For the U and V components of Ps, there are no samples present in the column position 1. The bilinear filter uses chroma components located at [0,0], [2,0], [0,1] and [2,1]. Since the chroma components are not sub sampled vertically, the remainder used to combine pixels vertically is Ry=0.5 (the same as for Y). However, horizontally, the scaling engine shifts the remainder by a factor of 2. So an X axis step function value of X=1.5 has a remainder Rx=0.75. Source chroma values are not replicated, they are completely interpolated using the four nearest chroma samples to approximate U and V at Ps.

52.3.1.6 YUV 4:2:0 Image Scaling

The following figure illustrates the positioning of YUV samples for the 4:2:0 formats. Chroma is sub sampled both horizontally and vertically. In this format, the chroma frame buffers contain ¼ the data that the luma frame buffers store.

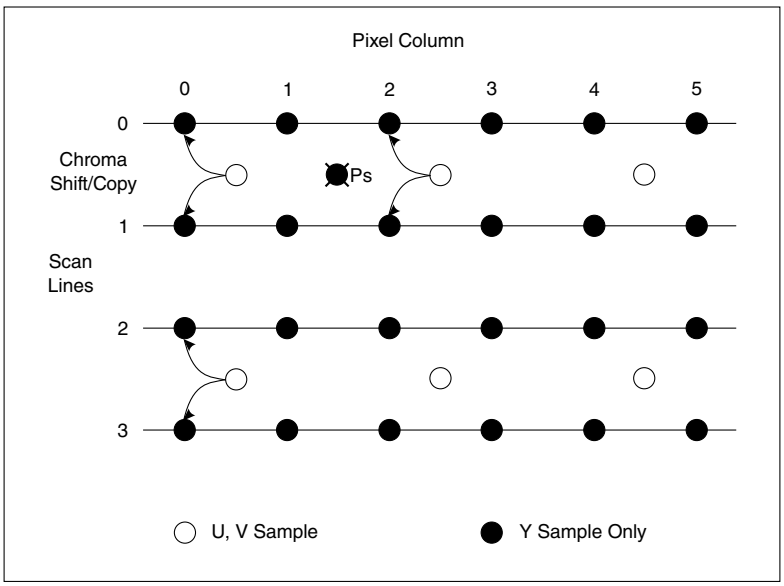

Figure 52-7. YUV Sample Positioning, 4:2:0

The Y output component for all scaled pixels in 4:2:0 formats are the same as for the 4:2:2 pixel formats.

The U and V output components have two considerations when computing the output pixel Ps.

1. All chroma samples from the input source image are shifted left and up by ½ a sample position of the input pixel matrix.
2. Odd scan lines are replicated using the previous even chroma scan line values. So, output image chroma values that map between even to odd scan lines are replicated in the vertical axis. In contrast, output image chroma values between odd to even scan lines are interpolated vertically.

The chroma values are interpolated horizontally as in the 4:2:2 pixel format.

As an example, consider the interpolated pixel Ps in the 4:2:0 diagram above. For the Y component, the interpolated output luma is a function of the Y values in the source frame buffer at position [1,0], [2,0], [1,1], [2,1].

For the U and V interpolated samples, the chroma values on scan line position 0.5 are shifted so that they coincide with the even luma sample points. They are also replicated so that a single chroma scan line is used twice. The chroma scan line at 0.5 is replicated to represent the 4:2:2 sample points for scan line 0 and 1. The chroma scan line at 2.5 is replicated to represent the 4:2:2 sample points for scan line 2 and 3. This pattern of chroma replication occurs for the entire source frame buffer during the scaling operation.

