions

80.5.1.1 EWM memory map

EWM base address: 4002_C000h

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)
0	Control Register (CTRL)	8	RW	00
1	Service Register (SERV)	8	WORZ	00
2	Compare Low Register (CMPL)	8	RWONCE	00
3	Compare High Register (CMPH)	8	RWONCE	FF
4	Clock Control Register (CLKCTRL)	8	RWONCE	00
5	Clock Prescaler Register (CLKPRESCALER)	8	RWONCE	00

80.5.1.2 Control Register (CTRL)

The CTRL register is cleared by any reset.

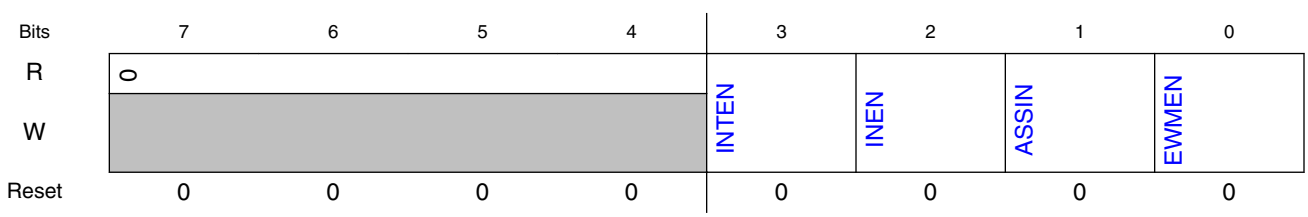
NOTE

INEN, ASSIN and EWMEN bits can be written once after a CPU reset. Modifying these bits more than once, generates a bus transfer error.

80.5.1.2.1 Offset

Register	Offset
CTRL	0h

80.5.1.2.2 Diagram



80.5.1.2.3 Fields

Field	Description
7-4	Reserved

Table continues on the next page...

Field	Description
—	
3 INTEN	Interrupt Enable. This bit when set and EWM_OUT_b is asserted, an interrupt request is generated. To de-assert interrupt request, user should clear this bit by writing 0. 0 - Deasserts the interrupt request. 1 - Generates an interrupt request, when EWM_OUT_b is asserted.
2 INEN	Input Enable. This bit when set, enables the EWM_in port. 0 - EWM_in port is disabled. 1 - EWM_in port is enabled.
1 ASSIN	EWM_in's Assertion State Select. Default assert state of the EWM_in signal is logic zero. Setting the ASSIN bit inverts the assert state of EWM_in signal to a logic one. 0 - Default assert state of the EWM_in signal. 1 - Inverts the assert state of EWM_in signal.
0 EWMEN	EWM enable. This bit when set, enables the EWM module. This resets the EWM counter to zero and deasserts the EWM_OUT_b signal. This bit when unset, keeps the EWM module disabled. It cannot be re-enabled until a next reset, due to the write-once nature of this bit. 0 - EWM module is disabled. 1 - EWM module is enabled.

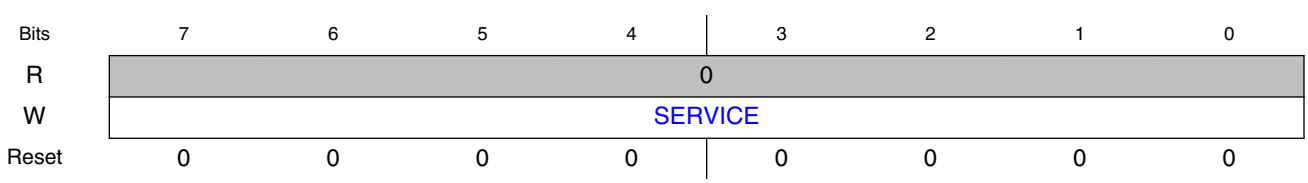
80.5.1.3 Service Register (SERV)

The SERV register provides the interface from the CPU to the EWM module. It is write-only and reads of this register return zero.

80.5.1.3.1 Offset

Register	Offset
SERV	1h

80.5.1.3.2 Diagram



80.5.1.3.3 Fields

Field	Description
7-0 SERVICE	SERVICE The EWM refresh mechanism requires the CPU to write two values to the SERV register: a first data byte of 0xB4, followed by a second data byte of 0x2C. The EWM refresh is invalid if either of the following conditions is true. • The first or second data byte is not written correctly. • The second data byte is not written within a fixed number of peripheral bus cycles of the first data byte. This fixed number of cycles is called *EWM_refresh_time* . 63 peripheral bus clock cycles are required for *EWM_refresh_time*

80.5.1.4 Compare Low Register (CMPL)

The CMPL register is reset to zero after a CPU reset. This provides no minimum time for the CPU to refresh the EWM counter.

NOTE

This register can be written only once after a CPU reset. Writing this register more than once generates a bus transfer error.

80.5.1.4.1 Offset

Register	Offset
CMPL	2h

80.5.1.4.2 Diagram

Reset	0	0	0	0	0	0	0	0

80.5.1.4.3 Fields

Field	Description
7-0 COMPAREL	COMPAREL To prevent runaway code from changing this field, software should write to this field after a CPU reset even if the (default) minimum refresh time is required.

80.5.1.5 Compare High Register (CMPH)

The CMPH register is reset to 0xFF after a CPU reset. This provides a maximum of 256 clocks time, for the CPU to refresh the EWM counter.

NOTE

This register can be written only once after a CPU reset. Writing this register more than once generates a bus transfer error.

NOTE

The valid values for CMPH are up to 0xFE because the EWM counter never expires when CMPH = 0xFF. The expiration happens only if EWM counter is greater than CMPH.

80.5.1.5.1 Offset

Register	Offset
CMPH	3h

Chapter 81
On Chip Cross Triggers Overview

81.1 Overview

This chip integrates an on-chip cross trigger network. The following diagram shows the cross trigger network of this device.

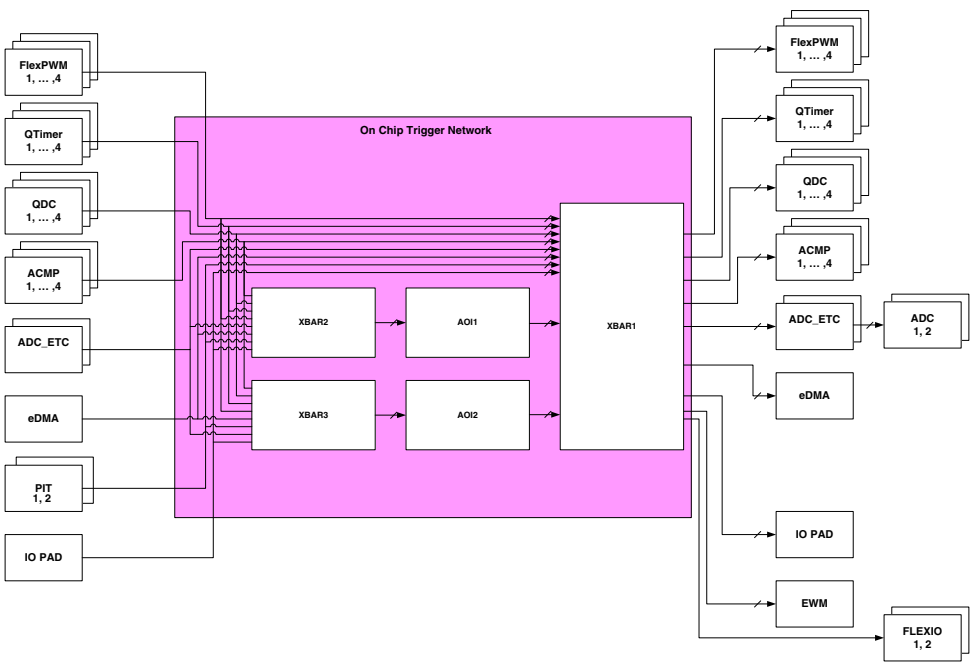

Figure 81-1. On-Chip Cross Trigger Network

81.1.1 Cross BAR (XBAR)

Each crossbar switch is an array of MUXes with shared inputs. Each mux output provides one output of the crossbar. The number of inputs and the number of MUXes/outputs is user configurable and registers are provided to select which of the shared inputs is routed

to each output. The crossbar switches are used to reconfigure data paths between peripherals (peripheral output to peripheral input) as well as between peripherals and GPIO.

81.1.2 And-Or-Inverter (AOI)

The AOI module provides an universal Boolean function generator using a four term sum of products expression, with each product term containing true or complement values of the four selected inputs (A, B, C, D).

82.2 Overview

The AND/OR/INVERT (AOI) module supports the generation of a configurable number of EVENT signals. Each output EVENTn is a configurable and/or/invert function of four associated AOI inputs: An, Bn, Cn, and Dn.

This module is designed to be integrated in conjunction with one or more inter-peripheral crossbar switch (XBAR) modules. A crossbar switch is typically used to select the 4*n AOI inputs from among available peripheral outputs and GPIO signals. The n EVENTn outputs from the AOI module are typically used as additional inputs to a second crossbar switch, adding to it the ability to connect to its outputs an arbitrary 4-input boolean function of its other inputs.

The AOI controller is a slave peripheral module connecting event input indicators from a variety of device modules and generating event output signals that can be routed to an inter-peripheral crossbar switch or other peripherals. Its programming model is accessed through the standard IPS (Sky Blue) slave interface. The module is designed to be very configurable in terms of the functionality of its integrated AOI functions.

82.2.1 Block Diagram

The AOI module supports a configurable number of event outputs, where each event output represents a user-programmed combinational boolean function based on four event inputs. The key features of this module include:

- Four dedicated inputs for each event output
- User-programmable combinational boolean function evaluation for each event output
- Memory-mapped device connected to a slave peripheral (IPS) bus
- Configurable number of event outputs

NOTE

The connections from the AOI module outputs to other functions is SoC-specific.

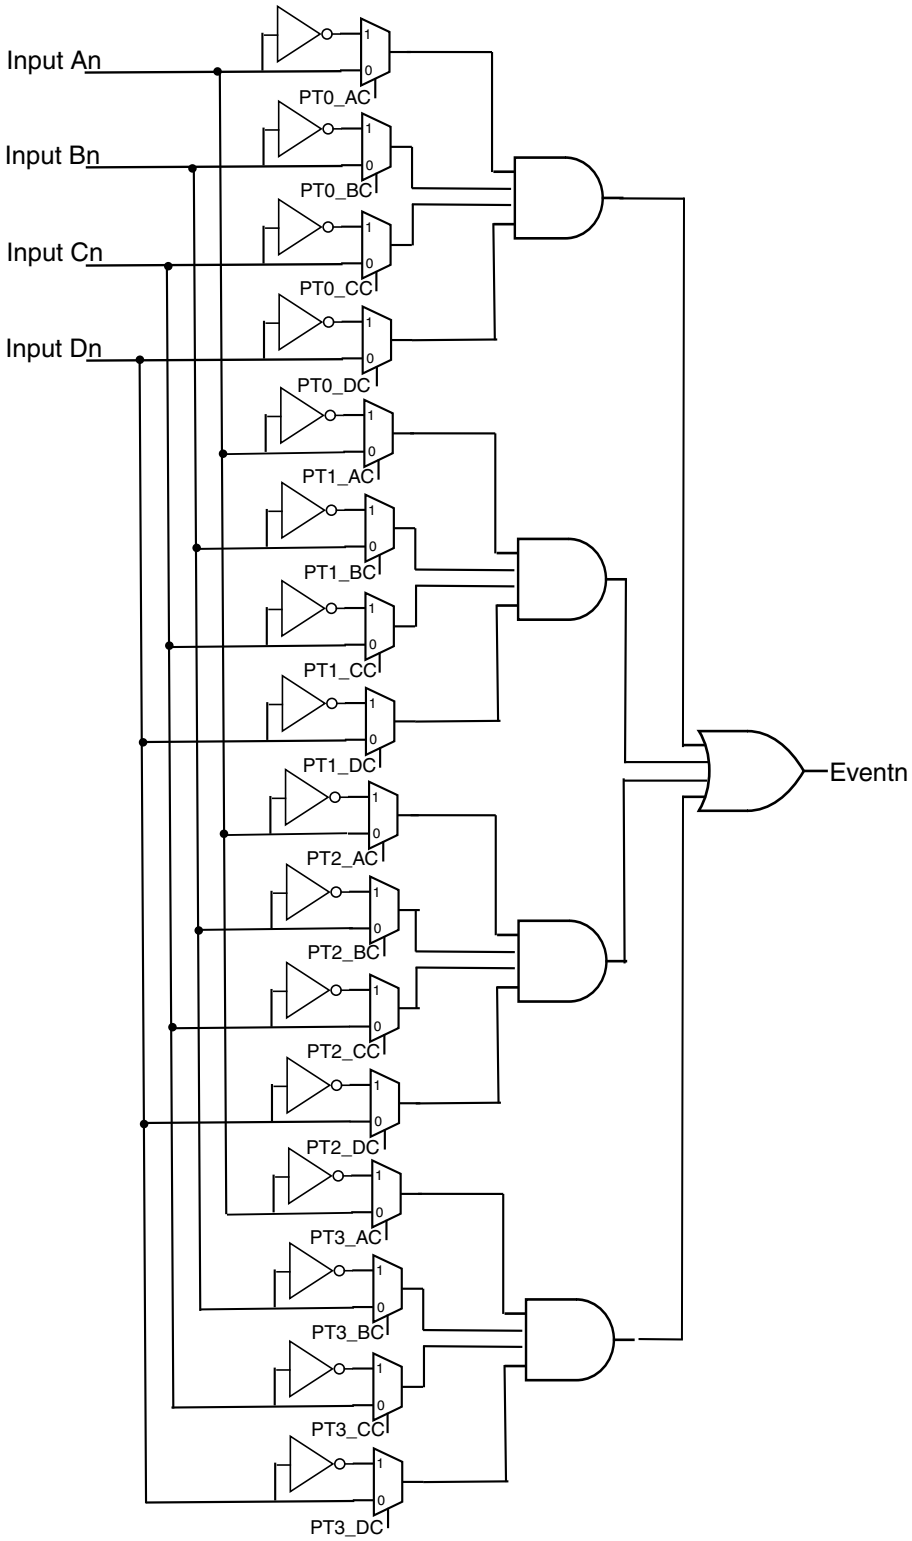

Figure 82-1. Simplified AOI Block Diagram

82.2.2 Features

The major features of the AOI module are summarized below:

- Highly programmable module for creating combinational boolean events for use as hardware triggers
  - Each channel has four event inputs and one output
  - Evaluates a combinational boolean expression as the sum of four products where each product term includes all four selected input sources available as true or complement values
  - Event output is formed as purely combinational logic and operates as a hardware trigger
- Memory-mapped device connected to the slave peripheral (IPS) bus
  - Programming model organized per channel for simplified software

82.2.3 Modes of Operation

The AOI module does not support any special modes of operation. As shown in Figure 82-1, its operation is primarily controlled by the selected event inputs and outputs. Additionally, as a memory-mapped device located on the slave peripheral bus, it responds based strictly on memory address for accesses to its programming model.

The AOI module resides in the slave peripheral *bus clock domain*.

82.3 Functional Description

The AOI is a highly programmable module for creating combinational boolean outputs for use as hardware triggers. Each AOI output channel, as shown in Figure 82-1, has one logic function:

- Evaluation of a combinational boolean expression as a sum of four products where each product term includes all four selected input sources available as true or complement values

A typical application of the AOI module is to be integrated with one or more inter-peripheral crossbar switch modules as illustrated in the following figure. The 20 external inputs are shared by two crossbar switch modules. The crossbar switch on the top is used to select the inputs to four 4-input AOI functions in the AOI module. The outputs of these four AOI functions are output from the AOI module and are added to the original 20 external inputs to provide a total of 24 inputs to the bottom crossbar switch. As a result, the bottom crossbar can not only direct any of the original 20 external inputs to any of its outputs, it can also now direct any one of four 4-input AOI functions of those external inputs to any of its outputs.

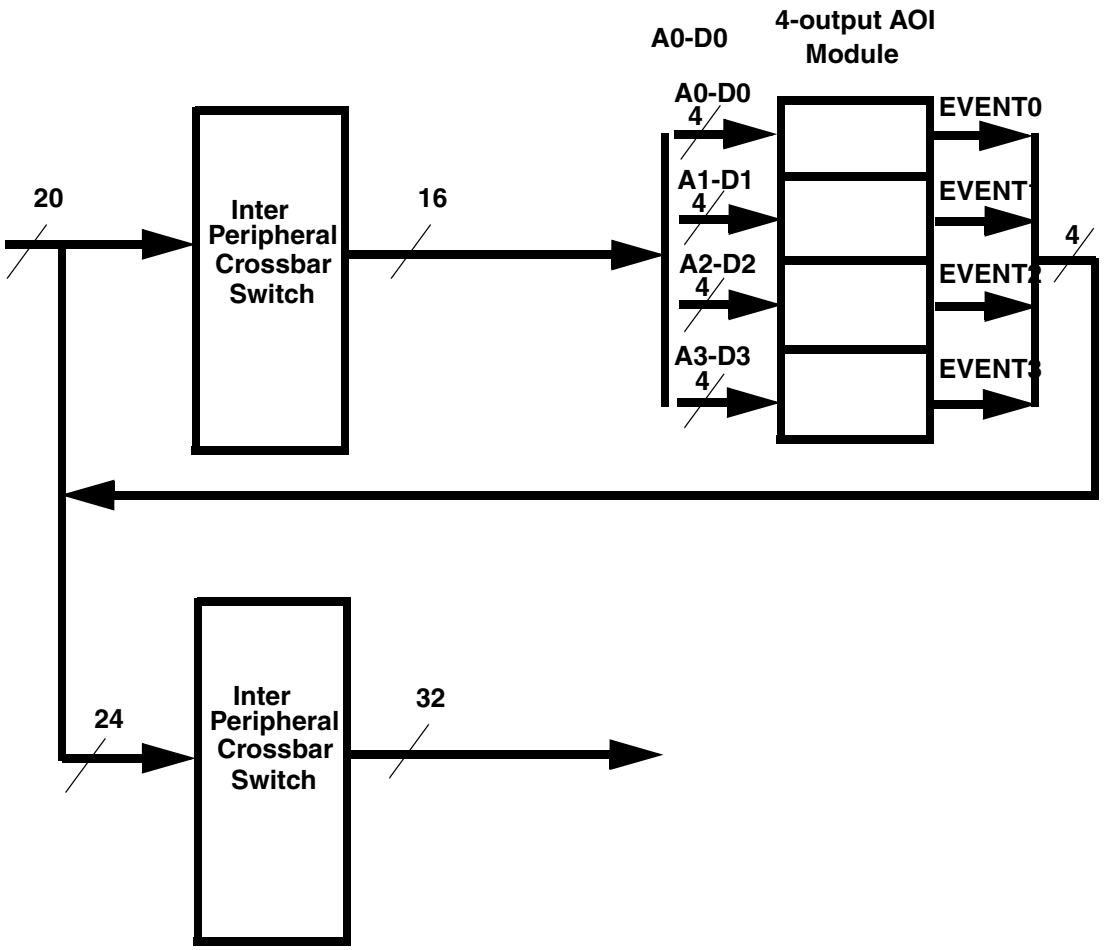

Figure 82-2. Integration Example of AOI with two Inter-Peripheral Crossbar Switches

82.3.1 Configuration Examples for the Boolean Function Evaluation

This section presents examples of the programming model configuration for simple boolean expressions.

The AOI module provides a universal boolean function generator using a four-term sum of products expression with each product term containing true or complement values of the four selected event inputs (A, B, C, D). Specifically, the event output is defined by the following “4 x 4” boolean expression:

```
EVENTn
    = (0,An,~An,1) & (0,Bn,~Bn,1) & (0,Cn,~Cn,1) & (0,Dn,~Dn,1)// product term 0
    | (0,An,~An,1) & (0,Bn,~Bn,1) & (0,Cn,~Cn,1) & (0,Dn,~Dn,1)// product term 1
```

```
    | (0,An,~An,1) & (0,Bn,~Bn,1) & (0,Cn,~Cn,1) & (0,Dn,~Dn,1)// product term 2
    | (0,An,~An,1) & (0,Bn,~Bn,1) & (0,Cn,~Cn,1) & (0,Dn,~Dn,1)// product term 3
```

where each selected input term in each product term can be configured to produce a logical 0 or 1 or pass the true or complement of the selected event input. Each product term uses eight bits of configuration information, two bits for each of the four selected event inputs. The actual boolean expression implemented in each channel is:

```
EVENTn
    = (PT0_AC[0] & An |  PT0_AC[1] & ~An)// product term 0
                      & (PT0_BC[0] &  Bn | PTO_BC[1] & ~Bn)
                      & (PT0_CC[0] &  Cn | PTO_CC[1] & ~Cn)
                      & (PT0_DC[0] &  Dn | PTO_DC[1] & ~Dn)

    | (PT1_AC[0] & An |  PT1_AC[1] & ~An)// product term 1
                      & (PT1_BC[0] &  Bn | PT1_BC[1] & ~Bn)
                      & (PT1_CC[0] &  Cn | PT1_CC[1] & ~Cn)
                      & (PT1_DC[0] &  Dn | PT1_DC[1] & ~Dn)

    | (PT2_AC[0] & An |  PT2_AC[1] & ~An)// product term 2
                      & (PT2_BC[0] &  Bn | PT2_BC[1] & ~Bn)
                      & (PT2_CC[0] &  Cn | PT2_CC[1] & ~Cn)
                      & (PT2_DC[0] &  Dn | PT2_DC[1] & ~Dn)

    | (PT3_AC[0] & An |  PT3_AC[1] & ~An)// product term 3
                      & (PT3_BC[0] &  Bn | PT3_BC[1] & ~Bn)
                      & (PT3_CC[0] &  Cn | PT3_CC[1] & ~Cn)
                      & (PT3_DC[0] &  Dn | PT3_DC[1] & ~Dn)
```

where the bits of the combined {BFCRT01n,BFCRT23n} registers correspond to the `PT{0-3}_{A,B,C,D}C[1:0]` terms in the equation.

Consider the settings of the combined 32-bit {BFCRT01n,BFCRT23n} registers for several simple boolean expressions as shown in Table 82-2.

Table 82-2. BFCRTn Values for Simple Boolean Expressions

Event Output Expression	PT0	PT1	PT2	PT3	{BFCRT01, BFCRT23}
A & B	A & B	0	0	0	01011111_00000000_00000000_00000000
A & B & C	A & B & C	0	0	0	01010111_00000000_00000000_00000000
(A & B & C) + D	A & B & C	D	0	0	01010111_11111101_00000000_00000000
A + B + C + D	A	B	C	D	01111111_11011111_11110111_11111101
(A & ~B) + (~A & B)	A & ~B	~A & B	0	0	01101111_10011111_00000000_00000000

As can be seen in these examples, the resulting logic provides a simple yet powerful boolean function evaluation for defining an event output.

82.3.2 AOI Timing Between Inputs and Outputs

Each EVENTn output of the AOI module is a combination function of its four dedicated inputs An, Bn, Cn, and Dn. Propagation through the AOI and any associated inter-peripheral crossbar switch modules is intended to be single bus clock cycle.

82.3.3 Clocks

The bus clock is used for register accesses by the system, but AOI functions themselves are asynchronous and do not use a clock.

82.4 External Signal Description

The AOI module does not directly support any external interfaces. There may be package input signals (indirectly) connected to the module as event inputs, but since the *AOI does not include any input synchronization hardware*, this function must be handled before the event input signals are routed into the module.

82.5 Memory Map and Register Descriptions

The AOI module supports access to its programming model via a 16-bit peripheral bus connection. The module is designed to support 16-bit accesses only. Functionality for accesses of other widths is undefined.

82.5.1 AOI register descriptions

The AOI module supports a specific number of event outputs. Each output EVENTn outputs a four-term AOI function of four binary inputs: An, Bn, Cn, and Dn. A pair of 16-bit registers configures this four-term AOI function: The two registers BFCRT01n and BFCRT23n define the configuration for the evaluation of the Boolean function defining EVENTn, where *n* is the event output channel number. The BFCRT01n register defines the configuration of product terms 0 and 1, and the BFCRT23n register defines the configuration of product terms 2 and 3.

The AOI module provides a universal Boolean function generator using a four-term sum of products expression with each product term containing true or complement values of the four selected event inputs (An, Bn, Cn, Dn). Specifically, the EVENTn output is defined by the following "4 x 4" Boolean expression:

```
EVENTn
    = (0,An,~An,1) & (0,Bn,~Bn,1) & (0,Cn,~Cn,1) & (0,Dn,~Dn,1)// product term 0
    | (0,An,~An,1) & (0,Bn,~Bn,1) & (0,Cn,~Cn,1) & (0,Dn,~Dn,1)// product term 1
    | (0,An,~An,1) & (0,Bn,~Bn,1) & (0,Cn,~Cn,1) & (0,Dn,~Dn,1)// product term 2
    | (0,An,~An,1) & (0,Bn,~Bn,1) & (0,Cn,~Cn,1) & (0,Dn,~Dn,1)// product term 3
```

where each selected input of each product term can be configured to produce a logical 0 or 1 or pass the true or complement of the selected event input. Each product term uses 8 bits of configuration information, 2 bits for each of the four selected event inputs. The resulting logic provides a simple yet powerful Boolean function evaluation for defining an event output.

These AOI functions are combinational in nature and are intended to be sampled and used synchronously.

Chapter 83
Inter-Peripheral Crossbar Switch A (XBARA)

83.1 Chip-specific XBAR information

Table 83-1. Reference links to related information

Topic	Related module(s)	Reference
System memory map	-	System Memory Map
Clocking	CCM	Clock Management Clock Control Module (CCM)
Power management	PMU	Power Management Power Management Unit
Signal multiplexing	IOMUX	External Signals and Pin Multiplexing IOMUX
Interrupts, DMA Events and XBAR Assignments	-	Interrupts, DMA Events and XBAR Assignments

On this device, for XBAR1 (see the XBARA chapter), the number of inputs is 144, and the number of outputs is 175. For XBAR2 and XBAR3 (see the XBARB chapter), the number of inputs is 98 , and the number of outputs is 16.

83.2 Overview

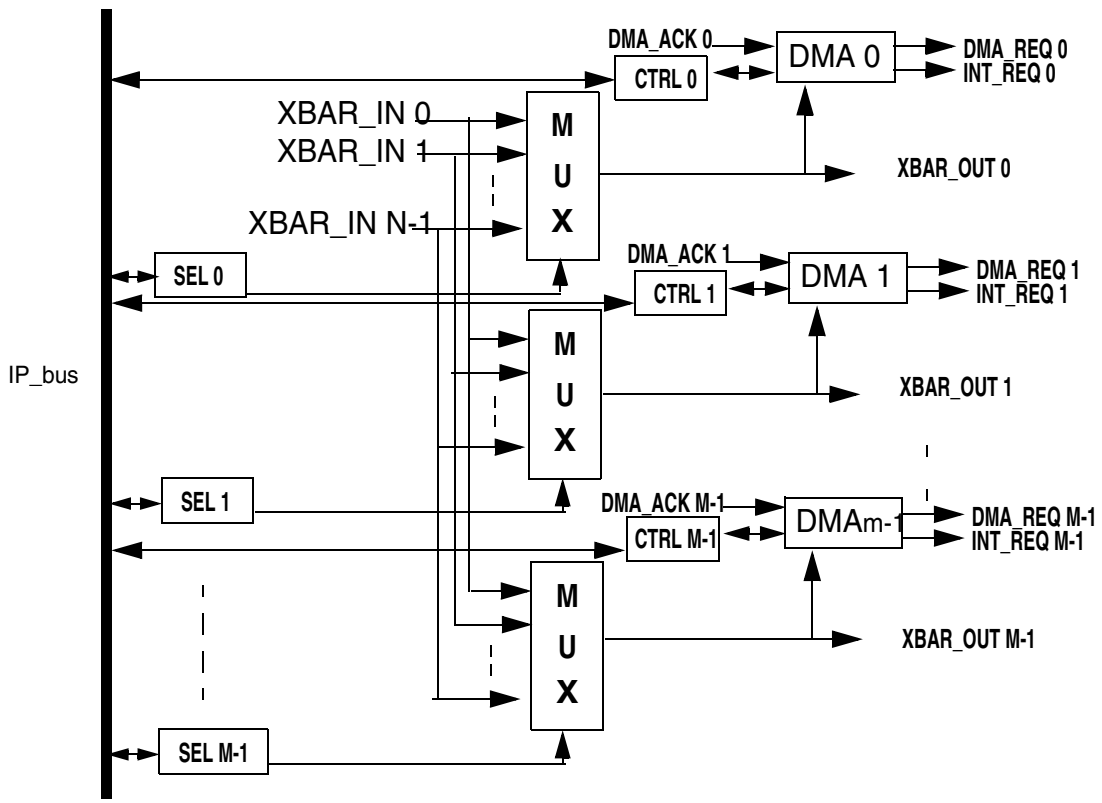
This module implements an array of M N-input combinational muxes. All muxes share the same N inputs in the same order, but each mux has its own independent select field.

The intended application of this module is to provide a flexible crossbar switch function that allows any input (typically from external GPIO or internal module outputs) to be connected to any output (typically to external GPIO or internal module inputs) under user control. This is used to allow user configuration of data paths between internal modules and between internal modules and GPIO.

A subset of the muxes can be configured to support edge detection and either interrupt or DMA request generation based on detected signal edges on the mux output. This allows signal transitions on the signals feeding the crossbar to trigger interrupts or initiate data transfers via DMA into or out of other system modules.

83.2.1 Block Diagram

The block diagram for XBAR is shown in Figure 83-1.



Note: Control field support can be restricted to a subset of outputs. CTRLn represents the memory mapped control fields in the XBAR_CTRL registers for each corresponding XBAR_OUT output. Control fields provide edge status, edge selection, and interrupt/DMA generation controls.

Figure 83-1. XBAR Block Diagram

83.2.2 Features

The XBAR module design includes these distinctive features:

- M identical N-input muxes with individual select fields.

- Edge detection with associated interrupt or DMA request generation for a subset of mux outputs.
- Memory mapped registers with IPBus interface for select and control fields.
- Register write protection input signal.

83.2.3 Modes of Operation

The XBAR module design operates in only a single mode of operation: Functional Mode. The various operation modes are detailed in Functional Mode.

83.3 Functional Description

83.3.1 General

The XBAR module has only one mode of operation, functional mode.

83.3.2 Functional Mode

The value of each mux output is XBAR_OUT[n] = XBAR_IN[SELn]. The SELn select values are configured in the XBAR_SEL registers. All muxes share the same inputs in the same order.

The following is an example to show how to specify the specific input for the specific output:

To select XBAR_IN03 to connect with XBAR_OUT07, according to the index of XBAR_OUT07, select the SEL07 (same number with the selected XBAR_OUT index) fields in the MSBs of the Select Register 3 XBAR_SEL3, and assign the index (0x03, Hexadecimal) of the selected XBAR_IN in it.

```
XBAR_SEL3 &= 0x0011; /*Clear the SEL7 fields
XBAR_SEL3 |= 0x0300; /*Assign the 0x03 to the SEL7 fields
```

A subset of XBAR_OUT[*] outputs has dedicated control fields in a Crossbar Control (XBAR_CTRL) register. Control fields provide the ability to perform edge detection on the corresponding XBAR_OUT output. Edge detection in turn can optionally be used to trigger an interrupt or DMA request. The intention is that, by detecting specified edges on signals propagating through the Crossbar, interrupts or DMA requests can be triggered to perform data transfers to or from other system components.

Control fields include an edge status field (STS), an detected edge type field (EDGE), and interrupt and DMA enable fields (IEN and DEN). STSn is set to 1 when an edge consistent with EDGEn occurs on XBAR_OUT[n]. STSn is cleared by writing 1 to it. Writing 0 as no effect. See Interrupts and DMA Requests for details on the use of STSn for DMA and interrupt request generation.

83.3.3 Clocks

All sequential functionality is controlled by the Bus Clock.

83.3.4 Resets

The XBAR module can be reset by only a hard reset, which forces all registers to their reset state.

83.3.5 Interrupts and DMA Requests

For each XBAR_OUT[*] output with XBAR_CTRL register support, DMA or interrupt functionality can be enabled by setting the corresponding XBAR_CTRL register bit DENn or IENn to 1. DENn and IENn should not be set to 1 at the same time for the same output XBAR_OUT[n].

Setting DENn to 1 enables DMA functionality for XBAR_OUT[n]. When DMA functionality is enabled, the output DMA_REQ[n] reflects the value of STSn. Thus the DMA request asserts when the edge specified by EDGEn is detected on XBAR_OUT[n]. Also, a rising edge on DMA_ACK[n] sets STSn to zero and thus clears the DMA request. When DEN is 0, DMA_REQ[n] is held low and DMA_ACK[n] is ignored.

Setting IENn to 1 enables interrupt functionality for XBAR_OUT[n]. When interrupt functionality is enabled, the output INT_REQ[n] reflects the value of STSn. Thus the interrupt request asserts when the edge specified by EDGEn is detected on XBAR_OUT[n]. The interrupt request is cleared by writing a 1 to STSn. When IENn is 0, INT_REQ[n] is held low.

83.4 External Signals

The following table summarizes the module's external signals.

Table 83-2. Control Signal Properties

Name	I/O Type	Function	Reset State	Notes
XBAR_OUT [0:NUMOUT-1]	O	Mux Outputs with configurable width	XBAR_IN[0]	
XBAR_IN [0:NUMIN-1]	I	Mux Inputs with configurable width	*	
DMA_REQ	O	DMA request	0	
INT_REQ	O	Interrupt request	0	
DMA_ACK	I	DMA acknowledge	0	

At reset, each output XBAR_OUT[*] contains the reset value of the signal driving XBAR_IN[0].

83.4.1 XBAR_OUT[0:NUM_OUT-1] - MUX Outputs

This is a one-dimensional array of the mux outputs. The value on each output XBAR_OUT[n] is determined by the setting of the corresponding memory mapped register SELn such that XBAR_OUT[n] = XBAR_IN[SELn].

83.4.2 XBAR_IN[0:NUM_IN-1] - MUX Inputs

This is a one-dimensional array consisting of the inputs shared by each mux. All muxes share the same inputs in the same order.

83.4.3 DMA_REQ[n] - DMA Request Output(s)

DMA_REQ[n] is a DMA request to the DMA controller.

83.4.4 DMA_ACK[n] - DMA Acknowledge Input(s)

DMA_ACK[n] is a DMA acknowledge input from the DMA controller.

83.4.5 INT_REQ[n] - Interrupt Request Output(s)

INT_REQ[n] is an interrupt request output to the interrupt controller.

83.5 Memory Map and Register Descriptions

The XBAR module has select registers and control registers.

In the XBAR select registers, the SELn fields select which of the shared inputs (XBAR_IN[*]) is muxed to each mux output (XBAR_OUT[*]). There is one SELn field per mux and therefore one per XBAR_OUT output. Crossbar output XBAR_OUT[n] presents the value of XBAR_IN[SELn]. Each select register contains two SELn fields. In the first select register, the LSBs contain the select field for mux 0, and the MSBs contain the select field for mux 1. The pattern repeats in subsequent select registers.

The actual signals connected to XBAR_IN and XBAR_OUT are application specific and are described in the Interrupts, DMA Events, and XBAR Assignments chapter details.

The XBAR control registers configure edge detection, interrupt, and DMA features for a subset of the XBAR_OUT[*] outputs.

83.5.89 Crossbar A Control Register 0 (XBARAx_CTRL0)

Use this register to configure edge detection, interrupt, and DMA features for the XBAR_OUT0 and XBAR_OUT1 outputs.

The XBAR_CTRL registers are organized similarly to the XBAR_SEL registers, with control fields for two XBAR_OUT outputs in each register. In control register 0, the LSBs contain the control fields for XBAR_OUT0, and the MSBs contain the control fields for XBAR_OUT1.

Address: 4003_C000h base + B0h offset = 4003_C0B0h

Bit	15	14	13	12	11	10	9	8
Read	0			STS1	EDGE1		IEN1	DEN1
Write				w1c				
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
Read	0			STS0	EDGE0		IEN0	DEN0
Write				w1c				
Reset	0	0	0	0	0	0	0	0

XBARAx_CTRL0 field descriptions

Field	Description
15–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 STS1	Edge detection status for XBAR_OUT1 This bit reflects the results of edge detection for XBAR_OUT1. This field is set to 1 when an edge consistent with the current setting of EDGE1 is detected on XBAR_OUT1. This field is cleared by writing 1 to it or by a DMA_ACK1 reception when DEN1 is set. Writing 0 to the field has no effect. When interrupt or DMA functionality is enabled for XBAR_OUT1, this field is 1 when the interrupt or DMA request is asserted and 0 when the interrupt or DMA request has been cleared. 0 Active edge not yet detected on XBAR_OUT1 1 Active edge detected on XBAR_OUT1
11–10 EDGE1	Active edge for edge detection on XBAR_OUT1 This field selects which edges on XBAR_OUT1 cause STS1 to assert. 00 STS1 never asserts 01 STS1 asserts on rising edges of XBAR_OUT1 10 STS1 asserts on falling edges of XBAR_OUT1 11 STS1 asserts on rising and falling edges of XBAR_OUT1
9 IEN1	Interrupt Enable for XBAR_OUT1 This bit enables the interrupt function on the corresponding XBAR_OUT1 output. When the interrupt is enabled, the output INT_REQ1 reflects the value STS1. When the interrupt is disabled, INT_REQ1 remains low. The interrupt request is cleared by writing a 1 to STS1. **Restriction:** IEN1 and DEN1 should not both be set to 1. 0 Interrupt disabled 1 Interrupt enabled
8 DEN1	DMA Enable for XBAR_OUT1 This bit enables the DMA function on the corresponding XBAR_OUT1 output. When enabled, DMA_REQ1 presents the value STS1. When disabled, the DMA_REQ1 output remains low. **Restriction:** IEN1 and DEN1 should not both be set to 1. 0 DMA disabled 1 DMA enabled
7–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 STS0	Edge detection status for XBAR_OUT0 This bit reflects the results of edge detection for XBAR_OUT0. This field is set to 1 when an edge consistent with the current setting of EDGE0 is detected on XBAR_OUT0. This field is cleared by writing 1 to it or by a DMA_ACK0 reception when DEN0 is set. Writing 0 to the field has no effect. When interrupt or DMA functionality is enabled for XBAR_OUT0, this field is 1 when the interrupt or DMA request is asserted and 0 when the interrupt or DMA request has been cleared.

Table continues on the next page...

XBARAx_CTRL0 field descriptions (continued)

Field	Description
	0 Active edge not yet detected on XBAR_OUT0 1 Active edge detected on XBAR_OUT0
3–2 EDGE0	Active edge for edge detection on XBAR_OUT0 This field selects which edges on XBAR_OUT0 cause STS0 to assert. 00 STS0 never asserts 01 STS0 asserts on rising edges of XBAR_OUT0 10 STS0 asserts on falling edges of XBAR_OUT0 11 STS0 asserts on rising and falling edges of XBAR_OUT0
1 IEN0	Interrupt Enable for XBAR_OUT0 This bit enables the interrupt function on the corresponding XBAR_OUT0 output. When the interrupt is enabled, the output INT_REQ0 reflects the value STS0. When the interrupt is disabled, INT_REQ0 remains low. The interrupt request is cleared by writing a 1 to STS0. **Restriction:** IEN0 and DEN0 should not both be set to 1. 0 Interrupt disabled 1 Interrupt enabled
0 DEN0	DMA Enable for XBAR_OUT0 This bit enables the DMA function on the corresponding XBAR_OUT0 output. When enabled, DMA_REQ0 presents the value STS0. When disabled, the DMA_REQ0 output remains low. **Restriction:** IEN0 and DEN0 should not both be set to 1. 0 DMA disabled 1 DMA enabled

83.5.90 Crossbar A Control Register 1 (XBARAx_CTRL1)

Use this register to configure edge detection, interrupt, and DMA features for the XBAR_OUT2 and XBAR_OUT3 outputs.

The XBAR_CTRL registers are organized similarly to the XBAR_SEL registers, with control fields for two XBAR_OUT outputs in each register. In control register 1, the LSBs contain the control fields for XBAR_OUT2, and the MSBs contain the control fields for XBAR_OUT3.

Address: 4003_C000h base + B2h offset = 4003_C0B2h

Bit	15	14	13	12	11	10	9	8

Write				w1c				
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
Read	0			STS2	EDGE2		IEN2	DEN2
Write				w1c				
Reset	0	0	0	0	0	0	0	0

XBARAx_CTRL1 field descriptions

Field	Description
15–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 STS3	Edge detection status for XBAR_OUT3 This bit reflects the results of edge detection for XBAR_OUT3. This field is set to 1 when an edge consistent with the current setting of EDGE3 is detected on XBAR_OUT3. This field is cleared by writing 1 to it or by a DMA_ACK3 reception when DEN3 is set. Writing 0 to the field has no effect. When interrupt or DMA functionality is enabled for XBAR_OUT3, this field is 1 when the interrupt or DMA request is asserted and 0 when the interrupt or DMA request has been cleared. 0 Active edge not yet detected on XBAR_OUT3 1 Active edge detected on XBAR_OUT3
11–10 EDGE3	Active edge for edge detection on XBAR_OUT3 This field selects which edges on XBAR_OUT3 cause STS3 to assert. 00 STS3 never asserts 01 STS3 asserts on rising edges of XBAR_OUT3 10 STS3 asserts on falling edges of XBAR_OUT3 11 STS3 asserts on rising and falling edges of XBAR_OUT3
9 IEN3	Interrupt Enable for XBAR_OUT3 This bit enables the interrupt function on the corresponding XBAR_OUT3 output. When the interrupt is enabled, the output INT_REQ3 reflects the value STS3. When the interrupt is disabled, INT_REQ3 remains low. The interrupt request is cleared by writing a 1 to STS3. **Restriction:** IEN3 and DEN3 should not both be set to 1. 0 Interrupt disabled 1 Interrupt enabled
8 DEN3	DMA Enable for XBAR_OUT3 This bit enables the DMA function on the corresponding XBAR_OUT3 output. When enabled, DMA_REQ3 presents the value STS3. When disabled, the DMA_REQ3 output remains low. **Restriction:** IEN3 and DEN3 should not both be set to 1. 0 DMA disabled 1 DMA enabled
7–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 STS2	Edge detection status for XBAR_OUT2 This bit reflects the results of edge detection for XBAR_OUT2.

Table continues on the next page...

XBARAx_CTRL1 field descriptions (continued)

Field	Description
	This field is set to 1 when an edge consistent with the current setting of EDGE2 is detected on XBAR_OUT2. This field is cleared by writing 1 to it or by a DMA_ACK2 reception when DEN2 is set. Writing 0 to the field has no effect. When interrupt or DMA functionality is enabled for XBAR_OUT2, this field is 1 when the interrupt or DMA request is asserted and 0 when the interrupt or DMA request has been cleared. 0 Active edge not yet detected on XBAR_OUT2 1 Active edge detected on XBAR_OUT2
3–2 EDGE2	Active edge for edge detection on XBAR_OUT2 This field selects which edges on XBAR_OUT2 cause STS2 to assert. 00 STS2 never asserts 01 STS2 asserts on rising edges of XBAR_OUT2 10 STS2 asserts on falling edges of XBAR_OUT2 11 STS2 asserts on rising and falling edges of XBAR_OUT2
1 IEN2	Interrupt Enable for XBAR_OUT2 This bit enables the interrupt function on the corresponding XBAR_OUT2 output. When the interrupt is enabled, the output INT_REQ2 reflects the value STS2. When the interrupt is disabled, INT_REQ2 remains low. The interrupt request is cleared by writing a 1 to STS2. **Restriction:** IEN2 and DEN2 should not both be set to 1. 0 Interrupt disabled 1 Interrupt enabled
0 DEN2	DMA Enable for XBAR_OUT2 This bit enables the DMA function on the corresponding XBAR_OUT2 output. When enabled, DMA_REQ2 presents the value STS2. When disabled, the DMA_REQ2 output remains low. **Restriction:** IEN2 and DEN2 should not both be set to 1. 0 DMA disabled 1 DMA enabled

Power management	PMU	Power Management Power Management Unit
Signal multiplexing	IOMUX	External Signals and Pin Multiplexing IOMUX
Interrupts, DMA Events and XBAR Assignments	-	Interrupts, DMA Events and XBAR Assignments

On this device, for XBAR1 (see the XBARA chapter), the number of inputs is 144, and the number of outputs is 175. For XBAR2 and XBAR3 (see the XBARB chapter), the number of inputs is 98 , and the number of outputs is 16.

84.2 Overview

For a description of the general features and functionality of this module, refer to the XBARA description.

84.3 Functional Description

For a functional description of this module, refer to the XBARA functional description.

84.4 External Signals

The following table summarizes the module's external signals.

Table 84-2. Control Signal Properties

Name	I/O Type	Function	Reset State	Notes
XBAR_OUT [0:NUMOUT-1]	O	Mux Outputs with configurable width	XBAR_IN[0]	
XBAR_IN [0:NUMIN-1]	I	Mux Inputs with configurable width	*	

At reset, each output XBAR_OUT[*] contains the reset value of the signal driving XBAR_IN[0].

84.4.1 XBAR_OUT[0:NUM_OUT-1] - MUX Outputs

This is a one-dimensional array of the mux outputs. The value on each output XBAR_OUT[n] is determined by the setting of the corresponding memory mapped register SELn such that XBAR_OUT[n] = XBAR_IN[SELn].

84.4.2 XBAR_IN[0:NUM_IN-1] - MUX Inputs

This is a one-dimensional array consisting of the inputs shared by each mux. All muxes share the same inputs in the same order.

84.5 Memory Map and Register Descriptions

This section provides information about the XBARB instance of the inter-peripheral crossbar switch.

This XBAR module has only select registers.

In the XBAR select registers, the SELn fields select which of the shared inputs (XBAR_IN[*]) is muxed to each mux output (XBAR_OUT[*]). There is one SELn field per mux and therefore one per XBAR_OUT output. Crossbar output XBAR_OUT[n]

presents the value of XBAR_IN[SELn]. Each select register contains two SELn fields. In the first select register, the LSBs contain the select field for mux 0, and the MSBs contain the select field for mux 1. The pattern repeats in subsequent select registers.

The actual signals connected to XBAR_IN and XBAR_OUT are application specific and are described in the Interrupts, DMA Events, and XBAR Assignments chapter details.

Chapter 85
Analog Overview

85.1 Overview

The following analog modules are integrated in this chip:

- Analog-Digital-Converter (ADC) - Supports up to 4.2MS/s sampling rate and up to 20 external analog inputs
- ADC External Trigger Control (ADC_ETC) - Enables multiple users to share a ADC module in a Time-Division-Multiplexing (TDM) method
- Comparator (CMP) - Operational over the entire supply range and features a integrated 8-bit DAC and a integrated 8 to 1 channel mux
- Digital-Analog-Converter (DAC) - 12-bit resolution with on-chip programmable reference generator output

Below is the simplified block diagram:

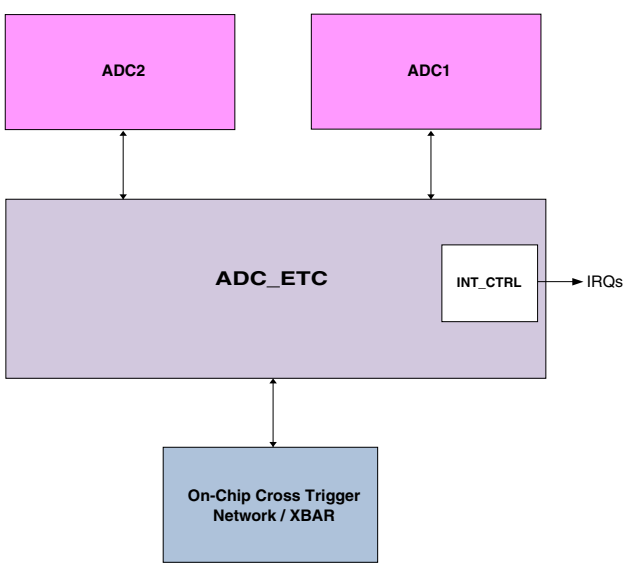

Figure 85-1. Block Diagram (Simplified)

85.1.1 Analog-to-Digital Converter (ADC)

The ADC module features a linear successive approximation algorithm with up to 12-bit singled-ended/13-bit differential resolution. ADC allows use of up to 8 trigger sources with priority level configuration, software or hardware trigger option for each, and 15 command buffers with independent options selection and channel sequence scanning. ADC also allows automatic compare function on results (less-than, greater-than, within range, or out of range). Conversion results are buffered in 16-entry FIFO with configurable watermark and overflow detection.

85.1.2 ADC External Trigger Control (ADC_ETC)

The ADC_ETC module enables multiple trigger sources to share the ADC modules in a TIME-Division-Multiplexing (TDM) way. It manages the external trigger mode (HWT) of the ADCs and supports up to x8 HWT for each ADC. It is capable of triggering dual ADCs in SyncMode (controlled by the same trigger source) or AsyncMode (controlled by separate trigger source). Every ADC HWT can be configured with a Back-to-Back (B2B) and Interrupt Enable (IE) settings and each external trigger can be configured with a fixed priority.

85.1.3 Comparator (CMP)

The analog comparator (CMP) allows for comparing two analog input voltages while the Analog MUX allows for selecting an analog input signal from eight channels. The CMP is operational across the full range of the supply voltage. The integrated 8-bit DAC provides a selectable voltage reference for applications where voltage reference is needed.

The CMPs share the same 1.8V reference voltage with the ADCs.

85.1.4 Digital-Analog Converter (DAC)

The DAC module is 12-bit resolution with on-chip programmable reference generator output. The voltage output range is from 1/4096 Vin to Vin, and the step is 1/4096 Vin, where Vin is the input voltage from ADC_VREFH.

Chapter 86
Analog Comparator (ACMP)

86.1 Chip-specific CMP information

Table 86-1. Reference links to related information

Topic	Related module(s)	Reference

Special considerations to use the ACMP for wakeup from system STANDBY mode

In order to use the ACMP module as a wakeup source when the chip is in system STANDBY mode, the clock for the ACMP must be configured to be OFF for the corresponding core mode that will be used with the system STANDBY request. The following table shows which combinations can be used for a STANDBY mode wakeup:

Table 86-3. STANDBY mode wakeup combinations

Clock Gate Level	WAIT STBY	STOP STBY	SUSPEND STBY
Clock needed in Run mode	N	Y	Y
Clock needed in Run and Wait	N	Y	Y
Clock needed in Run, Wait, and Stop	N	N	Y
Clock on in any mode	N	N	N

86.2 Overview

The comparator (CMP) module provides a circuit for comparing two analog input voltages. The comparator circuit is designed to operate across the full range of the supply voltage, known as rail-to-rail operation.

The Analog MUX (ANMUX) provides a circuit for selecting an analog input signal from eight channels. One signal is provided by the 8-bit digital-to-analog converter (DAC). The mux circuit is designed to operate across the full range of the supply voltage.

The DAC is a 256-tap resistor ladder network that provides a selectable voltage reference for applications requiring a voltage reference. The 256-tap resistor ladder network divides the supply reference V_{in} into 256 voltage levels. A 8-bit digital register input selects the output voltage level, which varies from V_{in} to $V_{in}/256$. V_{in} can be selected from two voltage sources, V_{in1} or V_{in2}.

86.2.1 CMP, DAC, and ANMUX diagram

The following figure shows the block diagram for the High-Speed Comparator, DAC, and ANMUX modules.

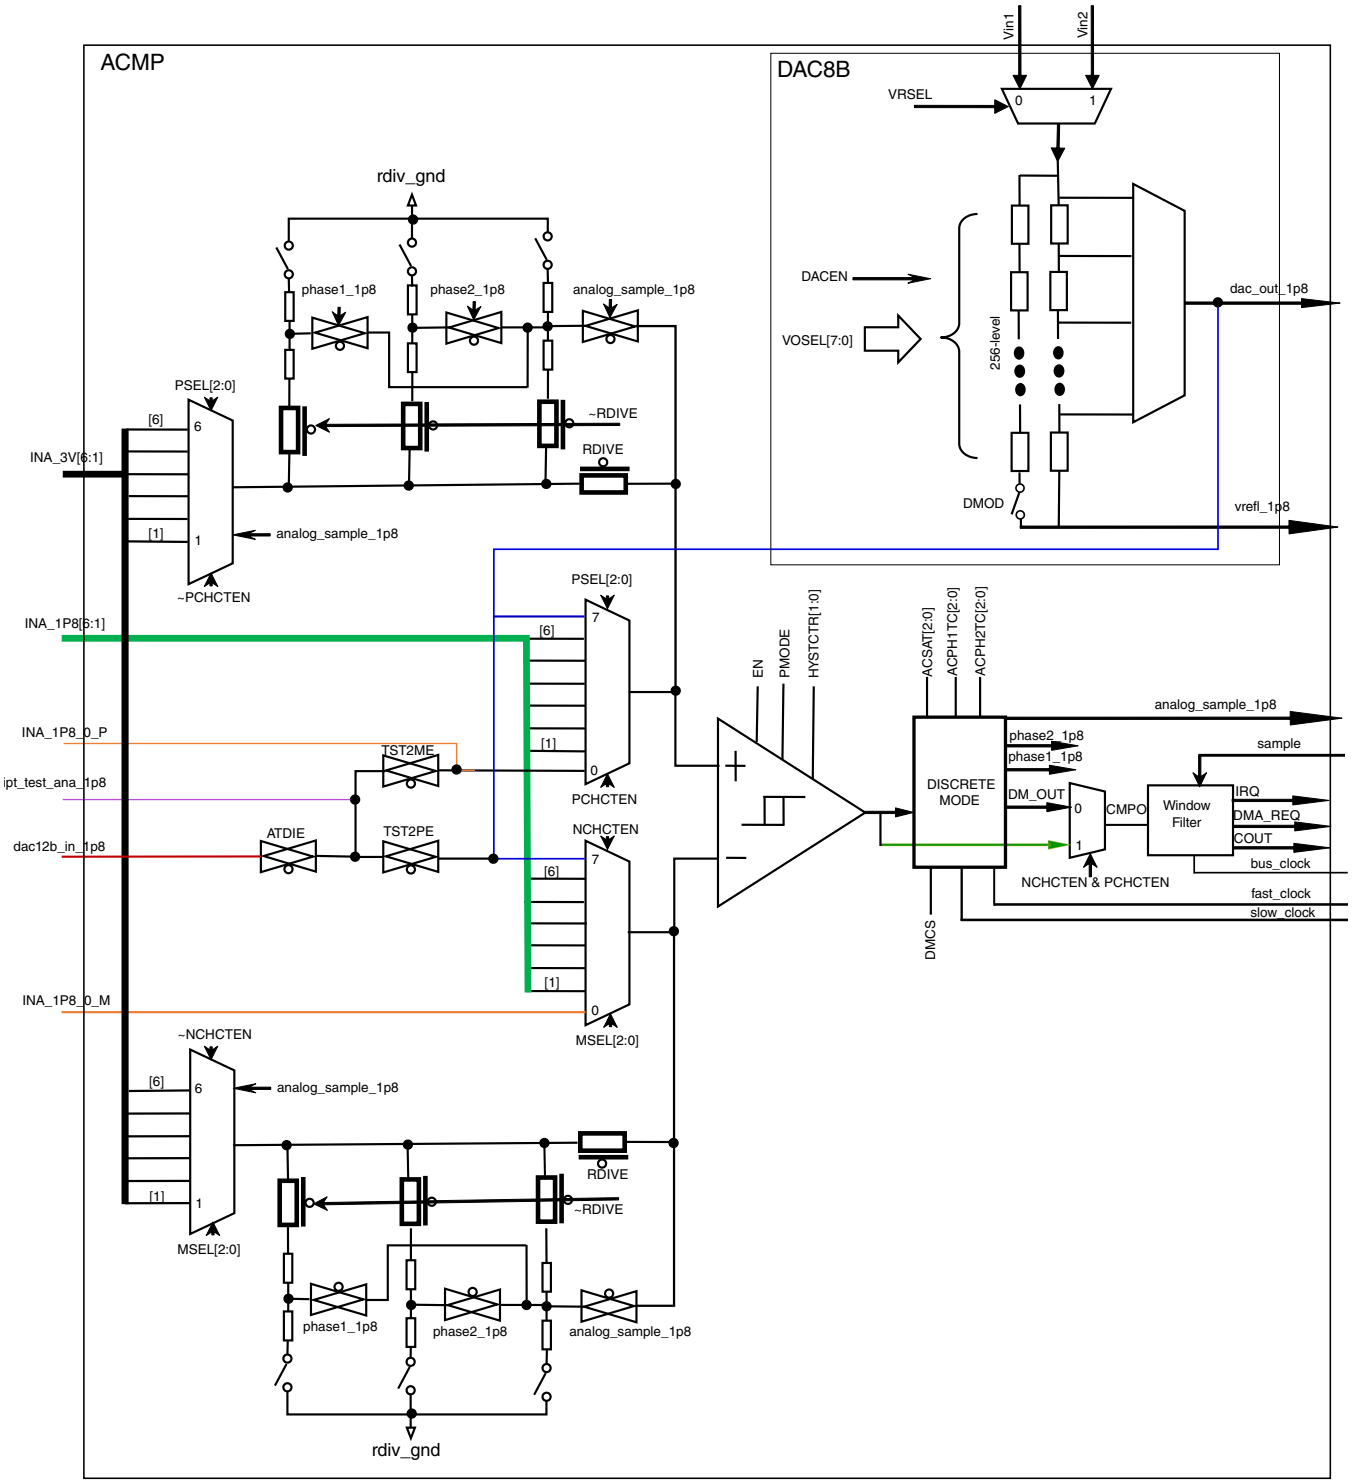

Figure 86-1. CMP high level diagram

86.2.2 CMP block diagram

The following figure shows the block diagram for the CMP module.

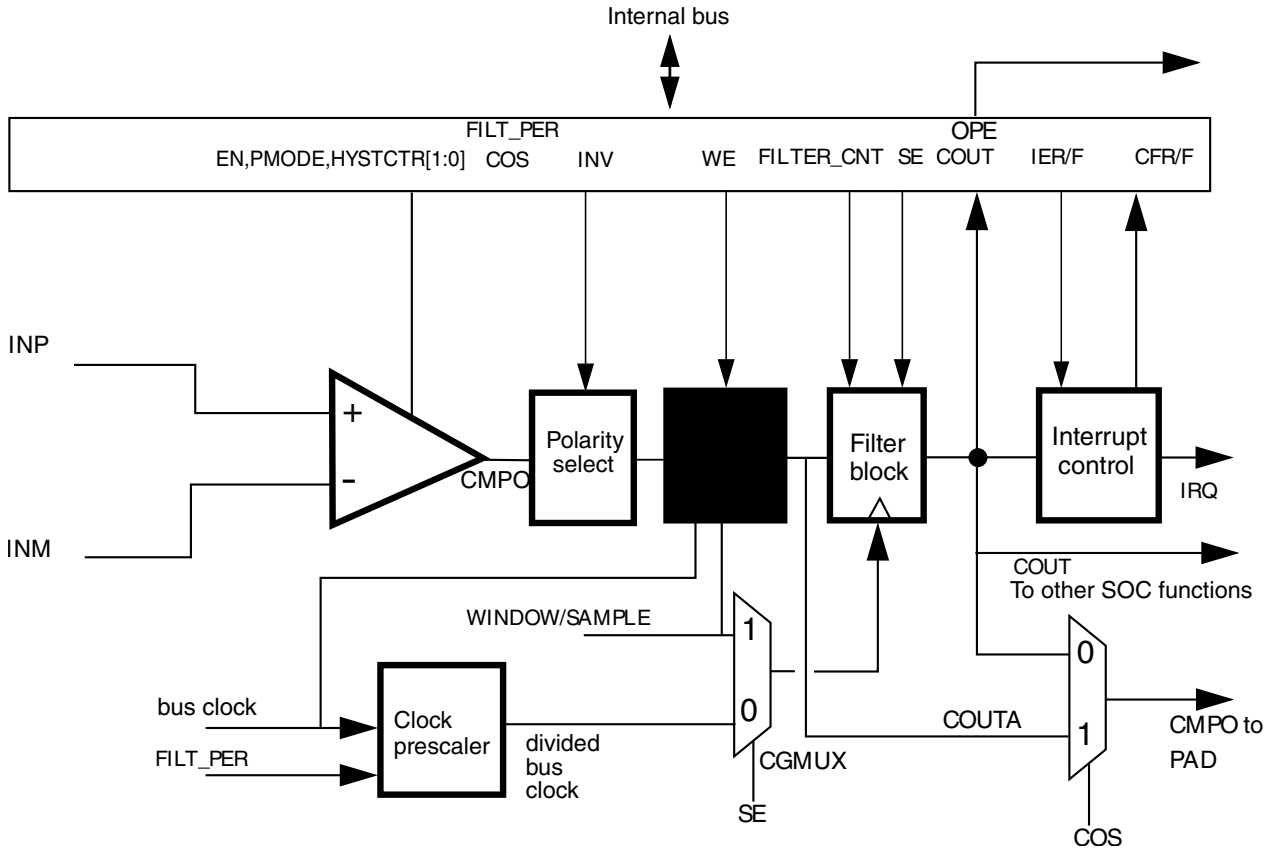

Figure 86-2. Comparator module block diagram

In the CMP block diagram:

- The Window Control block is bypassed when C0[WE] = 0.
- If C0[WE] = 1, the comparator output is sampled on every bus clock when WINDOW=1 to generate COUTA. Sampling does NOT occur when WINDOW = 0.
- The Filter block is bypassed when not in use.

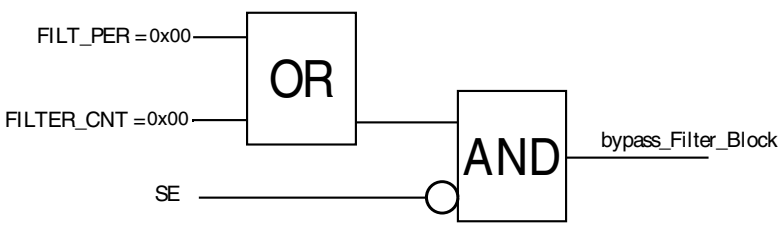

Figure 86-3. Filter block bypass logic

- The Filter block acts as a simple sampler if the filter is bypassed and C0[FILTER_CNT] is set to 0x01.
- The Filter block filters based on multiple samples when the filter is bypassed and C0[FILTER_CNT] is set greater than 0x01.

- If C0[SE] = 1, the external SAMPLE input is used as the sampling clock.
- IF C0[SE] = 0, the divided bus clock is used as the sampling clock.

- If enabled, the Filter block will incur up to one bus clock additional latency penalty on COUT due to the fact that COUT, which crosses clock domain boundaries, must be resynchronized to the bus clock.
- C0[WE] and C0[SE] are mutually exclusive.
- If enabled, the filter clock and the sample period must be at least 4 times slower than the system clock to the comparator.

86.2.3 Features

The following subsections list the features of the CMP, the 8-bit DAC, and the ANMUX.

86.2.3.1 CMP features

The CMP has the following features:

- Operational over the entire supply range
- Inputs may range from rail to rail
- Programmable hysteresis control
- Selectable interrupt on rising-edge, falling-edge, or both rising or falling edges of the comparator output
- Selectable inversion on comparator output
- Capability to produce a wide range of outputs such as:
  - Sampled
  - Windowed, which is ideal for certain PWM zero-crossing-detection applications
  - Digitally filtered:
    - Filter can be bypassed
    - Can be clocked via external SAMPLE signal or scaled bus clock
- External hysteresis can be used at the same time that the output filter is used for internal functions

- Two software selectable performance levels:
  - Shorter propagation delay at the expense of higher power
  - Low power, with longer propagation delay
- DMA transfer support
  - A comparison event can be selected to trigger a DMA transfer
- Functional in all MCU power modes
- The window and filter functions are not available in STOP modes
- The comparator can be triggered by other peripherals

86.2.3.2 8-bit DAC key features

The 8-bit DAC has the following features:

- 8-bit resolution
- Selectable supply reference source
- Configurable low power mode or high speed mode
- Power Down mode to conserve power when not in use
- Option to route the output of 8-bit DAC to the internal comparator input, where it can be selected as one of the CMP inputs as reference for comparison

86.2.3.3 ANMUX key features

The ANMUX has the following features:

- Two 8-to-1 channel MUXes for selection of the source for comparator input
- Operational over the entire supply range

86.3 CMP functional description

The CMP module can be used to compare two analog input voltages applied to INP and INM. CMPO is high when the non-inverting input is greater than the inverting input, and is low when the non-inverting input is less than the inverting input. This signal can be selectively inverted by setting CMP_C0[INVT] = 1.

CMP_C0[IER] and CMP_C0[IEF] are used to select the condition that causes the CMP module to assert an interrupt to the processor. CMP_C0[CFF] is set on a falling edge, and CMP_C0[CFR] is set on a rising edge of the comparator output. The optionally filtered CMPO can be read directly through CMP_C0[COUT].

86.3.1 CMP functional modes

There are three main sub-blocks to the CMP module:

- The comparator itself
- The window function
- The filter function

The filter, CMP_C0[FILTER_CNT], can be clocked from an internal or external clock source. The filter is programmable with respect to the number of samples that must agree before a change in the output is registered. In the simplest case, only one sample must agree. In this case, the filter acts as a simple sampler.

The external sample input is enabled using CMP_C0[SE]. When set, the output of the comparator is sampled only on rising edges of the sample input.

The "windowing mode" is enabled by setting CMP_C0[WE]. When set, the comparator output is sampled only when WINDOW=1. This feature can be used to ignore the comparator output during time periods in which the input voltages are not valid. This is especially useful when implementing zero-crossing-detection for certain PWM applications.

The comparator filter and sampling features can be combined as shown in the following table. Individual modes are discussed below.

Table 86-4. Comparator sample/filter controls

Mode #	CMP_C0[EN]	CMP_C0[WE]	CMP_C0[SE]	CMP_C0[FILTER_CNT]	CMP_C0[FPR]	Operation
1	0	X	X	X	X	**Disabled** See the Disabled mode (# 1).
2A	1	0	0	0x00	X	**Continuous Mode** See the Continuous mode (#s 2A & 2B).
2B	1	0	0	X	0x00	
3A	1	0	1	0x01	X	**Sampled, Non-Filtered mode** See the Sampled, Non-Filtered mode (#s 3A & 3B).
3B	1	0	0	0x01	> 0x00	
4A	1	0	1	> 0x01	X	**Sampled, Filtered mode** See the Sampled, Filtered mode (#s 4A & 4B).
4B	1	0	0	> 0x01	> 0x00	
5A	1	1	0	0x00	X	**Windowed mode** Comparator output is sampled on every rising bus clock edge when SAMPLE=1 to generate COUTA. See the Windowed mode (#s 5A & 5B).
5B	1	1	0	X	0x00	
6	1	1	0	0x01	0x01–0xFF	**Windowed/Resampled mode** Comparator output is sampled on every rising bus clock edge when SAMPLE=1 to generate COUTA, which is then resampled on an interval determined by CMP_C0[FPR] to generate COUT. See the Windowed/Resampled mode (# 6).
7	1	1	0	> 0x01	0x01–0xFF	**Windowed/Filtered mode** Comparator output is sampled on every rising bus clock edge when SAMPLE=1 to generate COUTA, which is then resampled and filtered to generate COUT. See the Windowed/Filtered mode (#7).
8	1	1	1	X	X	**Trigger mode** In RUN mode Comparator is configured to the modes same with these Modes #5A, #5B, #6 and #7 as elaborated in above rows depended on the CMP_C0[FILT_CNT] and CMP_C0[FPR] settings. In STOP mode, the comparator and possible the 8bit DAC is triggered work

Table continues on the next page...

Table 86-4. Comparator sample/filter controls (continued)

Mode #	CMP_C0[EN]	CMP_C0[WE]	CMP_C0[SE]	CMP_C0[FILTER_CNT]	CMP_C0[FPR]	Operation
						periodically and the active channels follow the round robin cycling scheme. See the Trigger mode.
All other combinations of CMP_C0[EN], CMP_C0[WE], CMP_C0[SE], CMP_C0[FILTER_CNT], and CMP_C0[FPR] are illegal.						

For cases where a comparator is used to drive a fault input, for example, for a motor-control module such as FTM or FlexPWM, it must be configured to operate in Continuous mode so that an external fault can immediately pass through the comparator to the target fault circuitry.

Note

Filtering and sampling settings must be changed only after setting CMP_C0[SE]=0, CMP_C0[FPR] =0 and CMP_C0[FILTER_CNT]=0x00. This resets the filter to a known state.

86.3.1.1 Disabled mode (# 1)

In Disabled mode, the analog comparator is non-functional and consumes no power. CMPO is 0 in this mode.

86.3.1.2 Continuous mode (#s 2A & 2B)

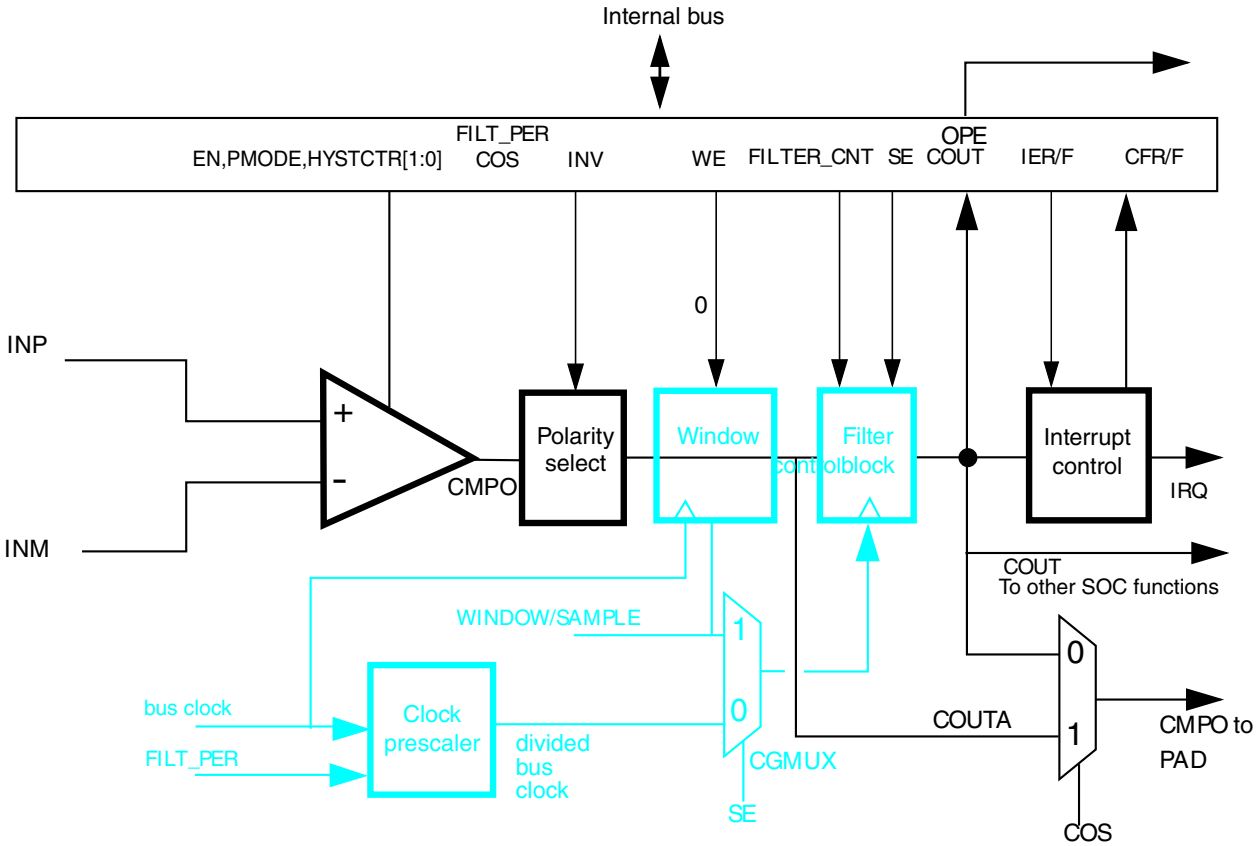

Figure 86-4. Comparator operation in Continuous mode

NOTE

See the chip configuration section for the source of sample/ window input.

The analog comparator block is powered and active. CMPO may be optionally inverted, but is not subject to external sampling or filtering. Both window control and filter blocks are completely bypassed. CMP_C0[COUT] is updated continuously. The path from comparator input pins to output pin is operating in combinational unclocked mode. COUT and COUTA are identical.

For control configurations that result in disabling the filter block, seeFigure 86-3 .

86.3.1.3 Sampled, Non-Filtered mode (#s 3A & 3B)

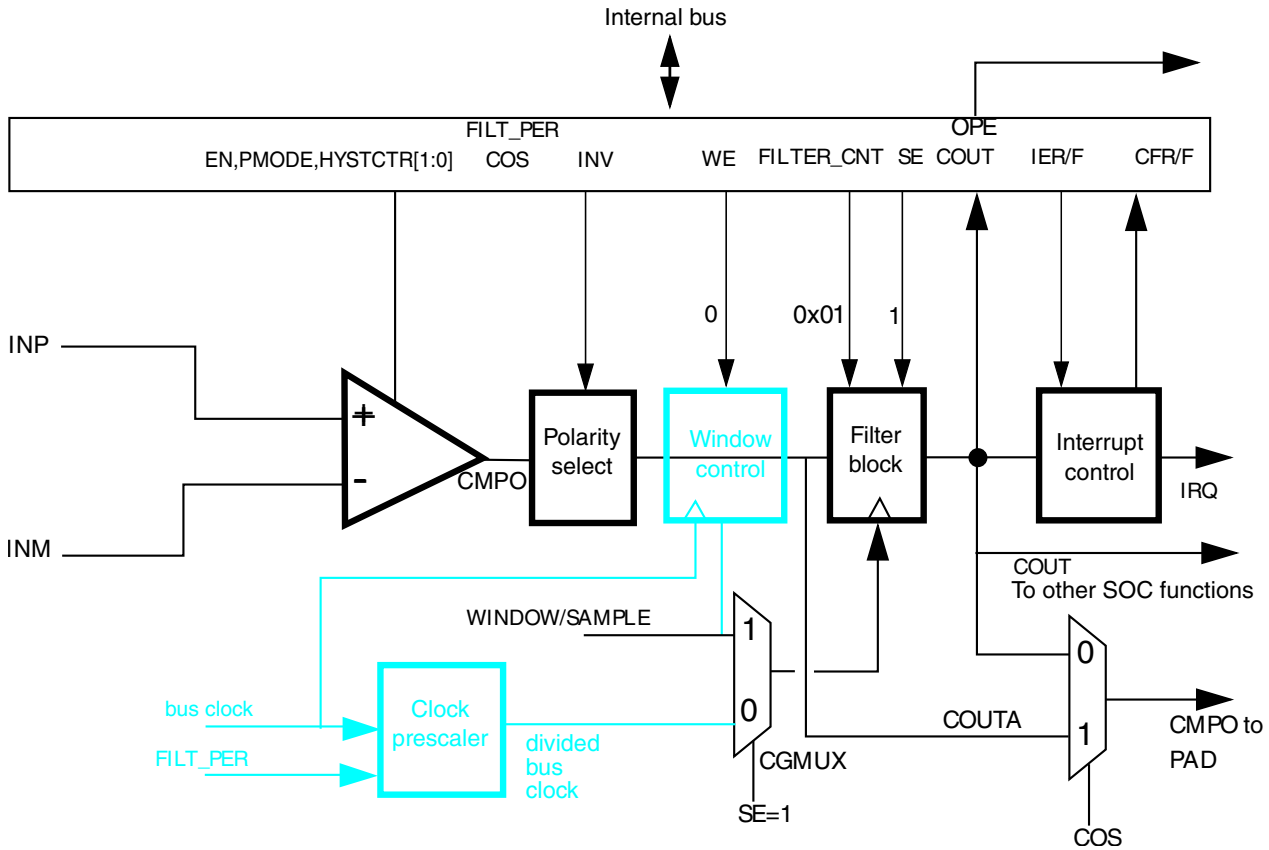

Figure 86-5. Sampled, Non-Filtered (# 3A): sampling point externally driven

In Sampled, Non-Filtered mode, the analog comparator block is powered and active. The path from analog inputs to COUTA is combinational unclocked. Windowing control is completely bypassed. COUTA is sampled whenever a rising edge is detected on the filter block clock input.

The only difference in operation between Sampled, Non-Filtered (# 3A) and Sampled, Non-Filtered (# 3B) is in how the clock to the filter block is derived. In #3A, the clock to filter block is externally derived while in #3B, the clock to filter block is internally derived.

The comparator filter has no other function than sample/hold of the comparator output in this mode (# 3B).

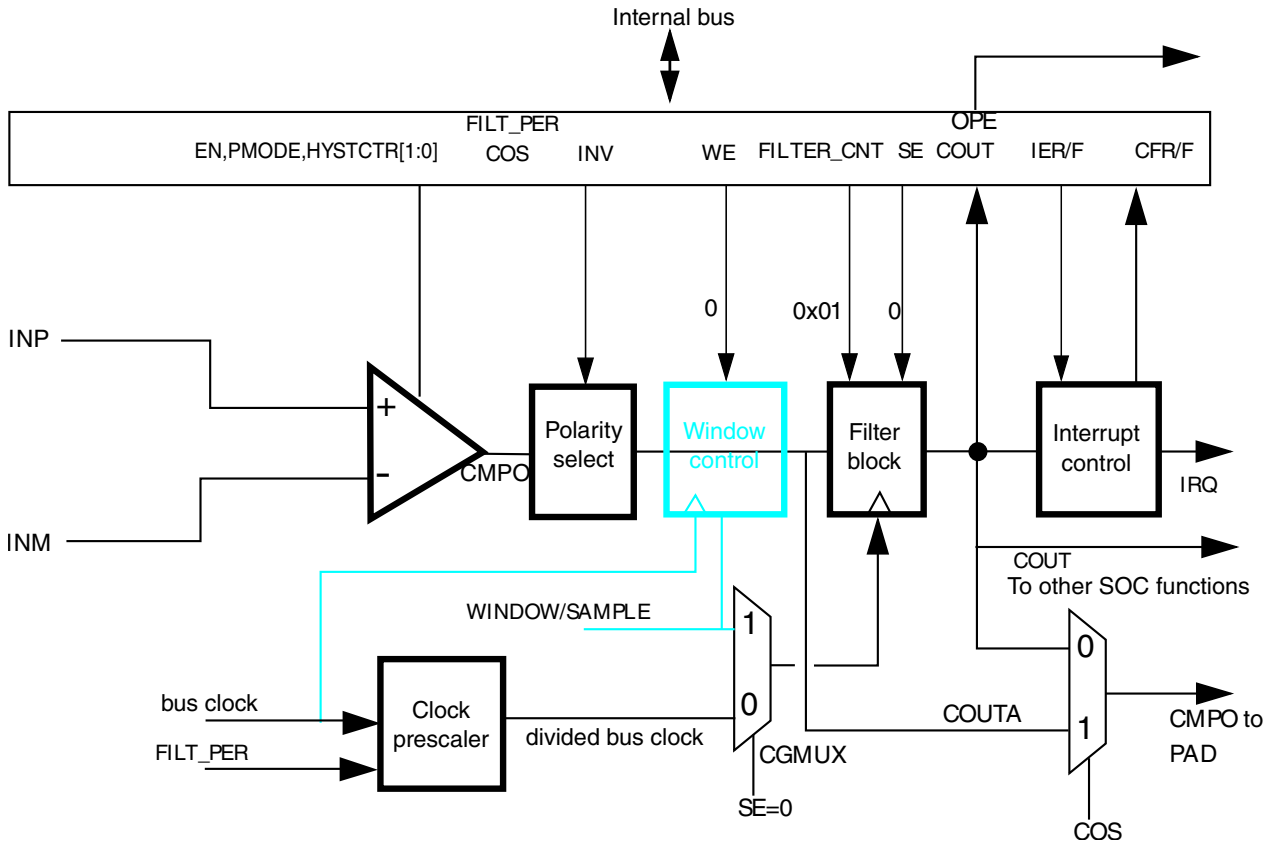

Figure 86-6. Sampled, Non-Filtered (# 3B): sampling interval internally derived

86.3.1.4 Sampled, Filtered mode (#s 4A & 4B)

In Sampled, Filtered mode, the analog comparator block is powered and active. The path from analog inputs to COUTA is combinational unclocked. Windowing control is completely bypassed. COUTA is sampled whenever a rising edge is detected on the filter block clock input.

The only difference in operation between Sampled, Non-Filtered (# 3A) and Sampled, Filtered (# 4A) is that, now, CMP_C0[FILTER_CNT]>1, which activates filter operation.

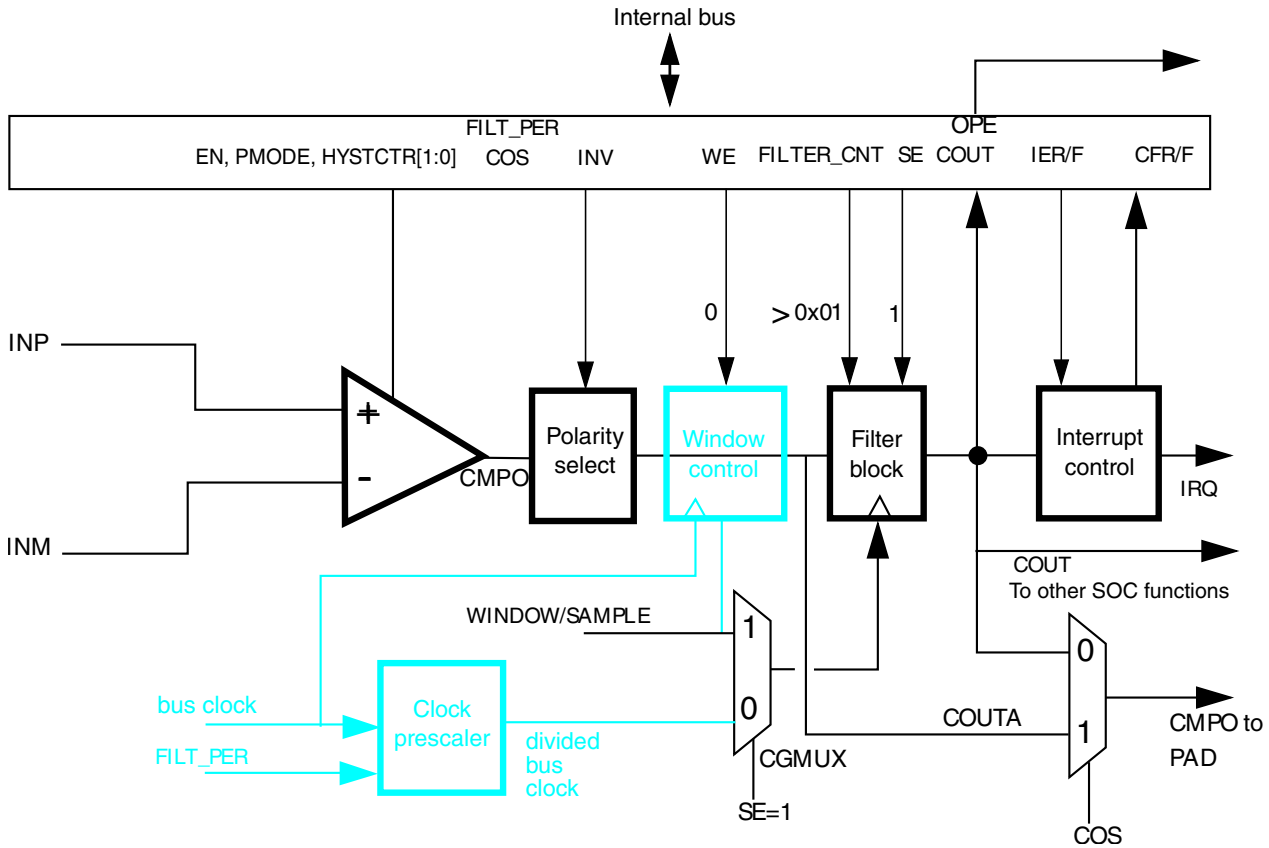

Figure 86-7. Sampled, Filtered (# 4A): sampling point externally driven

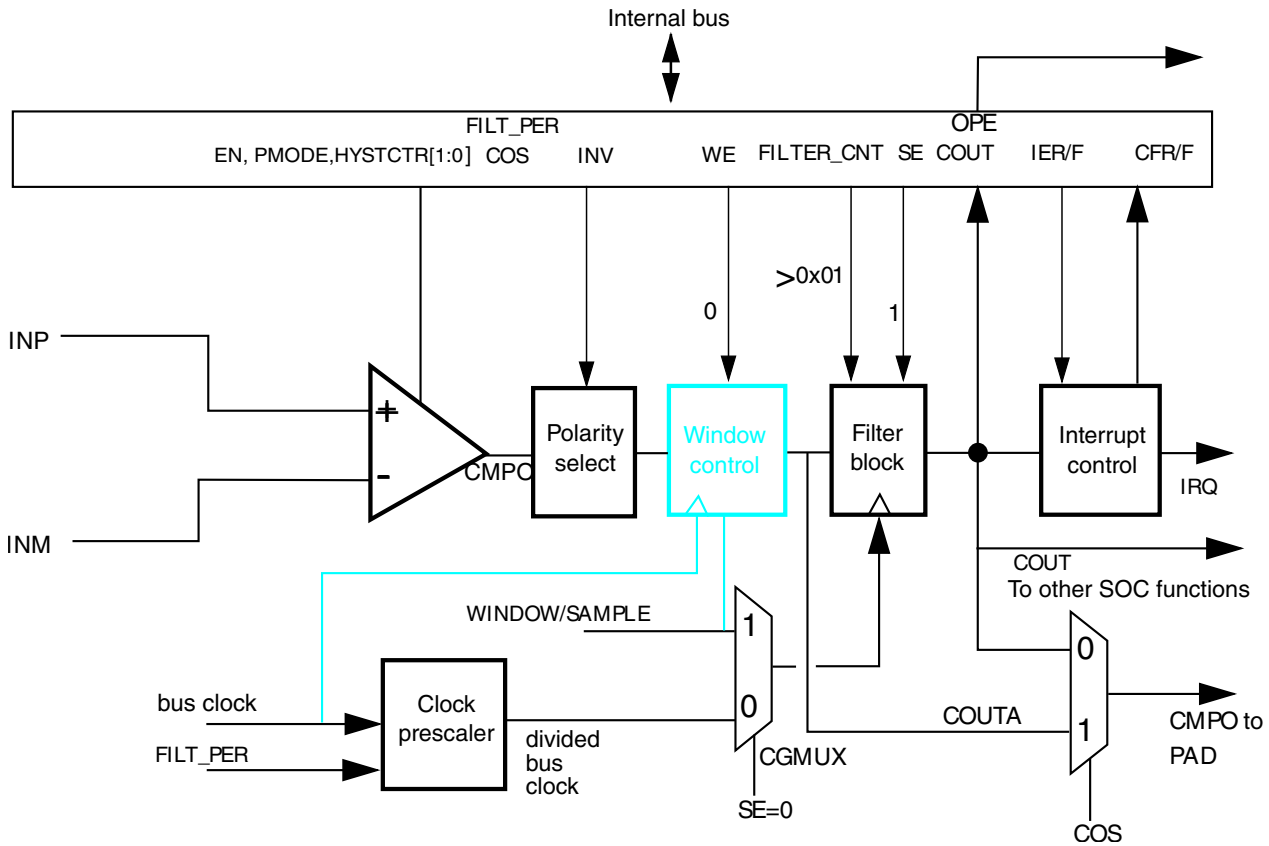

Figure 86-8. Sampled, Filtered (# 4B): sampling point internally derived

The only difference in operation between Sampled, Non-Filtered (# 3B) and Sampled, Filtered (# 4B) is that now, CMP_C0[FILTER_CNT]>1, which activates filter operation.

86.3.1.5 Windowed mode (#s 5A & 5B)

The following figure illustrates comparator operation in the Windowed mode, ignoring latency of the analog comparator, polarity select, and window control block. It also assumes that the polarity select is set to non-inverting state.

NOTE

The analog comparator output is passed to COUTA only when the WINDOW signal is high.

In actual operation, COUTA may lag the analog inputs by up to one bus clock cycle plus the combinational path delay through the comparator and polarity select logic.

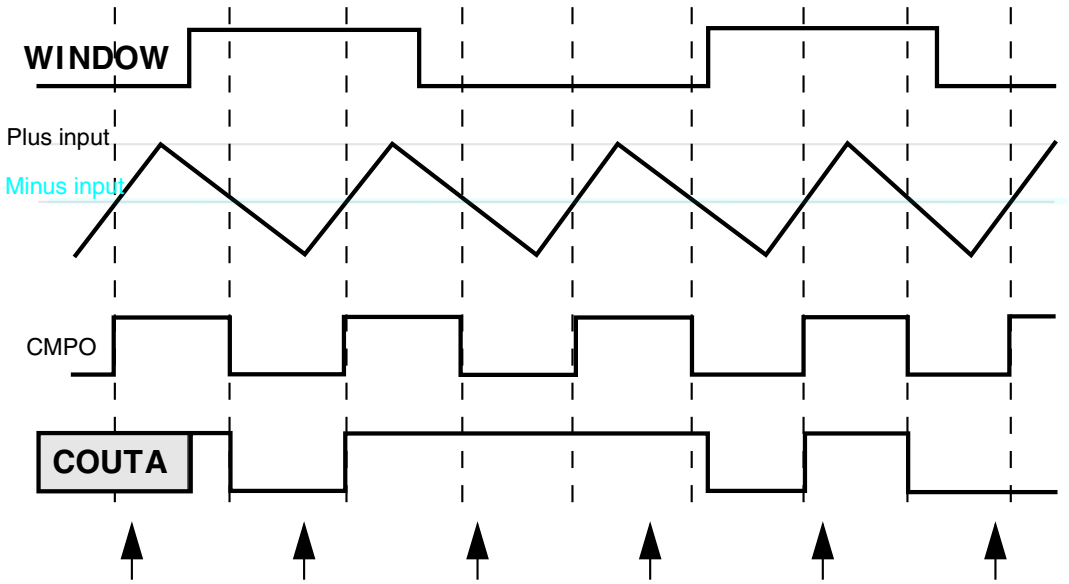

Figure 86-9. Windowed mode timing diagram

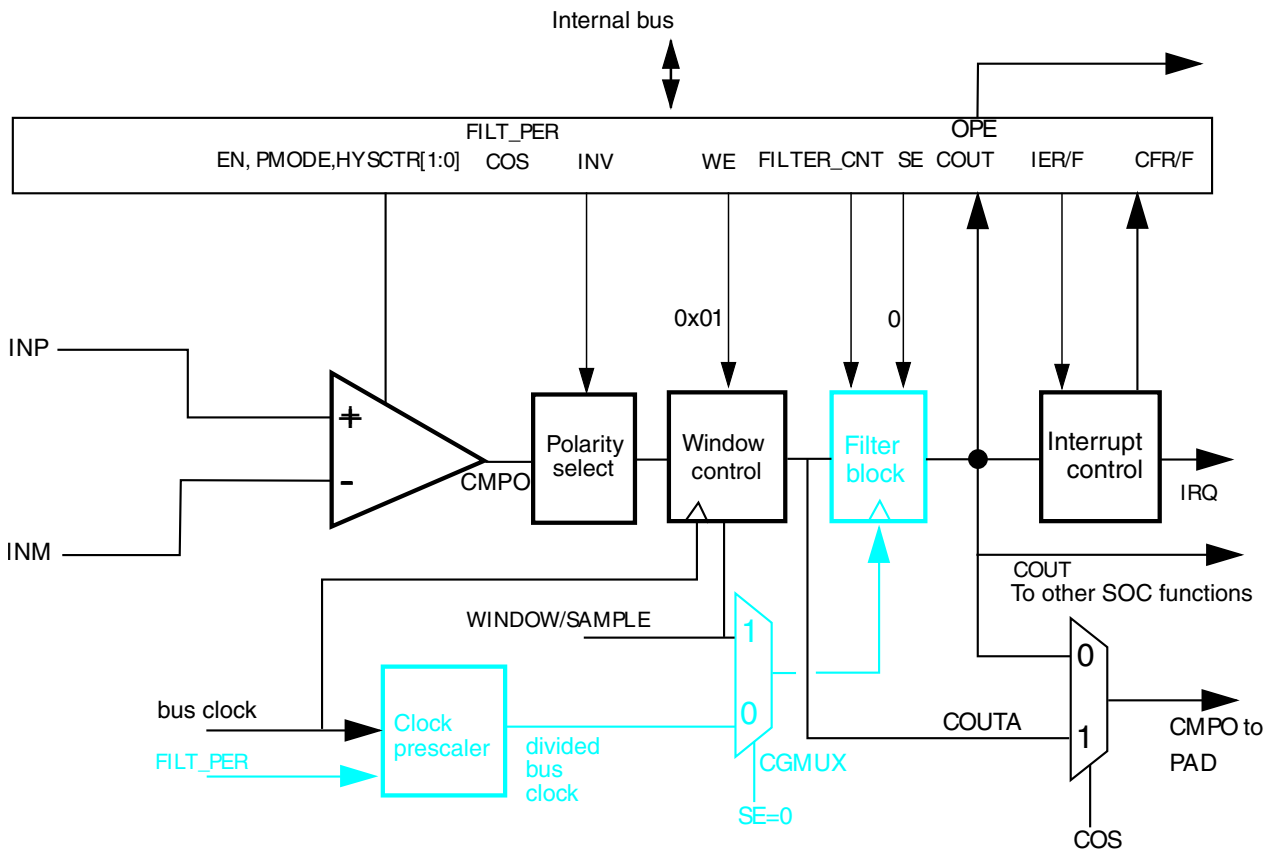

Figure 86-10. Windowed mode

For control configurations which result in disabling the filter block, seeFigure 86-3 .

When any windowed mode is active, COUTA is clocked by the bus clock whenever WINDOW = 1. The last latched value is held when WINDOW = 0.

86.3.1.6 Windowed/Resampled mode (# 6)

The following figure uses the same input stimulus shown in Figure 86-9, and adds resampling of COUTA to generate COUT. Samples are taken at the time points indicated by the arrows in the figure. Again, prop delays and latency are ignored for the sake of clarity.

This example was generated solely to demonstrate operation of the comparator in windowed/resampled mode, and does not reflect any specific application. Depending upon the sampling rate and window placement, COUT may not see zero-crossing events detected by the analog comparator. Sampling period and/or window placement must be carefully considered for a given application.

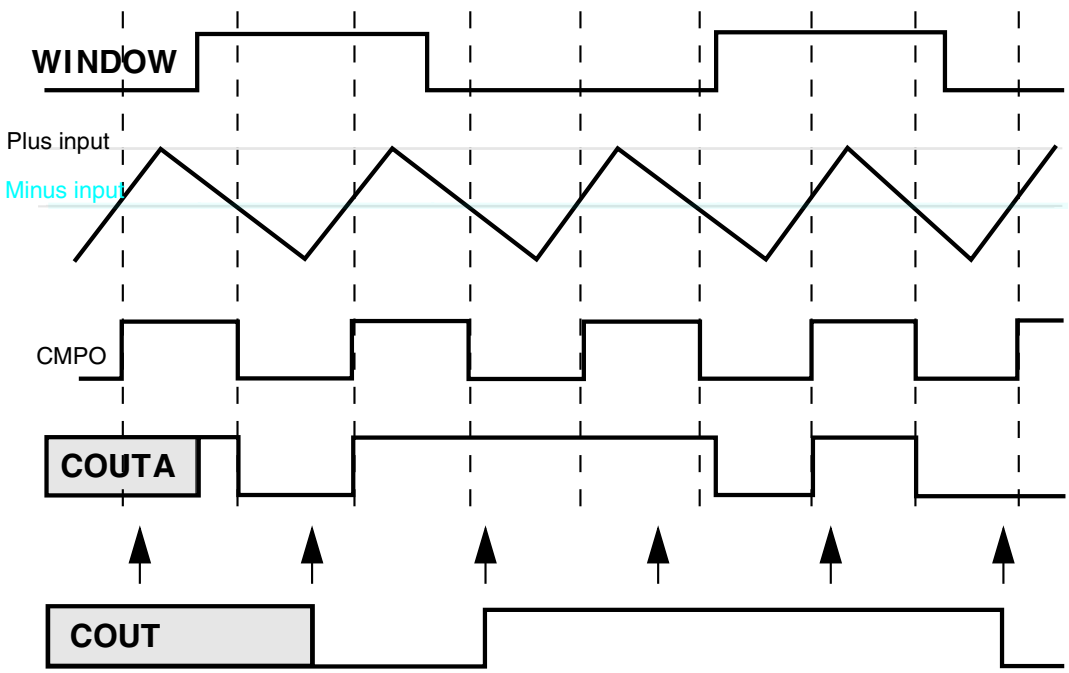

Figure 86-11. Windowed/resampled mode operation

This mode of operation results in an unfiltered string of comparator samples where the interval between the samples is determined by FPR[FILT_PER] and the bus clock rate. Configuration for this mode is virtually identical to that for the Windowed/Filtered Mode shown in the next section. The only difference is that the value of C0[FILTER_CNT] must be 1.