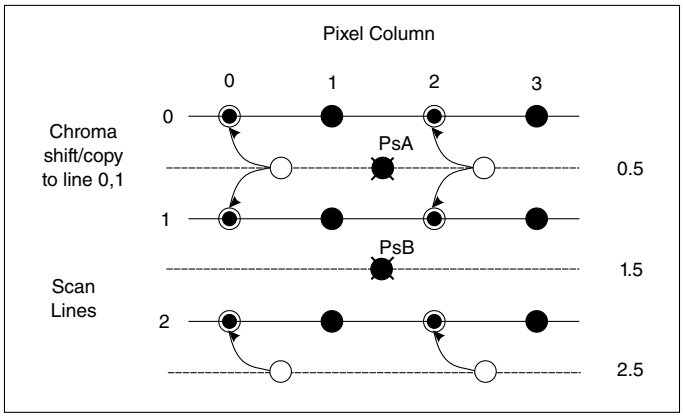

Figure 52-8. Scaled Chroma Computation Examples

The preceding diagram has two examples for the computation of the scaled chroma output pixel. For chroma at output position PsA (vertical position 0.5), interpolation occurs in the X axis using chroma values at column 0 and column 2. However, since line 0 and line 1 have equal chroma values due to chroma line replication, scaling in the Y axis results in replication of chroma values.

For chroma at output position PsB (vertical position 1.5), interpolation occurs in both the X and Y axis. The Y axis is an interpolation since the chroma values copied to scan line 1 and 2 and not the same.

In summary, any output image pixels that map to an odd scan line above and an even scan line below are interpolated vertically. Output image pixels that map to an even scan line above and an odd scan line below are replicated vertically.

52.3.1.7 RGB/YUV444 Image Scaling

For all RGB formats, the RGB pixels are converted up to RGB888 with 8 bits per each color component.

Then each color component is passed to the scaling engine and each component is treated in the same manor. The RGB scaling operation is the same as for the Y scaling operation described in the preceding sections. Also, YUV444 contains a byte for each color plane at each pixel location, so all three color components are scaled in the same manner.

52.3.1.8 Color Space Conversion (CSC)

The CSC unit converts pixels between color spaces. The CSC1 unit is right after the scaling unit and is dedicated to converting from YUV to RGB. All coefficients are programmed as two's compliment numbers and CSC unit can be bypassed if conversion is not desired in the pixel data path.

52.3.1.9 CSC1 Operation

The CSC1 module receives scaled YUV/YCbCr444 pixels from the scale engine and converts the pixels to the RGB888 color space only if CSC1 is enabled.

The CSC1 module will convert only to the RGB color space and it can be bypassed to allow YUV pixels through the data path. These pixels are loaded into the pixel FIFO for processing by subsequent modules in the pixel data path.

The following equations are used to perform YUV/YCbCr -> RGB conversion. The constants will be stored in the PXP control registers as two's compliment values to allow flexibility in the implementation and to allow for differences in the video encode and decode operations. In addition, this provides a software mechanism to manipulate brightness or contrast.

R = C0(Y+Yoffset) + C1(V+UVoffset)

G = C0(Y+Yoffset) + C3(U+UVoffset) + C2(V+UVoffset)

B = C0(Y+Yoffset) + C4(U+UVoffset)

Note: In the equations above, U and V are synonymous with Cb and Cr in regards to the color space format of the source frame buffer.

Saturation of each color channel is checked and corrected for excursions outside the nominal YUV/YCbCr color spaces. Overflow for the three channels are saturated at 0x255 and underflow is saturated at 0x00.

The table below indicates the expected coefficients for YUV and YCbCr modes of operation:

Coefficient	YUV	YCbCr
Yoffset	0x000	0x1F0 (-16)
UVoffset	0x000	0x180 (-128)
C0	0x100 (1.00)	0x12A (1.164)
C1	0x123 (1.140)	0x198 (1.596)
C2	0x76B (-0.581)	0x730 (-0.813)
C3	0x79B (-0.394)	0x79C (-0.392)

Table continues on the next page...

C4	0x208 (2.032)	0x204 (2.017)

52.3.1.10 YUV versus YCbCr Support

By default, the PXP color space coefficients are set to support the conversion of YUV data to RGB data.

If YCbCr input is present, software must change the coefficient registers appropriately (see the register definitions for values). Software must also set the YCBCR_MODE bit in the COEFF0 register to ensure proper conversion of YUV versus YCBCR data.

52.3.1.11 Alpha Blending/Color Key

Regardless of pixel input format, the PS and AS pixels are normalized to 32-bits, organized as one alpha and three data bytes. Alpha blending occurs in the RGB space, if blending is required, PS pixels should be converted to RGB space. If no alpha blending is required, then YUV pixels can bypass the alpha blending ALU without color space conversion. All pixels are processed by the pixel ALU, but the ALU operations can be disabled to achieve pixel pass through for either PS or AS source pixels.