86.3.1.7 Windowed/Filtered mode (#7)

This is the most complex mode of operation for the comparator block, as it uses both windowing and filtering features. It also has the highest latency of any of the modes. This can be approximated: up to 1 bus clock synchronization in the window function + ((C0[FILTER_CNT] * C0[FPR]) + 1) * bus clock for the filter function.

When any windowed mode is active, COUTA is clocked by the bus clock whenever WINDOW = 1. The last latched value is held when WINDOW = 0.

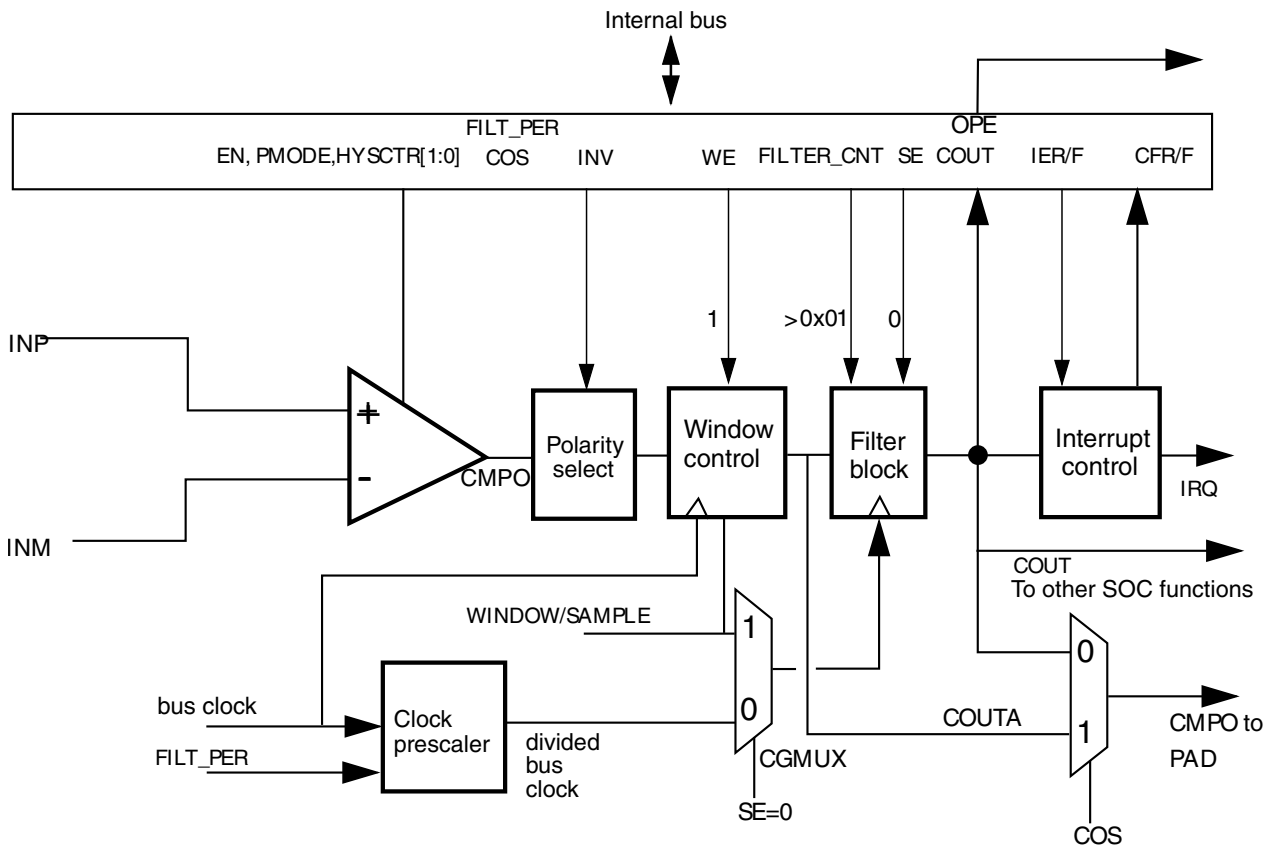

Figure 86-12. Windowed/Filtered mode

86.3.2 Low-pass filter

The low-pass filter operates on the unfiltered and unsynchronized and optionally inverted comparator output COUTA and generates the filtered and synchronized output COUT. Both COUTA and COUT can be configured as module outputs and are used for different purposes within the system.

Synchronization and edge detection are always used to determine status register bit values. They also apply to COUT for all sampling and windowed modes. Filtering can be performed using an internal timebase defined by CMP_C0[FPR], or using an external SAMPLE input to determine sample time.

The need for digital filtering and the amount of filtering is dependent on user requirements. Filtering can become more useful in the absence of an external hysteresis circuit. Without external hysteresis, high-frequency oscillations can be generated at COUTA when the selected INM and INP input voltages differ by less than the offset voltage of the differential comparator.

86.3.2.1 Enabling filter modes

Filter modes can be enabled by:

- Setting CMP_C0[FILTER_CNT] > 0x01 and
- Setting CMP_C0[FPR] to a nonzero value or setting C0[SE]=1

If using the divided bus clock to drive the filter, it samples COUTA every CMP_C0[FPR] bus clock cycles.

The filter output is at logic 0 when first initialized, and subsequently changes when all the consecutive CMP_C0[FILTER_CNT] samples agree that the output value has changed. In other words, CMP_C0[COUT] is 0 for some initial period, even when COUTA is at logic 1.

Setting all of CMP_C0[SE], CMP_C0[FPR] and CMP_C0[FILTER_CNT] to 0 disables the filter and eliminates switching current associated with the filtering process.

Note

Always switch to this setting prior to making any changes in filter parameters. This resets the filter to a known state. Switching CMP_C0[FILTER_CNT] on the fly without this intermediate step can result in unexpected behavior.

If CMP_C0[SE]=1, the filter samples COUTA on each positive transition of the sample input. The output state of the filter changes when all the consecutive CMP_C0[FILTER_CNT] samples agree that the output value has changed.

86.3.2.2 Latency issues

The value of CMP_C0[FPR] or SAMPLE period must be set such that the sampling period is just longer than the period of the expected noise. This way a noise spike will corrupt only one sample. The value of CMP_C0[FILTER_CNT] must be chosen to reduce the probability of noisy samples causing an incorrect transition to be recognized. The probability of an incorrect transition is defined as the probability of an incorrect sample raised to the power of CMP_C0[FILTER_CNT].

The values of CMP_C0[FPR] or SAMPLE period and CMP_C0[FILTER_CNT] must also be traded off against the desire for minimal latency in recognizing actual comparator output transitions. The probability of detecting an actual output change within the nominal latency is the probability of a correct sample raised to the power of CMP_C0[FILTER_CNT].

The following table summarizes maximum latency values for the various modes of operation *in the absence of noise*. Filtering latency is restarted each time an actual output transition is masked by noise.

Table 86-5. Comparator sample/filter maximum latencies

Mode #	CMP_C0[EN]	CMP_C0[WE]	CMP_C0[SE]	CMP_C0[FILTER_CNT]	Co[FPR]	Operation	Maximum latency[1]
1	0	X	X	X	X	Disabled	N/A
2A	1	0	0	0x00	X	Continuous Mode	T_{PD}
2B	1	0	0	X	0x00		
3A	1	0	1	0x01	X	Sampled, Non-Filtered mode	$T_{PD} + T_{SAMPLE} + T_{per}$
3B	1	0	0	0x01	> 0x00		T_{PD} + (CMP_C0[FPR] * T_{per}) + T_{per}
4A	1	0	1	> 0x01	X	Sampled, Filtered mode	T_{PD} + (CMP_C0[FILTER_CNT] * T_{SAMPLE}) + T_{per}
4B	1	0	0	> 0x01	> 0x00		T_{PD} + (CMP_C0[FILTER_CNT] * CMP_C0[FPR] x T_{per}) + T_{per}
5A	1	1	0	0x00	X	Windowed mode	$T_{PD} + T_{per}$
5B	1	1	0	X	0x00		$T_{PD} + T_{per}$
6	1	1	0	0x01	0x01 - 0xFF	Windowed / Resampled mode	T_{PD} + (CMP_C0[FPR] * T_{per}) + $2T_{per}$
7	1	1	0	> 0x01	0x01 - 0xFF	Windowed / Filtered mode	T_{PD} + (CMP_C0[FILTER_CNT] * CMP_C0[FPR] x T_{per}) + $2T_{per}$

1. T_{PD} represents the intrinsic delay of the analog component plus the polarity select logic. T_{SAMPLE} is the clock period of the external sample clock. T_{per} is the period of the bus clock.

NOTE

The delay in this table does not include the delay caused by the Discrete Mode.

86.3.3 CMP Discrete mode timing sequence

In order to support the 3 V domain input the analog comparator should be configured to work in Discrete Mode since the internal transistors are not 3 V tolerance. This section summarizes the possible configurations depending on the input range.

Note that the sample signal below means that the analog comparator samples the input analog input. It is different from the sample mode that occurs on the digital process to the final comparison result. Also, note that the cross domain round robin cycling (see Trigger mode) is not allowed.

1. When CMP_C3[PCHCTEN] and CMP_C3[NCHCTEN] are set to 1, the CMP is in continuous time operation. No special timing is required.
2. When either CMP_C3[PCHCTEN] or CMP_C3[NCHCTEN] is 0, it means at least one input comes from the 3V PAD.
   a. If CMP_C3[RDIVE] is zero, it means the input signal comes from 3V PAD, but its range still is in the range of 0 to 1.8V, no timing requirement for the generation of Phase1 and Phase2.

      In this condition, there are two modes for this comparator, high speed mode and low speed mode. Clock source may come from fast clock(16-20M)

      In Figure 86-13, the Analog ready indicates the analog settling time is reached and is ready for comparison. Tc is set by CMP_C3[ACSAT], in high speed mode, it is normally used as 1*T, 2*T, 4*T and 8*T where T is CLOCK period, and in low speed mode (CMP_C0[PMODE] = 0), CMP_C3[ACSAT] is normally used as 16*T, 32*T, 64*T and 256*T.

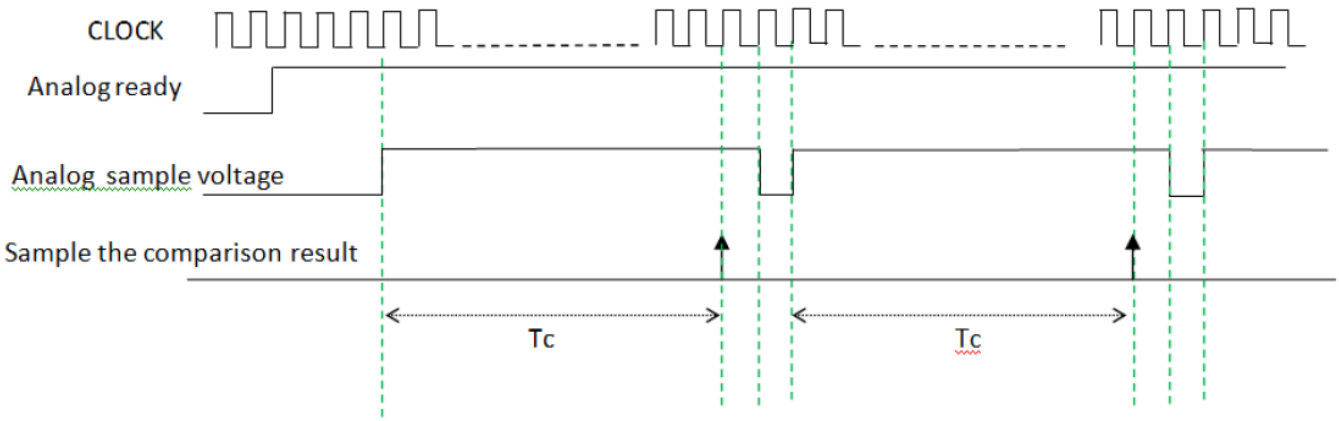

Figure 86-13. CMP_C3[RDIVE] = 0

b. If CMP_C3[RDIVE] == 1, it means the signals come from the 3V PAD and it could over 1.8 V, Phase1, Phase2 will be generated.

   If CMP is in high speed mode (CMP_C0[PMODE] = 1) , Tc, Phase1, and Phase2 can be set based on the possible combinations in Table 86-6.

   If CMP works in low speed mode, Phase1 is suggested to set to 1*T, Phase2 is suggested to set to 8*T, and Tc is normally set to 16*T, 32*T, 64*T and 256*T.

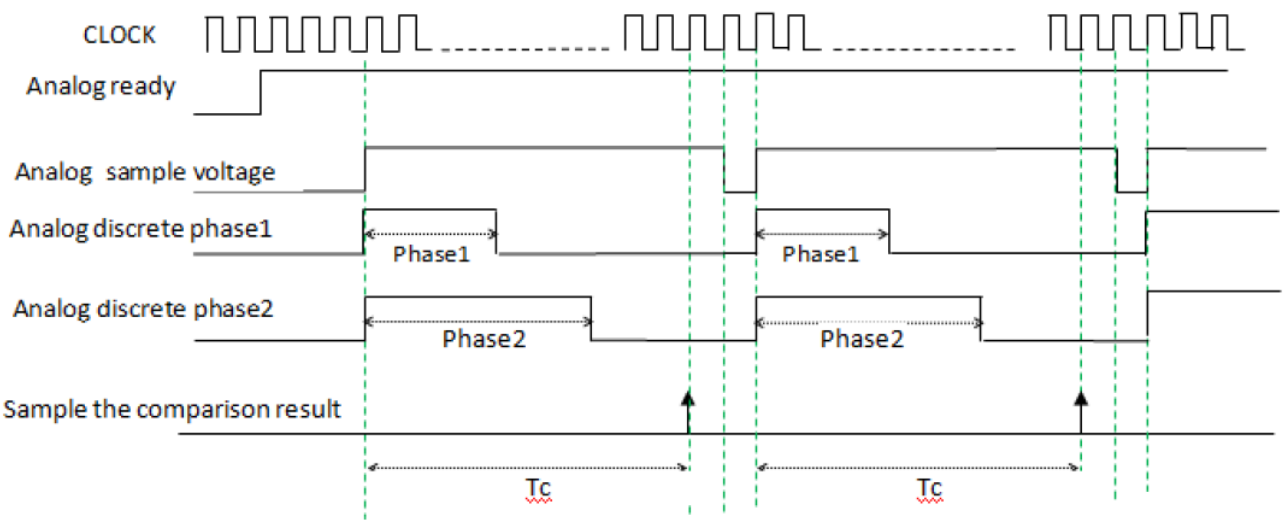

Figure 86-14. CMP_C3[RDIVE] = 1

Table 86-6. Possible Combinations of CMP_C3[ACSAT], CMP_C3[ACPH1TC] and CMP_C3[ACPH2TC]

Tc	Phase1	Phase2
1*T	1*T	1*T
2*T	2*T	2*T
4*T	4*T	4*T
8*T	8*T	8*T

Table continues on the next page...

Table 86-6. Possible Combinations of CMP_C3[ACSAT], CMP_C3[ACPH1TC] and CMP_C3[ACPH2TC] (continued)

Tc	Phase1	Phase2
16*T	1*T	16*T
32*T	1*T	32*T
64*T	1*T	64*T
256*T	0	16*T

If the clock comes from 32KHz slow clock(CMP_C3[DMCLKSEL] = 0), both analog phase 1 and phase 2 will be driven to 0 and Tc is limited to T as shown in the figure below.

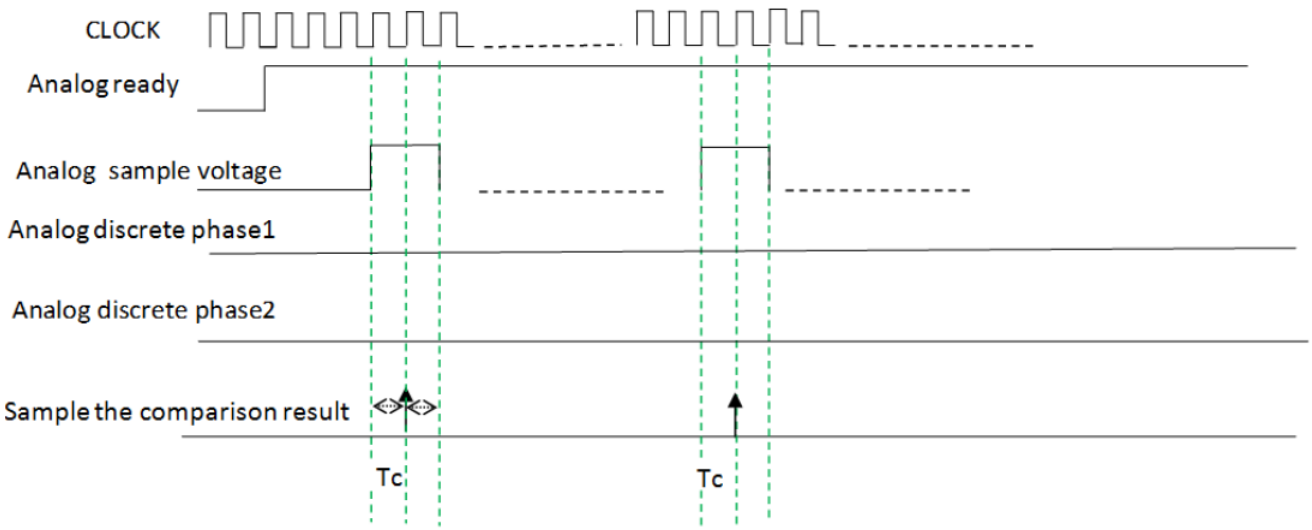

Figure 86-15. Slow (32 kHz) clock timing

86.3.4 CMP clocks

This module has the following clocks:

- Bus clock for register access and window/filter operation
- Fast clock for the discrete mode
- Slow clock for the discrete mode
- Round robin clock for the trigger mode

86.3.5 Interrupts

The CMP module is capable of generating an interrupt on either the rising- or falling-edge of the comparator output, or both. Assuming the CMP DMA enable bit is not set, the following table gives the conditions in which the interrupt request is asserted and deasserted.

Table 86-7. CMP interrupt generations

When	Then
CMP_C0[IER] and CMP_C0[CFR] are set	The interrupt request is asserted
CMP_C0[IEF] and CMP_C0[CFF] are set	The interrupt request is asserted
CMP_C0[IER] and CMP_C0[CFR] are cleared for a rising-edge interrupt	The interrupt request is deasserted
CMP_C0[IEF] and CMP_C0[CFF] are cleared for a falling-edge interrupt	The interrupt request is deasserted

86.3.6 DMA support

Normally, the CMP generates a CPU interrupt if there is a change on the COUT. When DMA support is enabled by setting CMP_C0[DMAEN] and the interrupt is enabled by setting CMP_C0[IER], CMP_C0[IEF], or both, the corresponding change on COUT forces a DMA transfer request rather than a CPU interrupt instead. When the DMA has completed the transfer, it sends a transfer completing indicator signal that deasserts the DMA transfer request and clears the flags (CMP_C0[CFR] and CMP_C0[CFF]) to allow a subsequent change on comparator output to occur and force another DMA request.

The comparator can remain functional in STOP modes. When DMA support is enabled by setting CMP_C0[DMAEN] and the interrupt is enabled by setting CMP_C0[IER], CMP_C0[IEF], or both, the corresponding change on COUT forces a DMA transfer request to wake up the system from STOP modes. After the data transfer has finished, the system will go back to STOP modes. Refer to the DMA chapters in the device reference manual for the asynchronous DMA function for details.

86.4 DAC functional description

This section provides DAC functional description.

86.4.1 Digital-to-analog converter block diagram

The following figure shows the block diagram of the DAC module. It contains a 256-tap resistor ladder network and a 256-to-1 multiplexer, which selects an output voltage from one of 256 distinct levels that outputs from DACO. It is controlled through the control register2(CMP_C1). Its supply reference source can be selected from two sources V_{in1} and V_{in2}. The module can be powered down or disabled when not in use. When in Disabled mode, DACO is connected to the analog ground.

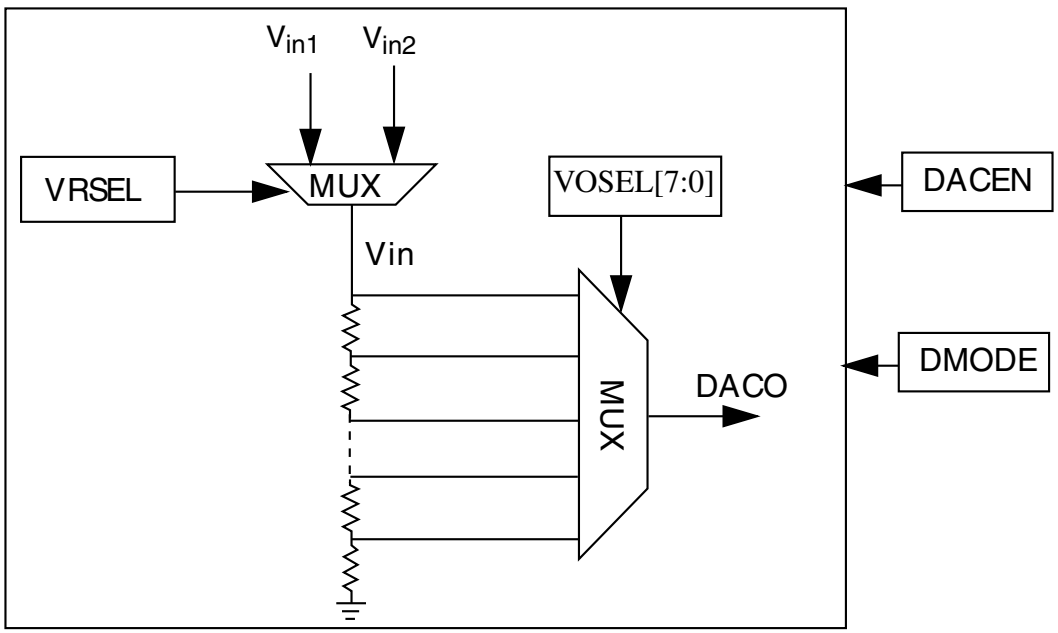

Figure 86-16. 8-bit DAC block diagram

86.4.2 Voltage reference source select

- V_{in1} must be used to connect to the primary voltage source as supply reference of 256 tap resistor ladder
- V_{in2} must be used to connect to an alternate voltage source, or primary source, if an alternate voltage source is not available

86.4.3 DAC resets

This module has a single reset input, corresponding to the chip-wide peripheral reset.

86.4.4 DAC clocks

This module has a single clock input, the bus clock.

86.4.5 DAC interrupts

This module has no interrupts.

86.4.6 Trigger mode

The CMP and the 8-bit DAC are designed to support the trigger mode operation, which is enabled when the MCU enters STOP modes with CMP_C0[WE], CMP_C0[SE] and CMP_C0[EN] are set.

With this mode enabled, the trigger events that include the operation clock and a trigger start signal will initiate a compare sequence that must first enable the CMP and DAC prior to performing a CMP operation and capturing the output. A fixed channel for either the plus side mux or the minus side mux is selected by software with CMP_C2[FXMP] and CMP_C2[FXMXCH]. It is a mandatory request that the round robin cycling period must be set longer than the time that all the active channels complete the specified comparison cycles specified by CMP_C2[NSAM].

The active channels selected by CMP_C1[CHN*n*] are then routed to the non-fixed channel mux and compared with the reference input in a round-robin manner. In order to meet the comparator stabilization time, after the configurable number of operation clocks defined by CMP_C2[NSAM], the comparison result is sampled for the selected channel. A software pre-programmed state for each channel is configured by writing to CMP_C2[ACO*n*] field. After all the active channels are sampled, if the comparison result changes from its pre-programmed state, the corresponding flag in CMP_C2[CH*n*F] is set. If CMP_C2[RRIE] is set, an asynchronous reset is asserted to bring the MCU out of STOP mode.

Note that these flags do not support generating a DMA transfer event.

This mode is active when the MCU is in STOP mode, so none of the window/filter functions are available. A basic assumption of this mode is that the selected inputs are changing at a much slower rate than the operation clock. It is suggested to configure the comparator in low power comparison mode as well. In programming the CMP_C2[INITMOD] registers it is need to make sure the INITMOD*round robin clock period must be longer than the initialization delay which can be referred from the chip datasheet.

The following diagram shows the basic flow of this mode. In the diagram, CMP_C1[CHN1], CMP_C1[CHN3], and CMP_C1[CHN4] are set, so channels #1, #3, and #4 are selected for round robin depended on their polarity setting. CMP_C2[NSAM] is set to 2'b01, so one clock later the comparison result of the selected channel is sampled. When channel #3 is compared, the result is sampled, and round robin ends. If any of the comparison results from channel #1, #3, or #4 changed from their programmed value (written to CMP_C2[ACO1], CMP_C2[ACO3], and CMP_C2[ACO4]), an interrupt is generated to wake up the MCU from the STOP mode. Software can then poll the CMP_C2[CH*n*F] to see which channel input(s) changed value during the STOP mode.

NOTE

In round robin mode, it should be ensured that the RTC_CLK period is greater than the comparison time corresponding to the value of CMPx_C0[PMODE].

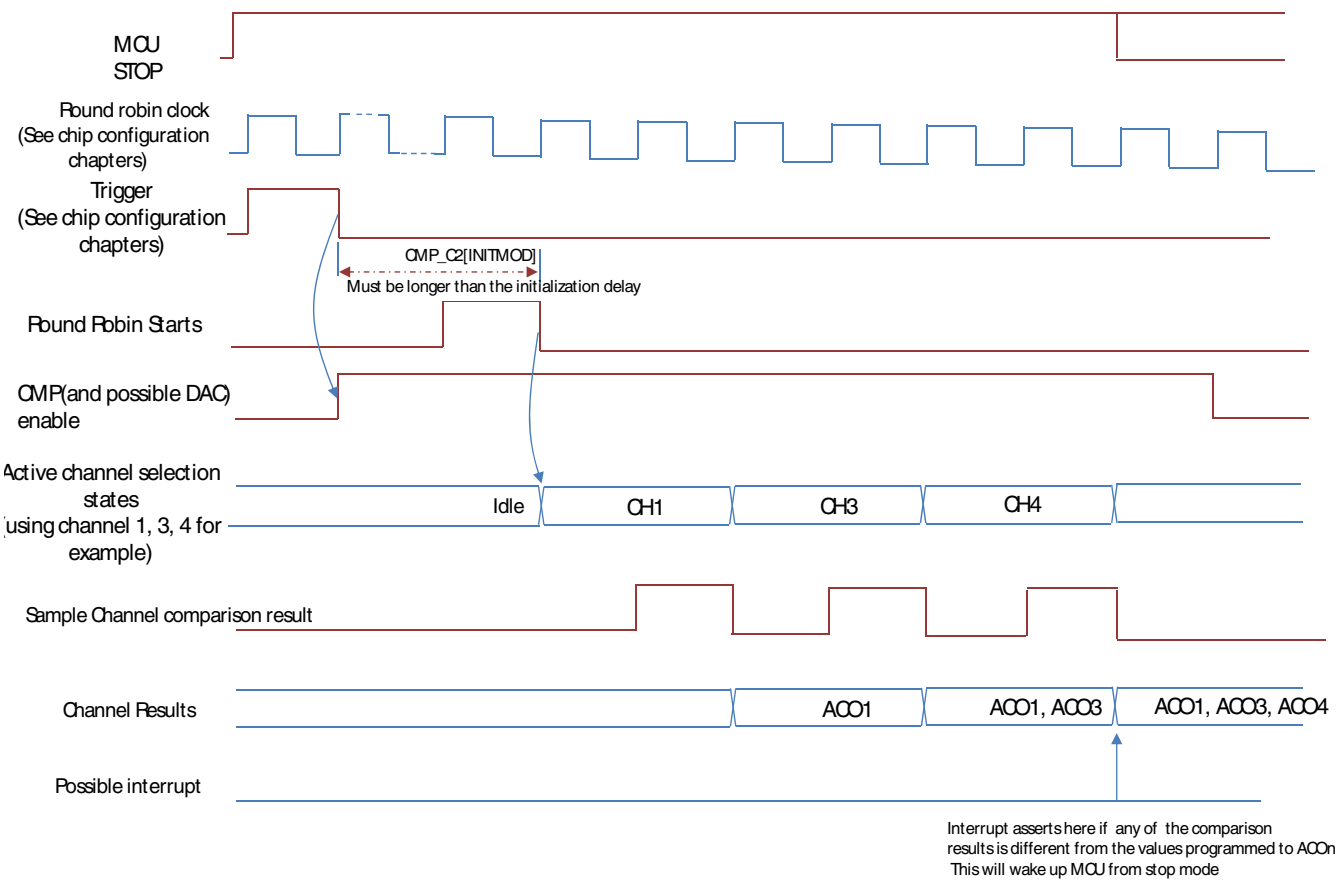

Figure 86-17. Trigger mode

86.5 CMP external signals

This section provides the comparator pin descriptions. The external 3V domain inputs INA_3V[6:1] and 1.8V domain INA_1P8[6:1], INA_1P8_0_P, INA_1P8_0_M are muxed by CMP_C1[PSEL] and CMP_C1[MSEL] before going to the positive and negative ports of the comparator respectively.

Table 86-8. CMP signal descriptions

Signal	Description	I/O
INA_3V[6:1]	The 3V domain analog inputs[6:1]	I
INA_1P8[6:1]	Analog 1.8V input channels [6:1].	I
INA_1P8_0_P	Analog 1.8V input channel 0 positive.	I
INA_1P8_0_m	Analog 1.8V input channel 0 minus.	I

NOTE

It is not recommended to compare 3V domain channel with 1.8V domain channel. If the 3V domain channel's voltage is smaller than 1.8V, in this case, it can be compared with 1.8V domain channel by setting C3[RDIVE] to 0.

86.5.1 External pins

The CMP has two analog inputs: INP and INM. Each of these pins can accept an input voltage that varies across the full operating range of the MCU. If the module is not enabled, each pin can be used as a digital input or output. Consult the specific MCU documentation to determine what functions are shared with these analog inputs.

The user can select either filtered or unfiltered comparator outputs for use on an external I/O pad.

86.6 Initialization

A typical startup sequence is as follows.

The time required to stabilize COUT is the power-on delay of the comparators plus the largest propagation delay from a selected analog source through the analog comparator, windowing function, and filter. See the datasheet for power-on delays of the comparators. The windowing function has a maximum of one bus clock period delay. The filter delay is specified in the Low-pass filter section.

During operation, the propagation delay of the selected data paths must always be considered. It may take many bus clock cycles for COUT and CMP_C0[CFR]/ CMP_C0[CFF] to reflect an input change or a configuration change to one of the components involved in the data path.

When programmed for filtering modes, COUT initially equals 0 until sufficient clock cycles have elapsed to fill all stages of the filter. This occurs even if COUTA is at a logic 1.

86.7 Memory map/register definitions

86.7.1 CMP register descriptions

86.7.1.1 CMP memory map

CMP1 base address: 401A_4000h

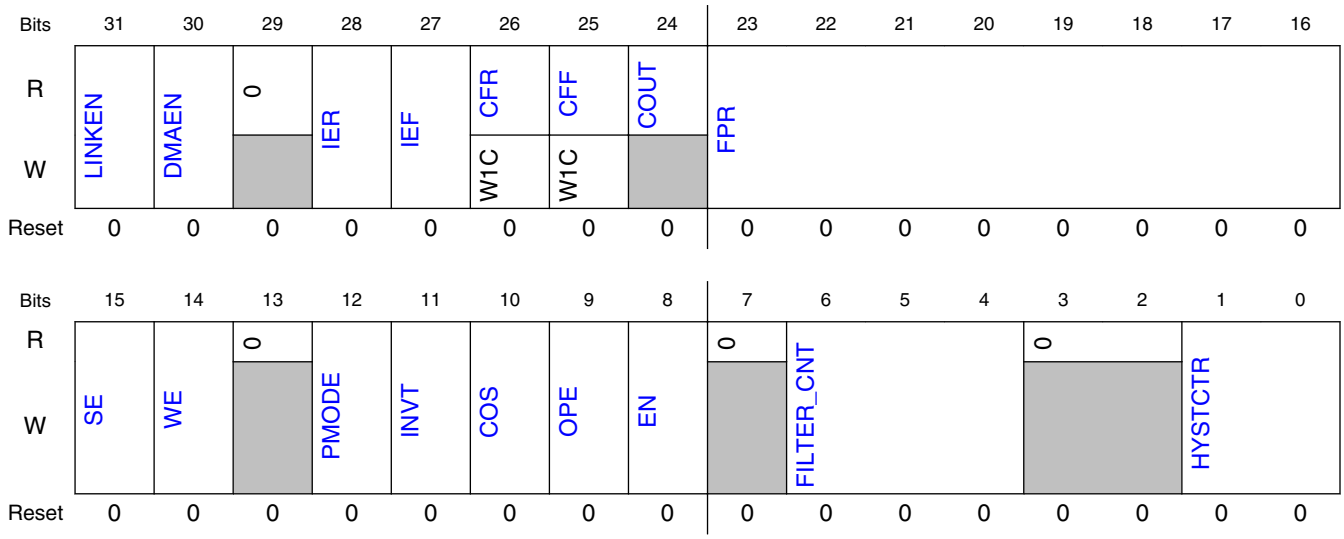
86.7.1.4.2 Diagram



86.7.1.4.3 Fields

Field	Description
31 LINKEN	CMP to DAC link enable. This bit is used to enable the link from CMP to DAC enables. When this bit is set, the DAC enable/disable is controlled by CMP_C0[EN] bit instead of CMP_C1[DACEN]. 0 - CMP to DAC link is disabled 1 - CMP to DAC link is enabled.
30 DMAEN	DMA Enable Enables the DMA transfer triggered from the CMP module. When this field and the corresponding interrupt enable bit are set, a DMA request is asserted when CFR or CFF is set. 0 - DMA is disabled. 1 - DMA is enabled.
29 —	Reserved
28 IER	Comparator Interrupt Enable Rising Enables the CFR interrupt from the CMP. When this field is set, an interrupt will be asserted when CFR is set. 0 - Interrupt is disabled. 1 - Interrupt is enabled.
27 IEF	Comparator Interrupt Enable Falling Enables the CFF interrupt from the CMP. When this field is set, an interrupt will be asserted when CFF is set. 0 - Interrupt is disabled. 1 - Interrupt is enabled.

Table continues on the next page...

Field	Description
26 CFR	Analog Comparator Flag Rising Detects a rising-edge on COUT, when set, during normal operation. CFR is cleared by writing 1 to it. During Stop modes, CFR is level sensitive 0 - A rising edge has not been detected on COUT. 1 - A rising edge on COUT has occurred.
25 CFF	Analog Comparator Flag Falling Detects a falling-edge on COUT, when set, during normal operation. CFF is cleared by writing 1 to it. During Stop modes, CFF is level senstive . 0 - A falling edge has not been detected on COUT. 1 - A falling edge on COUT has occurred.
24 COUT	Analog Comparator Output Returns the current value of the Analog Comparator output, when read. The field is reset to 0 and will read as C0[INVT] when the Analog Comparator module is disabled, that is, when C0[EN] = 0. Writes to this field are ignored.
23-16 FPR	Filter Sample Period Specifies the sampling period, in bus clock cycles, of the comparator output filter, when C1[SE] = 0. Setting FPR to 0x0 disables the filter. Filter programming and latency details are provided in the CMP functional description. This field has no effect when C0[SE]= 1. In that case, the external SAMPLE signal is used to determine the sampling period.
15 SE	Sample Enable If a write to this register attempts to set both SE and WE, then only Sampling mode is taking effect in MCU Run mode and the Round Robin Cycling(Trigger Mode) is enabled in MCU STOP mode. 0 - Sampling mode is not selected. 1 - Sampling mode is selected.
14 WE	Windowing Enable If a write to this register attempts to set both SE and WE, then only Sampling mode is taking effect in MCU Run mode and the Round Robin Cycling(Trigger Mode) is enabled in MCU STOP mode. 0 - Windowing mode is not selected. 1 - Windowing mode is selected.
13 —	Reserved
12 PMODE	Power Mode Select 0 - Low Speed (LS) comparison mode is selected. 1 - High Speed (HS) comparison mode is selected.
11 INVT	Comparator invert This bit allows selecting the polarity of the analog comparator function. It is also driven to the COUT output (on both the device pin and as C0[COUT]) when CR1[OPE]=0. 0 - Does not invert the comparator output. 1 - Inverts the comparator output.
10 COS	Comparator Output Select 0 - Set CMPO to equal COUT (filtered comparator output). 1 - Set CMPO to equal COUTA (unfiltered comparator output).

Table continues on the next page...

Field	Description
9 OPE	Comparator Output Pin Enable The OPE bit enables the path from the comparator output to a selected pin. 0 - When OPE is 0, the comparator output (after window/filter settings dependent on software configuration) is not available to a packaged pin. 1 - When OPE is 1, and if the software has configured the comparator to own a packaged pin, the comparator is available in a packaged pin.
8 EN	Comparator Module Enable The EN bit enables the Analog Comparator Module. When the module is not enabled, the analog part remains in the off state, and consumes no power. When the same input is selected from analog mux to the positive and negative port, the comparator is disabled automatically. 0 - Analog Comparator is disabled. 1 - Analog Comparator is enabled.
7 —	Reserved
6-4 FILTER_CNT	Filter Sample Count This field specifies the number of consecutive samples that must agree prior to the comparator ouput filter accepting a new output state. For information regarding filter programming and latency, please see the Functional Description. 000 - Filter is disabled. If SE = 1, then COUT is a logic zero (this is not a legal state, and is not recommended). If SE = 0, COUT = COUTA. 001 - 1 consecutive sample must agree (comparator output is simply sampled). 010 - 2 consecutive samples must agree. 011 - 3 consecutive samples must agree. 100 - 4 consecutive samples must agree. 101 - 5 consecutive samples must agree. 110 - 6 consecutive samples must agree. 111 - 7 consecutive samples must agree.
3-2 —	Reserved
1-0 HYSTCTR	Comparator hard block hysteresis control. See chip data sheet to get the actual hystersis value with each level 00 - The hard block output has level 0 hysteresis internally. 01 - The hard block output has level 1 hysteresis internally. 10 - The hard block output has level 2 hysteresis internally. 11 - The hard block output has level 3 hysteresis internally.

86.7.1.5 CMP Control Register 1 (C1)

The CMP Control Register 1 (C1) contains configuration options for CMP channel selection. It also includes the control for the analog DAC.

26-24 MSEL	Minus Input MUX Control These bits determine which input is selected for the negative mux. Refer to the chip configuation chapters to get the detailed connections about Reference Input{0,1,2,3,4,5} and Internal Negative Input 0. The 8b DAC output has been connected internally. Note: For the round robin mode of operation, Internal negative input 0 should be excluded from the activie channels and the fixed channel ports, meanwhile, the MSEL and PSEL bitfields in CMP_C1 register must have different values. 000 - Internal Negative Input 0 for Minus Channel -- Internal Minus Input 001 - External Input 1 for Minus Channel -- Reference Input 0 010 - External Input 2 for Minus Channel -- Reference Input 1 011 - External Input 3 for Minus Channel -- Reference Input 2 100 - External Input 4 for Minus Channel -- Reference Input 3 101 - External Input 5 for Minus Channel -- Reference Input 4 110 - External Input 6 for Minus Channel -- Reference Input 5 111 - Internal 8b DAC output
23-22 —	Reserved
21 CHN5	Channel 5 input enable Channel 5 of the input enable for the round-robin checker. If CHN5 is set, then the corresponding channel to the non-fixed mux port is enabled to check its voltage value in the round-robin mode. If the same channel is selected as the reference voltage, this bit has no effect.
20 CHN4	Channel 4 input enable Channel 4 of the input enable for the round-robin checker. If CHN4 is set, then the corresponding channel to the non-fixed mux port is enabled to check its voltage value in the round-robin mode. If the same channel is selected as the reference voltage, this bit has no effect.
19 CHN3	Channel 3 input enable Channel 3 of the input enable for the round-robin checker. If CHN3 is set, then the corresponding channel to the non-fixed mux port is enabled to check its voltage value in the round-robin mode. If the same channel is selected as the reference voltage, this bit has no effect.
18 CHN2	Channel 2 input enable Channel 2 of the input enable for the round-robin checker. If CHN2 is set, then the corresponding channel to the non-fixed mux port is enabled to check its voltage value in the round-robin mode. If the same channel is selected as the reference voltage, this bit has no effect.
17 CHN1	Channel 1 input enable Channel 1 of the input enable for the round-robin checker. If CHN1 is set, then the corresponding channel to the non-fixed mux port is enabled to check its voltage value in the round-robin mode. If the same channel is selected as the reference voltage, this bit has no effect.
16 CHN0	Channel 0 input enable Channel 0 of the input enable for the round-robin checker. If CHN0 is set, then the corresponding channel to the non-fixed mux port is enabled to check its voltage value in the round-robin mode. If the same channel is selected as the reference voltage, this bit has no effect.

87.1.1 LPADC instantiation information

This device contains two ADCs with up to 4.2Msps rate.

87.1.2 Number of ADC channels and channel assignments

The number of ADC1 channels present on the device is 12 split into 6 A channels and 6 B channels. The number of ADC2 channels present on device is 14. There are 26 channels in total. However, 6 channels are shared between ADC1 and ADC2.

The channel assignments are as determined in following figure:

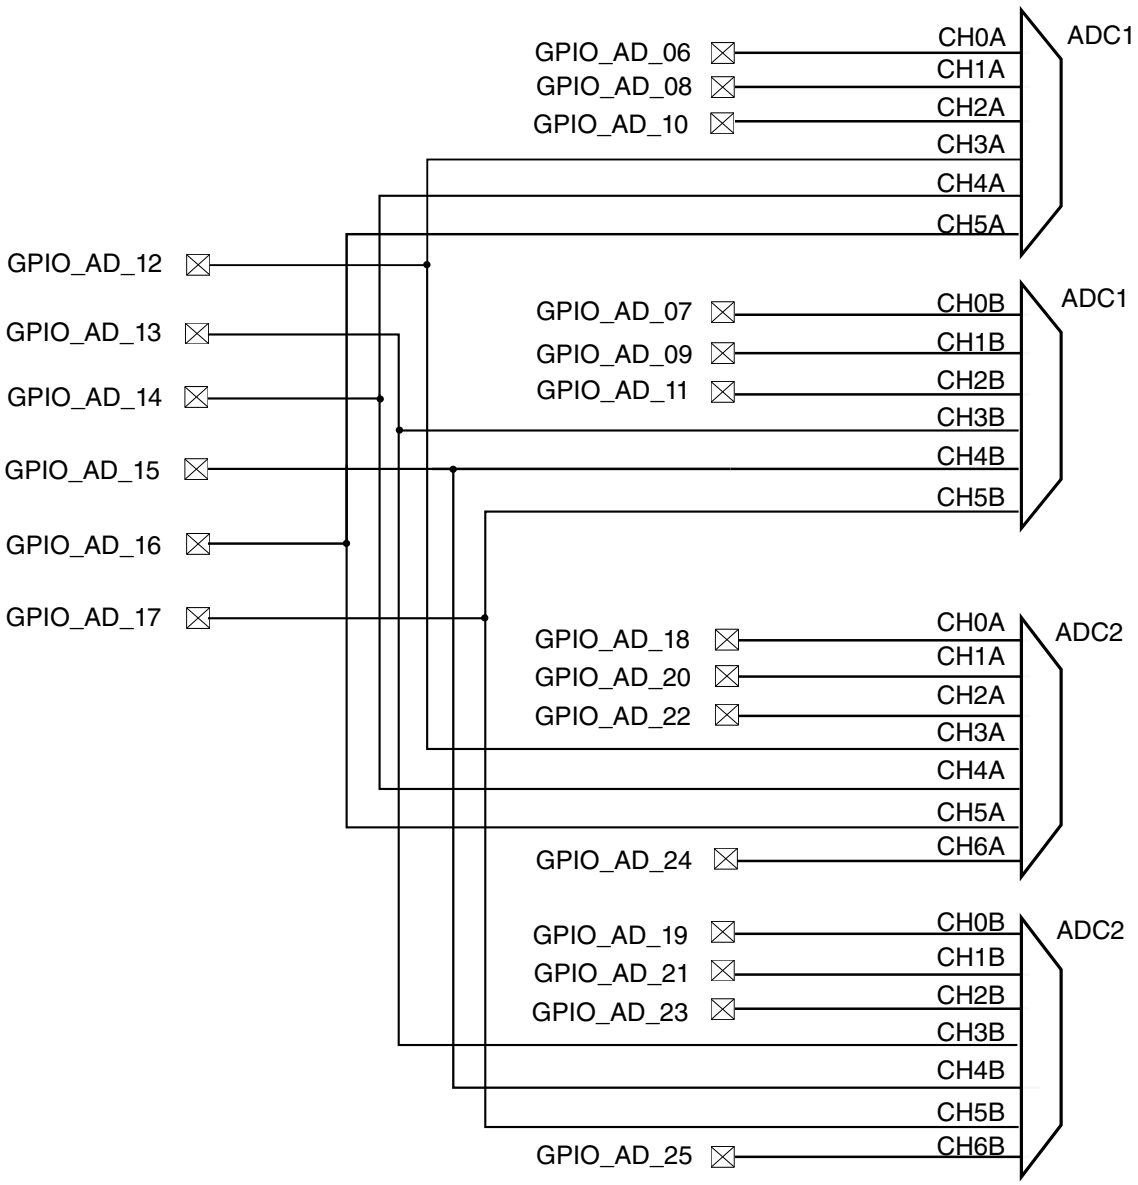

Figure 87-1. External sources channel assignments

Internal sources channel assignments:

- ADC1 CH6A – DAC output
- ADC2 CH7B – DAC output

Note

All external sources channel pairs can be used in differential mode.

87.1.3 LPADC low leakage stop mode

The low leakage stop mode is set by setting IOMUXC_GPR70[ADCx_IPG_STOP_MODE] = 1.

87.1.4 LPADC voltage reference options

The LPADC supports the following voltage reference options ADCx_CFG[REFSEL]:

- 00 - VREFH - connected as the primary reference option
- 01/10 - VDDA_ADC_1P8 - connected as the alternative reference option
- 11 - Reserved

NOTE

V_{SSA} and V_{REFL} is tied to common ground V_{SS} in package.

87.1.5 LPADC triggers

The LPADC supports both software and hardware triggers. The only hardware mechanism for triggering the LPADC is the ADC_ETC. The ADC_ETC itself can be triggered by other peripherals dedicated by interconnection via XBAR module. In total ADC_ETC can select one of the 8 ADC triggers (TRIG0-7) by configuring ADC_ETC->TRIGx_CHAIN_y_z[HWTSn] to initiate ADC conversion. Moreover, ADC_ETC can select also command executed with dedicated trigger by configuring ADC_ETC->TRIGx_CHAIN_y_z[CSELn] when ADCx->TCTRLx[CMD_SEL] = 1.

87.2 Overview

The 12-bit analog-to-digital converter (LPADC) is a successive approximation ADC designed for operation within an integrated microcontroller system-on-chip.

NOTE

For the chip specific modes of operation, see the power management information of the device.

87.2.1 Block diagram

The following figure is the LPADC module block diagram.

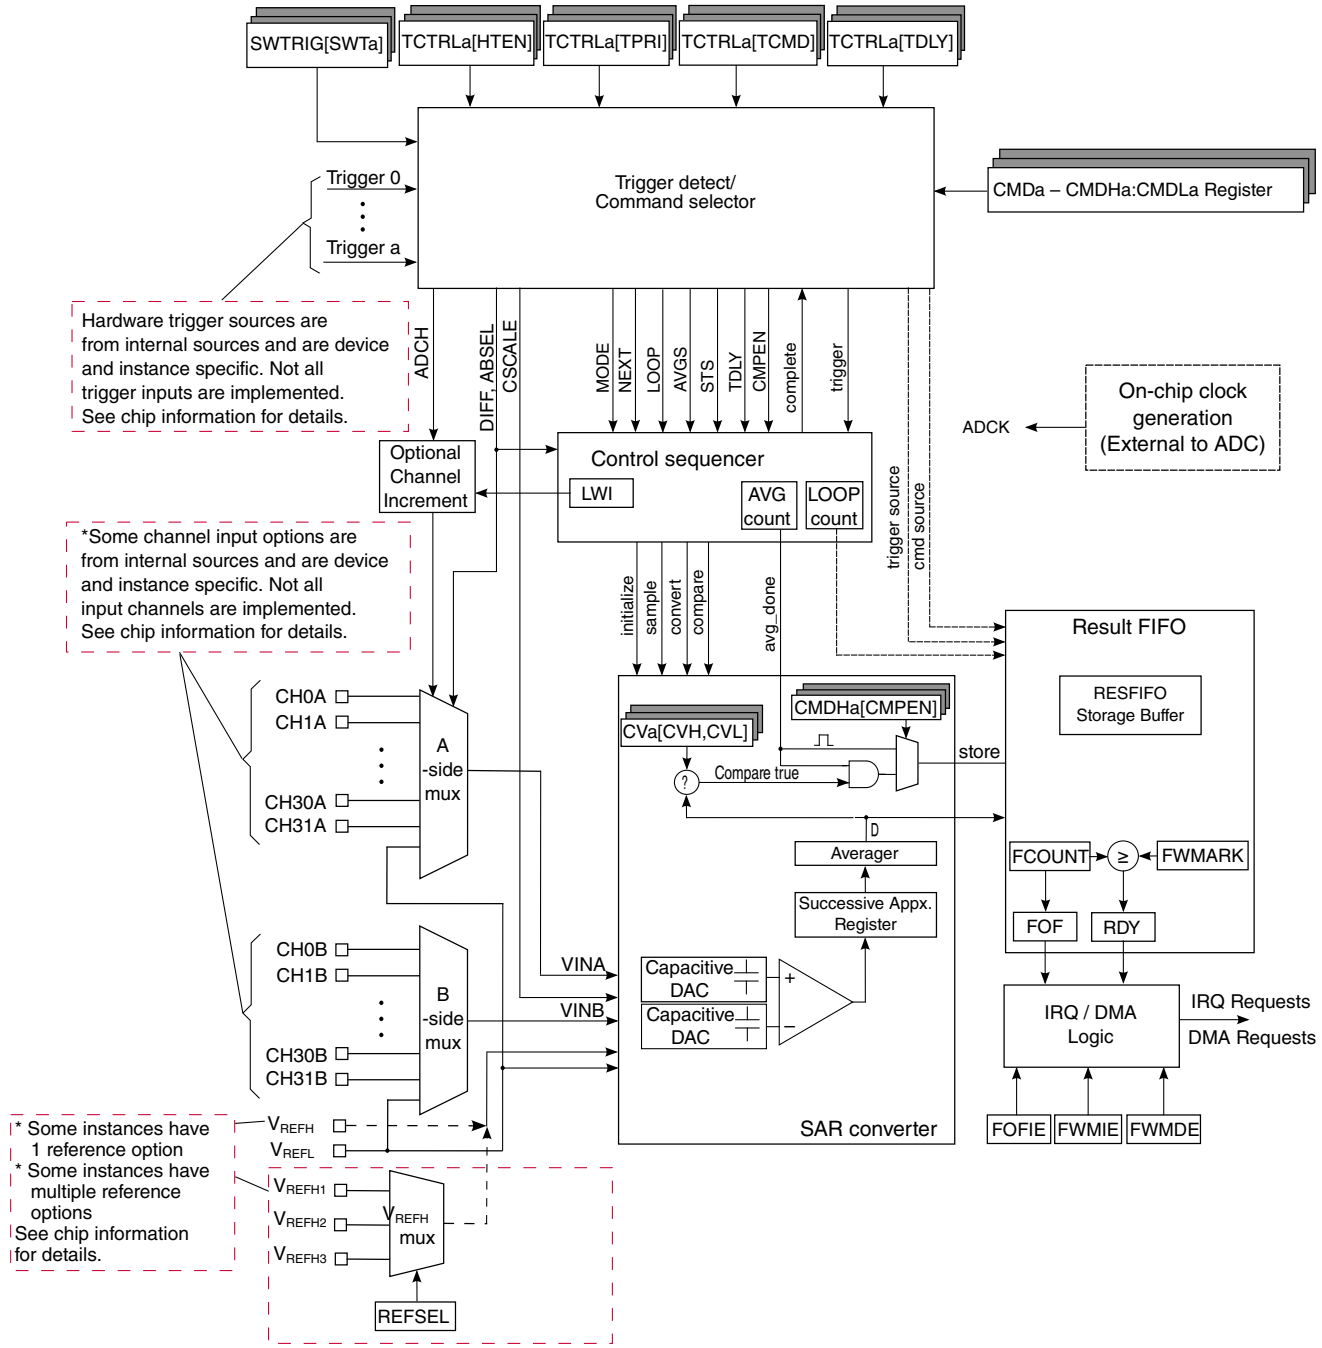

Figure 87-2. LPADC block diagram

87.2.2 Features

Following are the features of the LPADC module.

- Linear successive approximation algorithm

    - Differential operation with 13-bit resolution
    - Single-ended operation with 12-bit resolution
- Channel support for up to 64 analog input channels for conversion of external pins and from internal sources
    - Select external pin inputs paired for conversion as differential channel input
    - Measurement of on-chip analog sources such as DAC or temperature sensor
- Channel scaling allows input voltage levels higher than the ADC reference voltage
- Configurable analog input sample time
- Configurable speed options to accommodate operation in low power modes of the device.
- Trigger detect with up to 8 trigger sources with priority level configuration. Software or hardware trigger option for each.
- 15 command buffers allow independent options selection and channel sequence scanning.
- Automatic compare for less-than, greater-than, within range, or out-of-range with "store on true" and "repeat until true" options
- 16-entry conversion result data FIFO with configurable watermark and overflow detection
- Interrupt, DMA or polled operation

87.3 Functional description

The LPADC module performs analog-to-digital conversions on any of the software selectable analog input channels by a successive approximation algorithm. The module initializes to its lowest power state during reset and in Low-Power Stop mode. The LPADC analog circuits can optionally be pre-enabled for faster starts to conversions at the expense of higher idle currents. Conversions are initiated by selectable trigger events from software or hardware sources. The trigger detect logic includes a configurable enable and priority scheme for the available trigger sources. The module includes multiple command buffers that provide configurable flexibility for channel scanning and independent channel selections for different trigger sources. Multiple command buffers also allow variable option selection such as input scaling factor,differential vs. single-ended, sample time and averaging on a per-channel basis.

This module optionally averages the result of multiple conversions on a channel before storing the calculated result. The hardware average function is enabled by setting CMDH*a*[AVGS] bitfield to a non-zero value and operates in any of the conversion modes and configurations.

When the conversion and averaging loops are completed, the resulting data is placed in a FIFO data buffer along with other tag information associated with the result. A configurable watermark level supports interrupt or DMA requests when the number of stored datawords exceeds the setting.

The LPADC module optionally compares the result of a conversion with the contents of two value registers for less-than, greater-than, inside-range or outside-range detection. The compare function operates in any of the conversion modes and configurations.

The sequencing of an ADC command is summarized in the flow diagram shown below.

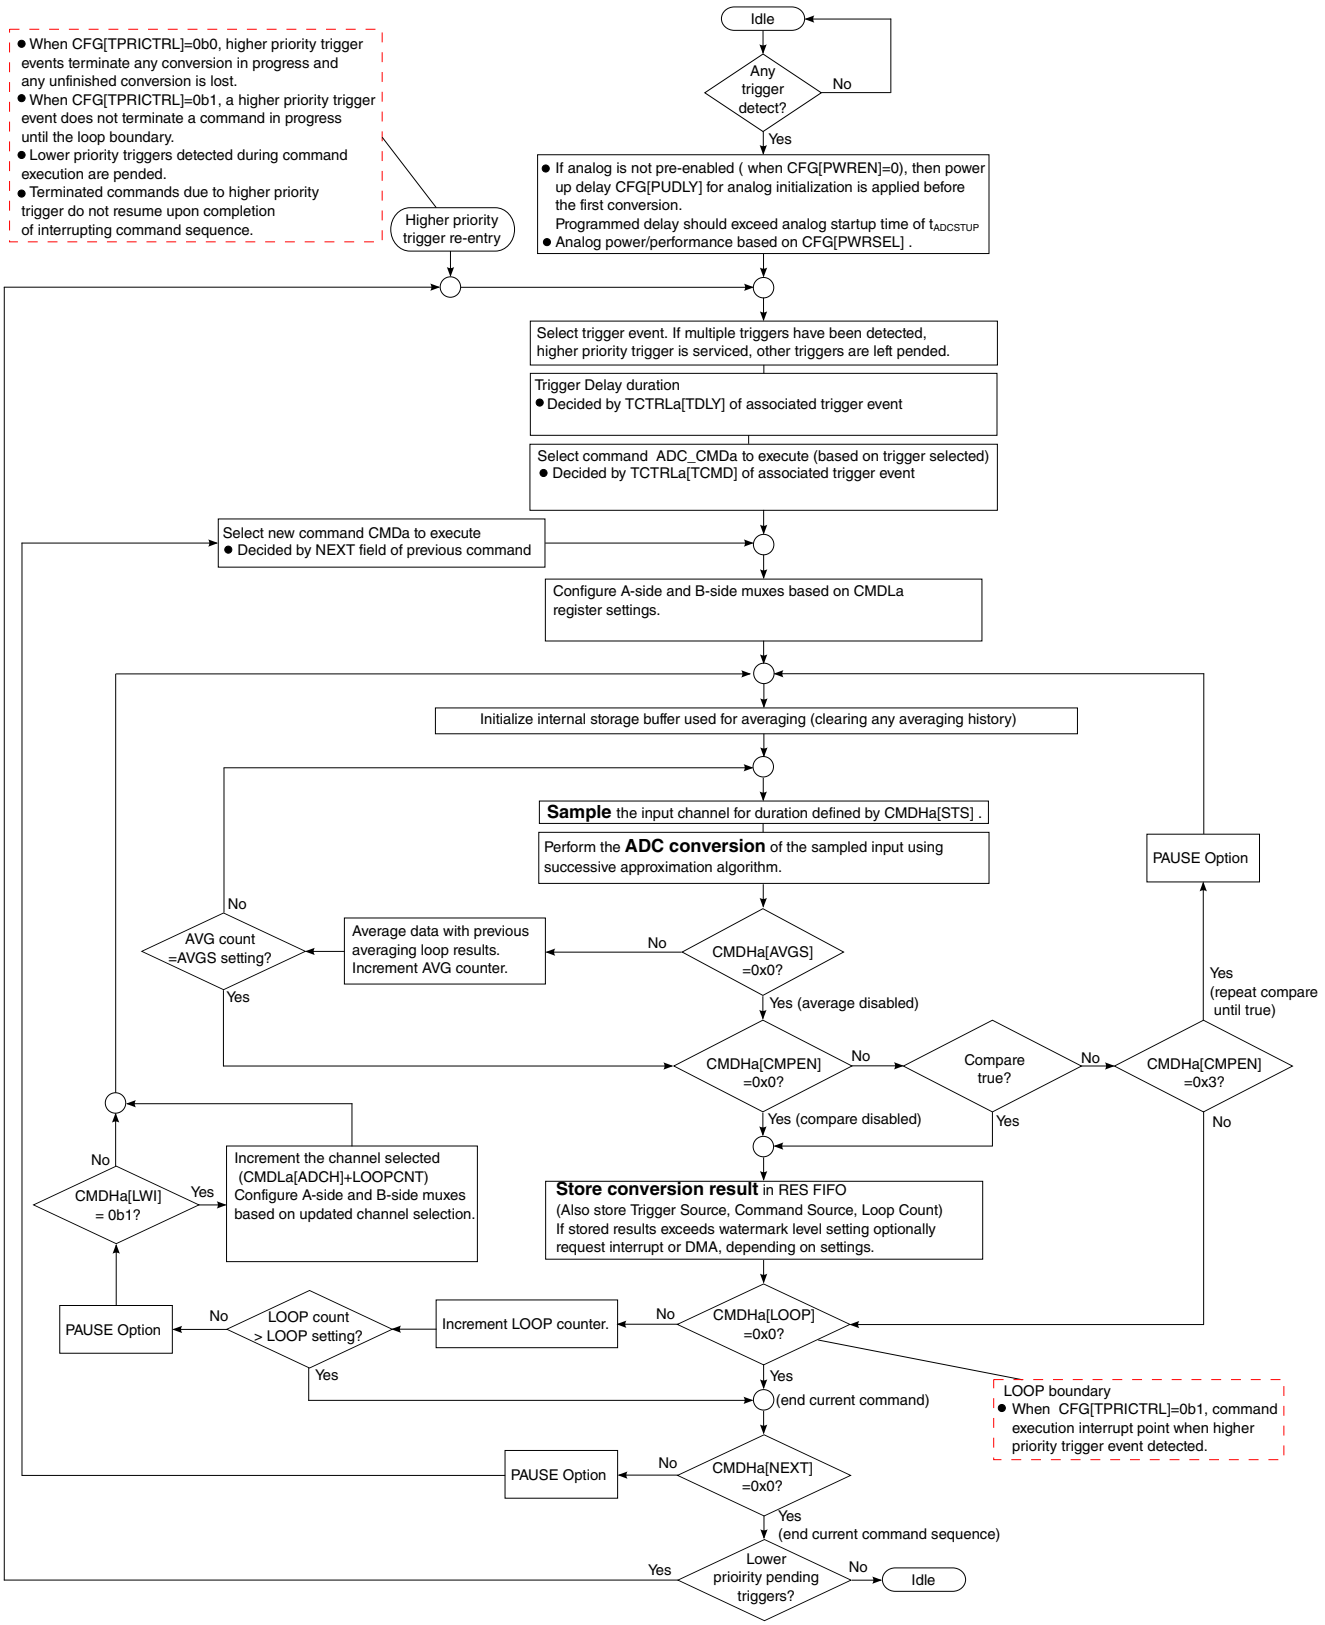

Figure 87-3. ADC command execution flow diagram

The figure below shows how LPADC interfaces with the ADC_ETC.

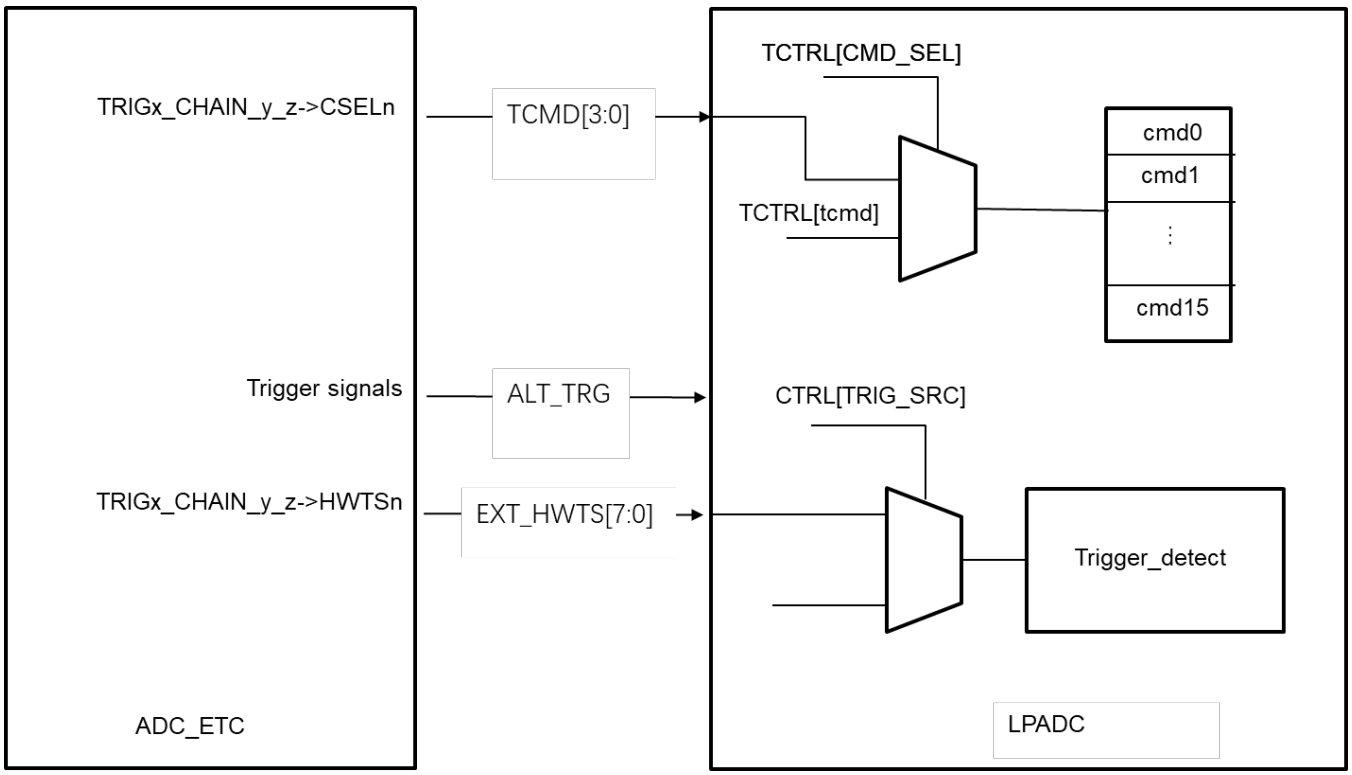

Figure 87-4. Trigger block diagram

The following is a description of the trigger signals that interface between the ADC_ETC and the LPADC:

- TCMD[3:0] is a hardware-controllable command selector, which could be sampled/ latched when EXT_HWTS[a] is high.
- EXT_HWTS is a hardware bus to select the trigger channel.
- ALT_TRIG is a hardware trigger signal. All channels share a same trigger signal, and need EXT_HWTS to indicate which channel it is from. EXT_HWTS needs to be at least one clock cycle ahead of trigger assertion.

TCMD, EXT_HWTS, and ALT_TRIG are synced with ipg_clk from SOC level.

87.3.1 Modes of operation

The table below shows the operation of LPADC module in various power modes.

Table 87-2. Chip modes supported by the ADC module

Chip mode	LPADC Operation
RUN	Normal operation

Table continues on the next page...

Table 87-2. Chip modes supported by the ADC module (continued)

Chip mode	LPADC Operation
STOP/WAIT	Can continue operating provided the Doze Enable bit (CTRL[DOZEN]) is clear and the module is using an external or internal clock source which remains operating during stop/wait modes. When the CTRL[DOZEN] bit is set, the module will wait for the current averaging iteration/FIFO storage to complete before acknowledging stop or wait mode entry.
LOW LEAKAGE STOP	The Doze Enable (CTRL[DOZEN]) bit is ignored and the ADC will wait for the current transfer to complete any pending operation before acknowledging low-leakage mode entry.

87.3.2 Voltage reference

The voltage reference high (V_{REFH}) used by the LPADC is supplied from either an on-chip voltage reference source or from an off-chip source supplied through external pins. V_{REFL} is always from an external pin and must be at the same voltage potential as V_{SSA}. See the chip configuration information on the voltage reference options specific to this packaged device.

This block supports a programmable selection of the voltage reference used for ADC conversions (via the CFG[REFSEL] field). See the chip configuration information on the voltage reference options specific to this packaged device.

NOTE

The external analog input pins can support higher input voltages than reference by scaling features implementation in ADCxCMDLy[CSCALE].

87.3.3 Power control

The default setting for the ADC analog circuits is disabled (CFG[PWREN] = 0) while the LPADC is in its Idle state. When a trigger is detected and ADC command processing is initiated, the analog circuits are enabled and require a period of initialization before the first conversion cycle. The CFG[PUDLY] should be programmed such that a delay duration longer than $t_{ADCSTUP}$ is incurred. Accuracy of the initial conversion(s) after activation is degraded if CFG[PUDLY] is set to too small a value.

Faster conversion startup times can be achieved by optionally setting the CFG[PWREN] field to pre-enable the analog circuits of the LPADC at the expense of power consumption even while the module is in an idle state. When CFG[PWREN] is set, the Power Enable timer is activated and enforces the minimum startup before detected triggers are allowed to initiate ADC conversions.

This module also has configuration options for controlling power and performance summarized in the table below. For example: To achieve the maximum sample rate, the highest power setting is required. See the device datasheet for specification of the available power modes.

Table 87-3. Power option settings

CFG[PWRSEL]	Description
0b00 (Default)	Level 1. Slowest speed/Lowest power setting.
0b01	Level 2.
0b10	Level 3.
0b11	Level 4. Fastest speed/highest power setting.

In the two highest power mode settings (CFG[PWRSEL]=0x2 or CFG[PWRSEL]=0x3) the LPADC will delay start of sampling for 16 ADC clock cycles on the initial conversion since being in its Idle state. This delay is in addition to any configured Power Up delay or trigger delay.

87.3.4 Clock operation

The LPADC operates from the ADCK clock input provided from an on-chip clock select block and is used by the SAR conversion control sequencing logic and the FIFO storage buffer. The ADCK frequency must fall within the specified frequency range for ADCK and will vary based on configuration of CFG[PWRSEL]. See the device datasheet for supported frequency ranges.

The LPADC continues operating in stop and wait modes provided the Doze Enable bit (CTRL[DOZEN]) is clear and the on-chip clock select block continues to supply an ADCK clock source. When the CTRL[DOZEN] bit is set, the module will wait for the current averaging iteration/FIFO storage to complete before acknowledging stop or wait mode entry.

87.3.5 Sample time, compare time, and total conversion time

Sample time is a time interval required to charge ADC sampling capacitance (bank of capacitances) by required ADC input channel voltage. Short sample time interval can cause the voltage across sampling capacitance at the end of sampling interval is not sufficient (lower that ADC input voltage) and consequentially it is used for ADC conversion which at the end results in inaccurate ADC results. Longer sample time interval affects resulting ADC sample rate. To get higher ADC sample rate (sample per second) with shorter sample time interval, it means to achieve best ADC performance analog source resistance RAS must be kept as low as possible, for example used operation amplifier out to be connected to ADC input. The sample time interval can be calculated based on STS field in ADC_CMDHx register and ADC clock:

Sample time interval = $(3+2^{STS})$*adc_clk

Compare (conversion) time is a time interval starting from sample time end (sample capacitance is charged by ADC input voltage) until conversion complete (ADC result is available in ADC result FIFO). Basically it represents a time during which ADC is executing successive approximation steps. This time interval is fixed to 17.5 ADC clock cycles (adc_clk).

Total conversion time represents a sum of sampling and compare time intervals. It is a time interval during which the conversion cannot be interrupted by another ADC trigger event to be able to finish successfully. The equation to calculate this is:

Total conversion time = sampling time + compare time

87.3.6 Trigger detect and command execution

See Figure 87-3 for a flow diagram of command execution sequencing.

LPADC command execution is initiated from up to 8 trigger sources. Each trigger can be software generated by writing 0b1 to the corresponding SWTRIG[SWT*n*] bitfield. Alternatively, hardware triggers can be generated from asynchronous input sources at the periphery of the module. The number and sources of hardware triggers implemented is device-specific. See the chip configuration information for description of available hardware trigger sources for this device.

Each hardware trigger source is enabled by setting the associated enable bit (TCTRL*a*[HTEN]). Each trigger source is assigned a priority via the associated priority control field (TCTRL*a*[TPRI]). Each of the trigger sources is configurably associated with a command in the command buffer via the associated command select field (TCTRL*a*[TCMD]).

When a hardware trigger input is enabled, hardware trigger events are detected on the rising-edge of the associated hardware trigger source.

If a trigger event occurs that is configured for a higher priority than the trigger source associated with the currently executing command, the current command is handled in one of two ways depending on the CFG[TPRICTRL] bitfield setting. When CFG[TPRICTRL]=0b0, a higher priority trigger causes an immediate command abort and the new command specified by the trigger is immediately started. When CFG[TPRICTRL]=0b1, a higher priority triggers allows the current conversion to complete (including averaging and compare functions) before the higher priority command is initiated.

If a lower priority trigger occurs (i.e., a trigger event occurs that is configured for a lower priority than the trigger source associated with the currently executing command), the trigger detect is pended until completion of the current command sequence.

At the completion of a command, the LPADC does not resume a previously interrupted command (or series of commands). The module begins command execution associated with the processing of lower priority pending triggers. If no trigger events are pending, the LPADC transitions to its idle state.

When a conversion is completed (including hardware averaging when AVGS is non-zero), the result is placed in the RESFIFO buffer. When an ADC command selects looping (when LOOP is non-zero) a command will store multiple conversion results to the FIFO during execution of that command.

At the end of command execution, the NEXT field of the command selects the next command to be executed. Multiple commands can be executed sequentially by configuration of each command's NEXT field. Setting the next command to 0x0 causes conversions to terminate at the completion of the command. Unending circular command execution is allowed by setting the NEXT field in the last command in a sequence to the first command in the sequence. It is also allowed for a command to set the next command to itself, resulting in a continuous conversion configuration. Lower priority trigger events cannot be serviced until a higher priority triggered command (or command sequence) completes.

Disabling the LPADC by writing 0b0 to the CTRL[ADCEN] bitfield terminates any active ADC command processing. Writing 0b0 to the CTRL[ADCEN] bitfield causes the current command (or command sequence) to terminate, clears any pending triggers, and sends the module to an Idle state.

87.3.7 Pause option

When the maximum conversion rate is not required by an application the effective conversion rate can be reduced by implementing periodic trigger events to initiate ADC conversions or by selecting a reduced frequency clock as the ADACK source. Both of these options are chip specific and are dependent on ADC triggering and clocking options external to the LPADC module. The latency associated with ADC analog power up delays results in a limit on the maximum conversion rate when using periodic triggering.

Another means of reducing conversion rates is by inserting a pause of a programmable duration between LOOP iterations, between commands in a sequence, and between conversions when command is executing in the "Compare Until True" configuration. When PAUSE[PAUSEEN] is set, the PAUSE[PAUSEDLY] field controls the duration of pausing during command execution sequencing. The pause delay is a count of (PAUSEDLY*4) ADCK cycles. The PAUSE register cannot be changed while the CTRL[ADCEN] bit is set. Writes to the PAUSE register while CTRL[ADCEN] is set are ignored.

See Figure 87-3 for the places during command execution sequencing where the pause is optionally inserted.

87.3.8 Result FIFO operation

The LPADC includes a 16 entry FIFO in which the result of ADC conversions are stored. In addition, a valid indicator bit, the trigger source, the source command and the loop count are also stored along with the data. FCTRL[FCOUNT] indicates how many valid datawords are stored in the RESFIFO.

A programmable watermark threshold supports configurable notification of data availability. When FCOUNT is greater than FCTRL[FWMARK], the STAT[RDY] flag is asserted. When IE[FWMIE] is set, a watermark interrupt request is issued. When DE[FWMDE] is set, a DMA request is issued. Reading RESFIFO provides the oldest unread dataword entry in the FIFO and decrements FCOUNT. When FCOUNT falls equal to or below FWMARK, the RDY flag is cleared.

The FIFO can be emptied by successive reads of RESFIFO. When the RESFIFO[VALID] bit is 1, the associated FIFO entry is valid. Reading RESFIFO when the FIFO is empty (when RESFIFO[VALID] is clear and FCOUNT=0x0) provides an undefined dataword. The FIFO is reset by writing 0b1 to the CTRL[RSTFIFO] bit.

If the LPADC attempts to store a dataword to the FIFO when the FIFO is full, the FIFO overflow flag (FCTRL[FOF]) is set. When IE[FOFIE] is set, an overflow interrupt request is issued. The STAT[FOF] flag is cleared by writing 1 to FOF. On overflow

events, no new data is stored and the data associated with the store that triggered the overflow is lost, the current ADC command (sequence) is aborted and all pending trigger events are discarded. No new triggers are detected until the overflow flag is cleared.

87.3.9 Compare function

After the input is sampled and converted and any averaging iterations are performed, the CMDH*a*[CMPEN] field guides operation of the automatic compare function to optionally only store when the compare operation is true. There are multiple options on command sequencing related to the compare function as summarized in the table below.

NOTE

Not all Command Buffers have an associated Compare Value register. The compare function is only available on Command Buffers that have a corresponding Compare Value register.

Table 87-4. Compare modes

CMDH*a*[CMPEN]	Compare Function	Description
0b00	Compare disabled	Do not perform compare operation. Always store the conversion result to the FIFO.
0b01	Reserved	
0b10	Store on true	Perform compare operation. Store conversion result to FIFO at end of comparison only if compare is true. If compare is false, do not store the result to the FIFO. In either the true or false condition, the LOOP setting is considered and increments the LOOP counter before deciding whether the current command has completed or additional LOOP iterations are required.
0b11	Repeat compare until true	Perform compare operation. Store conversion result to FIFO at end of comparison only if compare is true. Once the true condition is found the LOOP setting is considered and increments the LOOP counter before deciding whether the current command has completed or additional LOOP iterations are required. If the compare is false do not store the result to the FIFO. The conversion is repeated without consideration of LOOP setting and does not increment the LOOP counter.

Depending on CV*a*[CVH] and CV*a*[CVL] values programmed, the compare operation checks whether the result is less than, greater than, or if the result falls within or outside a range determined by two compare values. The compare values are used as described in the following table.

Table 87-5. Compare operations

CV*a*[CVL] vs. CV*a*[CVH]	Operation	Description
set CVL < CVH	Outside range	Compare true if the result is less than CVL value or greater than CVH value.

Table continues on the next page...

Table 87-5. Compare operations (continued)

CV*a*[CVL] vs. CV*a*[CVH]	Operation	Description
	(General form)	
set CVH to max value set CVL to compare point	Less than	Compare true if the result is less than CVL value.
set CVL to min value set CVH to compare point	Greater than	Compare true if the result is greater than CVH value.
set CVL > CVH	Inside range	Compare true if the result is less than CVL value and greater than CVH value.

Note

In low power modes where the LPADC continues to operate, the compare function can monitor the voltage and only wake the device when the compare condition is met.

87.4 Signal descriptions

The LPADC module supports up to 64 analog channel inputs with differential and single-ended conversion options for all channels. The module also requires supply and ground connections.

Table 87-6. LPADC signal descriptions

Signal	Description	I/O
V_{REFH}	ADC Analog Voltage Reference High Input	I
V_{DDA}_ADC_3P3	ADC Analog Power Supply Input 3.3V	I
V_{DDA}_ADC_1P8	ADC Analog Power Supply Input 1.8V	I
V_{SSA}	Analog Ground, Shorted with common ground VSS in package	I
V_{REFL}	Analog Ground, Shorted with common ground VSS in package	I
CH30A-CH0A	A-side Analog Channel Inputs	I
CH30B-CH0B	B-side Analog Channel Inputs	I

NOTE

The voltage reference (V_{REFH}) used by the LPADC is supplied from either an on-chip voltage reference source or from an off-chip source supplied through external pins. V_{REFL} is always from an external pin and must be at the same voltage potential as V_{SSA}. This block supports a programmable selection of the Voltage Reference used for ADC conversions (via the

CFG[REFSEL] field). See the chip configuration information on the voltage reference options specific to this packaged device.

87.4.1 Analog Power (V_{DDA}_ADC_3P3 and V_{DDA}_ADC_1P8)

The ADC analog portion uses V_{DDA}_ADC_3P3 and V_{DDA}_ADC_1P8 as its power connection. If externally available, connect the V_{DDA} pin to the same voltage potential as V_{DD}. External filtering may be necessary to ensure clean V_{DDA}_ADC_3P3 and V_{DDA}_ADC_1P8 for good results.

87.4.2 Analog Ground (V_{SSA})

The ADC analog portion uses V_{SSA} as its ground connection. In some packages, V_{SSA} is connected internally to V_{SS}. If externally available, connect the V_{SSA} pin to the same voltage potential as V_{SS}.

87.4.3 Analog Channel Inputs (CH*n*A and CH*n*B)

The CMDL*a*[ADCH], CMDL*a*[DIFF] and CMDL*a*[ABSEL] bitfields control selection of paired or individual input channels. Each ADC command independently makes a channel selection. Each ADCH channel selection has an associated A side and an associated B side input. Each ADCH pair can optionally be converted in a differential mode but only limited pairs are intended to be converted as differential channels (i.e., adjacent pins that have been designed with matched impedance). For the pin pairings available for differential conversions for your device, see the chip-specific information.

NOTE

Some of the input channels are from on-chip sources such as temperature sensors and reference voltage sources and may only be connected to individual instances of the ADC module. Some of the input channel options in the bitfield-setting descriptions may not be available for your device. Refer to the chip-specific information for the channels supported on this device.

87.5 Initialization

This section gives an example that provides some basic direction on how to initialize the LPADC module. The user can configure the module for 12-bit single-ended resolution or 13-bit differential resolution, single or continuous conversion, and a polled or interrupt approach, among many other options.

87.5.1 LPADC module initialization example

LPADC module should be properly initialized before it is configured according the application needs. It is important to get the LPADC module to work properly from its first conversion.

87.5.2 Initialization sequence

Before the LPADC module can be used to complete conversions, an initialization procedure must be performed. A typical sequence is:

1. ADC clock needs to be enabled prior writing into the LPADC registers. Set the ADC clock considering target application sample and conversion time requirements then enable ADC clock in CCM module.
2. Reset LPADC module by writing 1 (keep module in reset) and then 0 (release from reset) into the RST field in control register CTRL.
3. Reset ADC results FIFO by writing 1 into RSTFIFO field in control register CTRL.
4. Disable LPADC module (if not already) by writing 0 ADCEN field in control register CTRL. Keep ADC module disabled until not fully initialized.
5. Select proper voltage reference by writing appropriate value into the REFSEL field in configuration register CFG.
6. Configure correct LPADC module start-up, power and performance according to application needs.
    a. To achieve lower power consumption disable pre-enabling of ADC analog circuitry by writing 0 into the PWREN field in ADC configuration register CFG. Then based of application requirement configure power up delay by writing appropriate value in PUDLY field in ADC configuration register. Set lowest power configuration by writing 0 into PWRSEL field in ADC configuration register CFG.
    b. To achieve high ADC conversion rate enable pre-enabling of ADC circuitry by writing 1 into the PWREN field in ADC configuration register CFG. Set the

highest power setting by writing 0x3 into the PWRSEL field in ADC configuration register ADC->CFG.

c. For balanced configuration between the low power configuration and faster ADC speed follow the configuration of PWREN, PUDLY and PWRSEL fields somewhere between previous descripted configurations (a., b.).

NOTE

Steps 5 and 6 can be done at one time.

7. Enable ADC module by writing 1 into the ADCEN field in control register CTRL.

NOTE

Do not initiate any trigger for ADC conversion start prior its proper full configuration.

87.6 Application information

This section contains information for using the LPADC module in applications. The LPADC has been designed to be integrated into a microcontroller for use in embedded control applications requiring an A/D converter.

NOTE

This part represents general application consideration. For chip specific features see chapter chip-specific information at the beginning of LPADC module chapter or dedicated device datasheet.

87.6.1 External pins and routing

Very important role regarding to accurate ADC measurement plays components connected to LPADC module externally, including ADC analog module power supply, ADC reference as well as voltage sources connected to ADC inputs. All these voltage sources have their capability and impedances which can significantly affect measurement accuracy. Moreover the total source impedance is affected also by routing on PCB. In general, the rule is to minimize parasitic impedances (especially resistive and inductive) as much as possible to achieve better ADC performance.

Any noise generated on ADC reference or ADC input affects resulting digital result directly as defined by:

ADC result = $(V_{ADIN}/V_{ADCREF})(2^N-1)$

Where V_{ADCIN} represents the voltage at ADC input pin and V_{ADCREF} represents analog voltage reference at reference pin. The noise generated on analog power supply can also affect ADC measurement accuracy indirectly as it represents analog peripheral modules power supply.

NOTE

On some devices, there is only one power ground available externally, usually as V_{SS}. In such case digital ground (V_{SS}), analog ground (V_{SSA}) and negative reference voltage (VREFL) are tied together inside package.

87.6.1.1 Analog supply pins

Depending on the device, the analog power and analog ground pads of the LPADC module can be available as:

- Separate pins - when available on a separate pin, analog ground must be connected to the same voltage potential as digital ground, and analog power supply is recommended to be impedance isolated from digital power supply by ferrite bead, for example. Both analog power and analog ground must be routed carefully for maximum noise immunity and bypass capacitors must be placed as near as possible to the pin package.
- Analog ground is shared on the same pin as the MCU digital ground (connected internally).
- Analog power and analog ground are both shared with the MCU digital power and ground pins (connected internally) - In these cases, there are separate pads for the analog supplies bonded to the same pin as the corresponding digital supply so that some degree of isolation between the supplies is maintained.

If separate power supplies are used for analog and digital power, the ground connection between these supplies must be at the analog power pin. This must be the only ground connection between these supplies, if possible. Analog ground makes a good single point ground location.

87.6.1.2 Analog voltage reference pins

In addition to the analog supplies, the LPADC module can have connections to selectable reference voltage inputs used by the converter:

- V_{REFH} is the high reference voltage for the converter.
- V_{REFL} is the low reference voltage for the converter.

The ADC can be configured to accept more than one voltage reference pairs. Each pair contains a positive reference and a ground reference and they can represents additional external pins or internal sources based on MCU configuration (if reference voltage peripheral module available on device). One of these positive references may be shared on the same pin as analog power supply. As well as one of these ground references may be shared on the same pin as analog ground. It is chip specific, see the chip-specific information on the voltage references specific to this device.

If externally available, the positive reference may be driven by an external source to a level between the minimum VREFH and analog power supply potential. The positive reference VREFH must never exceed analog power supply level (see also device datasheet). If externally available, the ground reference must be connected to the same voltage potential as analog power supply ground. The voltage reference pairs must be routed carefully for maximum noise immunity and bypass capacitors placed as near as possible to the package.

AC current in the form of current spikes required to supply charge to the capacitor array at each successive approximation step is drawn through the VREFH and VREFL loop. The best external component value to meet this current demand can be found in corresponding device hardware development guide (HDUG). This capacitor is connected between VREFH and VREFL and must be placed as near as possible to the package pins. Resistance in the path is not recommended because the current causes a voltage drop that could result in conversion errors. Inductance in this path must be minimum, thus reduce parasitic inductance as much as possible.

87.6.1.3 Analog input pins

The external analog inputs are typically shared with digital I/O pins on MCU devices. Empirical data shows that capacitors on the analog inputs improve performance in the presence of noise or when the source impedance is high. Use of 0.01 μF capacitors with good high-frequency characteristics is sufficient. These capacitors are not necessary in all cases, but when used, they must be placed as near as possible to the package pins and be referenced to analog power ground. For proper conversion, the input voltage must fall between VREFH and VREFL. If corresponding device support scale factor (CSCALE) the maximum positive input voltage is defined as:

V_{INMAX} = (VREFH-VREFL)/Factor

For factor definition see CSCALE field description. If the input is equal to or exceeds VREFH, the converter circuit converts the signal to 0x7FFF (or 0xFFFF), which is full scale 12-bit single ended (or 13-bit differential) representation. If the input is equal to or less than VREFL, the converter circuit converts it to 0x000. Input voltages between

VREFH and VREFL are straight-line linear conversions. There is a brief current associated with VREFL when the sampling capacitor is charging. For minimal loss of accuracy due to current injection, pins adjacent to the analog input pins must not be transitioning during conversions.

87.6.2 Sources of error

Several sources of error exist for A/D conversions. These are discussed in the following sections.

NOTE

In the next sections, the errors description does not consider the LPADC module data result format, meaning 12-bit (13-bit) ADC resolution is represented by 16-bit results. Hence, one step up/down in digital results does not represents 1 digit (0b1) but 8 digits (0b1000).

87.6.2.1 Sampling error

For proper conversions, the input must be sampled long enough to achieve the proper accuracy. Higher source resistances or higher-accuracy sampling is possible by setting STS field in LPADC command high buffer register CMDHx (to increase the sample window) or decreasing ADC clock frequency to increase sample time. Care must be taken to not exceed the maximum analog source resistance R_{AS} of 5kohm which is connected externally. To achieve best performance analog source resistance R_{AS} must be kept as low as possible and time constant of external components (R_{AS} and C_{AS}) must be kept < 1ns. For example: datasheet values are achieved with RAS < 15.

NOTE

For guidance on selecting optimum external component values and converter parameters see AN4373: Cookbook for SAR ADC Measurements.

87.6.2.2 Pin leakage error

Leakage on the I/O pins can cause conversion error if the external analog source resistance (R_{AS}) is high. If this error cannot be tolerated by the application, keep R_{AS} :

R_{AS} < (analog power supply voltage)/(2*N*$I_{leakage}$)

$I_{leakage}$ can be found in corresponding device datasheet and N represents ADC resolution 12-bit. With this value of R_{AS} it is possible to achieve less than 1/4LSB leakage error.

87.6.2.3 Noise-induced errors

System noise that occurs during the sample or conversion process can affect the accuracy of the conversion. The ADC accuracy numbers are guaranteed as specified only if the following conditions are met:

- There is dedicated value (see corresponding device hardware development user guide (HDUG)) high dynamic capable and low-ESR capacitor connected as close as possible to VREFH and VREFL (if available externally in package).
- There is dedicated value (see corresponding device hardware development user guide (HDUG)) high dynamic capable and low-ESR capacitor from analog power supply to analog power ground.
- If inductive isolation is used from the primary supply, an additional 1 µF capacitor is placed from analog power supply to analog power ground.
- Analog ground (and VREFL, if available externally) is connected to digital ground at a quiet point in the ground plane.
- Operate the MCU in wait or stop mode before initiating (hardware triggered conversions) or immediately after initiating (hardware or software triggered conversions) the ADC conversion. For software triggered conversions, immediately follow the write to software trigger register (SWTRIG) with a wait instruction or stop instruction.
- There is no I/O switching, input or output, on the MCU during the conversion. There are some situations where external system activity causes radiated or conducted noise emissions or excessive digital power supply noise is coupled into the LPADC. In these situations, or when the MCU cannot be placed in wait or stop or I/O activity cannot be halted, these recommended actions may reduce the effect of noise on the accuracy:
  - Place a 0.01 µF capacitor (C_{AS}) between the selected ADC input and ADC voltage reference low VREFL (if available externally) or analog power ground. This improves noise issues, but affects the sample rate based on the external analog source resistance.
  - Average the result by converting the analog input many times in succession and dividing the sum of the results. Four samples are required to eliminate the effect of a 1LSB, one-time error.

87.6.2.4 Code width and quantization error

The LPADC quantizes the ideal straight-line transfer function into 4096 steps (in 12-bit mode). Each step ideally has the same height (1 code) and width. The width is defined as the delta between the transition points to one code and the next. The ideal code width for an N bit converter (in this case N can be 12), defined as 1LSB, is:

$1LSB = (VREFH-VREFL)/(2^N)$

There is an inherent quantization error due to the digitization of the result. The code transitions when the voltage is at the midpoint between the points where the straight line transfer function is exactly represented by the actual transfer function. Therefore, the quantization error will be +/- 1/2 LSB (see figure below). As a consequence, however, the code width of the first (0x000) conversion is only 1/2 LSB and the code width of the last 0x7FFF (0xFFFF) is 1.5 LSB.

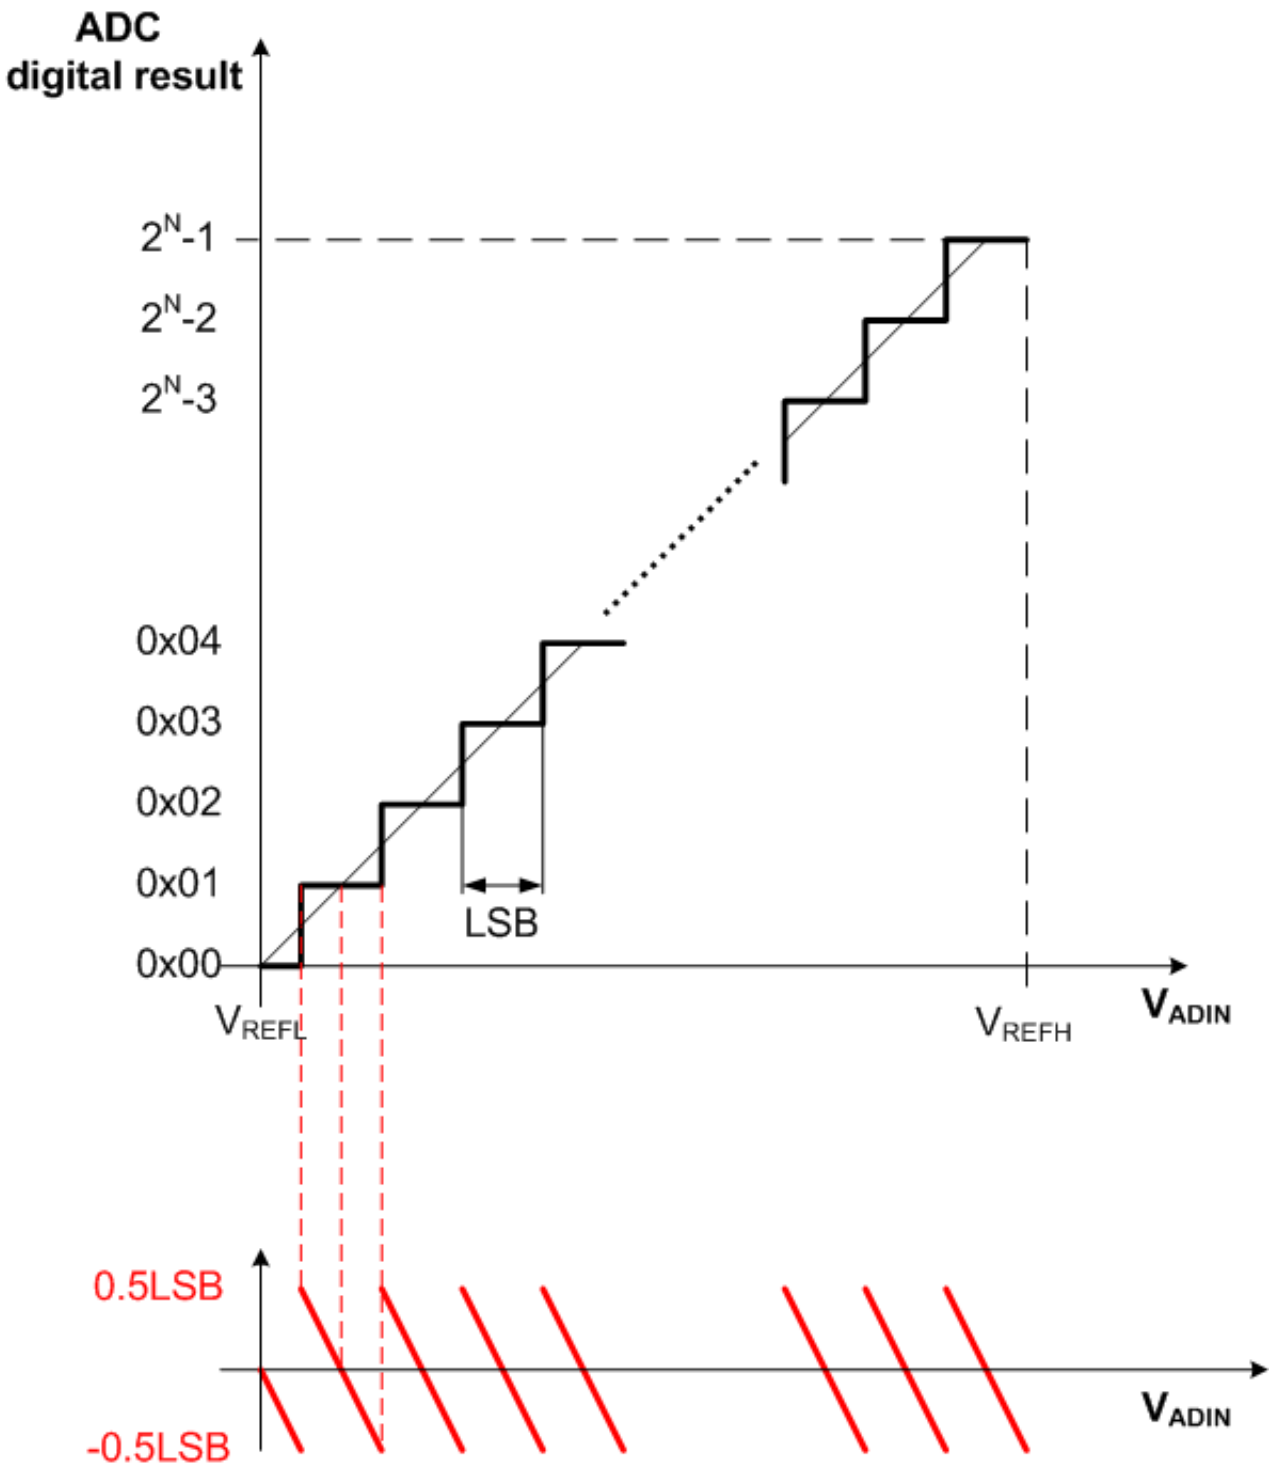

Figure 87-5. Quantization error

87.6.2.5 Linearity errors

The LPADC may also exhibit non-linearity of several forms. Every effort has been made to reduce these errors but the system should be aware of them because they affect overall accuracy.