52.3.1.12 Alpha Blend

The alpha value for an individual pixel represents a mathematical weighting factor applied to the AS pixel. An alpha value of 0x00 corresponds to a transparent pixel and a value of 0xFF corresponds to an opaque pixel.

The effective alpha value for an AS pixel is determined by the AS_CTRL[ALPHA] and AS_CTRL[ALPHA_CTRL] register fields. If AS_CTRL[ALPHA_CTRL] = ALPHA_OVERRIDE , the alpha value for the pixel is taken from the AS_CTRL[ALPHA] . This can be useful for applying a constant alpha to an entire image or for image formats that don't include an alpha value. If AS_CTRL[ALPHA_CTRL] = ALPHA_MULTIPLY, the pixel's alpha value will be multiplied by the pixel's ALPHA value in order to allow scaling of the pixel's alpha or to provide better control for pixel formats such as ARGB1555, which only contains a single bit of alpha.

For each color channel, the equation used to blend two source pixels is defined below:

Gá = PIO programmed global alpha (8-bit value).
Eá = Embedded alpha associated with AS pixel.
á = (Gá * Eá + 0x80)/128, and á doesn't exceed a value of 128

The result for the red channel as an example:

R[7:0] = (á * PS.r) + ((1 - á) * AS.r)

When á is 0xff, the PS pixel will not be blended with the AS pixel, but PS will be passed as the output pixel and will not be blended with AS. In this case, AS will be discarded. Likewise, if á is 0x00 for a given pixel, AS will be loaded as the output pixel.

AS_CTRL[ALPHA_INVERT] provides the option to invert the final alpha value. This essentially inverts the effect the alpha value has on the AS and PS blending operation.

52.3.1.12.1 Porter-Duff Alpha Blend

Porter-Duff blend includes 12 blending modes to describe digital image composite. These processes include:

- Clear
- Source Only
- Destination Only
- Source Over
- Source In
- Source Out
- Source Atop
- Destination Over
- Destination In
- Destination Out
- Destination Atop
- XOR

Through these processes it can achieve any 2D image composite.

To control the blending modes, please see the following picture. Please see PORTER_DUFF_CTRL register for more details.