These errors are:

- Zero-scale error (EZS) (sometimes called offset) — This error is defined as the difference between the actual code width of the first conversion and the ideal code width. If the first conversion is 0x001, the difference between the actual 0x001 code width and its ideal is used.

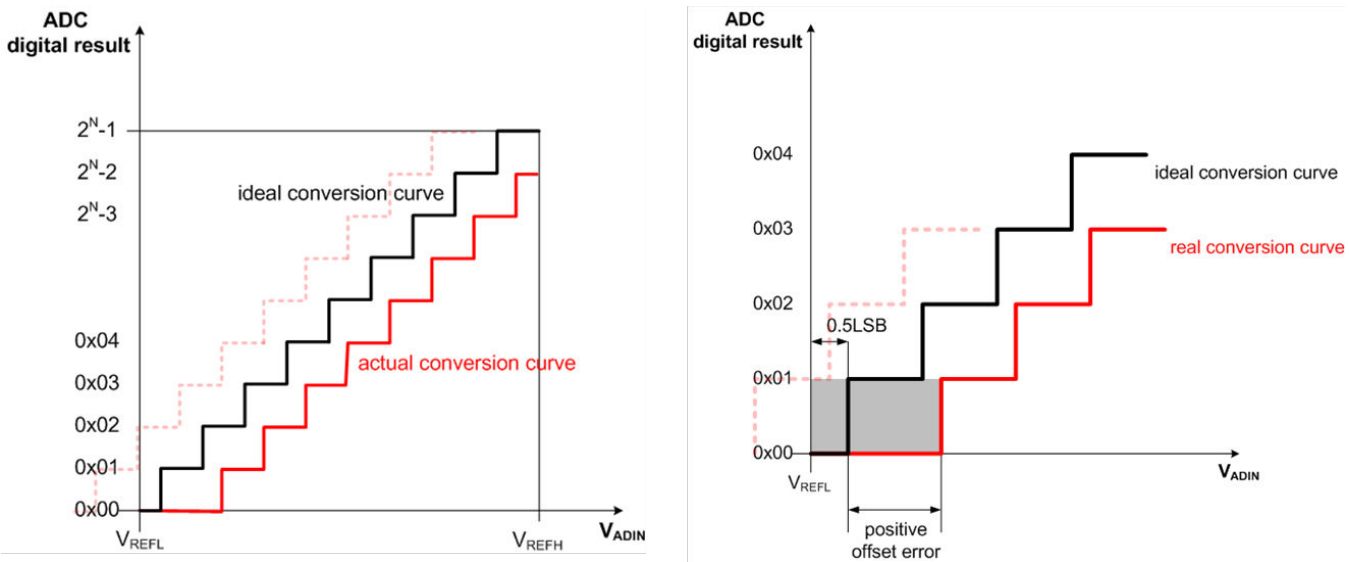

Figure 87-6. Zero-scale (offset) error

- Full-scale error (EFS) — This error is defined as the difference between the actual code width of the last conversion and the ideal code width. If the last conversion is 0x7FFF (or 0xFFFF), the difference between the actual 0x7FFF (or 0xFFFF) code width and its ideal is used.

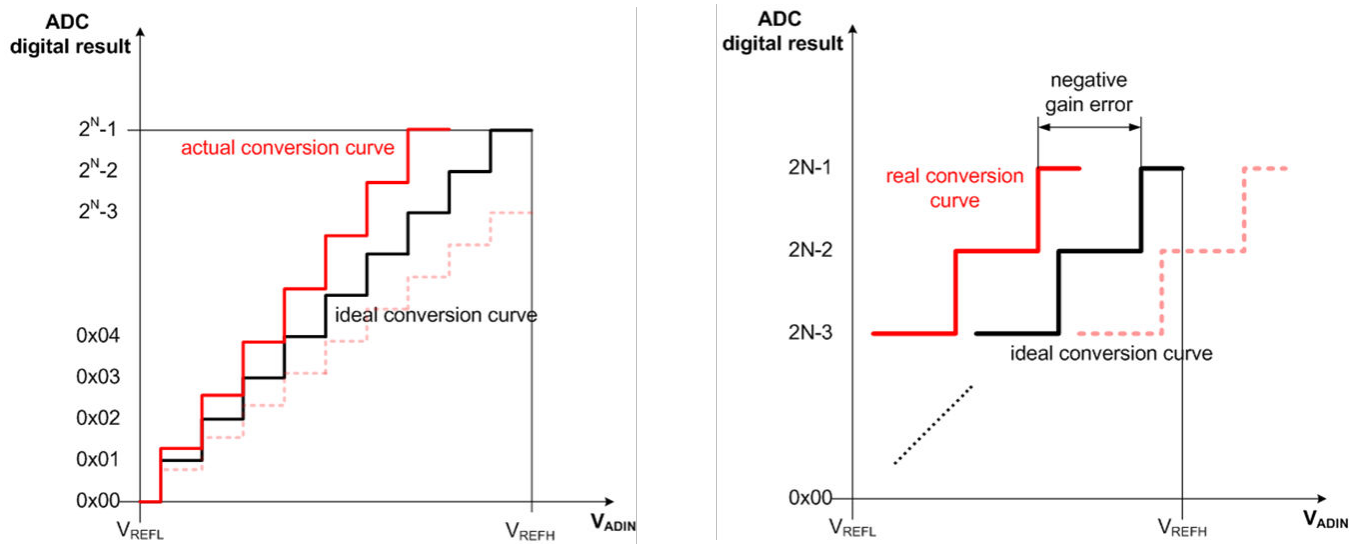

Figure 87-7. Full-scale (gain) error

- Differential non-linearity (DNL) — This error is defined as the worst-case difference between the actual code width and the ideal code width for all conversions.

$$DNL = MAX\left\{\frac{width_i - 1LSB}{1LSB}\right\}$$

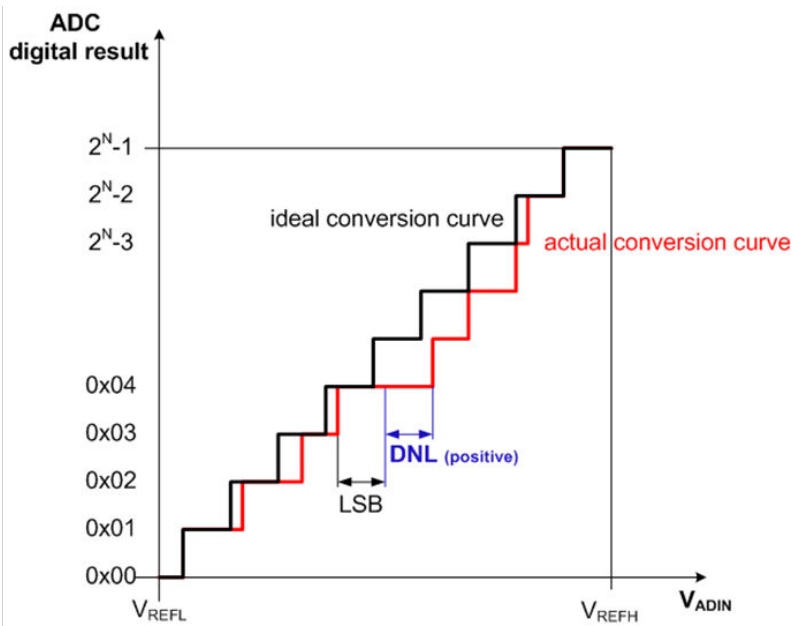

Figure 87-8. Differential non-linearity error

- Integral non-linearity (INL) — This error is defined as the highest-value the (absolute value of the) running sum of DNL achieves. More simply, this is the worst-case difference of the actual transition voltage to a given code and its corresponding ideal transition voltage, for all codes.

$$INL = MAX\left\{\frac{\sum_{i=0}^{N} width_i - N.LSB}{1LSB}\right\}$$

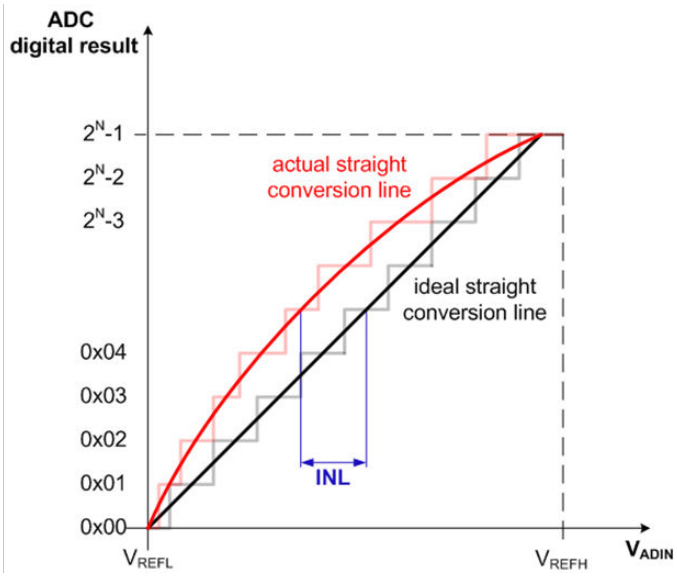

Figure 87-9. Integral non-linearity error

- Total unadjusted error (TUE) — This error is defined as the difference between the actual transfer function and the ideal straight-line transfer function and includes all forms of error.

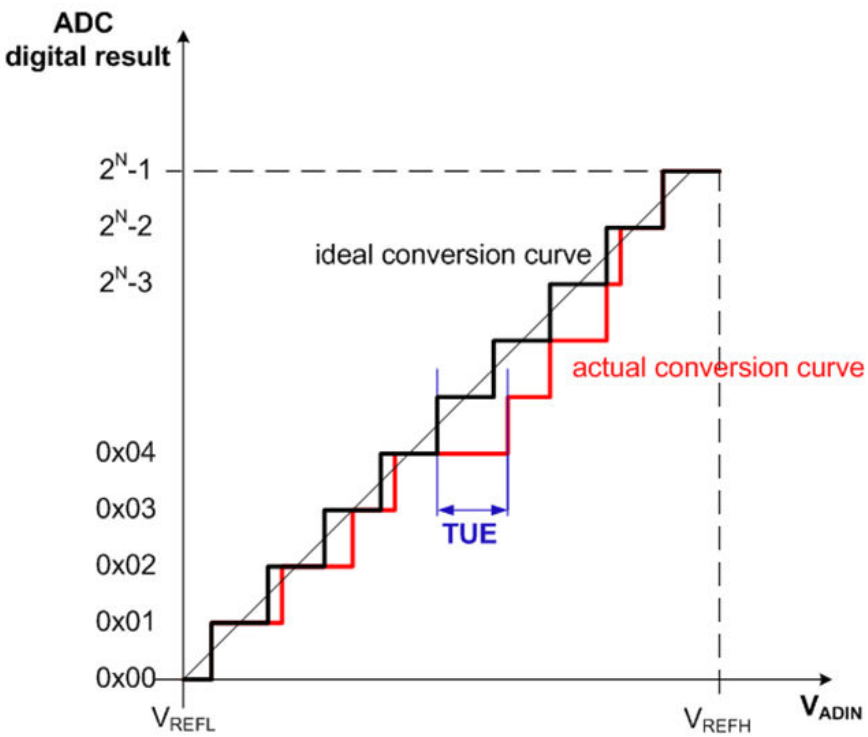

Figure 87-10. Total unadjusted error

87.6.2.6 Code jitter, non-monotonicity, and missing codes

Analog-to-digital converters are susceptible to three special forms of error. These are code jitter, non-monotonicity, and missing codes. Code jitter is when, at certain points, a given input voltage converts to one of two values when sampled repeatedly. Ideally, when the input voltage is infinitesimally smaller than the transition voltage, the converter yields the lower code (and vice-versa). However, even small amounts of system noise can cause the converter to be indeterminate (between two codes) for a range of input voltages around the transition voltage. This range is around 2 LSB in 12-bit mode, and increases with noise. This error may be reduced by repeatedly sampling the input and averaging the result. Additionally the techniques discussed in Noise-Induced Errors reduces this error.

- Non-monotonicity is defined as when, except for code jitter, the converter converts to a lower code for a higher input voltage.
- Missing codes are those values never converted for any input value.

87.7 Memory map and register definition

This section includes the LPADC module memory map and detailed descriptions of all registers.

87.7.1 LPADC register descriptions

This section describes the LPADC registers.

87.7.1.2 Version ID Register (VERID)

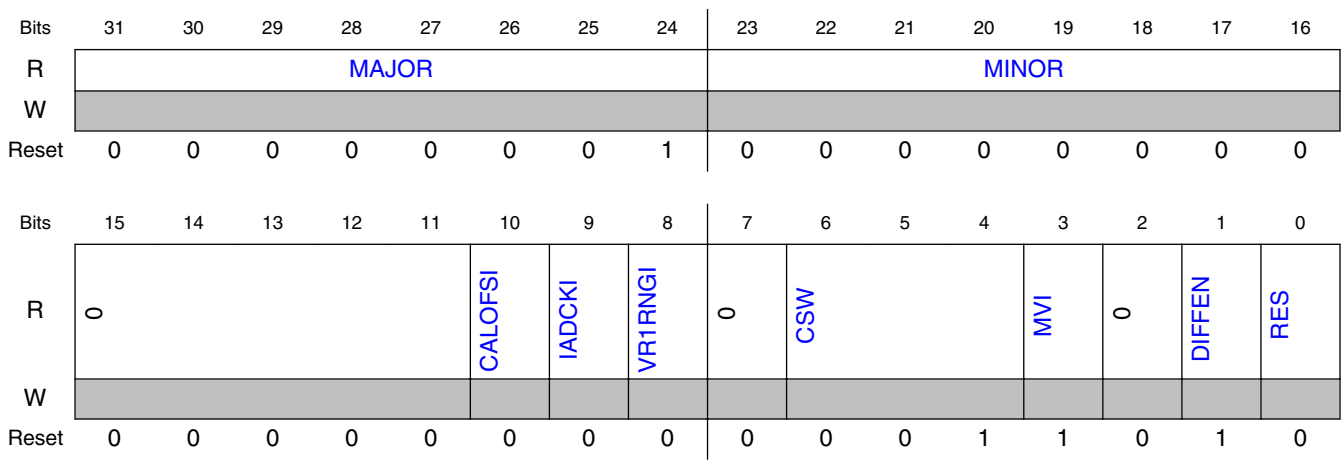
87.7.1.2.1 Offset

Register	Offset
VERID	0h

87.7.1.2.2 Function

The Version ID Register (VERID) indicates the version integrated for this instance on the device and also indicates inclusion/exclusion of several optional features.

87.7.1.2.3 Diagram



87.7.1.2.4 Fields

Field	Function
31-24 MAJOR	Major Version Number This read-only field returns the major version number for the module specification.
23-16 MINOR	Minor Version Number This read-only field returns the minor version number for the module specification.
15-11 —	Reserved This read-only field is reserved and always has the value 0.
10 CALOFSI	Calibration Offset Function Implemented This read-only field indicates if a calibration function and trimming control register are implemented. When supported, the CFG[CALOFS] and OFSTRIM[OFSTRIM] fields are available in support of this function. 0b - Offset calibration and offset trimming not implemented. 1b - Offset calibration and offset trimming implemented.
9	Internal LPADC Clock implemented

Table continues on the next page...

Field	Function
IADCKI	This read-only field indicates if this implementation of the LPADC includes an internal clock source. When supported, the CFG[ADCKEN] field is available and documented for enabling the clock source. When available, this clock source is used in clock selection logic external to the module for use within the system. 0b - Internal clock source not implemented. 1b - Internal clock source (and CFG[ADCKEN]) implemented.
8 VR1RNGI	Voltage Reference 1 Range Control Bit Implemented This read-only field indicates if a control bit is implemented for selecting the input voltage range on Voltage Reference Option 1.When range control is required, the CFG[VREF1RNG] field is available and documented for controlling the Voltage Reference Option 1. 0b - Range control not required. CFG[VREF1RNG] is not implemented. 1b - Range control required. CFG[VREF1RNG] is implemented.
7 —	Reserved This read-only field is reserved and always has the value 0.
6-4 CSW	Channel Scale Width This read-only field indicates if channel scaling is supported by this implementation. When supported, each command buffer has a control field (CMDLa[CSCALE]) for setting input scaling. 000b - Channel scaling not supported. 001b - Channel scaling supported. 1-bit CSCALE control field. 110b - Channel scaling supported. 6-bit CSCALE control field.
3 MVI	Multi Vref Implemented This read-only field indicates if multiple Voltage Reference inputs are supported by this implementation. When multiple voltage references are supported, the CFG[REFSEL] field is available and documented for selecting the Voltage Reference High options. 0b - Single voltage reference input supported. 1b - Multiple voltage reference inputs supported.
2 —	Reserved This read-only field is reserved and always has the value 0.
1 DIFFEN	Differential Supported This read-only field indicates if differential operation is supported by this implementation. When supported, each command buffer has control fields (CMDLa[DIFF] and CMDLa[ABSEL]) for configuring for differential operation and expanding the number of supported channels from 32 to 64. 0b - Differential operation not supported. 1b - Differential operation supported. CMDLa[DIFF] and CMDLa[ABSEL] control fields implemented.
0 RES	Resolution This read-only field indicates the maximum accuracy supported by this implementation. When RES=1, each command buffer has a control field (CMDLa[MODE]) for selecting resolution of conversions for the associated command. 0b - Up to 13-bit differential/12-bit single ended resolution supported. 1b - Up to 16-bit differential/15-bit single ended resolution supported.

87.7.1.3 Parameter Register (PARAM)

87.7.1.3.1 Offset

Register	Offset
PARAM	4h

87.7.1.3.2 Function

The Parameter Register (PARAM) indicates the size of several variable integration options for this instance on the device.

87.7.1.3.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	CMD_NUM								CV_NUM							
W																
Reset	0	0	0	0	1	1	1	1	0	0	0	0	0	1	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	FIFOSIZE								TRIG_NUM							
W																
Reset	0	0	0	1	0	0	0	0	0	0	0	0	1	0	0	0

87.7.1.3.4 Fields

Field	Function
31-24 CMD_NUM	Command Buffer Number Number of command buffers implemented. 0000_1111b - 15 command buffers implemented
23-16 CV_NUM	Compare Value Number Number of compare value registers implemented. 0000_0100b - 4 compare value registers implemented
15-8 FIFOSIZE	Result FIFO Depth The maximum number of conversion datawords that can be stored in the result FIFO before an overflow occurs. This field is read-only. 0001_0000b - Result FIFO depth = 16 datawords.
7-0 TRIG_NUM	Trigger Number Number of Triggers implemented. 0000_1000b - 8 hardware triggers implemented

87.7.1.4 LPADC Control Register (CTRL)

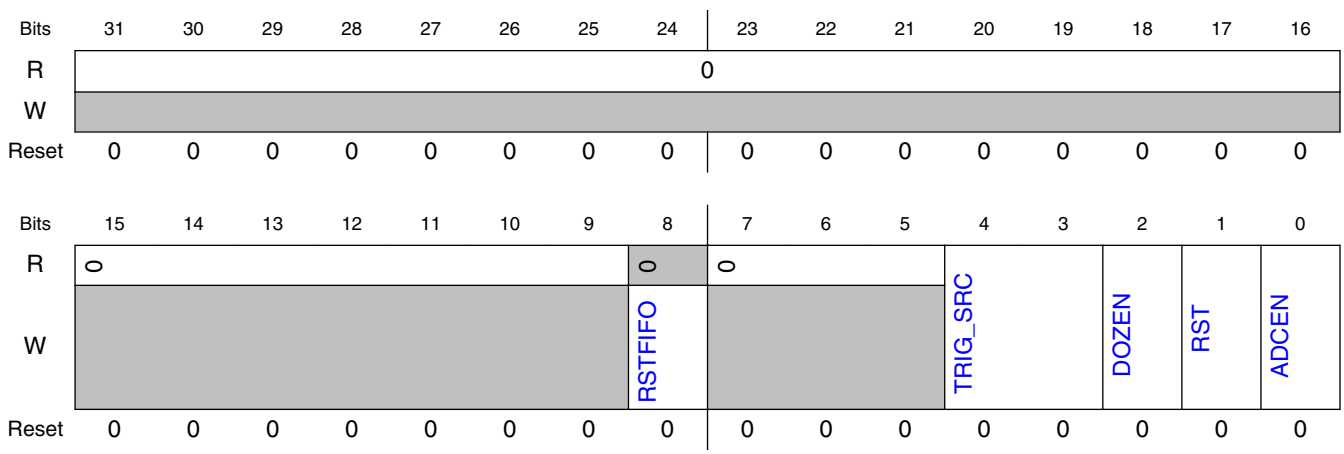
87.7.1.4.1 Offset

Register	Offset
CTRL	10h

87.7.1.4.2 Function

The LPADC Control Register (CTRL) controls various basic functions of the LPADC, such as enables of the ADC and Doze, reset of FIFO and software, and selection of hardware trigger source.

87.7.1.4.3 Diagram



87.7.1.4.4 Fields

Field	Function
31-9 —	Reserved This read-only field is reserved and always has the value 0.
8 RSTFIFO	Reset FIFO 0b - No effect. 1b - FIFO is reset.
7-5 —	Reserved This read-only field is reserved and always has the value 0.
4-3 TRIG_SRC	Hardware trigger source selection 00b - ADC_ETC hw trigger , and HW trigger are enabled 01b - ADC_ETC hw trigger is enabled 10b - HW trigger is enabled

Table continues on the next page...

Field	Function
	11b - Reserved
2 DOZEN	Doze Enable Controls system transition to Stop and Wait power modes while LPADC is converting. When DOZEN is clear, immediate entries to Wait or Stop are allowed. Note that the selected clock source provided from the on-chip clock source must be able to continue operating. When the DOZEN bit is set, the LPADC waits for the current compare iteration/FIFO storage to complete before acknowledging stop or wait mode entry. When the system is entering a Low Leakage Stop mode, the DOZEN bit is ignored and the module waits for the current transfer to complete any pending operation before acknowledging low leakage mode entry. 0b - LPADC is enabled in Doze mode. 1b - LPADC is disabled in Doze mode.
1 RST	Software Reset Resets all internal logic and registers, except the Control Register. Remains set until cleared by software. 0b - LPADC logic is not reset. 1b - LPADC logic is reset.
0 ADCEN	LPADC Enable 0b - LPADC is disabled. 1b - LPADC is enabled.

87.7.1.5 LPADC Status Register (STAT)

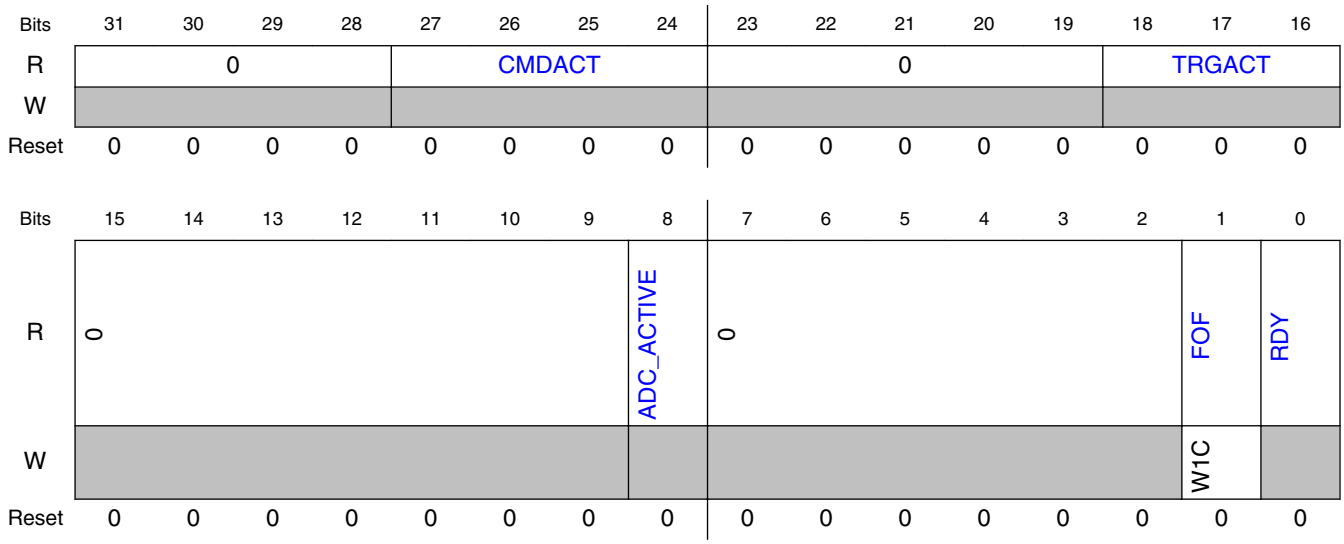
87.7.1.5.1 Offset

Register	Offset
STAT	14h

87.7.1.5.2 Function

The LPADC Status Register (STAT) provides the current status of the LPADC module.

87.7.1.5.3 Diagram



87.7.1.5.4 Fields

Field	Function
31-28 —	Reserved This read-only field is reserved and always has the value 0.
27-24 CMDACT	Command Active CMDACT is a read-only status field indicating the command that is actively being processed. 0000b - No command is currently in progress. 0001b - Command 1 currently being executed. 0010b - Command 2 currently being executed. 0011b-1111b - Associated command number is currently being executed.
23-19 —	Reserved This read-only field is reserved and always has the value 0.
18-16 TRGACT	Trigger Active TRGACT is a read-only status field indicating the trigger associated with the command actively being processed. TRGACT only has meaning when CMDACT is non-zero. 000b - Command (sequence) associated with Trigger 0 currently being executed. 001b - Command (sequence) associated with Trigger 1 currently being executed. 010b - Command (sequence) associated with Trigger 2 currently being executed. 011b-111b - Command (sequence) from the associated Trigger number is currently being executed.
15-9 —	Reserved This read-only field is reserved and always has the value 0.
8 ADC_ACTIVE	ADC Active This flag shows if the module is currently processing a conversion, or has pending triggers to service. When the LPADC is IDLE, this bit will be set to 0b0. 0b - The LPADC is IDLE. There are no pending triggers to service and no active commands are being processed.

Table continues on the next page...

Field	Function
	1b - The LPADC is processing a conversion, running through the power up delay, or servicing a trigger.
7-2 —	Reserved This read-only field is reserved and always has the value 0.
1 FOF	Result FIFO Overflow Flag Indicates that more data has been written to the Result FIFO than it can hold. The newer data is not stored and the FIFO remains holding the original contents. This field asserts regardless of the value of IE[FOFIE]. However, an interrupt request is issued only if IE[FOFIE] is set. This flag is cleared by writing a 1. 0b - No result FIFO overflow has occurred since the last time the flag was cleared. 1b - At least one result FIFO overflow has occurred since the last time the flag was cleared.
0 RDY	Result FIFO Ready Flag Indicates when the number of valid datawords in the result FIFO is greater than the watermark level set in the FCTRL[FWMARK] bitfield. This field asserts regardless of the value of FWMIE. However, an interrupt request or DMA request occurs only when the associated control bit (IE[FWMIE] or DE[FWMDE]) is set. This flag is cleared when the FCOUNT (which decrements on each read of the RESFIFO register) is less than or equal to the watermark level set in the FCTRL[FWMARK] bitfield. 0b - Result FIFO data level not above watermark level. 1b - Result FIFO holding data above watermark level.

87.7.1.6 Interrupt Enable Register (IE)

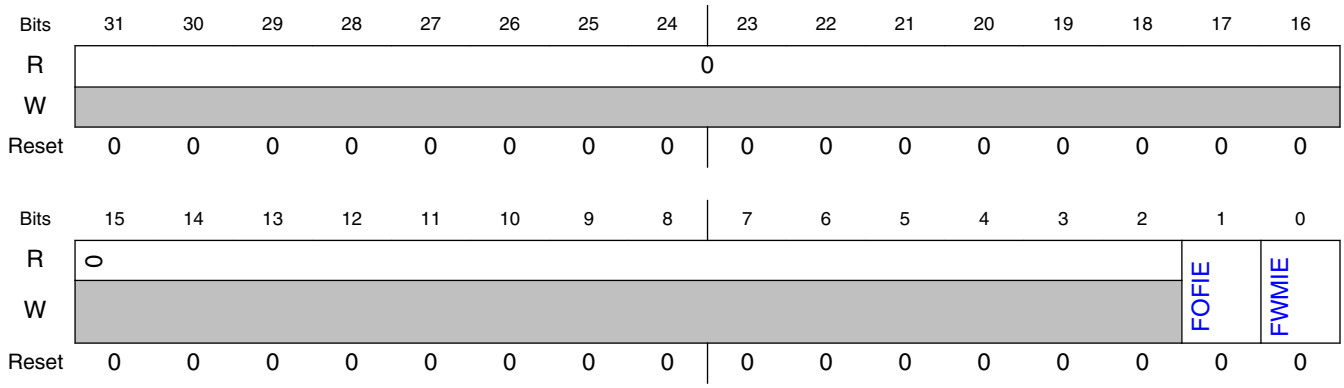
87.7.1.6.1 Offset

Register	Offset
IE	18h

87.7.1.6.2 Function

The Interrupt Enable Register (IE) controls the interrupt enable function of FIFO Watermark and Result FIFO Overflow.

87.7.1.6.3 Diagram



87.7.1.6.4 Fields

Field	Function
31-2 —	Reserved This read-only field is reserved and always has the value 0.
1 FOFIE	Result FIFO Overflow Interrupt Enable Configures ADC to generate overflow interrupt requests when FOF flag is asserted. 0b - FIFO overflow interrupts are not enabled. 1b - FIFO overflow interrupts are enabled.
0 FWMIE	FIFO Watermark Interrupt Enable Configures the module to generate watermark interrupt requests when RDY flag is asserted. 0b - FIFO watermark interrupts are not enabled. 1b - FIFO watermark interrupts are enabled.

87.7.1.7 DMA Enable Register (DE)

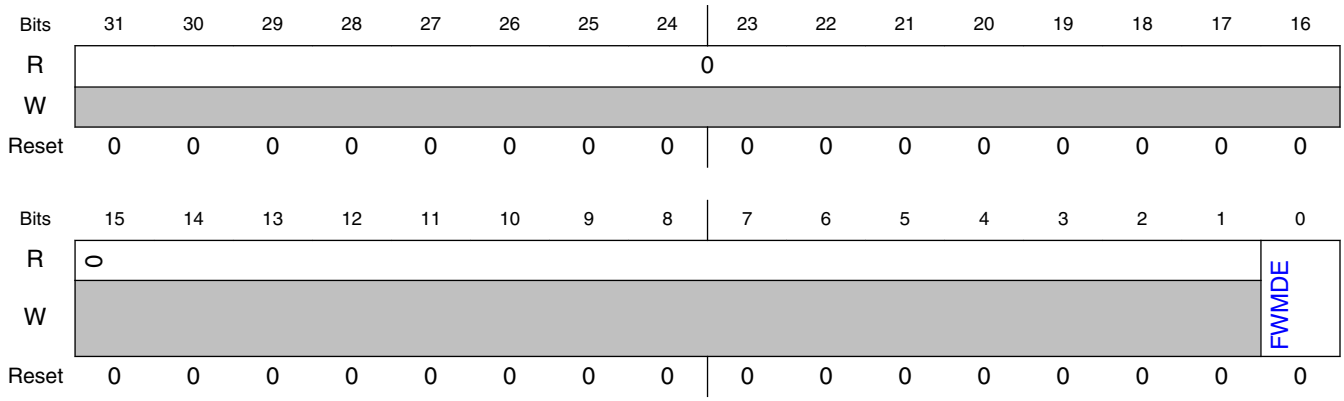
87.7.1.7.1 Offset

Register	Offset
DE	1Ch

87.7.1.7.2 Function

The DMA Enable Register (DE) controls the DMA enable function of FIFO Watermark.

87.7.1.7.3 Diagram



87.7.1.7.4 Fields

Field	Function
31-1 —	Reserved This read-only field is reserved and always has the value 0.
0 FWMDE	FIFO Watermark DMA Enable Configures ADC to generate DMA requests when RDY flag is asserted. 0b - DMA request disabled. 1b - DMA request enabled.

87.7.1.8 LPADC Configuration Register (CFG)

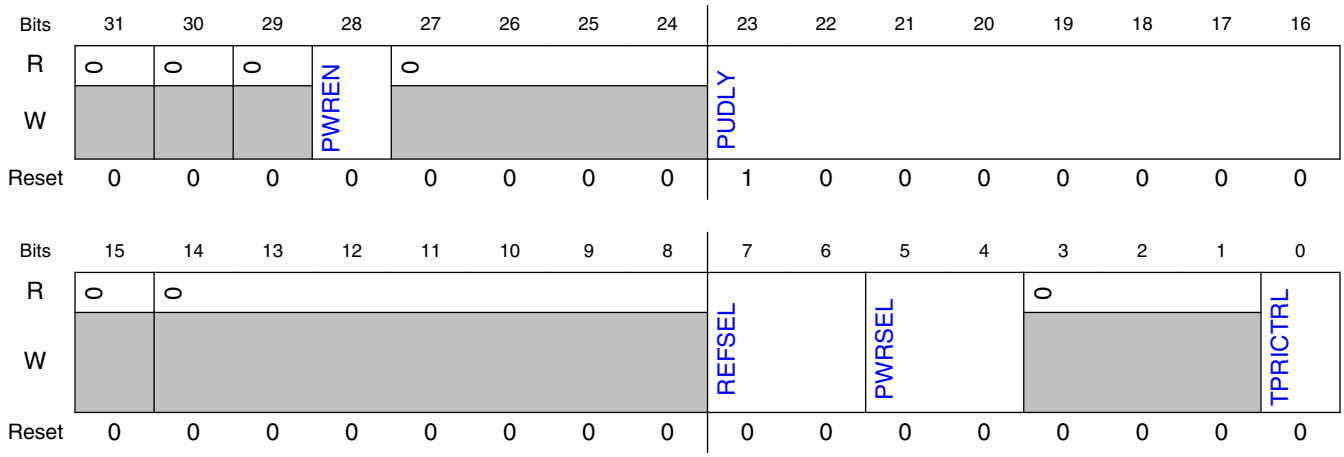
87.7.1.8.1 Offset

Register	Offset
CFG	20h

87.7.1.8.2 Function

The LPADC Configuration Register (CFG) controls ADC functions that are common to all commands. The CFG cannot be changed while the CTRL[ADCEN] bit is set. Writes to CFG while CTRL[ADCEN] is set are ignored.

87.7.1.8.3 Diagram



87.7.1.8.4 Fields

Field	Function
31 —	Reserved This read-only field is reserved and always has the value 0.
30 —	Reserved This read-only field is reserved and always has the value 0.
29 —	Reserved This read-only field is reserved and always has the value 0.
28 PWREN	LPADC Analog Pre-Enable Enables the LPADC analog circuits. When setting CFG[PWREN], user code should delay for a period exceeding the analog startup time of $t_{ADCSTUP}$ before enabling the LPADC for operation. The module is still operational even when CFG[PWREN] is left clear but command execution start is delayed for a period defined by CFG[PUDLY]. 0b - LPADC analog circuits are only enabled while conversions are active. Performance is affected due to analog startup delays. 1b - LPADC analog circuits are pre-enabled and ready to execute conversions without startup delays (at the cost of higher DC current consumption). When PWREN is set, the power up delay is enforced such that any detected trigger does not begin ADC operation until the power up delay time has passed.
27-24 —	Reserved This read-only field is reserved and always has the value 0.
23-16 PUDLY	Power Up Delay When CFG[PWREN]=0b0, the LPADC analog circuits are only powered while the module is active and there is a counted delay defined by CFG[PUDLY] after an initial trigger transitions the LPADC from its Idle state to allow time for the analog circuits to stabilize. The startup delay count of (PUDLY*4) ADCK cycles must result in a longer delay than the analog startup time of $t_{ADCSTUP}$. Accuracy of the initial conversion after activation is degraded if CFG[PUDLY] is set to too small a value. When CFG[PWREN]=0b1 prior to LPADC activation, the analog circuits are pre-enabled and the activation delay defined by CFG[PUDLY] is bypassed.

Table continues on the next page...

Field	Function
15 —	Reserved This read-only field is reserved and always has the value 0.
14-8 —	Reserved This read-only field is reserved and always has the value 0.
7-6 REFSEL	Voltage Reference Selection Selects the voltage reference high used for conversions. **NOTE:** See the chip configuration information on the voltage reference options specific to this packaged device. 00b - (Default) Option 1 setting. 01b - Option 2 setting. 10b - Option 3 setting. 11b - Reserved
5-4 PWRSEL	Power Configuration Select Configures the module for power and performance. In the highest power setting, the highest conversion rates are possible. The highest power setting corresponds to 0b11 with decreasing power down to 0b00. 00b - Level 1 (Lowest power setting) 01b - Level 2 10b - Level 3 11b - Level 4 (Highest power setting)
3-1 —	Reserved This read-only field is reserved and always has the value 0.
0 TPRICTRL	LPADC trigger priority control This bitfield controls how higher priority triggers are handled. See Trigger detect and command execution for a detailed explanation trigger event handling. 0b - If a higher priority trigger is detected during command processing, the current conversion is aborted and the new command specified by the trigger is started. 1b - If a higher priority trigger is received during command processing, the current conversion is completed (including averaging iterations if enabled) and stored to the RESFIFO before the higher priority trigger/command is initiated. Note that compare until true commands can be interrupted prior to resulting in a true conversion.

87.7.1.9 LPADC Pause Register (PAUSE)

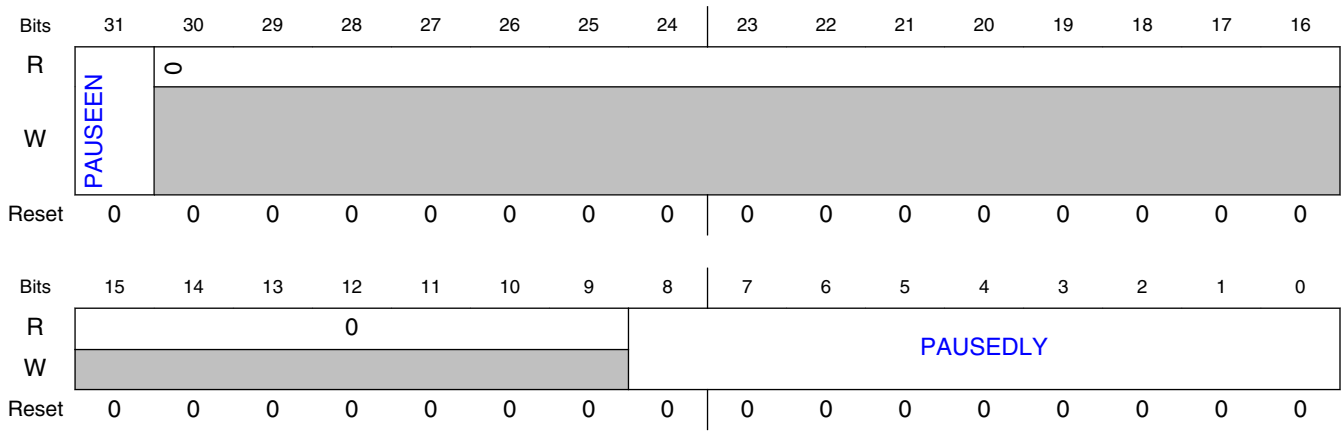
87.7.1.9.1 Offset

Register	Offset
PAUSE	24h

87.7.1.9.2 Function

The LPADC Pause Register (PAUSE) controls an optional inserted delay between conversions. PAUSE cannot be changed while the CTRL[ADCEN] bit is set. Writes to PAUSE while CTRL[ADCEN] is set are ignored.

87.7.1.9.3 Diagram



87.7.1.9.4 Fields

Field	Function
31 PAUSEEN	PAUSE Option Enable Enables the LPADC pausing function. When enabled, a programmable delay is inserted during command execution sequencing between LOOP iterations, between commands in a sequence, and between conversions when command is executing in for "Compare Until True" configuration. 0b - Pause operation disabled 1b - Pause operation enabled
30-9 —	Reserved This read-only field is reserved and always has the value 0.
8-0 PAUSEDLY	Pause Delay When PAUSEEN is set, the PAUSEDLY field controls the duration of pausing during command exection sequencing. The pause delay is a count of (PAUSEDLY*4) ADCK cycles.

87.7.1.10 LPADC FIFO Control Register (FCTRL)

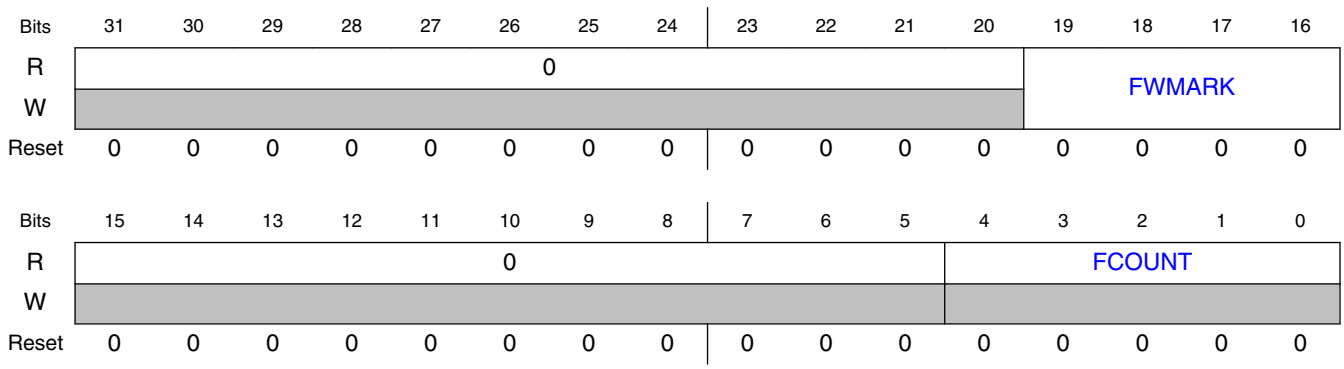
87.7.1.10.1 Offset

Register	Offset
FCTRL	30h

87.7.1.10.2 Function

The LPADC FIFO Control Register (FCTRL) controls the selection of Watermark level and provides the counter for the result FIFO.

87.7.1.10.3 Diagram



87.7.1.10.4 Fields

Field	Function
31-20 —	Reserved This read-only field is reserved and always has the value 0.
19-16 FWMARK	Watermark level selection FWMARK is a programmable threshold setting. When the number of datawords stored in the ADC Result FIFO is greater than the value in this field, the STAT[RDY] flag is asserted to indicate stored data has reached the programmable threshold. When IE[FWMIE] is set, an interrupt request is generated. When DE[FWMDE] is set, a DMA request is generated. 0000b - Generates STAT[RDY] flag after 1st successful conversion – single conversion 0001b - Generates STAT[RDY] flag after 2nd successful conversion 0010b - Generates STAT[RDY] flag after 3rd successful conversion 0011b - Generates STAT[RDY] flag after 4th successful conversion 0100b - Generates STAT[RDY] flag after 5th successful conversion 0101b - Generates STAT[RDY] flag after 6th successful conversion 0110b - Generates STAT[RDY] flag after 7th successful conversion 0111b - Generates STAT[RDY] flag after 8th successful conversion 1000b - Generates STAT[RDY] flag after 9th successful conversion 1001b - Generates STAT[RDY] flag after 10th successful conversion 1010b - Generates STAT[RDY] flag after 11th successful conversion 1011b - Generates STAT[RDY] flag after 12th successful conversion 1100b - Generates STAT[RDY] flag after 13th successful conversion 1101b - Generates STAT[RDY] flag after 14th successful conversion 1110b - Generates STAT[RDY] flag after 15th successful conversion 1111b - Generates STAT[RDY] flag after 16th successful conversion
15-5 —	Reserved This read-only field is reserved and always has the value 0.

Table continues on the next page...

Field	Function
4-0 FCOUNT	Result FIFO counter This read-only field indicates the number of datawords that are stored in the result FIFO. This value may be used in conjunction with PARAM[FIFOSIZE] to calculate how much room is left in the result FIFO. FCOUNT is incremented with each store of new data to the result FIFO and decrements with each read of the result FIFO. The FIFO is reset by writing to the CTRL[RSTFIFO] bit, resulting in FCTRL[FCOUNT] initialized to 0x0. 0_0000b - No data stored in FIFO 0_0001b - 1 dataword stored in FIFO 0_0010b - 2 datawords stored in FIFO 0_0100b - 4 datawords stored in FIFO 0_1000b - 8 datawords stored in FIFO 1_0000b - 16 datawords stored in FIFO

87.7.1.11 Software Trigger Register (SWTRIG)

87.7.1.11.1 Offset

Register	Offset
SWTRIG	34h

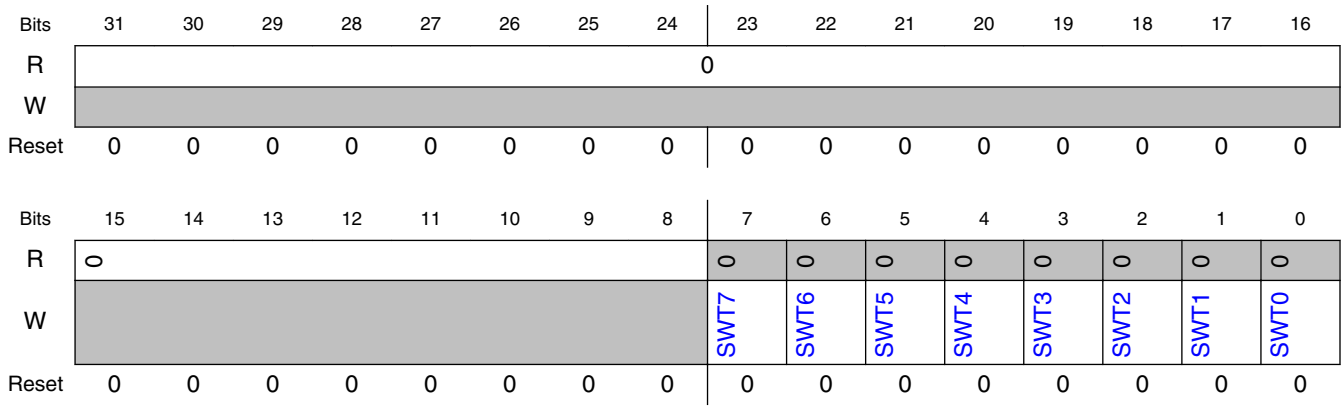
87.7.1.11.2 Function

The Software Trigger Register (SWTRIG) is written to initiate software triggered conversions. Writes to SWTRIG register are ignored while CTRL[ADCEN] is clear.

NOTE

There is a synchronization delay of 3 ADCK clock cycles when writing to set CTRL[ADCEN]. Writes to SWTRIG will continue to be ignored ultil CTRL[ADCEN] can propagate into the ADCK domain.

87.7.1.11.3 Diagram



87.7.1.11.4 Fields

Field	Function
31-8 —	Reserved This read-only field is reserved and always has the value 0.
7 SWT7	Software trigger 7 event Write 1 to SWT7 generates a trigger 7 event. Writing 1 to SWT7 is ignored while the trigger 7 event is being serviced or is pending. 0b - No trigger 7 event generated. 1b - Trigger 7 event generated.
6 SWT6	Software trigger 6 event Write 1 to SWT6 generates a trigger 6 event. Writing 1 to SWT6 is ignored while the trigger 6 event is being serviced or is pending. 0b - No trigger 6 event generated. 1b - Trigger 6 event generated.
5 SWT5	Software trigger 5 event Write 1 to SWT5 generates a trigger 5 event. Writing 1 to SWT5 is ignored while the trigger 5 event is being serviced or is pending. 0b - No trigger 5 event generated. 1b - Trigger 5 event generated.
4 SWT4	Software trigger 4 event Write 1 to SWT4 generates a trigger 4 event. Writing 1 to SWT4 is ignored while the trigger 4 event is being serviced or is pending. 0b - No trigger 4 event generated. 1b - Trigger 4 event generated.
3 SWT3	Software trigger 3 event Write 1 to SWT3 generates a trigger 3 event. Writing 1 to SWT3 is ignored while the trigger 3 event is being serviced or is pending. 0b - No trigger 3 event generated. 1b - Trigger 3 event generated.
2 SWT2	Software trigger 2 event

Table continues on the next page...

Field	Function
	Write 1 to SWT2 generates a trigger 2 event. Writing 1 to SWT2 is ignored while the trigger 2 event is being serviced or is pending. 0b - No trigger 2 event generated. 1b - Trigger 2 event generated.
1 SWT1	Software trigger 1 event Write 1 to SWT1 generates a trigger 1 event. Writing 1 to SWT1 is ignored while the trigger 1 event is being serviced or is pending. 0b - No trigger 1 event generated. 1b - Trigger 1 event generated.
0 SWT0	Software trigger 0 event Write 1 to SWT0 generates a trigger 0 event. Writing 1 to SWT0 is ignored while the trigger 0 event is being serviced or is pending. 0b - No trigger 0 event generated. 1b - Trigger 0 event generated.

87.7.1.12 Trigger Control Register (TCTRL0 - TCTRL7)

87.7.1.12.1 Offset

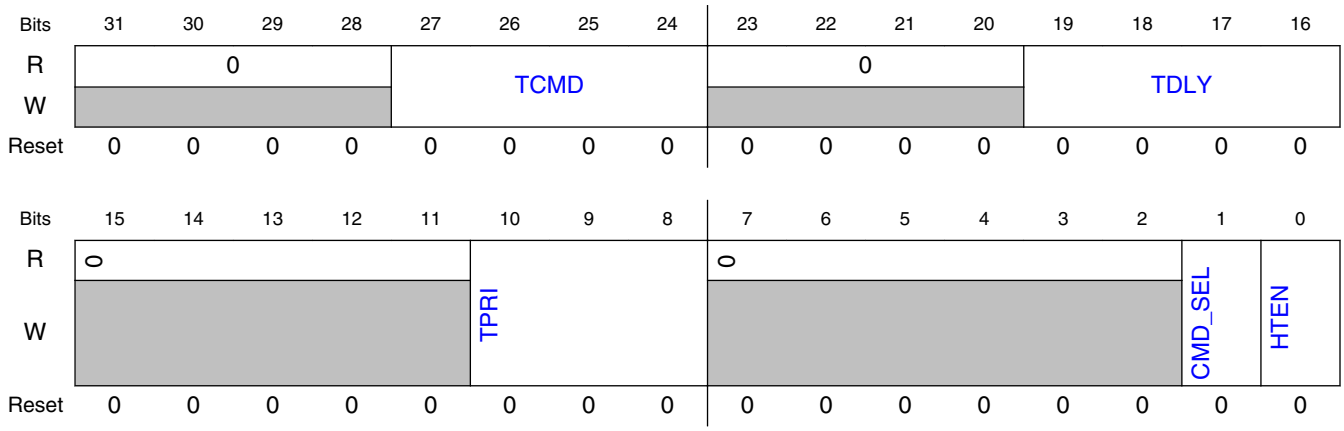
For a = 0 to 7:

Register	Offset
TCTRLa	C0h + (a × 4h)

87.7.1.12.2 Function

The Trigger Control (TCTRL*a*) register implements control fields associated with each implemented trigger source. When the LPADC is actively executing commands, only one of the TCTRL*a* registers is actively controlling ADC conversions. The active trigger can be detected by STAT[TRGACT] and activity of the trigger is dedicated by SWTRIG[SWT0-7] (within ADC module) or by HWTS0-7 (within ADC_ETC module). The actively controlling TCTRL*a* register cannot be updated while the LPADC is active. A write to a TCTRL*a* registers while that trigger control register is controlling the ADC operation is ignored.

87.7.1.12.3 Diagram



87.7.1.12.4 Fields

Field	Function
31-28 —	Reserved This read-only field is reserved and always has the value 0.
27-24 TCMD	Trigger command select Selects the command from command buffer to execute upon detection of the associated trigger event. When a trigger is received while the LPADC is busy converting and the new trigger has higher priority than trigger associated with the current command being executed, the command in this register, associated with the new trigger, is executed under control of CFG[TPRICTRL]. When CFG[TPRICTRL]=0b0, the interruption due to higher priority trigger event is immediate. When CFG[TPRICTRL]=0b1, the current conversion (including any hardware averaging) is allowed to complete and the interruption is at the next loop boundary. 0000b - Not a valid selection from the command buffer. Trigger event is ignored. 0001b - CMD1 is executed 0010b-1110b - Corresponding CMD is executed 1111b - CMD15 is executed
23-20 —	Reserved This read-only field is reserved and always has the value 0.
19-16 TDLY	Trigger delay select Selects the trigger delay duration to wait at the start of servicing a trigger event. Each trigger source has an associated programmable delay prior to beginning an initial conversion. When TDLY field is clear, then no delay is incurred. When TDLY is set to a non-zero value, the duration for the delay is 2^{TDLY} ADCK cycles.
15-11 —	Reserved This read-only field is reserved and always has the value 0.
10-8 TPRI	Trigger priority setting This bitfield sets the priority of the associated trigger source. If two or more triggers have the same priority level setting, the lower order trigger event has the higher priority (e. g., if Trigger 0 and Trigger 1 are both pending triggers and TCTRL0[TPRI] is configured the same as TCTRL1[TPRI], then the command associated with Trigger 0 is serviced first). 000b - Set to highest priority, Level 1

Table continues on the next page...

Field	Function
	001b-110b - Set to corresponding priority level 111b - Set to lowest priority, Level 8
7-2 —	Reserved This read-only field is reserved and always has the value 0.
1 CMD_SEL	The command number is selected by software TCMD or hardware tcmd signal 0b - TCTRLa[TCMD] will determine the command 1b - Software TCDM is bypassed , and hardware TCMD from ADC_ETC module will be used. The trigger command is then defined by ADC hardware trigger command selection field in ADC_ETC->TRIGx_CHAINy_z_n[CSEL].
0 HTEN	Trigger enable Enables hardware trigger source to initiate conversion on the rising-edge of the input trigger source. **NOTE:** Enabling hardware trigger does not disable software triggers. 0b - Hardware trigger source disabled 1b - Hardware trigger source enabled

87.7.1.13 LPADC Command Low Buffer Register (CMDL1 - CMDL15)

87.7.1.13.1 Offset

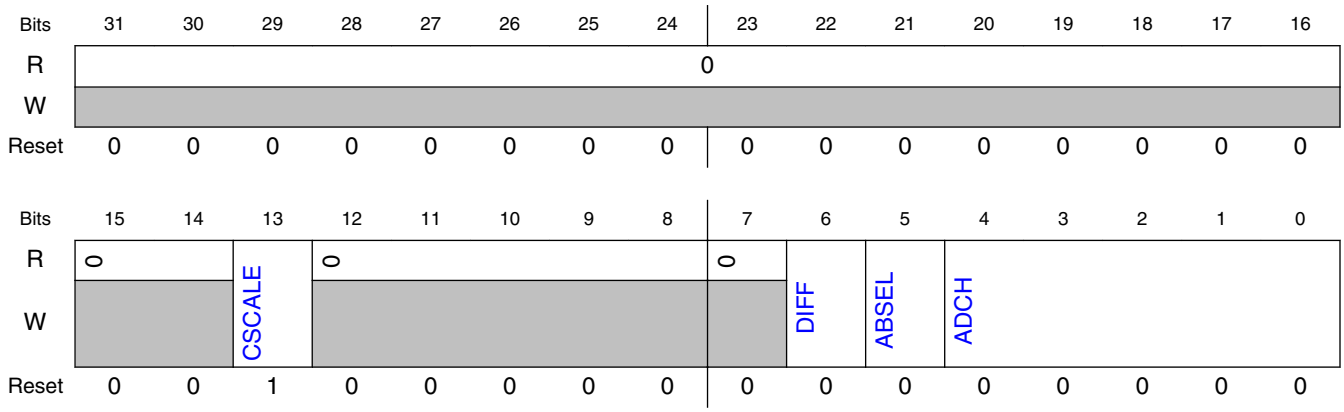
For a = 1 to 15:

Register	Offset
CMDLa	F8h + (a × 8h)

87.7.1.13.2 Function

There are 15 command buffers (CMD*a*), each constructed from two 32-bit registers (CMDL*a*:CMDH*a*) that can be configured for different channel select and varying conversion options. Any of the command buffers is selected and used as the controlling command by association to a trigger event via configuration of the TCTRL*a*[TCMD] bitfield. When the LPADC is actively executing commands, only one of the CMD buffers is actively controlling ADC conversions. The actively controlling CMD buffer cannot be updated while the LPADC is active. A write to a CMD buffer while that CMD buffer is controlling the ADC operation is ignored.

87.7.1.13.3 Diagram



87.7.1.13.4 Fields

Field	Function
31-14 —	Reserved This read-only field is reserved and always has the value 0.
13 CSCALE	Channel Scale Reduces the selected ADC analog channel input voltage level by a factor. The maximum possible voltage on the ADC channel input should be considered when selecting a CSCALE value to ensure that the reducing factor always results voltage level at or below the VREFH reference. This reducing capability allows conversion of analog inputs higher than VREFH. A-side and B-side channel inputs are both scaled using the CSCALE field. For example: if VREFH is 1.54V and CSCALE = 0, then the ADC input voltage can be up to 3.3V because 1.54*(64/30)=3.3. 0b - Scale selected analog channel (Factor of 30/64) 1b - (Default) Full scale (Factor of 1)
12-8 —	Reserved This read-only field is reserved and always has the value 0.
7 —	Reserved This read-only field is reserved and always has the value 0.
6 DIFF	Differential Mode Enable Configures the LPADC to operate in differential mode or single-ended mode. 0b - Single-ended mode. 1b - Differential mode.
5 ABSEL	A-side vs. B-side Select When DIFF=0b0, ABSEL selects the channel from either the A-side or B-side channel inputs. When DIFF=0b1, ABSEL configures the ADC result to be (CHnA-CHnB) or (CHnB-CHnA). 0b - When DIFF=0b0, the associated A-side channel is converted as single-ended. When DIFF=0b1, the ADC result is (CHnA-CHnB). 1b - When DIFF=0b0, the associated B-side channel is converted as single-ended. When DIFF=0b1, the ADC result is (CHnB-CHnA).
4-0	Input channel select

Field	Function
ADCH	Each ADCH channel selection has an associated A side and an associated B side input. The ADCH setting in conjunction with the DIFF and ABSEL bitfield settings selects the input from one of the channel inputs or one of the input pairs. See the DIFF and ABSEL bitfield descriptions. **NOTE:** Not all pairs are intended to be converted as differential channels. For the pin pairings available for differential conversions for your device, see the Chip Configuration details. **NOTE:** Some of the input channels are from internal resources such as temperature sensors and voltage sources and may only be connected to individual instances of the ADC module. Some of the input channel options in the bitfield-setting descriptions might not be available for your device. For the ADC channel assignments for your device, see the chip-specific information. 0_0000b - Select CH0A or CH0B or CH0A/CH0B pair. 0_0001b - Select CH1A or CH1B or CH1A/CH1B pair. 0_0010b - Select CH2A or CH2B or CH2A/CH2B pair. 0_0011b - Select CH3A or CH3B or CH3A/CH3B pair. 0_0100b-1_1101b - Select corresponding channel CHnA or CHnB or CHnA/CHnB pair. 1_1110b - Select CH30A or CH30B or CH30A/CH30B pair. 1_1111b - Select CH31A or CH31B or CH31A/CH31B pair.

87.7.1.14 LPADC Command High Buffer Register (CMDH1 - CMDH4)

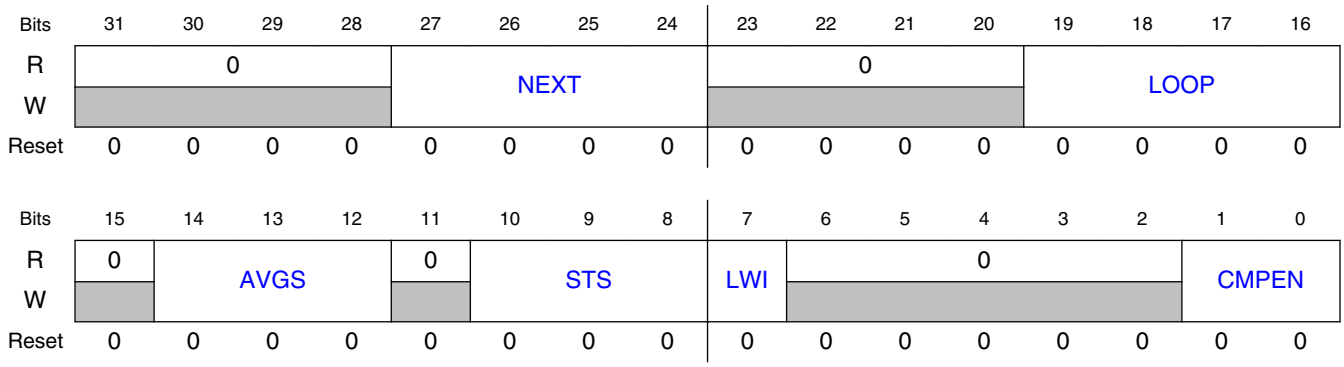
87.7.1.14.1 Offset

Register	Offset
CMDH1	104h
CMDH2	10Ch
CMDH3	114h
CMDH4	11Ch

87.7.1.14.2 Function

There are 15 command buffers (CMD*a*), each constructed from two 32-bit registers (CMDL*a*:CMDH*a*) that can be configured for different channel select and varying conversion options. Any of the command buffers is selected and used as the controlling command by association to a trigger event via configuration of the TCTRL*a*[TCMD] bitfield. When the LPADC is actively executing commands, only one of the CMD buffers is actively controlling ADC conversions. The actively controlling CMD buffer cannot be updated while the LPADC is active. A write to a CMD buffer while that CMD buffer is controlling ADC operation is ignored.

87.7.1.14.3 Diagram



87.7.1.14.4 Fields

Field	Function
31-28 —	Reserved This read-only field is reserved and always has the value 0.
27-24 NEXT	Next Command Select Selects the next command to be executed after this command completes. Multiple commands can be configured in a scan configuration by linking the next command in a daisy-chain sequence. The command buffer number is not indicative of any particular order and the order of execution is strictly controlled by the NEXT field (for example, a sequence of commands could be CMD2, CMD1, CMD3). Unending circular command execution is allowed by setting the NEXT field in the last command in a sequence to the first command in the sequence. It is also allowed for a command to set the next command to itself, resulting in a continuous conversion configuration. Setting the next command to 0x0 causes conversions to terminate at the completion of the command. Lower priority trigger events cannot be serviced until a higher priority triggered command (or sequence of commands) completes. 0000b - No next command defined. Terminate conversions at completion of current command. If lower priority trigger pending, begin command associated with lower priority trigger. 0001b - Select CMD1 command buffer register as next command. 0010b-1110b - Select corresponding CMD command buffer register as next command 1111b - Select CMD15 command buffer register as next command.
23-20 —	Reserved This read-only field is reserved and always has the value 0.
19-16 LOOP	Loop Count Select Selects how many times this command executes (and stores conversion result to RESFIFO) before finish and transition to the next command or Idle state. LWI field controls whether a single channel is converted on each iteration or auto channel increment results in channel scanning functionality. 0000b - Looping not enabled. Command executes 1 time. 0001b - Loop 1 time. Command executes 2 times. 0010b - Loop 2 times. Command executes 3 times. 0011b-1110b - Loop corresponding number of times. Command executes LOOP+1 times. 1111b - Loop 15 times. Command executes 16 times.
15 —	Reserved This read-only field is reserved and always has the value 0.
14-12	Hardware Average Select

Table continues on the next page...

Field	Function
AVGS	Selects how many ADC conversions are averaged to create the ADC result (2^{AVGS}). An internal storage buffer is used to capture temporary results while the averaging iterations are executed. Hardware averaging is a nested loop control and does not extend across LOOP boundaries. See Functional description for more detailed description on usage of AVGS, LOOP, and NEXT bitfields in command execution sequencing. 000b - Single conversion. 001b - 2 conversions averaged. 010b - 4 conversions averaged. 011b - 8 conversions averaged. 100b - 16 conversions averaged. 101b - 32 conversions averaged. 110b - 64 conversions averaged. 111b - 128 conversions averaged.
11 —	Reserved This read-only field is reserved and always has the value 0.
10-8 STS	Sample Time Select When programmed to 000 the minimum sample time of 3.5 ADCK cycles is selected. When STS is programmed to a non-zero value the sample time is ($3.5 + 2^{STS}$) ADCK cycles. The shortest sample time maximizes conversion speed for lower impedance inputs. Extending sample time allows higher impedance inputs to be accurately sampled. Longer sample times can also be used to lower overall power consumption when command looping and sequencing is configured and high conversion rates are not required. 000b - Minimum sample time of 3.5 ADCK cycles. 001b - $3.5 + 2^1$ ADCK cycles; 5.5 ADCK cycles total sample time. 010b - $3.5 + 2^2$ ADCK cycles; 7.5 ADCK cycles total sample time. 011b - $3.5 + 2^3$ ADCK cycles; 11.5 ADCK cycles total sample time. 100b - $3.5 + 2^4$ ADCK cycles; 19.5 ADCK cycles total sample time. 101b - $3.5 + 2^5$ ADCK cycles; 35.5 ADCK cycles total sample time. 110b - $3.5 + 2^6$ ADCK cycles; 67.5 ADCK cycles total sample time. 111b - $3.5 + 2^7$ ADCK cycles; 131.5 ADCK cycles total sample time.
7 LWI	Loop with Increment When LWI is clear, the LOOP field selects the number of times the selected channel is converted consecutively. When LWI is set, auto channel incrementing is enabled and the LOOP field defines how many consecutive channels are converted as part of the command execution. Example 1: LOOP = 0x8, LWI = 0b0, ABSEL = 0b0, ADCH = 0xD. Convert on channel 13A 8 times. Example 2: LOOP = 0x8, LWI= 0b1, ABSEL = 0b0, ADCH = 0xD. Run channels 13A, 14A, 15A, ... 20A each one time. Maximum channel scanning using a single command buffer then is defined by the maximum value of the LOOP field (16). **NOTE:** When LWI is set, the minimum sample length must be extended to CMDHa[STS] = 0x3. 0b - Auto channel increment disabled 1b - Auto channel increment enabled
6-2 —	Reserved This read-only field is reserved and always has the value 0.
1-0 CMPEN	Compare Function Enable After an ADC channel input is sampled and converted and any averaging iterations are performed, the CMDH*a*[CMPEN] field guides operation of the automatic compare function to optionally only store when the compare operation is true. When compare is enabled, the conversion result is compared to the compare value registers (CV*a*[CVH] and CV*a*[CVL]). There are multiple options on command sequencing related to the compare function. See Compare function for a detailed explanation of the compare options.

Field	Function
	NOTE: Not all Command Buffers have implemented the CMPEN field. The CMPEN field is only available in Command Buffers that have a corresponding Compare Value register. 00b - Compare disabled. 01b - Reserved 10b - Compare enabled. Store on true. 11b - Compare enabled. Repeat channel acquisition (sample/convert/compare) until true.

87.7.1.15 LPADC Command High Buffer Register (CMDH5 - CMDH15)

87.7.1.15.1 Offset

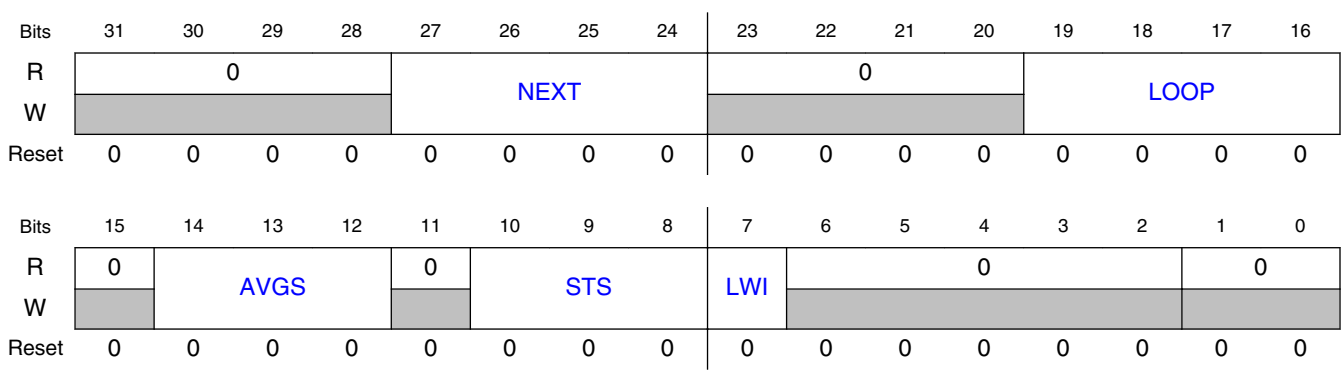
For a = 5 to 15:

Register	Offset
CMDHa	FCh + (a × 8h)

87.7.1.15.2 Function

There are 15 command buffers (CMD*a*), each constructed from two 32-bit registers (CMDL*a*:CMDH*a*) that can be configured for different channel select and varying conversion options. Any of the command buffers is selected and used as the controlling command by association to a trigger event via configuration of the TCTRL*a*[TCMD] bitfield. When the LPADC is actively executing commands, only one of the CMD buffers is actively controlling ADC conversions. The actively controlling CMD buffer cannot be updated while the LPADC is active. A write to a CMD buffer while that CMD buffer is controlling ADC operation is ignored.

87.7.1.15.3 Diagram



87.7.1.15.4 Fields

Field	Function
31-28 —	Reserved This read-only field is reserved and always has the value 0.
27-24 NEXT	Next Command Select Selects the next command to be executed after this command completes. Multiple commands can be configured in a scan configuration by linking the next command in a daisy-chain sequence. The command buffer number is not indicative of any particular order and the order of execution is strictly controlled by the NEXT field (for example, a sequence of commands could be CMD2, CMD1, CMD3). Unending circular command execution is allowed by setting the NEXT field in the last command in a sequence to the first command in the sequence. It is also allowed for a command to set the next command to itself, resulting in a continuous conversion configuration. Setting the next command to 0x0 causes conversions to terminate at the completion of the command. Lower priority trigger events cannot be serviced until a higher priority triggered command (or sequence of commands) completes. 0000b - No next command defined. Terminate conversions at completion of current command. If lower priority trigger pending, begin command associated with lower priority trigger. 0001b - Select CMD1 command buffer register as next command. 0010b-1110b - Select corresponding CMD command buffer register as next command 1111b - Select CMD15 command buffer register as next command.
23-20 —	Reserved This read-only field is reserved and always has the value 0.
19-16 LOOP	Loop Count Select Selects how many times this command executes (and stores conversion result to RESFIFO) before finish and transition to the next command or Idle state. LWI field controls whether a single channel is converted on each iteration or auto channel increment results in channel scanning functionality. 0000b - Looping not enabled. Command executes 1 time. 0001b - Loop 1 time. Command executes 2 times. 0010b - Loop 2 times. Command executes 3 times. 0011b-1110b - Loop corresponding number of times. Command executes LOOP+1 times. 1111b - Loop 15 times. Command executes 16 times.
15 —	Reserved This read-only field is reserved and always has the value 0.
14-12 AVGS	Hardware Average Select Selects how many ADC conversions are averaged to create the ADC result (2^{AVGS}). An internal storage buffer is used to capture temporary results while the averaging iterations are executed. Hardware averaging is a nested loop control and does not extend across LOOP boundaries. See Functional description for more detailed description on usage of AVGS, LOOP, and NEXT bitfields in command execution sequencing. 000b - Single conversion. 001b - 2 conversions averaged. 010b - 4 conversions averaged. 011b - 8 conversions averaged. 100b - 16 conversions averaged. 101b - 32 conversions averaged. 110b - 64 conversions averaged. 111b - 128 conversions averaged.
11 —	Reserved This read-only field is reserved and always has the value 0.

1-0 —	Reserved This read-only field is reserved and always has the value 0.

87.7.1.16 Compare Value Register (CV1 - CV4)

87.7.1.16.1 Offset

Register	Offset
CV1	200h
CV2	204h
CV3	208h
CV4	20Ch

87.7.1.16.2 Function

The Compare Value Registers (CV*a*) contain values used to compare the conversion result when the compare function is enabled. This register is formatted in the same way as the D field in the RESFIFO registers in different modes of operation for both bit position definition and value format using unsigned or signed 2's complement. There is a direct association of each compare value register to a specific command buffer register (i.e., CV1 is only used during execution of CMD1 command).

NOTE

Not all Command Buffers have an associated Compare Value register. The compare function is only available on Command Buffers that have a corresponding Compare Value register.

When the LPADC is actively executing commands, the CV*a* register associated with the active command (CMD*a*) cannot be updated and writes to associated CV*a* register during this time are ignored.

87.7.1.16.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	CVH															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	CVL															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

87.7.1.16.4 Fields

Field	Function
31-16 CVH	Compare Value High. The compare function can be configured to check whether the result is less than, greater than, or if the result falls within or outside a range determined by two compare values. After the input is sampled and converted and any averaging iterations are performed, the compare values in CVL and CVH are optionally used in a compare operation on the result. See Compare function for a description on how CVH is used. For example. CVH represents 16-bit high level compare value. In cooperation with CVL and CMDHa[CMPEN] represents limit value for compare function: When CVL < CVH, it represents “outside range” compare function and the compare is true if results is less than CVL value and greater than CVH value. When CVL > CVH, it represents “inside range” compare function and the compare is true if results is less than CVL value and greater than CVH value.

Table continues on the next page...

Field	Function
	When CVL is min value and CVH any other than max value, it represents “greater than” compare function and the compare is true if results is greater than CVH value. When CVL is any other than min and CVH is max value, it represents “less than” compare function and the compare is true if results is greater than CVH value. When CVL is min value and CVH max value, the compare is never true. When CVL is max value and CVH min value, the compare is always true.
15-0 CVL	Compare Value Low The compare function can be configured to check whether the result is less than, greater than, or if the result falls within or outside a range determined by two compare values. After the input is sampled and converted and any averaging iterations are performed, the compare values in CVL and CVH are optionally used in a compare operation on the result. See Compare function for a description on how CVL is used.

87.7.1.17 LPADC Data Result FIFO Register (RESFIFO)

87.7.1.17.1 Offset

Register	Offset
RESFIFO	300h

87.7.1.17.2 Function

The LPADC Data Result FIFO Register (RESFIFO) is a 16 entry FIFO that stores the data result of ADC conversions. In addition, several tag fields of source command and trigger information are stored along with the data. FCTRL[FCOUNT] indicates how many valid datawords are stored in the RESFIFO. Reading RESFIFO provides the oldest unread dataword entry in the FIFO and decrements FCOUNT. The FIFO can be emptied by successive reads of RESFIFO. The FIFO is reset by writing 0b1 to the CTRL[RSTFIFO] bit.

The following table describes the format of data in the result FIFO in the different modes of operation. The sign bit is the (MSB) in signed 2's complement modes. For example, when configured for 12-bit single-ended mode, D[15] and D[2:0] are cleared. When configured for 13-bit differential mode, D[15] is the sign bit and D[2:0] are cleared.

Table 87-7. Data result register format description

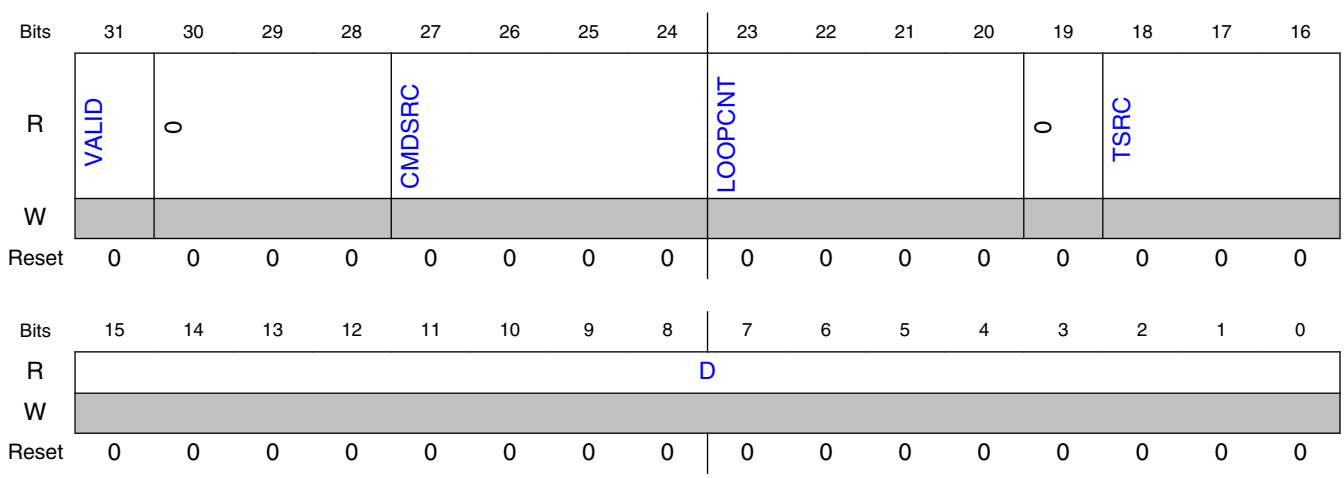
Conversion mode	D15	D14	D13	D12	D11	D10	D9	D8	D7	D6	D5	D4	D3	D2	D1	D0	Format
13-bit differential	S	D	D	D	D	D	D	D	D	D	D	D	D	0	0	0	Signed 2's complement, left-justified, zero extended
12-bit single-ended	0	D	D	D	D	D	D	D	D	D	D	D	D	0	0	0	Unsigned, zero in D[15] and D[2:0]

NOTE

S: Sign bit;

D: Data, which is 2's complement data if indicated

87.7.1.17.3 Diagram



87.7.1.17.4 Fields

Field	Function
31 VALID	FIFO entry is valid Indicate the FIFO entry is valid. When the FIFO is holding data the VALID bit is set. When the FIFO is empty the VALID bit is clear. 0b - FIFO is empty. Discard any read from RESFIFO.

Table continues on the next page...

Field	Function
	1b - FIFO record read from RESFIFO is valid.
30-28 —	Reserved This read-only field is reserved and always has the value 0.
27-24 CMDSRC	Command Buffer Source Indicates the command buffer being executed that generated this result. 0000b - Not a valid value CMDSRC value for a dataword in RESFIFO. 0x0 is only found in initial FIFO state prior to an ADC conversion result dataword being stored to a RESFIFO buffer. 0001b - CMD1 buffer used as control settings for this conversion. 0010b-1110b - Corresponding command buffer used as control settings for this conversion. 1111b - CMD15 buffer used as control settings for this conversion.
23-20 LOOPCNT	Loop count value Indicates the loop count value during command execution that generated this result. When CMDH*a*[LOOP] is non-zero, the command execution stores off a result multiple times during command execution (at the loop boundary). 0000b - Result is from initial conversion in command. 0001b - Result is from second conversion in command. 0010b-1110b - Result is from LOOPCNT+1 conversion in command. 1111b - Result is from 16th conversion in command.
19 —	Reserved This read-only field is reserved and always has the value 0.
18-16 TSRC	Trigger Source Indicate the trigger source that initiated a conversion and generated this result. When multiple commands are chained together using the NEXT field, the TSRC field for all datawords stored to the RESFIFO indicate the trigger source that started the sequence of commands. 000b - Trigger source 0 initiated this conversion. 001b - Trigger source 1 initiated this conversion. 010b-110b - Corresponding trigger source initiated this conversion. 111b - Trigger source 7 initiated this conversion.
15-0 D	Data result The formatting for the data in D is summarized in Table 87-7.

Chapter 88
ADC External Trigger Control (ADC_ETC)

NOTE

No TSC module in this device.

NOTE

The bit 30 in ADC_ETC Global Control Register (CTRL) must be cleared after reset when ADC2 is used.

88.2 Overview

The ADC External Trigger Control (ADC_ETC) module enables multiple trigger sources to share the ADC modules in a TIME-Division-Multiplexing (TDM) way. The triggers of ADC_ETC are from Cross BAR(XBAR). The triggers TRIG0-TRIG3 belong to channel0 and control ADC1, while TRIG4-TRIG7 belong to channel1 and control ADC2. The

ADC_ETC also supports SyncMode. When TRIGa_CTRL[SYNC_MODE] is set, the ADC_ETC trigger source will control ADC1 and ADC2 synchronously. The ADC_ETC can support interrupt mode and DMA mode (controlled independently).

NOTE

The trigger in this chapter refers the trigger of ADC_ETC, except when referring to the ADC trigger explicitly.

88.2.1 Block diagram

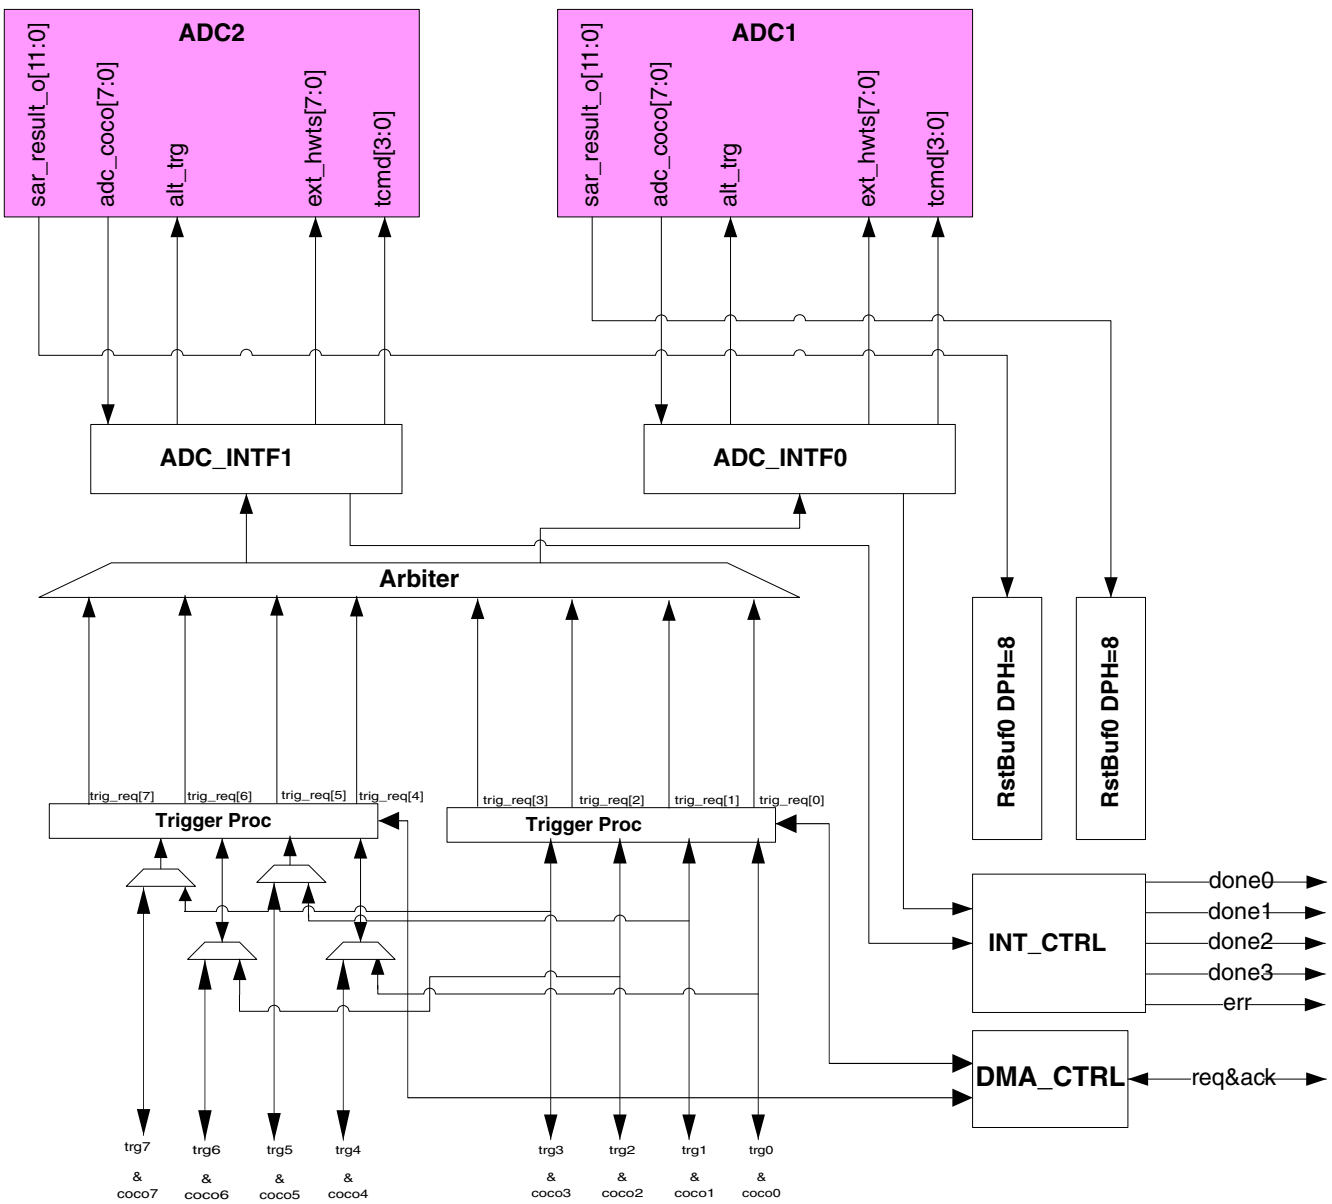

Figure 88-1. ADC_ETC block diagram

NOTE

The ADC1 and ADC2 in ADC_ETC block diagram are functionally same as the module described in ADC chapter, but they have different interface. The ADC control interfaces, which are between ADC_ETC and ADCs, operate as below:

- ADC_ETC puts trigger number of ADC on ext_hwts[7:0], puts the TCMD for this ADC trigger on the port tcmd[3:0]. And meanwhile sets alt_trg to send a trigger to ADC.
- ADC start a conversion after receiving a trigger from the ADC control interface. And the behavior of the conversion is configured by the ext_hwts, the TCMD of ext_hwts and the CMD defined by the command buffer inside ADC.
- When conversion done, ADC will send back sar_result[11:0] as the result of the conversion, together with adc_coco[7:0] to identify which ext_hwts this result is for.

NOTE

The adc_coco signals are internal signals, which are hidden from ADC module and handled by ADC and ADC_ETC automatically.

88.2.2 Features

The ADC_ETC includes the following features:

- External Trigger Interface
  - ADC control interface is connected with 2 ADCs, and support up to 8 Hardware External Trigger (ext_hwts[7:0] in ADC_ETC block diagram) for each ADC
- Capable of triggering dual ADCs in SyncMode or AsyncMode:
  - In SyncMode ADC1 and ADC2 are controlled by the same trigger source of ADC_ETC.
  - In AsyncMode ADC1 and ADC2 are controlled by separate trigger source of ADC_ETC.
- Support up to 8 external trigger inputs, input from XBAR (4 for each ADC, TRIG0-TRIG3 for ADC1, and TRIG4-TRIG7 for ADC2).
  - One external trigger of ADC_ETC can launch up to 8 sequential triggers to ADC, which are called a trigger chain, and each trigger is called a segment of the trigger chain.

    - Flexible ADC trigger interval and initial delay control.
    - Each trigger of ADC_ETC can be configured as HW or SW trigger mode.
- ADC result holding and status reporting
- ADC_ETC trigger auto hold and arbitration
    - Each trigger of ADC_ETC can be configured with a fixed priority. External trigger with the highest priority is severed first.
    - Hold one trigger event upon when it failed to win the arbitration or ADC is busy.
- Supports ADC trigger interface cascading
- Supports interrupt mode. When interrupt mode is selected and one ADC conversion is done, an interrupt request signal will be generated on one of the Done0~Done3 interrupt outputs.
- Supports DMA mode. When DMA is enabled and one ADC conversion is done, a DMA request will be sent. 2 trigger modes of DMA can be selected by configuring CTRL[DMA_MODE_SEL].

88.3 Functional description

The ADC_ETC block works with XBAR to share with the ADC modules. The following sections describe functional details of the ADC_ETC module.

88.3.1 Operations

This section describes the ADC_ETC module's operations.

The trigger process is used to handle the multiple trigger sources based on the settings in registers. CTRL[TRIG_ENABLE] can be used to mask the input hardware trigger sources. TRIGa_CTRL[TRIG_MODE] selects the hardware trigger source or software trigger source for TRIGa of ADC_ETC. The selected trigger source is double synchronized to a synchronous positive pulse and the pulse will be sent to the arbiter after initial delay defined by TRIGa_COUNTER[INIT_DELAY].

If TRIGa_CTRL[SYNC_MODE] is set, the trigger process will control TRIGa and TRIG(a+4) synchronously. In this mode, the initial delay of TRIGa and TRIG(a+4) is controlled by the settings of TRIGa, while other settings are independent.

The trigger process diagram is indicated as below:

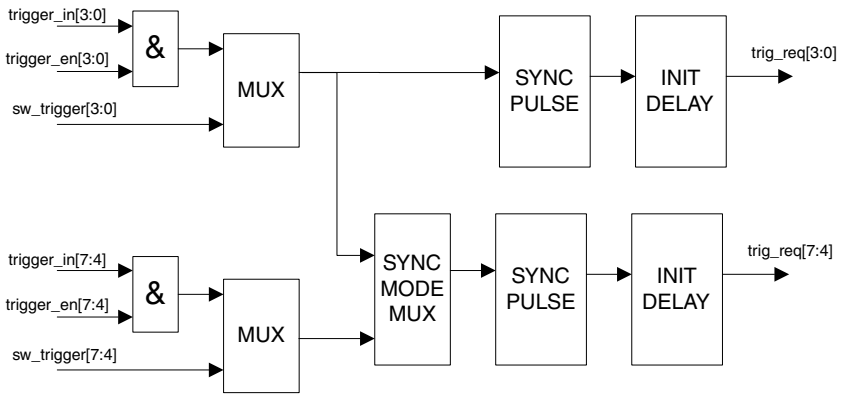

Figure 88-2. Trigger process diagram

As showing in ADC_ETC block diagram, the trig_req[7:0] output from trigger process will go to the arbiter with a queue module.

The arbiter trigger will approve the request from XBAR which has the highest priority defined in TRIGa_CTRL[TRIG_PRIORITY]. There are total of eight priority levels available for each trigger request, where 7 is the highest priority level and 0 is the lowest priority level. In SYNC mode, the trigger requests applied at the same time that have the same priority level should NOT be more than two; if more than two trigger requests are needed, they should have different priority level. In non-SYNC mode, if multiple trigger requests have the same priority level, then the round-robin mechanism is applied, and the trigger with a larger level-number owns the higher priority. The trigger request is granted only when the previous trigger has finished and the ADC module is IDLE. When in SYNC mode, the trigger request is granted only when both ADC modules are IDLE state.

When there is a trigger request that is granted, the ADC_ETC sends several triggers of ADC as a chain of trigger, with ext_hwts[7:0] as ADC trigger selection signal, and with tcmd[3:0] defining the TCMD to ADC. When the ADC conversion done, the ADC sends back adc_coco to the ADC_ETC, which has the same width as ext_hwts and indicates which trigger the current sar_result_o is for, then the ADC_ETC stores the ADC converted results into the internal registers .

At the same time, the corresponding bit in the CHAINx_DONE bit field of ETC_TRIG Control Register is set, and interrupt asserts according to the software configuration. After that, the next trigger is sent after a interval delay configured by TRIGa_COUNTER[SAMPLE_INTERVAL], until all triggers in the chain are processed. When complete the the last trigger in chain, ADC_ETC sends the coco signal to mark the end of one of ADC_ETC external trigger, and a DMA request will be generated if DMA_CTRL[TIRGa_ENABLE] is set to 1.

Each ADC trigger in the trigger chains, initiated by trigger requests of ADC_ETC, has separate configurations by software. These configurations include Interrupt enable (IE_EN), Interrupt selection (IE), Back to Back ADC trigger (B2B), HWTS and CSEL to ADC. The ADC_ETC have interrupt outputs of Done0, Done1, Done2, Done3 and Error Interrupt. The Done0/1/2/3 interrupts are controlled by software for each ADC trigger. IEx_EN controls the enable of the IRQ, while IEx selects which port the interrupt occurs on. (If IEx_EN is set, IEx from 2'b00 to 2'b11 select Done0/1/2/3, otherwise IEx is meaningless). Error interrupt occurs when there is an external trigger ignored by ADC_ETC due to the previous trigger not finished yet.

The ETC-ADC interface timing is indicated in below diagrams:

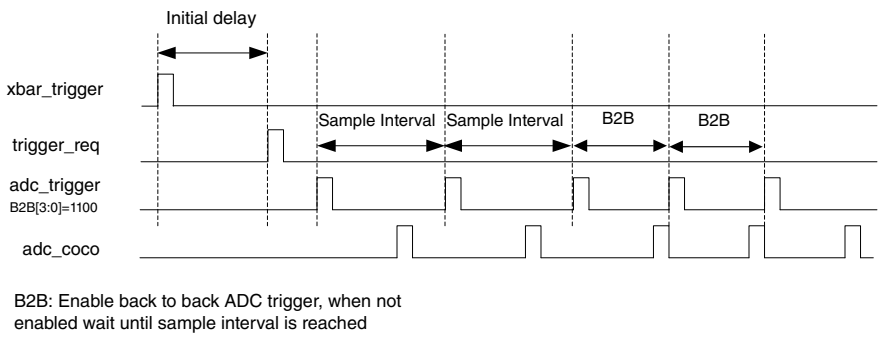

Figure 88-3. ETC-ADC interface timing

After one ADC conversion, the next trigger in the chain starts as soon as possible if B2B is enabled. Otherwise the next trigger does not start until waiting until interval delay in reached.

As showing in ETC-ADC interface timing, due to B2B[3:0]=1100, the slots after the first and second adc_trigger are equal to interval delay, but the slots after the third and fourth adc_trigger are shorter.

The length of initial delay and interval delay are configurable, the formulas to calculate initial delay and interval delay are described in the description of the TRIGa_COUNTER.

88.3.2 Clocks

The ADC_ETC module has one global functional clock: ipg_clk. The ipg_clk is used for register read/write operations, also all the functionality inside the ADC_ETC module are synchronized to this clock.

The XBAR may be synchronous or asynchronous with the ADC_ETC clock.

88.3.3 Reset

The ADC_ETC has two resets: ipg_hard_async_reset_b and sw_reset_n. The ipg_hard_async_reset_b is a hardware reset, which resets all registers in ADC_ETC block. The sw_reset_n is a software reset, which can reset all registers except itself by software.

NOTE

sw_reset_n is generated by writting logic 1 into CRTL[SOFTRST], while ipg_hard_async_reset_b is generated by SoC hardware.

88.4 Initialization

Before using the ADC_ETC module, the following initialization procedure must be performed:

1. Configure the Global Control bits, include selecting DMA mode, enabling triggers which will be used, and setting pre-division factor.
2. Set DMA enable bits as needed.
3. Configure control bits for each enabled trigger, include enabling or disabling synchronization mode, assigning trigger priority, setting the length of trigger chain, selecting trigger mode and setting the initial and interval delay of this trigger.
4. According to the length of trigger chain, several segments of the chain should be configured. The configurations of each segment contain:
    a. setting the DONE interrupt for this chain, enabling or disabling B2B mode;
    b. selecting which trigger of ADC will be triggered, setting the ADC command.

After the initialization of ADC_ETC, the initialization of the ADC module should also be confirmed before launching a trigger to ADC_ETC.

88.5 Application information

This section describes applications supported by the ADC_ETC module.

88.5.1 ADC Trigger Concept – Dual PMSM motor control

ADC_ETC's flexible configuration is suitable for complex application timing design. The following describes the configuration scheme of ADC_ETC for dual motor control. There is a 180-degrees phase lag between the PWMs of dual motors, and on this basis ADC_ETC uses the triggers from eFlexPWM to implement time division sampling of analog signals of dual motors.