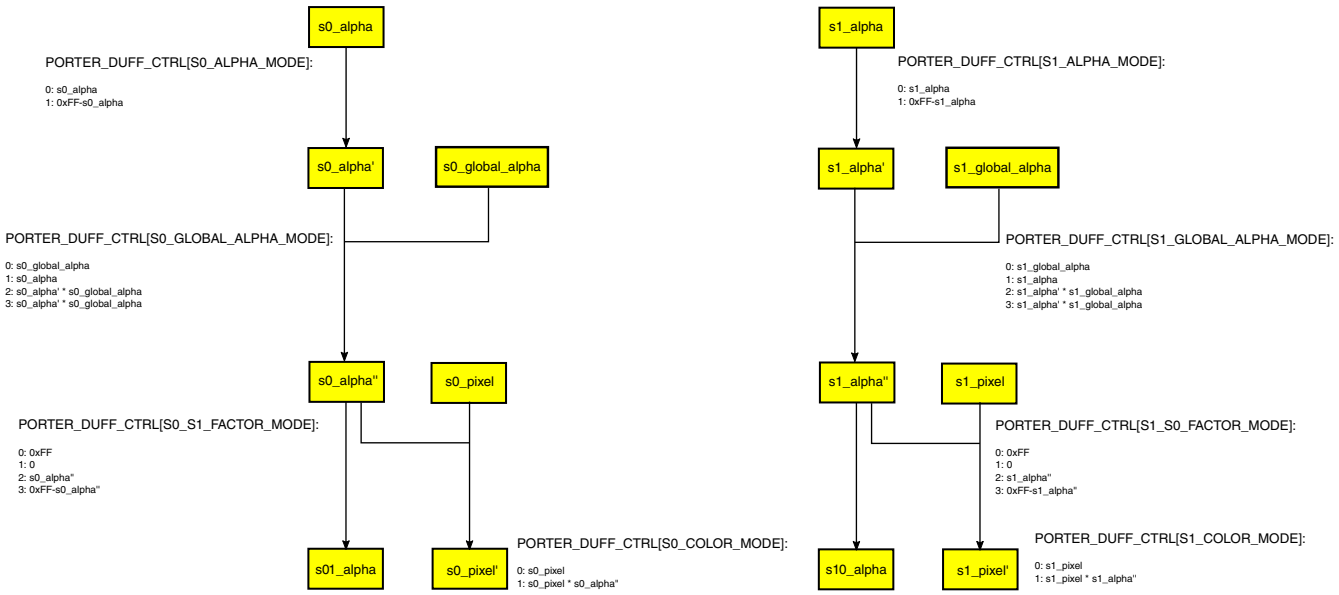

Figure 52-9. Porter-Duff Alpha Blend

image output = s01_alpha × s1_pixel' + s10_alpha × s0_pixel'

alpha output = s10_alpha × s0_alpha'' + s01_alpha × s1_alpha''

NOTE

s0 refer to PS and s1 refer to AS.

52.3.1.13 Color Key

The color key function is provided to create transparent effects on the output pixel.

Color keying is applied on the input pixels after they are converted to 8-bits for each red, green, and blue color channels (color keys are not applied directly to 16-bit pixel formats but to their corresponding 24-bit representation). A color key range is programmable for both PS and AS pixels. If the PS 24-bit pixel is within the PS color key range, then AS is passed through the pixel pipeline. In this case, alpha blending does NOT occur. Conversely, if AS is within AS color key range, then AS is passed via the PXP data pipeline. If both PS and AS color key tests pass, then the back ground color register is passed onto following PXP processing components in the pipeline.

The condition for color keying to be satisfied is:

CK0.r.low <= PS.r <= CK0.r.high

CK0.g.low <= PS.g <= CK0.g.high

CK0.b.low <= PS.b <= CK0.b.high

For example, if the "red" 8-bit value for the PS pixel (or PS.r) is between the color key low and high values (CK0.r.l and CK0.r.h), the condition is true for the red color plane. When All three color planes meet this condition, PS pixel is invisible in output register.

To disable color keying, program the low color key register value to 0xff and the high value to 0x00. This will guarantee that the color key range test will never be true.

52.3.1.14 Rotation

There is a single rotation resource integrated into the PXP. The location of this resource within the PXP data path is programmable. Rotation can occur after compositing the AS and PS buffers in the output stage.

As an alternative configuration, the PS buffer can be rotated and later composited with the AS surface that is not rotated. There is a single configuration bit that provides the configuration of where rotation is implemented within the PXP.

To rotate graphics, the hardware must read pixels in one direction across a frame buffer and write them in a alternate orientation. For the 90 and 270 degree cases, this means that lines of pixels must either be read or written vertically in a frame buffer.