The figure below presents the synchronization between ADC and PWMs.

Once eFlexPWM1 counter reaches submodule 1 VAL4, ADC_ETC will be triggered to control ADCs to sampling analog signal of motor 1. After ADC conversation done, ADC_ETC_DONE0 interrupt is enabled to run motor 1 control algorithm. Once eFlexPWM2 counter reaches submodule 0 VAL4, ADC_ETC will be triggered to control ADCs to sampling analog signal of motor 2. After ADC conversation done, ADC_ETC_DONE1 interrupt is enabled to run motor 2 control algorithm.

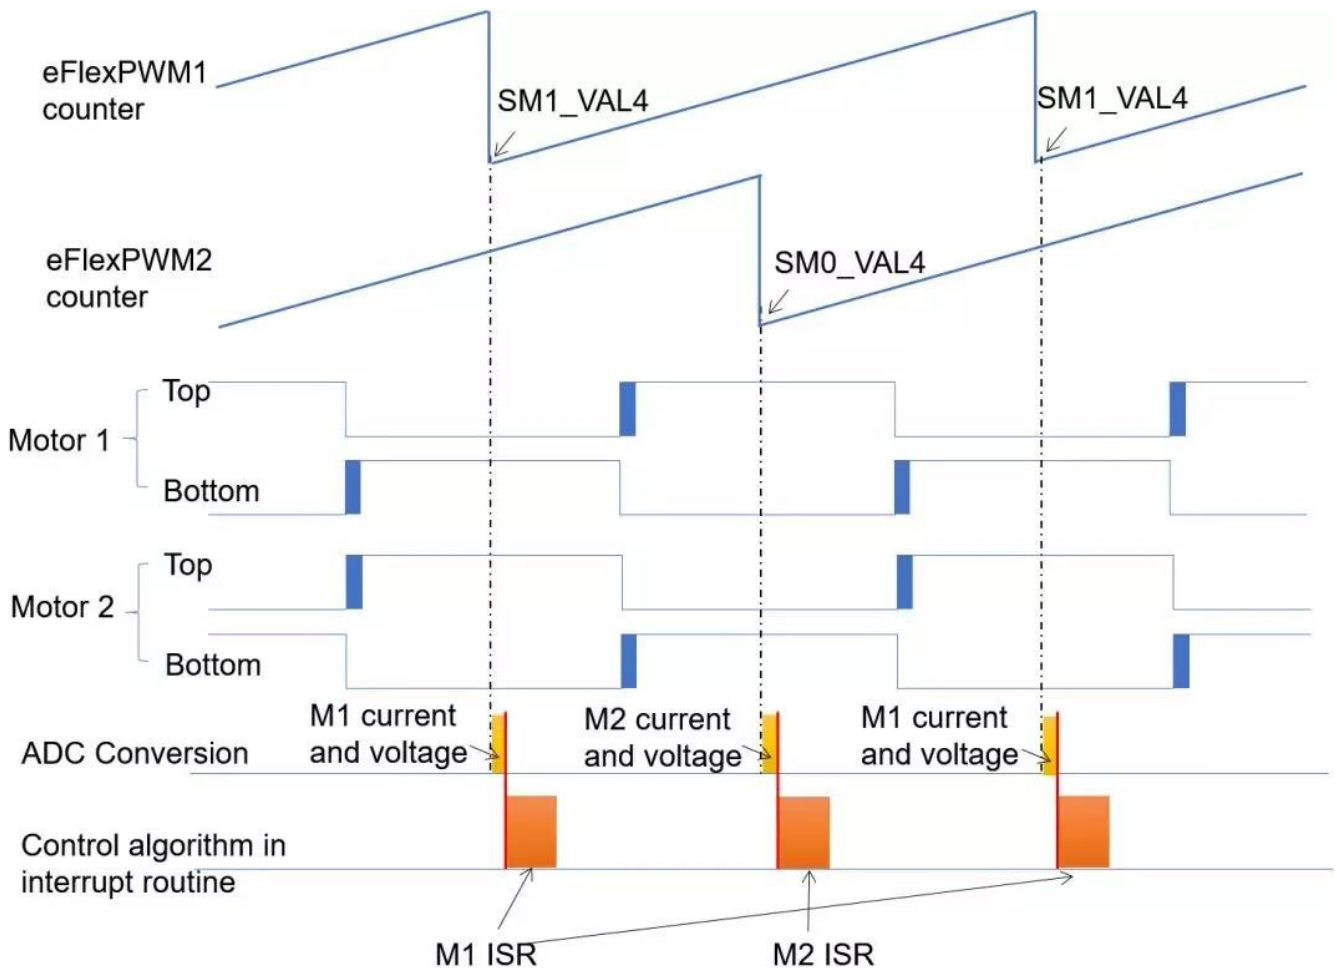

Figure 88-4. Synchronization between ADC and PWMs

The external triggers are generated from the Cross BAR (XBAR) or other sources. The ADC scan is started via ADC_ETC. The following is the key configuration point for this application.

- Enable external XBAR trigger 0 and 1, both ADCs have their own trigger segments.
- The trigger chain length is set to 2. The back-to-back ADC trigger mode is enabled.
- Enable the Sync Mode. In the Sync Mode, ADC1 and ADC2 are controlled by the same trigger source.
- Both trigger chain has their own finished interrupt. When Chain 4 triggered by TRIG0 is finished, enable DONE0 interrupt. When Chain 5 triggered by TRIG1 is finished, enable DONE1 interrupt.

The figure below shows configuration of ADC_ETC to control dual ADCs in this dual motor application.

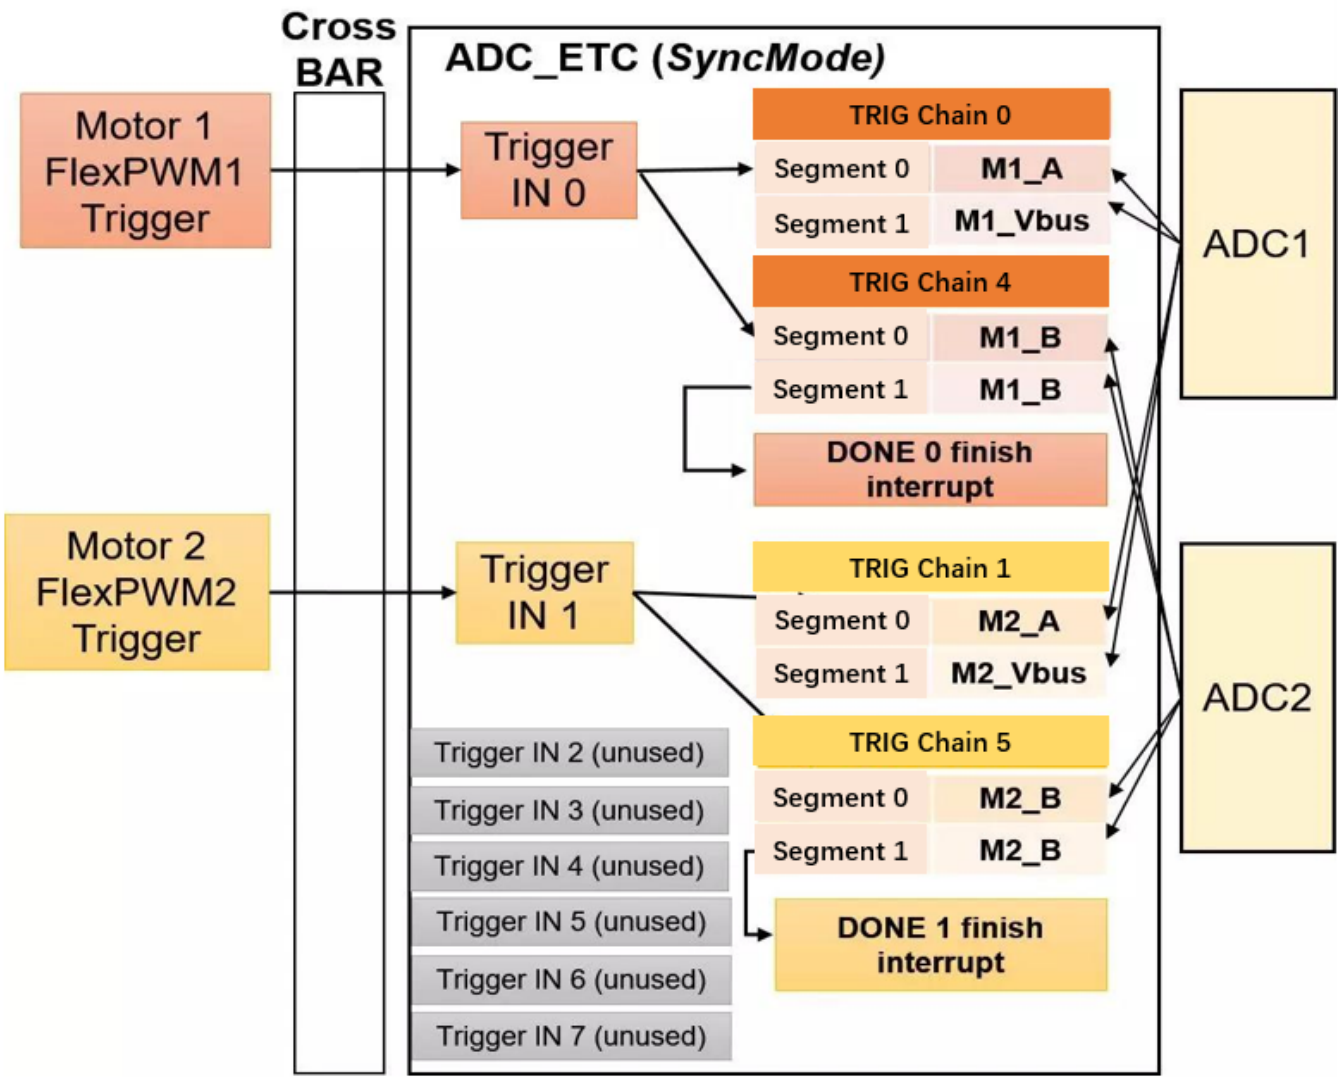

Figure 88-5. The configuration of ADC_ETC for dual motor control

88.6 Memory Map and register definition

This section includes the ADC_ETC module memory map and detailed descriptions of all registers.

88.6.1 ADC_ETC register descriptions

The descriptions below will list the memory map and give detailed explanations for all registers and the bit fields of the registers.

88.6.1.1 ADC_ETC memory map

ADC_ETC base address: 4004_8000h

Offset	Register	Width (In bits)	Access	Reset value
0h	ADC_ETC Global Control Register (CTRL)	32	RW	C000_0000h
4h	ETC DONE0 and DONE1 IRQ State Register (DONE0_1_IRQ)	32	RW	0000_0000h
8h	ETC DONE_2, DONE_3 and DONE_ERR IRQ State Register (DONE2_3_ERR_IRQ)	32	RW	0000_0000h

88.6.1.2 ADC_ETC Global Control Register (CTRL)

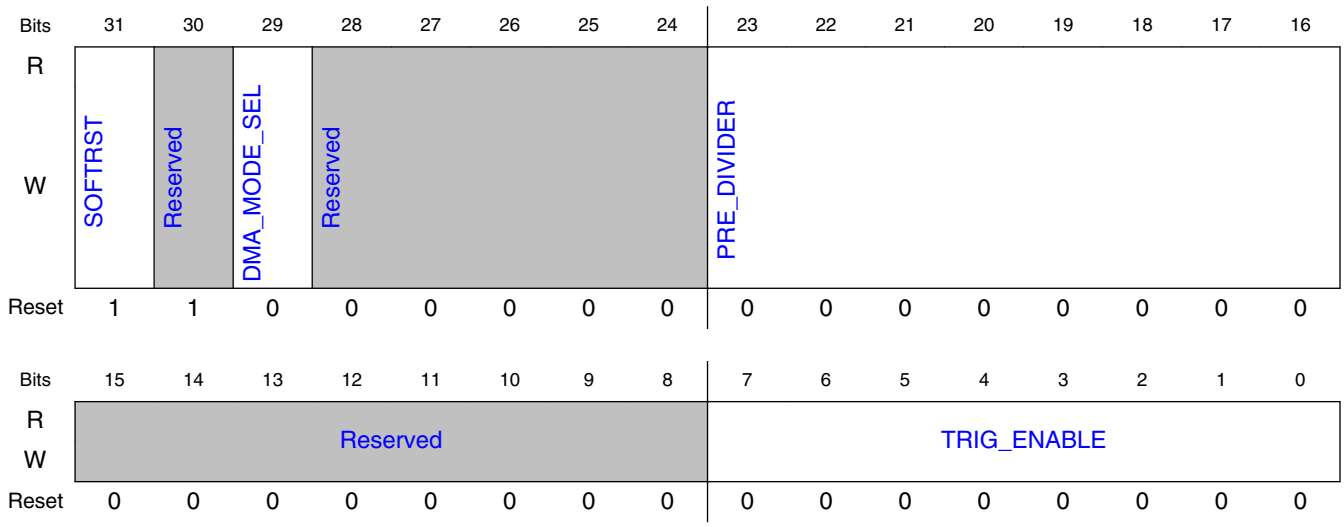
88.6.1.2.1 Offset

Register	Offset
CTRL	0h

88.6.1.2.2 Function

This register controls various global functions of the ADC_ETC, such as enabling the external XBAR triggers, setting the pre-division factor for trigger delay and interval, and selecting the trigger type of the DMA_REQ. In addition, this register contains SOFTRST to reset all registers inside ADC_ETC.

88.6.1.2.3 Diagram



88.6.1.2.4 Fields

Field	Function
31 SOFTRST	Software synchronous reset, active high. 0b - ADC_ETC works normally. 1b - All registers inside ADC_ETC will be reset to the default value.
30 —	Reserved
29 DMA_MODE_SEL	Select the trigger type of the DMA_REQ. 0b - Trig DMA_REQ with latched signal, REQ will be cleared when ACK and source request cleared. 1b - Trig DMA_REQ with pulsed signal, REQ will be cleared by ACK only.
28-24 —	Reserved
23-16 PRE_DIVIDER	Pre-divider for trig delay and interval. The meaning of this field will be explained in the description of TRIGa_COUNTER.
15-8 —	Reserved

Table continues on the next page...

Field	Function
7-0 TRIG_ENABLE	TRIG enable register. 0000_0000b - disable all 8 external XBAR triggers. 0000_0001b - enable external XBAR trigger0. 0000_0010b - enable external XBAR trigger1. 0000_0011b - enable external XBAR trigger0 and trigger1. 1111_1111b - enable all 8 external XBAR triggers.

88.6.1.3 ETC DONE0 and DONE1 IRQ State Register (DONE0_1_IRQ)

88.6.1.3.1 Offset

Register	Offset
DONE0_1_IRQ	4h

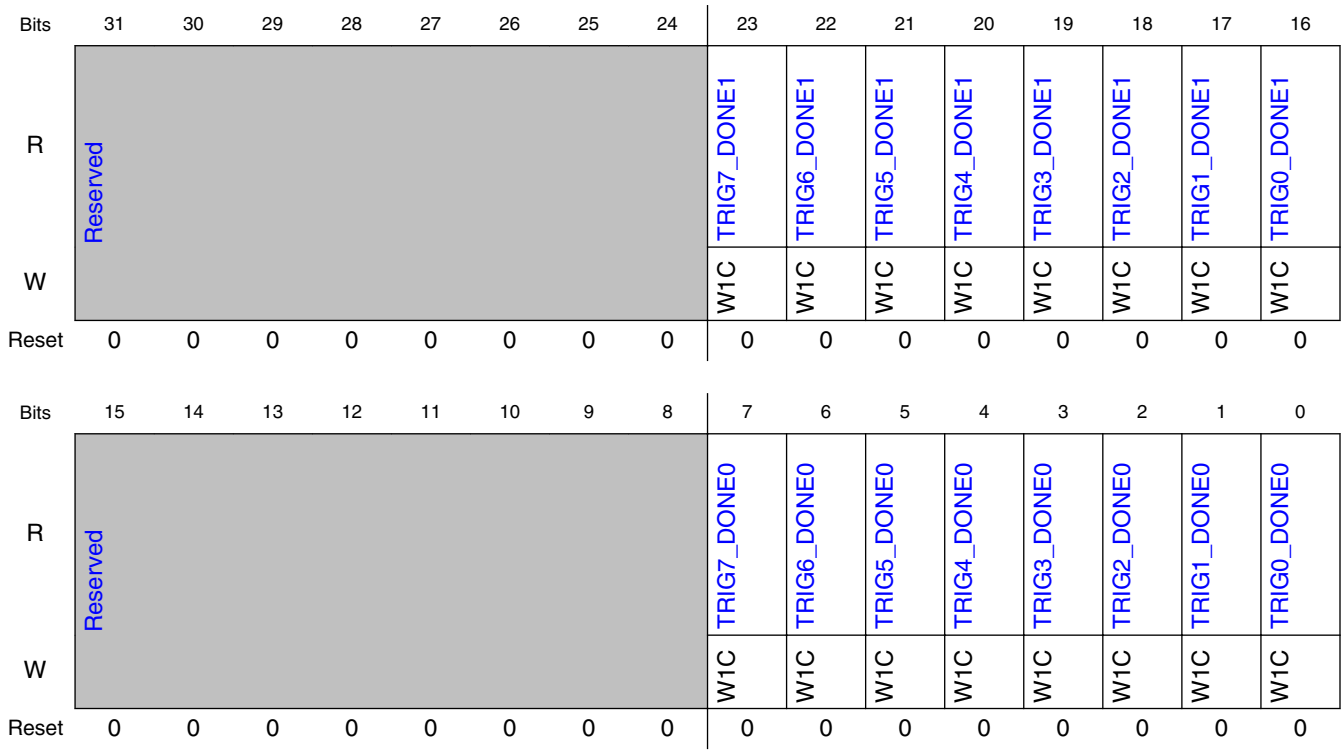
88.6.1.3.2 Function

This register has the state for ETC DONE0 and DONE1 interrupts.

NOTE

The IRQs can be cleared by writing 1 to the corresponding bits.

88.6.1.3.3 Diagram



88.6.1.3.4 Fields

Field	Function
31-24 —	Reserved
23 TRIG7_DONE1	TRIG7 done1 interrupt detection. 0b - No TRIG7_DONE1 interrupt detected 1b - TRIG7_DONE1 interrupt detected
22 TRIG6_DONE1	TRIG6 done1 interrupt detection. 0b - No TRIG6_DONE1 interrupt detected 1b - TRIG6_DONE1 interrupt detected
21 TRIG5_DONE1	TRIG5 done1 interrupt detection. 0b - No TRIG5_DONE1 interrupt detected 1b - TRIG5_DONE1 interrupt detected
20 TRIG4_DONE1	TRIG4 done1 interrupt detection. 0b - No TRIG4_DONE1 interrupt detected 1b - TRIG4_DONE1 interrupt detected

88.6.1.5 ETC DMA control Register (DMA_CTRL)

88.6.1.5.1 Offset

Register	Offset
DMA_CTRL	Ch

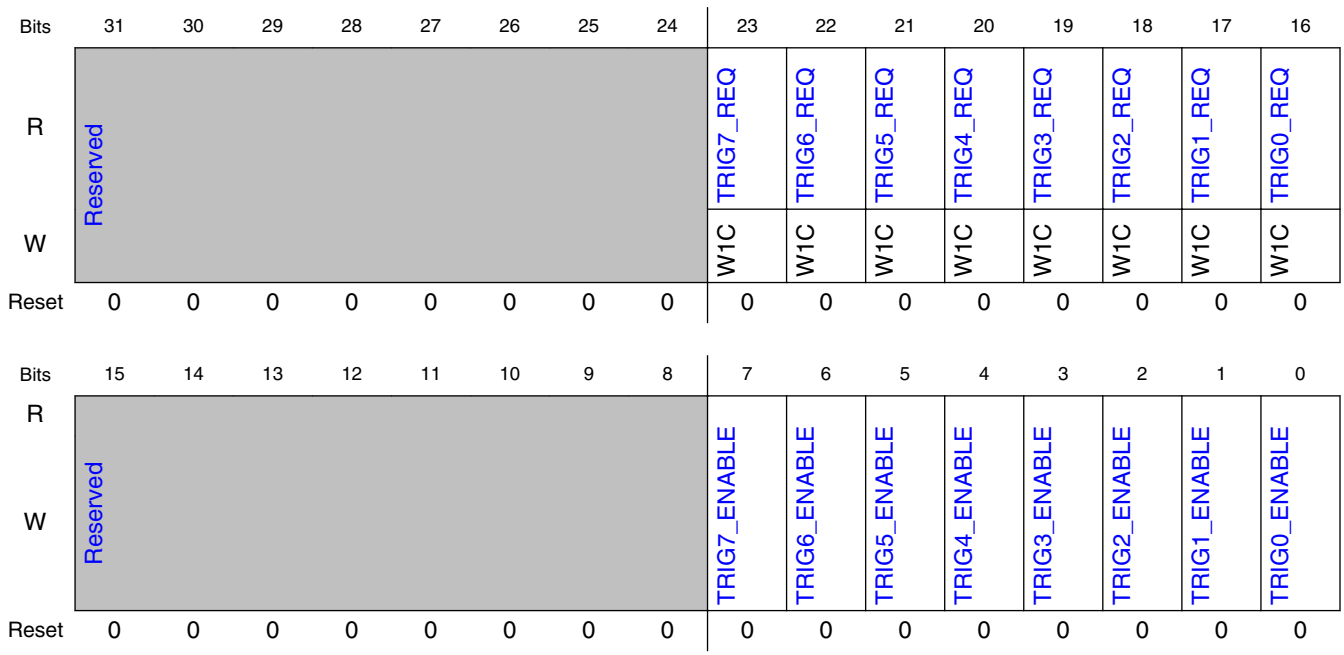
88.6.1.5.2 Function

This register has the control and status bit for the DMA of ADC_ETC. Each trigger has separate enabling and status bit in this register. The control bit enables the DMA request for each trigger, and the status bit indicates whether the corresponding trigger request was detected.

NOTE

TRIGa_REQ can be cleard by writing 1 to the corresponding bit.

88.6.1.5.3 Diagram



88.6.1.5.4 Fields

Field	Function
31-24 —	Reserved
23 TRIG7_REQ	Flag bit for DMA request. TRIG7_REQ being active indicates trigger7 done and a DMA transmission is needed. If TRIG7_ENABLE is also set, a DMA request will be sent. 0b - TRIG7_REQ not detected. 1b - TRIG7_REQ detected.
22 TRIG6_REQ	Flag bit for DMA request. TRIG6_REQ being active indicates trigger6 done and a DMA transmission is needed. If TRIG6_ENABLE is also set, a DMA request will be sent. 0b - TRIG6_REQ not detected. 1b - TRIG6_REQ detected.
21 TRIG5_REQ	Flag bit for DMA request. TRIG5_REQ being active indicates trigger5 done and a DMA transmission is needed. If TRIG5_ENABLE is also set, a DMA request will be sent. 0b - TRIG5_REQ not detected. 1b - TRIG5_REQ detected.
20 TRIG4_REQ	Flag bit for DMA request. TRIG4_REQ being active indicates trigger4 done and a DMA transmission is needed. If TRIG4_ENABLE is also set, a DMA request will be sent.

Table continues on the next page...

Field	Function
	0b - TRIG4_REQ not detected. 1b - TRIG4_REQ detected.
19 TRIG3_REQ	Flag bit for DMA request. TRIG3_REQ being active indicates trigger3 done and a DMA transmission is needed. If TRIG3_ENABLE is also set, a DMA request will be sent. 0b - TRIG3_REQ not detected. 1b - TRIG3_REQ detected.
18 TRIG2_REQ	Flag bit for DMA request. TRIG2_REQ being active indicates trigger2 done and a DMA transmission is needed. If TRIG2_ENABLE is also set, a DMA request will be sent. 0b - TRIG2_REQ not detected. 1b - TRIG2_REQ detected.
17 TRIG1_REQ	Flag bit for DMA request. TRIG1_REQ being active indicates trigger1 done and a DMA transmission is needed. If TRIG1_ENABLE is also set, a DMA request will be sent. 0b - TRIG1_REQ not detected. 1b - TRIG1_REQ detected.
16 TRIG0_REQ	Flag bit for DMA request. TRIG0_REQ being active indicates trigger0 done and a DMA transmission is needed. If TRIG0_ENABLE is also set, a DMA request will be sent. 0b - TRIG0_REQ not detected. 1b - TRIG0_REQ detected.
15-8 —	Reserved
7 TRIG7_ENABLE	Enable DMA request when TRIG7 done. 0b - TRIG7 DMA request disabled. 1b - TRIG7 DMA request enabled.
6 TRIG6_ENABLE	Enable DMA request when TRIG6 done. 0b - TRIG6 DMA request disabled. 1b - TRIG6 DMA request enabled.
5 TRIG5_ENABLE	Enable DMA request when TRIG5 done. 0b - TRIG5 DMA request disabled. 1b - TRIG5 DMA request enabled.
4 TRIG4_ENABLE	Enable DMA request when TRIG4 done. 0b - TRIG4 DMA request disabled. 1b - TRIG4 DMA request enabled.
3 TRIG3_ENABLE	Enable DMA request when TRIG3 done. 0b - TRIG3 DMA request disabled. 1b - TRIG3 DMA request enabled.
2 TRIG2_ENABLE	Enable DMA request when TRIG2 done. 0b - TRIG2 DMA request disabled. 1b - TRIG2 DMA request enabled.
1 TRIG1_ENABLE	Enable DMA request when TRIG1 done. 0b - TRIG1 DMA request disabled. 1b - TRIG1 DMA request enabled.
0 TRIG0_ENABLE	Enable DMA request when TRIG0 done. 0b - TRIG0 DMA request disabled. 1b - TRIG0 DMA request enabled.

88.6.1.6 ETC_TRIG Control Register (TRIG0_CTRL - TRIG7_CTRL)

88.6.1.6.1 Offset

For a = 0 to 7:

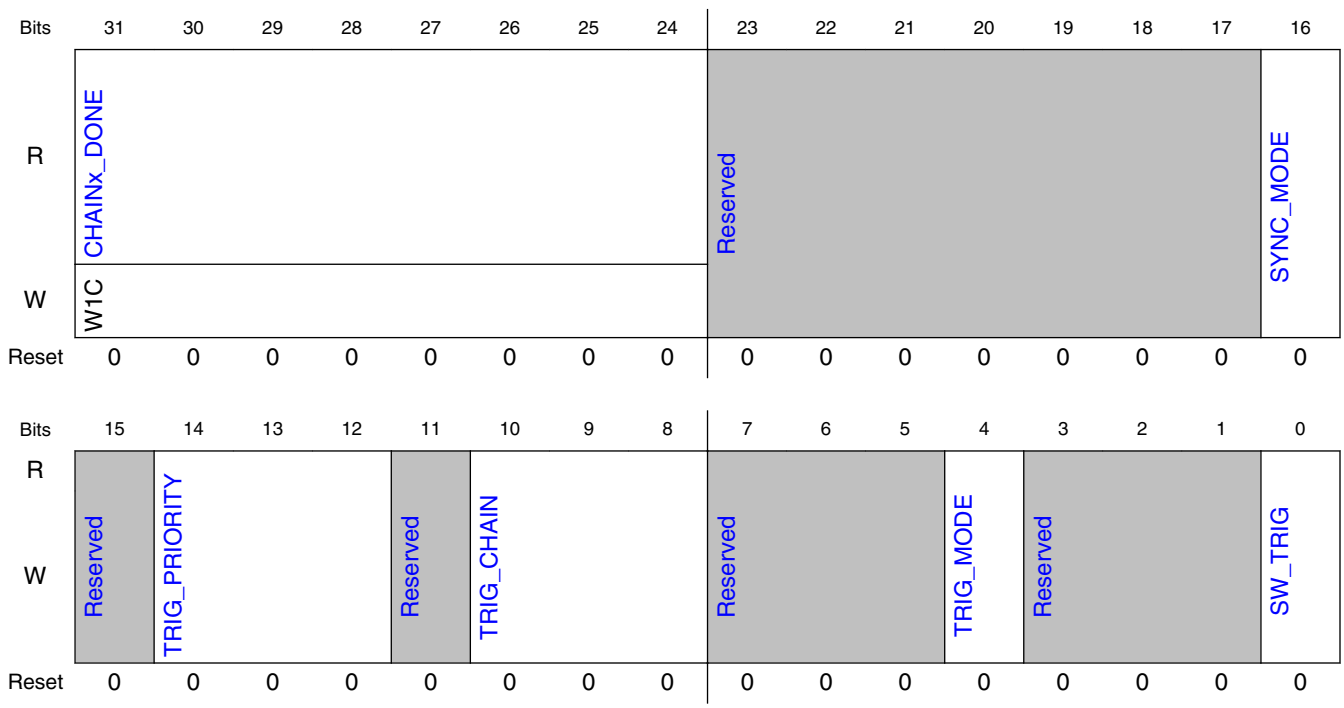
Register	Offset
TRIGa_CTRL	10h + (a × 28h)

88.6.1.6.2 Function

This register contains the control bits for trigger, such as selecting synchronization mode, setting trigger priority and setting the length of trigger chain. It also contains a bit for selecting trigger mode between hardware trigger and software trigger, and a self-clearing bit for launching a software trigger.

The maximum length of trigger chain is 8, so there are 8 status bits in this register.

88.6.1.6.3 Diagram



88.6.1.6.4 Fields

Field	Function
31-24 CHAINx_DONE	Segment x done detection. Each trigger of ADC_ETC supports up to 8 segments, and each segment will launch a trigger of ADC to start an ADC convertion. Bit 24 is for segment 0 and bit 31 is for segment 7. **NOTE:** Each bit in this field is cleared by writing a logic 1 to it. 0000_0000b - segment x done not detected. 0000_0001b - segment x done detected.
23-17 —	Reserved
16 SYNC_MODE	Trigger synchronization mode selection. **NOTE:** Setting SYNC_MODE = 1 for TRIGa or TRIG(a+4) represents the same meaning. 0b - Synchronization mode disabled, TRIGa and TRIG(a+4) are triggered independently. 1b - Synchronization mode enabled, TRIGa and TRIG(a+4) are triggered by TRIGa source synchronously.
15 —	Reserved
14-12 TRIG_PRIORITY	External trigger priority, 7 is highest priority, while 0 is lowest. **NOTE:** When more than one triggers use the same level setting of priority, then round-robin mechanism implemented and the trigger with larger number owns the higher priority.
11 —	Reserved
10-8 TRIG_CHAIN	The number of segments inside the trigger chain of TRIGa. 000b - Trigger chain length is 1 001b - Trigger chain length is 2 010b - Trigger chain length is 3 011b - Trigger chain length is 4 100b - Trigger chain length is 5 101b - Trigger chain length is 6 110b - Trigger chain length is 7 111b - Trigger chain length is 8
7-5 —	Reserved
4 TRIG_MODE	Trigger mode selection. 0b - Hardware trigger. The softerware trigger will be ignored. 1b - Software trigger. The hardware trigger will be ignored.
3-1 —	Reserved
0 SW_TRIG	Software trigger. **NOTE:** This field is self-clearing. 0b - No software trigger event generated. 1b - Software trigger event generated.

88.6.1.7 ETC_TRIG Counter Register (TRIG0_COUNTER - TRIG7_COUNTER)

88.6.1.7.1 Offset

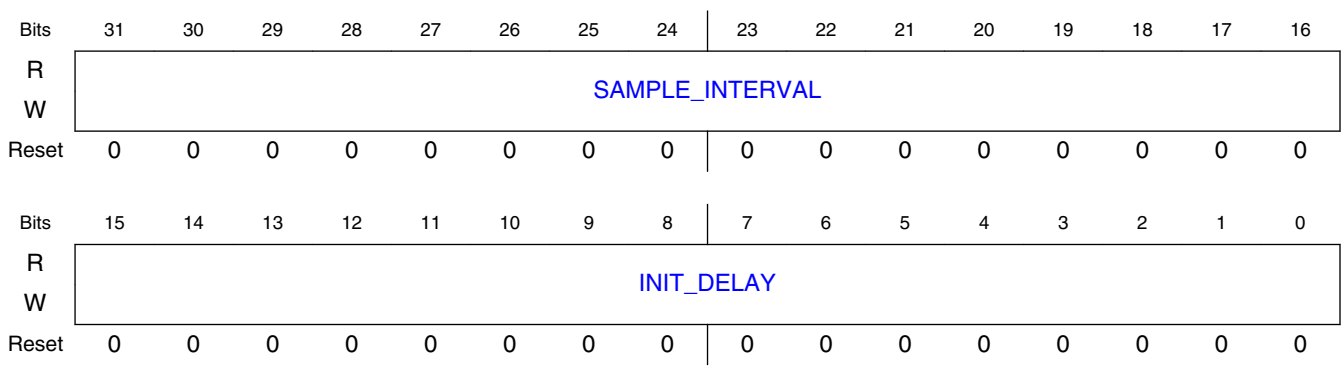
For a = 0 to 7:

Register	Offset
TRIGa_COUNTER	14h + (a × 28h)

88.6.1.7.2 Function

This register controls the initial delay ahead the first ADC trigger and interval delay between ADC triggers launched by the same ADC_ETC trigger.

88.6.1.7.3 Diagram



88.6.1.7.4 Fields

Field	Function
31-16 SAMPLE_INTERVAL	TRIGGER sampling interval counter. When B2B is unset: Interval_delay = (SAMPLE_INTERVAL+1)*(PRE_DIVIDER+1)*ipg_clk
15-0 INIT_DELAY	TRIGGER initial delay counter. Initial_delay = (INIT_DELAY+1)*(PRE_DIVIDER+1)*ipg_clk

88.6.1.8 ETC_TRIG Chain 0/1 Register (TRIG0_CHAIN_1_0 - TRIG7_CHAIN_1_0)

88.6.1.8.1 Offset

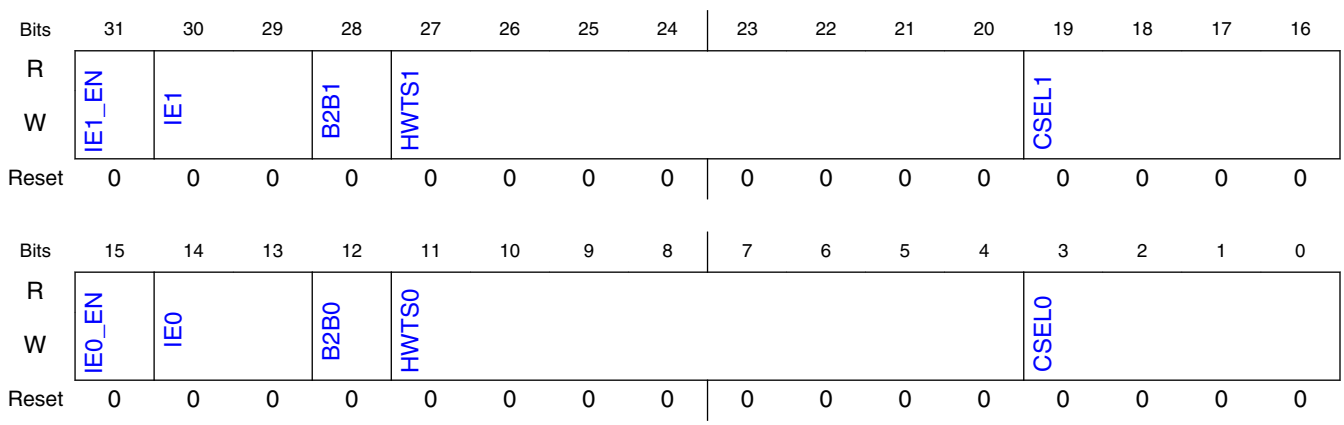
For a = 0 to 7:

Register	Offset
TRIGa_CHAIN_1_0	18h + (a × 28h)

88.6.1.8.2 Function

This register controls ETC_TRIG segment 0/1 configuration, such as enabling and selecting interrupt, setting back-to-back mode,selecting ADC trigger and trigger command.

88.6.1.8.3 Diagram



88.6.1.8.4 Fields

Field	Function
31 IE1_EN	IRQ enable of segment 1. 0b - Interrupt DONE disabled. 1b - Interrupt DONE enabled. When segment 1 finish, an interrupt will be generated on the specific port configured by the IE1.
30-29 IE1	Segment 1 interrupt enable. (This bit field is meaningful only when IE1_EN is set) 00b - Generate interrupt on Done0 when Segment 1 finish. 01b - Generate interrupt on Done1 when Segment 1 finish. 10b - Generate interrupt on Done2 when Segment 1 finish.

Table continues on the next page...

Field	Function
	11b - Generate interrupt on Done3 when Segment 1 finish.
28 B2B1	Segment 1 B2B 0b - Disable B2B. Wait until delay value defined by TRIG1_COUNTER[SAMPLE_INTERVAL] is reached 1b - Enable B2B. When Segment 0 finished (ADC COCO) then automatically trigger next ADC conversion, no need to wait until interval delay reached.
27-20 HWTS1	Segment 1 HWTS ADC hardware trigger selection. This field will control the ext_hwts of ADC (see the ADC_ETC block diagram). **NOTE:** Please keep only one bit set at the same time. 0000_0000b - no trigger selected 0000_0001b - ADC TRIG0 selected 0000_0010b - ADC TRIG1 selected 0000_0100b - ADC TRIG2 selected 0000_1000b - ADC TRIG3 selected 0001_0000b - ADC TRIG4 selected 0010_0000b - ADC TRIG5 selected 0100_0000b - ADC TRIG6 selected 1000_0000b - ADC TRIG7 selected
19-16 CSEL1	ADC hardware trigger command selection. For more information, see the ADC chapter. **NOTE:** TCRTLx[CMD_SEL] of ADC should be set to 1. 0000b - Not a valid selection from the command buffer. Trigger event is ignored. 0001b - ADC CMD1 selected. 0010b - ADC CMD2 selected. 0011b - ADC CMD3 selected. 0100b - ADC CMD4 selected. 0101b - ADC CMD5 selected. 0110b - ADC CMD6 selected. 0111b - ADC CMD7 selected. 1000b - ADC CMD8 selected. 1001b - ADC CMD9 selected. 1010b - ADC CMD10 selected. 1011b - ADC CMD11 selected. 1100b - ADC CMD12 selected. 1101b - ADC CMD13 selected. 1110b - ADC CMD14 selected. 1111b - ADC CMD15 selected.
15 IE0_EN	IRQ enable of segment 0. 0b - Interrupt DONE disabled. 1b - Interrupt DONE enabled. When segment 0 finish, an interrupt will be generated on the specific port configured by the IE0.
14-13 IE0	Segment 0 interrupt enable. (This bit field is meaningful only when IE0_EN is set) 00b - Generate interrupt on Done0 when segment 0 finish. 01b - Generate interrupt on Done1 when segment 0 finish. 10b - Generate interrupt on Done2 when segment 0 finish. 11b - Generate interrupt on Done3 when segment 0 finish.
12 B2B0	Segment 0 B2B 0b - Disable B2B. Wait until delay value defined by TRIG0_COUNTER[SAMPLE_INTERVAL] is reached 1b - Enable B2B. When Segment 0 finished (ADC COCO) then automatically trigger next ADC conversion, no need to wait until interval delay reached.

Table continues on the next page...

Field	Function
11-4 HWTS0	Segment 0 HWTS ADC hardware trigger selection. This field will control the ext_hwts of ADC (see the ADC_ETC block diagram). **NOTE:** Please keep only one bit set at the same time. 0000_0000b - no trigger selected 0000_0001b - ADC TRIG0 selected 0000_0010b - ADC TRIG1 selected 0000_0100b - ADC TRIG2 selected 0000_1000b - ADC TRIG3 selected 0001_0000b - ADC TRIG4 selected 0010_0000b - ADC TRIG5 selected 0100_0000b - ADC TRIG6 selected 1000_0000b - ADC TRIG7 selected
3-0 CSEL0	ADC hardware trigger command selection. For more information, see the ADC chapter. **NOTE:** TCRTLx[CMD_SEL] of ADC should be set to 1. 0000b - Not a valid selection from the command buffer. Trigger event is ignored. 0001b - ADC CMD1 selected. 0010b - ADC CMD2 selected. 0011b - ADC CMD3 selected. 0100b - ADC CMD4 selected. 0101b - ADC CMD5 selected. 0110b - ADC CMD6 selected. 0111b - ADC CMD7 selected. 1000b - ADC CMD8 selected. 1001b - ADC CMD9 selected. 1010b - ADC CMD10 selected. 1011b - ADC CMD11 selected. 1100b - ADC CMD12 selected. 1101b - ADC CMD13 selected. 1110b - ADC CMD14 selected. 1111b - ADC CMD15 selected.

88.6.1.9 ETC_TRIG Chain 2/3 Register (TRIG0_CHAIN_3_2 - TRIG7_CHAIN_3_2)

88.6.1.9.1 Offset

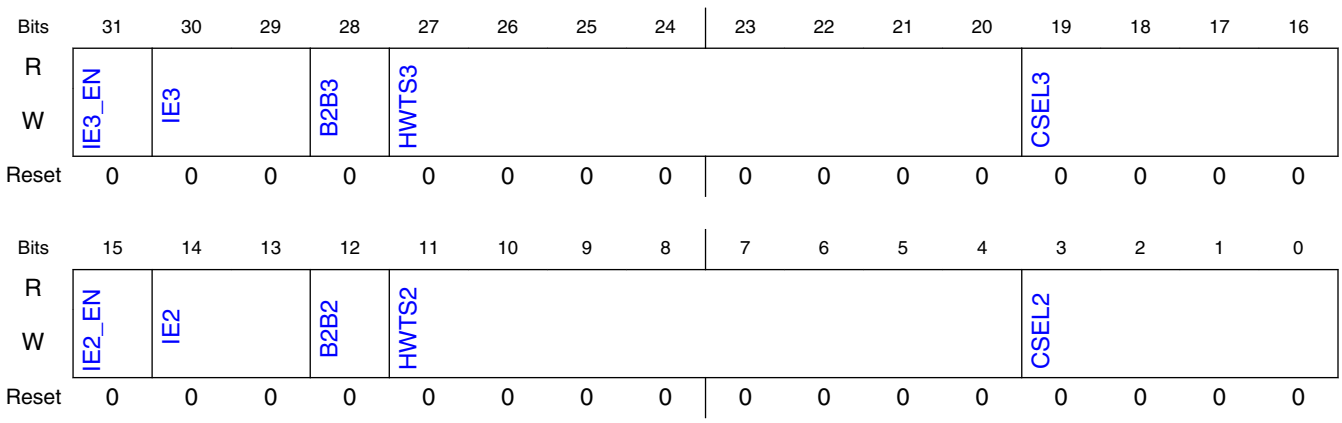
For a = 0 to 7:

Register	Offset
TRIGa_CHAIN_3_2	1Ch + (a × 28h)

88.6.1.9.2 Function

This register controls ETC_TRIG segment 2/3 configuration, such as enabling and selecting interrupt, setting back-to-back mode,selecting ADC trigger and trigger command.

88.6.1.9.3 Diagram



88.6.1.9.4 Fields

Field	Function
31 IE3_EN	IRQ enable of segment 3. 0b - Interrupt DONE disabled. 1b - Interrupt DONE enabled. When segment 3 finish, an interrupt will be generated on the specific port configured by the IE3.
30-29 IE3	Segment 3 interrupt enable. (This bit field is meaningful only when IE3_EN is set) 00b - Generate interrupt on Done0 when segment 3 finish. 01b - Generate interrupt on Done1 when segment 3 finish. 10b - Generate interrupt on Done2 when segment 3 finish. 11b - Generate interrupt on Done3 when segment 3 finish.
28 B2B3	Segment 3 B2B 0b - Disable B2B. Wait until delay value defined by TRIG3_COUNTER[SAMPLE_INTERVAL] is reached 1b - Enable B2B. When Segment 0 finished (ADC COCO) then automatically trigger next ADC conversion, no need to wait until interval delay reached.
27-20 HWTS3	Segment 3 HWTS ADC hardware trigger selection. This field will control the ext_hwts of ADC (see the ADC_ETC block diagram). **NOTE:** Please keep only one bit set at the same time. 0000_0000b - no trigger selected 0000_0001b - ADC TRIG0 selected 0000_0010b - ADC TRIG1 selected 0000_0100b - ADC TRIG2 selected

Table continues on the next page...

Field	Function
	0000_1000b - ADC TRIG3 selected 0001_0000b - ADC TRIG4 selected 0010_0000b - ADC TRIG5 selected 0100_0000b - ADC TRIG6 selected 1000_0000b - ADC TRIG7 selected
19-16 CSEL3	ADC hardware trigger command selection. For more information, see the ADC chapter. **NOTE:** TCRTLx[CMD_SEL] of ADC should be set to 1. 0000b - Not a valid selection from the command buffer. Trigger event is ignored. 0001b - ADC CMD1 selected. 0010b - ADC CMD2 selected. 0011b - ADC CMD3 selected. 0100b - ADC CMD4 selected. 0101b - ADC CMD5 selected. 0110b - ADC CMD6 selected. 0111b - ADC CMD7 selected. 1000b - ADC CMD8 selected. 1001b - ADC CMD9 selected. 1010b - ADC CMD10 selected. 1011b - ADC CMD11 selected. 1100b - ADC CMD12 selected. 1101b - ADC CMD13 selected. 1110b - ADC CMD14 selected. 1111b - ADC CMD15 selected.
15 IE2_EN	IRQ enable of segment 2. 0b - Interrupt DONE disabled. 1b - Interrupt DONE enabled. When segment 2 finish, an interrupt will be generated on the specific port configured by the IE2.
14-13 IE2	Segment 2 interrupt enable. (This bit field is meaningful only when IE2_EN is set) 00b - Generate interrupt on Done0 when segment 2 finish. 01b - Generate interrupt on Done1 when segment 2 finish. 10b - Generate interrupt on Done2 when segment 2 finish. 11b - Generate interrupt on Done3 when segment 2 finish.
12 B2B2	Segment 2 B2B 0b - Disable B2B. Wait until delay value defined by TRIG2_COUNTER[SAMPLE_INTERVAL] is reached 1b - Enable B2B. When Segment 0 finished (ADC COCO) then automatically trigger next ADC conversion, no need to wait until interval delay reached.
11-4 HWTS2	Segment 2 HWTS ADC hardware trigger selection. This field will control the ext_hwts of ADC (see the ADC_ETC block diagram). **NOTE:** Please keep only one bit set at the same time. 0000_0000b - no trigger selected 0000_0001b - ADC TRIG0 selected 0000_0010b - ADC TRIG1 selected 0000_0100b - ADC TRIG2 selected 0000_1000b - ADC TRIG3 selected 0001_0000b - ADC TRIG4 selected 0010_0000b - ADC TRIG5 selected 0100_0000b - ADC TRIG6 selected 1000_0000b - ADC TRIG7 selected
3-0	ADC hardware trigger command selection. For more information, see the ADC chapter.

Field	Function
CSEL2	**NOTE:** TCRTLx[CMD_SEL] of ADC should be set to 1. 0000b - Not a valid selection from the command buffer. Trigger event is ignored. 0001b - ADC CMD1 selected. 0010b - ADC CMD2 selected. 0011b - ADC CMD3 selected. 0100b - ADC CMD4 selected. 0101b - ADC CMD5 selected. 0110b - ADC CMD6 selected. 0111b - ADC CMD7 selected. 1000b - ADC CMD8 selected. 1001b - ADC CMD9 selected. 1010b - ADC CMD10 selected. 1011b - ADC CMD11 selected. 1100b - ADC CMD12 selected. 1101b - ADC CMD13 selected. 1110b - ADC CMD14 selected. 1111b - ADC CMD15 selected.