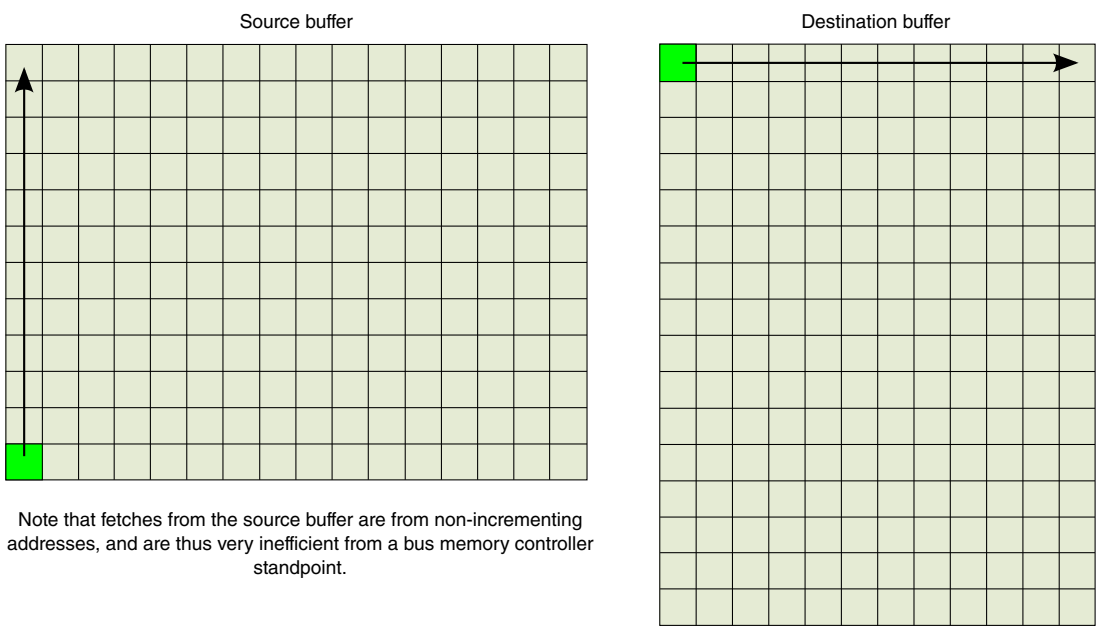

Figure 52-10. Rotation Read and Write

In order to rotate efficiently, multiple columns must be rotated to enable the engine to both fetch and store bursts of pixels, thus improving memory performance. The simplest method of doing this is to operate on square blocks of pixels. To rotate the image, each sub-block of pixels must be rotated by the required rotation angle.

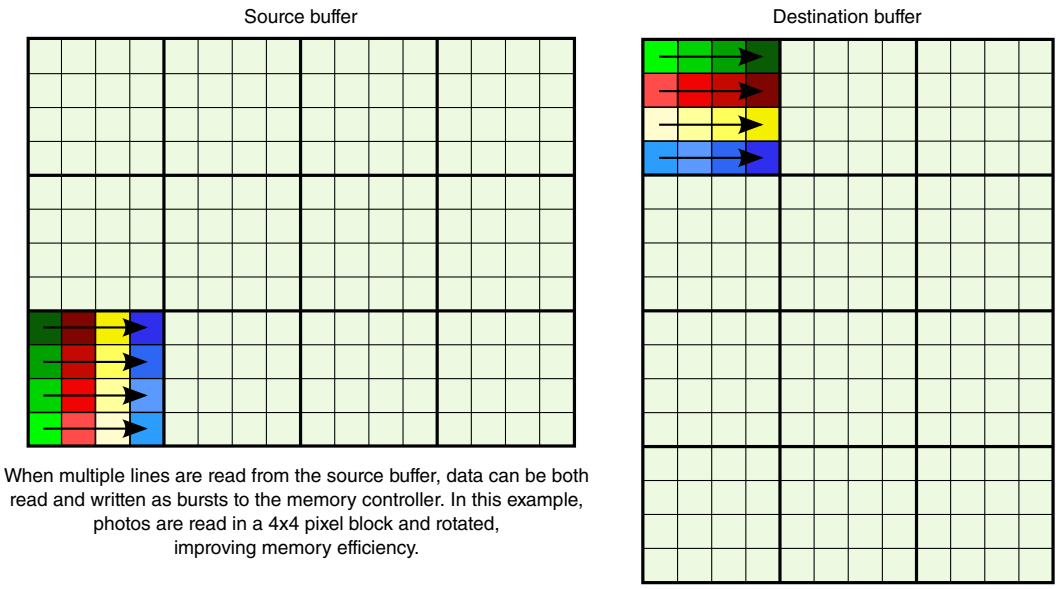

Figure 52-11. Rotated Sub-blocks

To manage the rotation process, the source image can be broken into a grid of sub-blocks that have coordinates as shown in the diagram below. In addition to rotating the sub-block, each block must be translated to a new coordinate location. For each of the rotation angles (0, 90, 180, 270), it is possible to define a simple algorithm for computing the new translated grid address. The hardware must then simply compute the memory address from the base grid address for both load and store operations.