88.6.1.10 ETC_TRIG Chain 4/5 Register (TRIG0_CHAIN_5_4 - TRIG7_CHAIN_5_4)

88.6.1.10.1 Offset

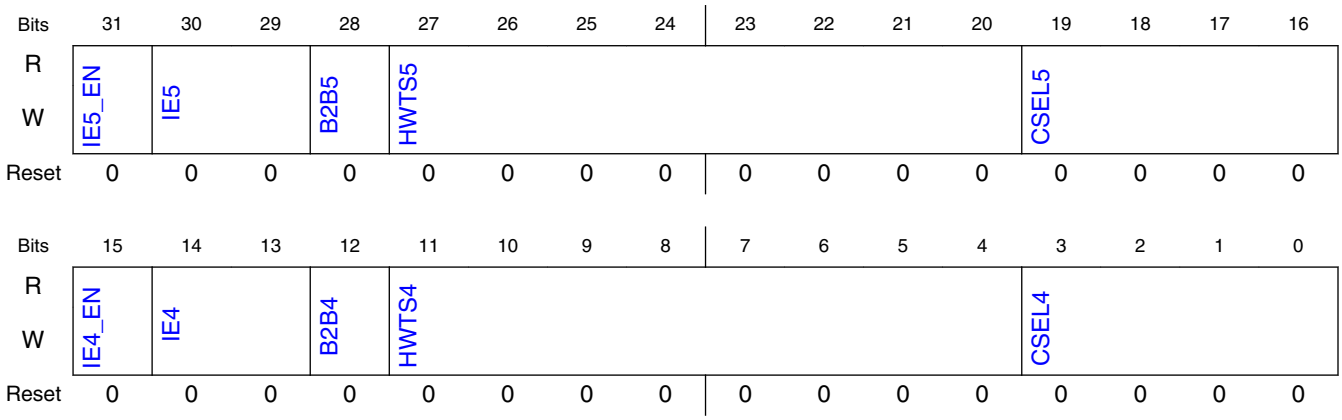
For a = 0 to 7:

Register	Offset
TRIGa_CHAIN_5_4	20h + (a × 28h)

88.6.1.10.2 Function

This register controls ETC_TRIG segment 4/5 configuration, such as enabling and selecting interrupt, setting back-to-back mode,selecting ADC trigger and trigger command.

88.6.1.10.3 Diagram



88.6.1.10.4 Fields

Field	Function
31 IE5_EN	IRQ enable of segment 5. 0b - Interrupt DONE disabled. 1b - Interrupt DONE enabled. When segment 5 finish, an interrupt will be generated on the specific port configured by the IE5.
30-29 IE5	Segment 5 interrupt enable. (This bit field is meaningful only when IE5_EN is set) 00b - Generate interrupt on Done0 when segment 5 finish. 01b - Generate interrupt on Done1 when segment 5 finish. 10b - Generate interrupt on Done2 when segment 5 finish. 11b - Generate interrupt on Done3 when segment 5 finish.
28 B2B5	Segment 5 B2B 0b - Disable B2B. Wait until delay value defined by TRIG5_COUNTER[SAMPLE_INTERVAL] is reached 1b - Enable B2B. When Segment 0 finished (ADC COCO) then automatically trigger next ADC conversion, no need to wait until interval delay reached.
27-20 HWTS5	Segment 5 HWTS ADC hardware trigger selection. This field will control the ext_hwts of ADC (see the ADC_ETC block diagram). **NOTE:** Please keep only one bit set at the same time. 0000_0000b - no trigger selected 0000_0001b - ADC TRIG0 selected 0000_0010b - ADC TRIG1 selected 0000_0100b - ADC TRIG2 selected 0000_1000b - ADC TRIG3 selected 0001_0000b - ADC TRIG4 selected 0010_0000b - ADC TRIG5 selected 0100_0000b - ADC TRIG6 selected 1000_0000b - ADC TRIG7 selected
19-16 CSEL5	ADC hardware trigger command selection. For more information, see the ADC chapter. **NOTE:** TCRTLx[CMD_SEL] of ADC should be set to 1. 0000b - Not a valid selection from the command buffer. Trigger event is ignored.

Table continues on the next page...

Field	Function
	0001b - ADC CMD1 selected. 0010b - ADC CMD2 selected. 0011b - ADC CMD3 selected. 0100b - ADC CMD4 selected. 0101b - ADC CMD5 selected. 0110b - ADC CMD6 selected. 0111b - ADC CMD7 selected. 1000b - ADC CMD8 selected. 1001b - ADC CMD9 selected. 1010b - ADC CMD10 selected. 1011b - ADC CMD11 selected. 1100b - ADC CMD12 selected. 1101b - ADC CMD13 selected. 1110b - ADC CMD14 selected. 1111b - ADC CMD15 selected.
15 IE4_EN	IRQ enable of segment 4. 0b - Interrupt DONE disabled. 1b - Interrupt DONE enabled. When segment 4 finish, an interrupt will be generated on the specific port configured by the IE4.
14-13 IE4	Segment 4 interrupt enable. (This bit field is meaningful only when IE4_EN is set) 00b - Generate interrupt on Done0 when segment 4 finish. 01b - Generate interrupt on Done1 when segment 4 finish. 10b - Generate interrupt on Done2 when segment 4 finish. 11b - Generate interrupt on Done3 when segment 4 finish.
12 B2B4	Segment 4 B2B 0b - Disable B2B. Wait until delay value defined by TRIG4_COUNTER[SAMPLE_INTERVAL] is reached 1b - Enable B2B. When Segment 0 finished (ADC COCO) then automatically trigger next ADC conversion, no need to wait until interval delay reached.
11-4 HWTS4	Segment 4 HWTS ADC hardware trigger selection. This field will control the ext_hwts of ADC (see the ADC_ETC block diagram). **NOTE:** Please keep only one bit set at the same time. 0000_0000b - no trigger selected 0000_0001b - ADC TRIG0 selected 0000_0010b - ADC TRIG1 selected 0000_0100b - ADC TRIG2 selected 0000_1000b - ADC TRIG3 selected 0001_0000b - ADC TRIG4 selected 0010_0000b - ADC TRIG5 selected 0100_0000b - ADC TRIG6 selected 1000_0000b - ADC TRIG7 selected
3-0 CSEL4	ADC hardware trigger command selection. 88.6.1.11.4 Fields

Field	Function
31 IE7_EN	IRQ enable of segment 7. 0b - Interrupt DONE disabled. 1b - Interrupt DONE enabled. When segment 7 finish, an interrupt will be generated on the specific port configured by the IE7.
30-29 IE7	Segment 7 interrupt enable. (This bit field is meaningful only when IE7_EN is set) 00b - Generate interrupt on Done0 when segment 7 finish. 01b - Generate interrupt on Done1 when segment 7 finish. 10b - Generate interrupt on Done2 when segment 7 finish. 11b - Generate interrupt on Done3 when segment 7 finish.
28 B2B7	Segment 7 B2B 0b - Disable B2B. Wait until delay value defined by TRIG7_COUNTER[SAMPLE_INTERVAL] is reached 1b - Enable B2B. When Segment 0 finished (ADC COCO) then automatically trigger next ADC conversion, no need to wait until interval delay reached.
27-20 HWTS7	Segment 7 HWTS ADC hardware trigger selection. This field will control the ext_hwts of ADC (see the ADC_ETC block diagram). **NOTE:** Please keep only one bit set at the same time. 0000_0000b - no trigger selected 0000_0001b - ADC TRIG0 selected 0000_0010b - ADC TRIG1 selected 0000_0100b - ADC TRIG2 selected 0000_1000b - ADC TRIG3 selected 0001_0000b - ADC TRIG4 selected 0010_0000b - ADC TRIG5 selected 0100_0000b - ADC TRIG6 selected 1000_0000b - ADC TRIG7 selected
19-16 CSEL7	ADC hardware trigger command selection. For more information, see the ADC chapter. **NOTE:** TCRTLx[CMD_SEL] of ADC should be set to 1. 0000b - Not a valid selection from the command buffer. Trigger event is ignored. 0001b - ADC CMD1 selected. 0010b - ADC CMD2 selected. 0011b - ADC CMD3 selected. 0100b - ADC CMD4 selected. 0101b - ADC CMD5 selected. 0110b - ADC CMD6 selected. 0111b - ADC CMD7 selected. 1000b - ADC CMD8 selected. 1001b - ADC CMD9 selected. 1010b - ADC CMD10 selected. 1011b - ADC CMD11 selected. 1100b - ADC CMD12 selected. 1101b - ADC CMD13 selected. 1110b - ADC CMD14 selected. 1111b - ADC CMD15 selected.
15 IE6_EN	IRQ enable of segment 6. 0b - Interrupt DONE disabled. 1b - Interrupt DONE enabled. When segment 6 finish, an interrupt will be generated on the specific port configured by the IE6.

Table continues on the next page...

Field	Function
14-13 IE6	Segment 6 interrupt enable. (This bit field is meaningful only when IE6_EN is set) 00b - Generate interrupt on Done0 when segment 6 finish. 01b - Generate interrupt on Done1 when segment 6 finish. 10b - Generate interrupt on Done2 when segment 6 finish. 11b - Generate interrupt on Done3 when segment 6 finish.
12 B2B6	Segment 6 B2B 0b - Disable B2B. Wait until delay value defined by TRIG6_COUNTER[SAMPLE_INTERVAL] is reached 1b - Enable B2B. When Segment 0 finished (ADC COCO) then automatically trigger next ADC conversion, no need to wait until interval delay reached.
11-4 HWTS6	Segment 6 HWTS ADC hardware trigger selection. This field will control the ext_hwts of ADC (see the ADC_ETC block diagram). **NOTE:** Please keep only one bit set at the same time. 0000_0000b - no trigger selected 0000_0001b - ADC TRIG0 selected 0000_0010b - ADC TRIG1 selected 0000_0100b - ADC TRIG2 selected 0000_1000b - ADC TRIG3 selected 0001_0000b - ADC TRIG4 selected 0010_0000b - ADC TRIG5 selected 0100_0000b - ADC TRIG6 selected 1000_0000b - ADC TRIG7 selected
3-0 CSEL6	ADC hardware trigger command selection. For more information, see the ADC chapter. **NOTE:** TCRTLx[CMD_SEL] of ADC should be set to 1. 0000b - Not a valid selection from the command buffer. Trigger event is ignored. 0001b - ADC CMD1 selected. 0010b - ADC CMD2 selected. 0011b - ADC CMD3 selected. 0100b - ADC CMD4 selected. 0101b - ADC CMD5 selected. 0110b - ADC CMD6 selected. 0111b - ADC CMD7 selected. 1000b - ADC CMD8 selected. 1001b - ADC CMD9 selected. 1010b - ADC CMD10 selected. 1011b - ADC CMD11 selected. 1100b - ADC CMD12 selected. 1101b - ADC CMD13 selected. 1110b - ADC CMD14 selected. 1111b - ADC CMD15 selected.

88.6.1.12 ETC_TRIG Result Data 1/0 Register (TRIG0_RESULT_1_0 - TRIG7_RESULT_1_0)

88.6.1.12.1 Offset

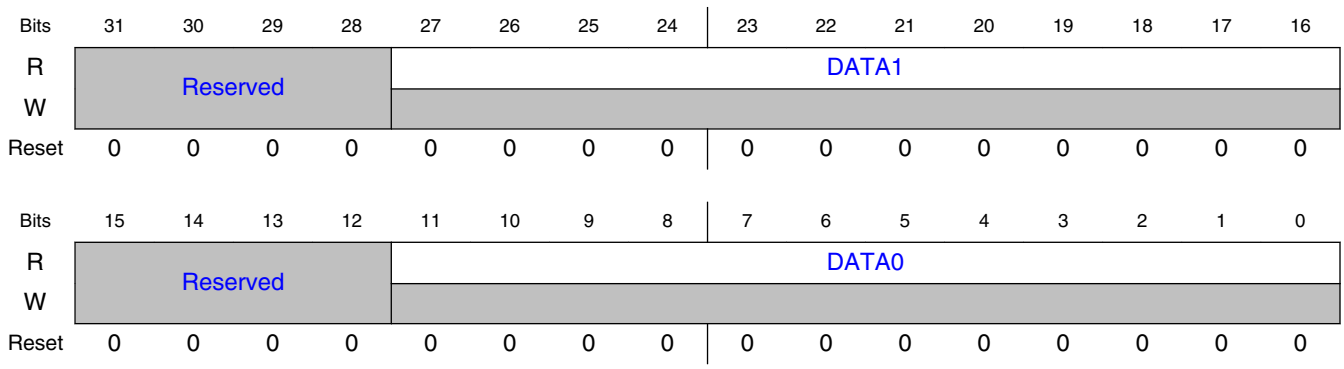
For a = 0 to 7:

Register	Offset
TRIGa_RESULT_1_0	28h + (a × 28h)

88.6.1.12.2 Function

This register stores the results of the ADC conversions corresponding to segment 0 and segment 1 of TRIGa.

88.6.1.12.3 Diagram



88.6.1.12.4 Fields

Field	Function
31-28 —	Reserved
27-16 DATA1	Result DATA1 **NOTE:** The sign bit from ADC result FIFO is ignored by ETC_TRIG result, so only 12-bit unsigned results is supported by ADC_ETC module.
15-12 —	Reserved
11-0 DATA0	Result DATA0 **NOTE:** The sign bit from ADC result FIFO is ignored by ETC_TRIG result, so only 12-bit unsigned results is supported by ADC_ETC module.

88.6.1.13 ETC_TRIG Result Data 3/2 Register (TRIG0_RESULT_3_2 - TRIG7_RESULT_3_2)

88.6.1.13.1 Offset

For a = 0 to 7:

Register	Offset
TRIGa_RESULT_3_2	2Ch + (a × 28h)

88.6.1.13.2 Function

This register stores the results of the ADC conversions corresponding to segment 2 and segment 3 of TRIGa.

11-0 DATA6	Result DATA6 **NOTE:** The sign bit from ADC result FIFO is ignored by ETC_TRIG result, so only 12-bit unsigned results is supported by ADC_ETC module.

Chapter 89
Digital-to-Analog Converters (DAC)

89.1 Chip-specific DAC information

Table 89-1. Reference links to related information

Topic	Related module(s)	Reference
System memory map	-	System Memory Map
Clocking	CCM	Clock Management Clock Control Module (CCM)
Power management	PMU	Power Management Power Management Unit
Signal multiplexing	IOMUX	External Signals and Pin Multiplexing IOMUX
Interrupts, DMA Events and XBAR Assignments	-	Interrupts, DMA Events and XBAR Assignments

The only DAC reference option for this chip is VREFH, which uses the ADC_VREFH pin. VREFL uses the ADC_VREFL pin. DACRFS must be set to 1.

There is no hw trigger option defined for DAC on this chip.

IREF2 is not available on this chip.

89.2 Overview

The 12-bit digital-to-analog converter (DAC) is a low-power, general-purpose DAC. The output of the DAC can be placed on an external pin or set as one of the inputs to the analog comparator, op-amps, or ADC.

89.2.1 Block diagram

The block diagram of the DAC module is as follows:

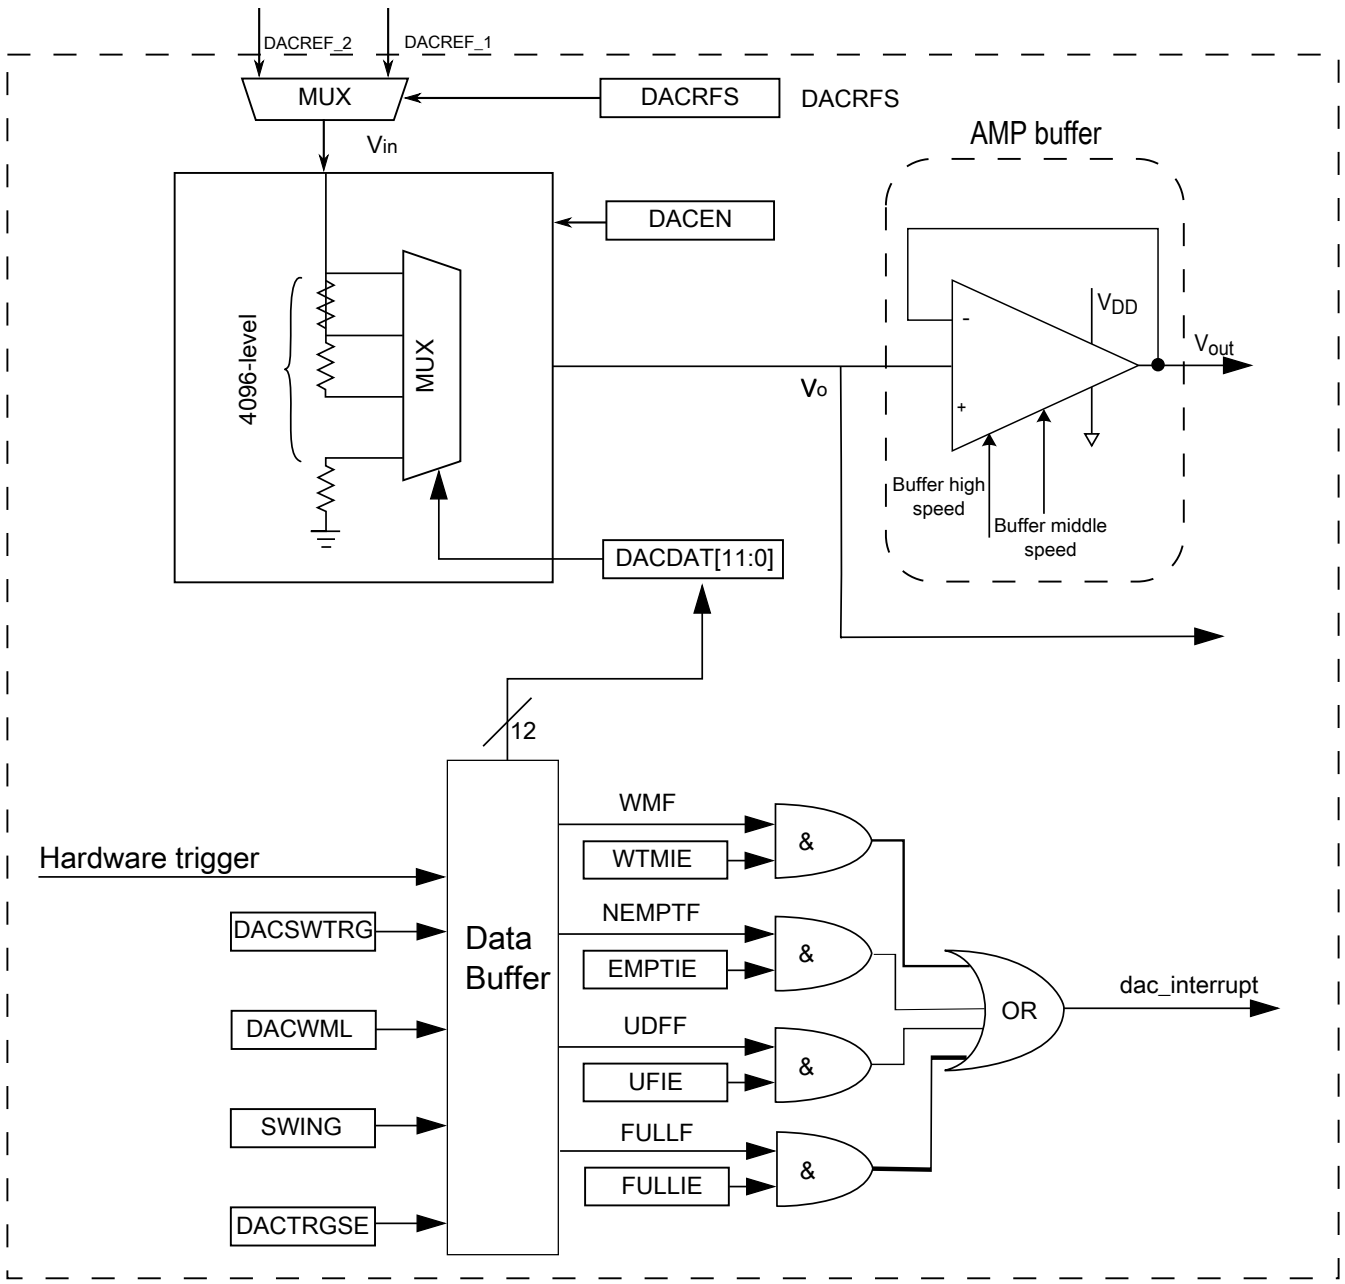

Figure 89-1. DAC block diagram

89.2.2 Features

The features of the DAC module include:

- On-chip programmable reference generator output. The voltage output range is from 1⁄4096 V_{in} to V_{in}, and the step is 1⁄4096 V_{in}, where V_{in} is the input voltage.
- V_{in} can be selected from two reference sources. See Chip-Specific Information section.
- 16 -word data buffer supported with configurable watermark and multiple operation modes
- DMA support

89.3 Functional description

The 12-bit DAC module can select one of the two reference inputs - DACREF_1 and DACREF_2 as the DAC reference voltage, V_{in} by C0[DACRFS]. See the chip-specific DAC information to determine the source options for DACREF_1 and DACREF_2.

When the DAC is enabled, it converts the data in DATA[11:0] or the data from the DAC data buffer to a stepped analog output voltage. The output voltage range is from V_{in} to V_{in}/4096, and the step is V_{in}/4096.

89.3.1 FIFO mode

In FIFO mode, the buffer is organized as a FIFO. For a valid write to the DATA register, the data is put into the FIFO, and the write pointer is automatically incremented. The module is connected internally to a 32-bit interface. For any 16-bit or 8-bit FIFO access, address bit[1] needs to be 0; otherwise, the write is ignored. A successful 32-bit FIFO write increases the write pointer by one.

For an 8-bit write, the LSB determines which byte lane is written to. Only if both the byte lanes are written to, will the write pointer increase. The user needs to ensure that an 8-bit access is done in pair, and both the upper and lower bytes are written. There is no priority for which byte is written to first.

FIFO mode needs to be enabled with DACCR[FIFOEN].

89.3.2 DAC data buffer operation

When the DAC FIFO is disabled, and the one entry buffer is enabled, the DAC converts the data in the buffer to analog output voltage. Any write to the DATA register will replace the data in the buffer and push data to analog conversion without trigger support.

When the IP interface bus access (IPS) is in write state, the write speed of DATA[DATA0] is high. However, the analog part of the DAC cannot convert data at the same speed. Therefore, the multi write speed limit needs to be defined in the firmware.

89.3.3 DAC interrupts

There are several interrupts and associated flags that can be configured for the DAC buffer.

FIFO request flag

The FIFO request flag is set based on the number of entries in the FIFO and the FIFO watermark configuration. This flag is set when the number of entries in any of the enabled FIFOs is less than or equal to the FIFO watermark configuration and is automatically cleared when the number of entries in FIFO is greater than the FIFO watermark configuration. The FIFO request flag can generate an interrupt or a DMA request.

FIFO warning flag

The FIFO warning flag is set based on the number of entries in the FIFO. The empty flag and full flags are both warning flags. The FIFO warning flag can generate an interrupt, or a DMA request (for empty flag only).

FIFO error flag

The FIFO error flag is set when overflow and underflow happens.

89.3.4 DMA operation

When DMA is enabled, DMA requests are generated instead of interrupt requests. The DMA Done signal clears the DMA request.

The status register flags are still set and are cleared automatically when the DMA completes.

89.3.5 Resets

During reset, the DAC is configured in the default mode and is disabled.

89.3.6 Low-Power mode operation

The following table shows the wait mode and the stop mode operation of the DAC module.

Table 89-2. Modes of operation

Modes of operation	Description
Wait mode	The DAC will operate normally, if enabled.
Stop mode	If enabled, the DAC module continues to operate normally, with the hardware trigger initiating the conversion.

NOTE

The assignment of module modes to core modes is chip-specific. For module-to-core mode assignments, see the chapter that describes how modules are configured.

89.3.7 Background Debug Mode Operation

When the microcontroller is in active background debug mode, the DAC continues to operate normally.

89.4 Memory map/register definition

The DAC has registers to control analog comparator and programmable voltage divider to perform the digital-to-analog functions.

89.4.1 DAC register descriptions

89.4.1.1 DAC memory map

DAC base address: 4006_4000h

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)
0	Version Identifier Register (VERID)	32	RO	0100_0000
4	Parameter Register (PARAM)	32	RO	0000_0003
8	DAC Data Register (DATA)	32	WO	0000_0000
C	DAC Status and Control Register (CR)	32	RW	0000_0002
10	DAC FIFO Pointer Register (PTR)	32	RO	0000_0000
14	DAC Status and Control Register 2 (CR2)	32	RW	0000_0000

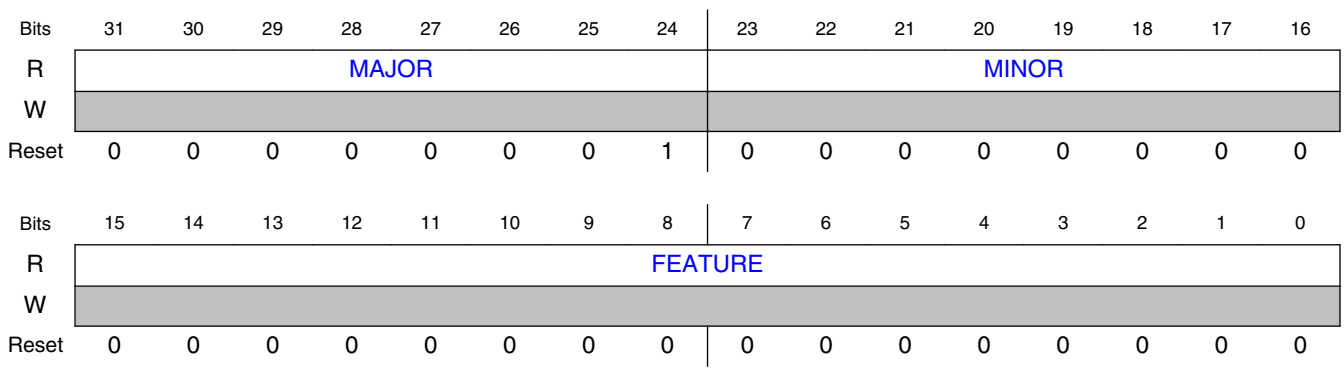
89.4.1.2 Version Identifier Register (VERID)

The Version ID register indicates the version integrated for this instance on the device.

89.4.1.2.1 Offset

Register	Offset
VERID	0h

89.4.1.2.2 Diagram



89.4.1.2.3 Fields

Field	Description
31-24	Major version number
MAJOR	This read-only field returns the major version number for the module specification.
23-16	Minor version number

Table continues on the next page...

Field	Description
MINOR	This read-only field returns the minor version number for the module specification.
15-0 FEATURE	Feature Identification Number This read-only field returns the feature set number. 0000000000000000 - Standard feature set 0000000000000001 - C40 feature set 0000000000000010 - 5V DAC feature set 0000000000000100 - ADC BIST feature set

89.4.1.3 Parameter Register (PARAM)

The Parameter register indicates the feature parameters for this instance on the device.

89.4.1.3.1 Offset

Register	Offset
PARAM	4h

89.4.1.3.2 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	0													FIFOSZ		
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1

89.4.1.3.3 Fields

Field	Description
31-3 —	Reserved
2-0	FIFO size

Field	Description
FIFOSZ	The number of words in the DAC FIFO is 2^(FIFOSZ+1). 000 - FIFO depth is 2 001 - FIFO depth is 4 010 - FIFO depth is 8 011 - FIFO depth is 16 100 - FIFO depth is 32 101 - FIFO depth is 64 110 - FIFO depth is 128 111 - FIFO depth is 256

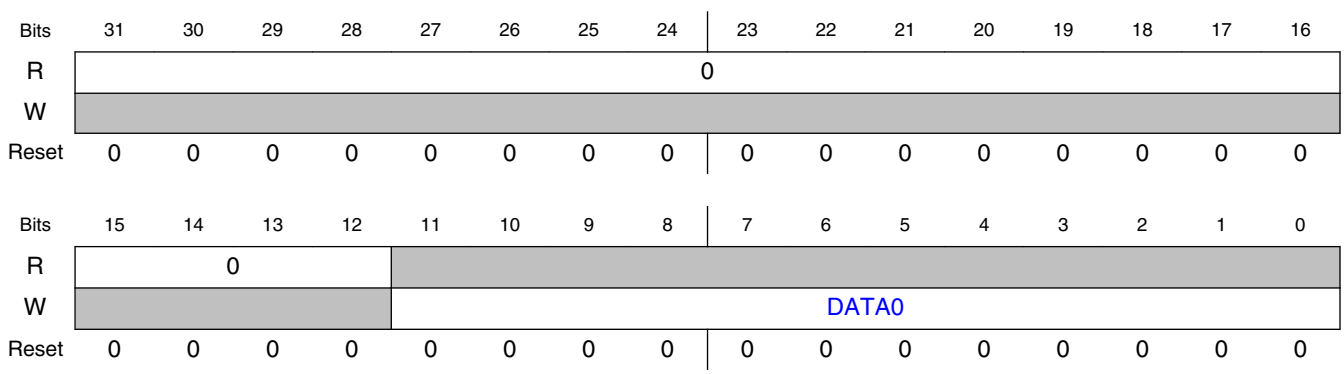
89.4.1.4 DAC Data Register (DATA)

The DAC Data Register holds the entry of FIFO in FIFO mode. It also works as the data buffer for buffer mode.

89.4.1.4.1 Offset

Register	Offset
DATA	8h

89.4.1.4.2 Diagram



89.4.1.4.3 Fields

Field	Description
31-12	Reserved

Table continues on the next page...

Field	Description
—	
11-0 DATA0	FIFO DATA0

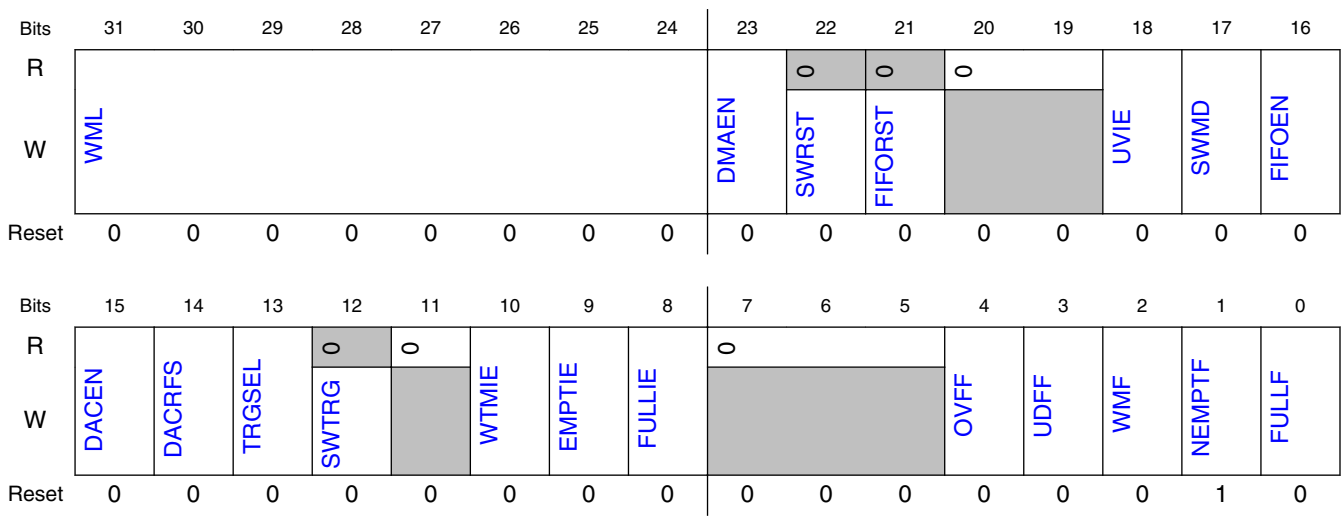
89.4.1.5 DAC Status and Control Register (CR)

The DAC Status and Control Register contains configuration options for the DAC operation, such as DMA and interrupt, trigger select and FIFO mode select. It also includes the FIFO status flags.

89.4.1.5.1 Offset

Register	Offset
CR	Ch

89.4.1.5.2 Diagram



89.4.1.5.3 Fields

Field	Description
31-24 WML	Watermark Level Select MAX is the FIFO size.

Table continues on the next page...

Field	Description
	NOTE: If the FIFO depth is 2, then all settings are treated the same. That is, if the FIFO is not full, the watermark status bit and NEMPTF will be set. One of the status bits maybe needed for DMA or IRQ request.
23 DMAEN	DMA Enable Select 0 - DMA is disabled. 1 - DMA is enabled. When DMA is enabled, the DMA request will be generated by original interrupts. The interrupts will not be presented on this module at the same time.
22 SWRST	Software reset Resets all internal logic and registers, in case of any failure during the Low-power mode. This field is written to only to trigger reset, self clear, or read 0.
21 FIFORST	FIFO Reset Resets the FIFO pointers. Reading this field will always return zero. FIFO pointers should only be reset when the DAC is disabled. This field can be used to configure both pointers to the same address to reset the FIFO as empty. This field is written to only to trigger reset, self clear, or read zero. 0 - No effect 1 - FIFO reset
20-19 —	Reserved
18 UVIE	Underflow and overflow interrupt enable 0 - Underflow and overflow interrupt is disabled. 1 - Underflow and overflow interrupt is enabled.
17 SWMD	DAC FIFO Mode Select In Swing back mode, the FIFO must be set up such that the FIFO is full. In Swing back mode, a trigger changes the read pointer to make it swing between the FIFO Full and Nearly Empty state. That is, the trigger increases the read pointer till FIFO is nearly empty and decreases the read pointer till the FIFO is full, and so on. 0 - Normal mode 1 - Swing back mode
16 FIFOEN	FIFO Enable 0 - FIFO is disabled and only one level buffer is enabled. Any data written from this buffer goes to conversion. 1 - FIFO is enabled. Data will first read from FIFO to buffer then go to conversion.
15 DACEN	DAC Enable Starts the Programmable Reference Generator operation. 0 - The DAC system is disabled. 1 - The DAC system is enabled.
14 DACRFS	DAC Reference Select 0 - The DAC selects DACREF_1 as the reference voltage. 1 - The DAC selects DACREF_2 as the reference voltage.
13 TRGSEL	DAC Trigger Select 0 - The DAC hardware trigger is selected. 1 - The DAC software trigger is selected.

Table continues on the next page...

Field	Description
12 SWTRG	DAC Software Trigger Active high. This is a write-only field, which always reads 0. If DAC software trigger is selected and FIFO is enabled, writing 1 to this field will advance the FIFO read pointer once. **NOTE:** It is not suggested to adopt hardware trigger and software trigger in mixed use, during continuous conversions. 0 - The DAC soft trigger is not valid. 1 - The DAC soft trigger is valid.
11 —	Reserved
10 WTMIE	Watermark Interrupt Enable 0 - Watermark interrupt is disabled. 1 - Watermark interrupt is enabled.
9 EMPTIE	Nearly Empty Interrupt Enable 0 - FIFO Nearly Empty interrupt is disabled. 1 - FIFO Nearly Empty interrupt is enabled.
8 FULLIE	Full Interrupt Enable 0 - FIFO Full interrupt is disabled. 1 - FIFO Full interrupt is enabled.
7-5 —	Reserved
4 OVFF	Overflow Flag This is the FIFO overflow status flag. This flag indicates that more data has been written into FIFO than it can hold. This field asserts regardless of the value of UVIE. However, an interrupt is issued to the host only if UVIE is set. This flag is cleared by writing a 1 to it. 0 - No overflow has occurred since the last time the flag was cleared. 1 - At least one FIFO overflow has occurred since the last time the flag was cleared.
3 UDFF	Underflow Flag This is the FIFO underflow status flag. If this field is set, it means that there is a new trigger after NEMPTF is set. This field asserts regardless of the value of UVIE. However, an interrupt is issued to the host only if UVIE is set. This flag is cleared by writing a 1 to it. 0 - No underflow has occurred since the last time the flag was cleared. 1 - At least one trigger underflow has occurred since the last time the flag was cleared.
2 WMF	FIFO Watermark Status Flag This field is set if the remaining FIFO data is less than or equal to the watermark setting. It is cleared automatically by writing data into FIFO by DMA or CPU. Write to this bit is ignored in FIFO mode. 0 - The DAC buffer read pointer has not reached the watermark level. 1 - The DAC buffer read pointer has reached the watermark level.
1 NEMPTF	Nearly Empty Flag This is the FIFO nearly empty flag. It is set when only one data remains in FIFO. 0 - More than one data is available in the FIFO. 1 - One data is available in the FIFO.

Table continues on the next page...

Field	Description
0 FULLF	Full Flag This is the FIFO Full status bit. This means that the FIFO read pointer equals the write pointer, because of the write pointer increase. This field is cleared if any DAC trigger is making the DAC read pointer increase. Any write to this field is ignored in FIFO mode. 0 - FIFO is not full. 1 - FIFO is full.

89.4.1.6 DAC FIFO Pointer Register (PTR)

The DAC FIFO Pointer Register contains the FIFO read pointer and write pointer.

89.4.1.6.1 Offset

Register	Offset
PTR	10h

89.4.1.6.2 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0								DACRFP

89.4.1.6.3 Fields

Field	Description
31-24 —	Reserved
23-16 DACRFP	DACRFP This is the FIFO read pointer.

Table continues on the next page...

Field	Description
	NOTE: The read pointer is later than the trigger for one cycle. After the conversion finishes and the next trigger comes, then the read pointer updates in the hardware trigger mode.
15-8 —	Reserved
7-0 DACWFP	DACWFP This is the FIFO write pointer. It's value is initially set to equal the read pointer value automatically, and the FIFO status is empty. Both write pointer and read pointer in FIFO mode do not change by IPS read access.

89.4.1.7 DAC Status and Control Register 2 (CR2)

The DAC Status and Control Register 2 contains configuration options for the analog DAC.

NOTE

For CR2[6:4] (IREF and IREF1), it is suggested to enable one of the bits to reduce power. If more than one bit is selected, the power consumption will increase but the conversion rate will also speed up.

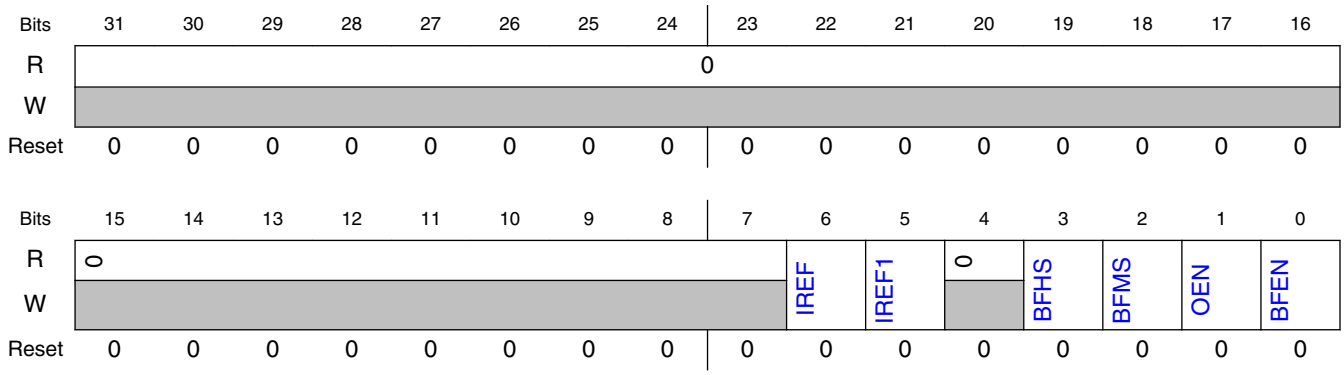
NOTE

IREF works in all modes, but the operation mode of IREF1 depends on PMC.

89.4.1.7.1 Offset

Register	Offset
CR2	14h

89.4.1.7.2 Diagram



89.4.1.7.3 Fields

31-7 —	Reserved
6 IREF	Internal Current Reference Select 0 - Internal Current Reference not selected 1 - Internal Current Reference selected
5 IREF1	Internal ZTC (Zero Temperature Coefficient) Current Reference Select 0 - Internal ZTC Current Reference not selected 1 - Internal ZTC Current Reference selected
4 —	Reserved
3 BFHS	Buffer High Speed Select 0 - Buffer high speed not selected 1 - Buffer high speed selected
2 BFMS	Buffer Middle Speed Select 0 - Buffer middle speed not selected 1 - Buffer middle speed selected
1 OEN	Optional Enable 0 - Output buffer is not bypassed 1 - Output buffer is bypassed
0 BFEN	Buffer Enable 0 - Opamp is not used as buffer 1 - Opamp is used as buffer

Appendix A
Revision History

A.1 Substantive changes from revision 4 to revision 5

Substantive changes from revision 4 to revision 5 are as follows:

A.1.1 Interrupts and DMA Events Revision History

No substantive changes

Topic Cross-Reference	Change Description
CM4 interrupts	Updated IRQ 87 as reserved.
CM7 interrupts	Updated IRQ 87 as reserved.

A.1.2 System Boot Revision History

Topic Cross-Reference	Change Description
FlexSPI Configuration Block and Full FlexSPI RAM configuration block	Updated Description of Bit 7 for controllerMiscOption
Boot mode pin settings	Updated the section
GPIO boot overrides	Removed Package pin GPIO_LPSR_02 and 03
FlexSPI NOR Dual Image Boot	Added this section
Image vector table structure	Updated Image vector table structure
HAB API vector table addresses	Updated the section

A.1.3 IOMUXC Revision History

Topic Cross-Reference	Change Description
IOMUXC register descriptions	Updated Pull Up/Down Config Field to Pull Select and Pull Select Field to Pull Enable for all instances.
IOMUXC register descriptions	
-	GPIO0 and GPIO25 are added in IOMUXC LPSR GPR register description section.
-	Removed all references of "keep" from IOMUXC LPSR register description.
-	Removed all references of "Highz" from IOMUXC register description section.

A.1.4 GPIO Revision History

Topic Cross-Reference	Change Description
	Removed Schmitt trigger, Drive strength, and Open drain topics
GPIO pad structure	Updated GPIO pad functional diagram

A.1.5 CCM Revision History

Topic Cross-Reference	Change Description
	• Updated "Trustzone, and Domain" to "Access control schemes" and "Trustzone authentication" to "access authentication" • In CCM memory map, updated the description of LOCK_TZ bit. • Open bit 0 in GPR_PRIVATE1 register
Analog IP (AI) Interface	Updated Step3 for write operaton and Step2 for read operation
System Clocks	Updated System Clocks Table as gptX_ipg_clk_32k Clook Root to OSC32K and gptX_igp_clk_highfreq Clook Root to "ref_1m_clk (1MHz clock generated from the 400MHz RC oscillator)"
PLL Enable Sequence	Updated PLL enable sequence

A.1.6 XTALOSC Revision History

Topic Cross-Reference	Change Description
	• Reserved BYPASS_EN bit for 24MHz OSC Control Register • Reserved CLKGATE_400MEG bit for 400MHz RCOSC Control1 Register • Updated System Clocks Table for gpio13_ipg_clk_s

A.1.7 PMU Revision History

Topic Cross-Reference	Change Description
	• Updated PMU_LDO_LPSR_ANA_REGISTER

A.1.8 DCDC Revision History

Topic Cross-Reference	Change Description
Recommended configuration	Updated the Recommended configuration.
-	Updated the section "Application mode".

A.1.9 XECC Revision History

No substantive changes

Topic Cross-Reference	Change Description
ECC Region 0 Base Address (ECC_BASE_ADDR0)	Updated description for ECC_BASE_ADDR0

A.1.10 uSDHC Revision History

Topic Cross-Reference	Change Description
	• Added a note in chip-specific section

A.1.11 RDC Revision History

Topic Cross-Reference	Change Description
Chip-specific RDC Information	Added a note "When a buffered write..."

A.1.12 PXP Revision History

Topic Cross-Reference	Change Description
	• Updated Processed Surface (PS) Control Register • Added a note below PXP_CSC1_COEF0[YCBCR_MODE] • •

A.1.13 FlexCAN Revision History

Topic Cross-Reference	Change Description
Chip-specific FLEXCAN information	Added a note

A.1.14 LPSPI Revision History

Topic Cross-Reference	Change Description
-	• Updated "Signal description" section • Added Host Request feature

A.1.15 FlexPWM Revision History

- Added a note in chip-specific section.

A.1.16 CPU Watchdog Timer (WDOG 3,4) Revision History

Topic Cross-Reference	Change Description
	• Added chip-specific information for clock source

Draft — A draft status on a document indicates that the content is still under internal review and subject to formal approval, which may result in modifications or additions. NXP Semiconductors does not give any representations or warranties as to the accuracy or completeness of information included in a draft version of a document and shall have no liability for the consequences of use of such information.

Disclaimers

Limited warranty and liability — Information in this document is believed to be accurate and reliable. However, NXP Semiconductors does not give any representations or warranties, expressed or implied, as to the accuracy or completeness of such information and shall have no liability for the consequences of use of such information. NXP Semiconductors takes no responsibility for the content in this document if provided by an information source outside of NXP Semiconductors.

In no event shall NXP Semiconductors be liable for any indirect, incidental, punitive, special or consequential damages (including - without limitation - lost profits, lost savings, business interruption, costs related to the removal or replacement of any products or rework charges) whether or not such damages are based on tort (including negligence), warranty, breach of contract or any other legal theory.

Notwithstanding any damages that customer might incur for any reason whatsoever, NXP Semiconductors' aggregate and cumulative liability towards customer for the products described herein shall be limited in accordance with the Terms and conditions of commercial sale of NXP Semiconductors.

Right to make changes — NXP Semiconductors reserves the right to make changes to information published in this document, including without limitation specifications and product descriptions, at any time and without notice. This document supersedes and replaces all information supplied prior to the publication hereof.

Applications — Applications that are described herein for any of these products are for illustrative purposes only. NXP Semiconductors makes no representation or warranty that such applications will be suitable for the specified use without further testing or modification.

Customers are responsible for the design and operation of their applications and products using NXP Semiconductors products, and NXP Semiconductors accepts no liability for any assistance with applications or customer product design. It is customer's sole responsibility to determine whether the NXP Semiconductors product is suitable and fit for the customer's applications and products planned, as well as for the planned application and use of customer's third party customer(s). Customers should provide appropriate design and operating safeguards to minimize the risks associated with their applications and products.

NXP Semiconductors does not accept any liability related to any default, damage, costs or problem which is based on any weakness or default in the customer's applications or products, or the application or use by customer's third party customer(s). Customer is responsible for doing all necessary testing for the customer's applications and products using NXP Semiconductors products in order to avoid a default of the applications and the products or of the application or use by customer's third party customer(s). NXP does not accept any liability in this respect.

Terms and conditions of commercial sale — NXP Semiconductors products are sold subject to the general terms and conditions of commercial sale, as published at https://www.nxp.com/profile/terms, unless otherwise agreed in a valid written individual agreement. In case an individual agreement is concluded only the terms and conditions of the respective agreement shall apply. NXP Semiconductors hereby expressly objects to applying the customer's general terms and conditions with regard to the purchase of NXP Semiconductors products by customer.

Suitability for use in automotive applications — This NXP product has been qualified for use in automotive applications. If this product is used by customer in the development of, or for incorporation into, products or services (a) used in safety critical applications or (b) in which failure could lead to death, personal injury, or severe physical or environmental damage (such products and services hereinafter referred to as "Critical Applications"), then customer makes the ultimate design decisions regarding its products and is solely responsible for compliance with all legal, regulatory, safety, and security related requirements concerning its products, regardless of any information or support that may be provided by NXP. As such, customer assumes all risk related to use of any products in Critical Applications and NXP and its suppliers shall not be liable for any such use by customer. Accordingly, customer will indemnify and hold NXP harmless from any claims, liabilities, damages and associated costs and expenses (including attorneys' fees) that NXP may incur related to customer's incorporation of any product in a Critical Application.

Export control — This document as well as the item(s) described herein may be subject to export control regulations. Export might require a prior authorization from competent authorities.

HTML publications — An HTML version, if available, of this document is provided as a courtesy. Definitive information is contained in the applicable document in PDF format. If there is a discrepancy between the HTML document and the PDF document, the PDF document has priority.

Translations — A non-English (translated) version of a document, including the legal information in that document, is for reference only. The English version shall prevail in case of any discrepancy between the translated and English versions.

Security — Customer understands that all NXP products may be subject to unidentified vulnerabilities or may support established security standards or specifications with known limitations. Customer is responsible for the design and operation of its applications and products throughout their lifecycles to reduce the effect of these vulnerabilities on customer's applications and products. Customer's responsibility also extends to other open and/or proprietary technologies supported by NXP products for use in customer's applications. NXP accepts no liability for any vulnerability. Customer should regularly check security updates from NXP and follow up appropriately.

Customer shall select products with security features that best meet rules, regulations, and standards of the intended application and make the ultimate design decisions regarding its products and is solely responsible for compliance with all legal, regulatory, and security related requirements concerning its products, regardless of any information or support that may be provided by NXP.

NXP has a Product Security Incident Response Team (PSIRT) (reachable at PSIRT@nxp.com) that manages the investigation, reporting, and solution release to security vulnerabilities of NXP products.

NXP B.V. — NXP B.V. is not an operating company and it does not distribute or sell products.