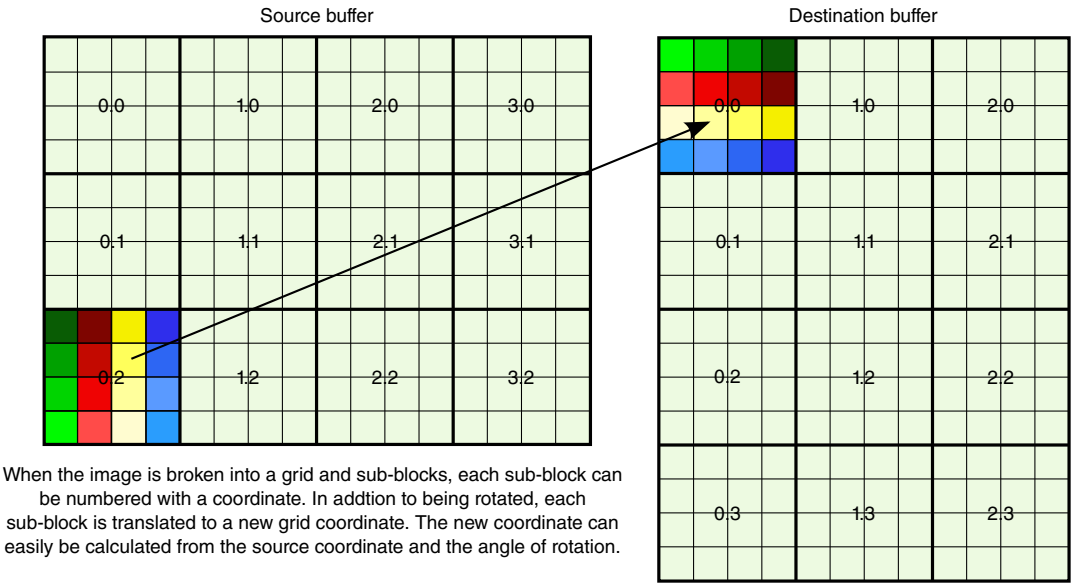

Figure 52-12. Grid of Sub-Blocks with Coordinates

In order to balance the requirements of reasonable burst sizes to the memory controller as well as keep the hardware storage requirements to a minimum, the blending/rotation engine will operate on either 8x8 or 16x16 pixel blocks. When using the Rotate engine with the input fetch engine, you need to program the input fetch engine to work in 8x8 block mode.

NOTE

An important artifact of the PXP is when rotating a source image and the output is NOT divisible by the block size selected. The output engine essentially truncates any output pixels after the desired number of pixels has been written. Since the output buffer is written as a horizontal row of blocks, the incorrect pixels could be truncated and the final output image can look shifted. In the case where the block size is programmed to 8x8, and the output size that is programmed is 12x12, then there is a remainder of 4 pixels that will be truncated in either the X and/or Y axis when the PXP operation is complete. The output will be shifted by 4 pixels in this example. To compensate for this, the source base address needs to be adjusted so the correct pixels get truncated and the image does not look shifted. In this example, with 90 degrees of rotation, the PS base address should be adjusted by 4 times the actual PS base address -(4*pitch).

52.3.1.15 Output Buffer

The output buffer engine accepts data from the PXP pixel pipeline and issues requests to transfer the output pixels to external DRAM or the internal SRAM double buffer row of blocks.

52.3.1.16 Address calculator

Each of the blocks will manage its own fetch address using a common address calculator block that computes real addresses from a base address and relative block offset from the base.

Each block will then perform the multiple line fetches (or stores) required to perform the operation. This hides all the address buffer computations from the processing blocks and allows each block to simply track the coordinate of the block it is working on.

52.3.1.17 Block size selection

The PXP can be configured to process blocks that are either 8x8 pixels or 16x16 pixels with the REG_CTRL[BLOCK_SIZE] control bit.

When selecting a 16x16 pixel block size, the accesses to fetch AS and PS images and write the final frame buffer are more efficient since twice as much data is requested and processed per memory request.

When optimizing the system for memory bandwidth and image processing time, configure the PXP to process 16x16 pixel blocks.

52.3.1.18 Interlaced Video Support

The PXP has some minimal ability to generate interlaced video content from a progressive source. There two available options, based on the bandwidth requirements and how software is managing video frames.

The PXP can either interlace on the input side (by reading every other line of input data) or on the output side (by writing the individual lines of video into two separate fields). Generally, output interleaving should be used since it is the most flexible mode (it allows scaling and full overlay support) and it only requires a single pass of the PXP to generate two separate output fields.

Input interleaving can be beneficial in cases where the PXP is running at 60fps, since it requires fewer fetches to produce the output data. There is no direct hardware support for input interleaving, in that, there is no configuration bit that can be set to alter how the PXP processes a frame for input interleaving. Input interleaving is achieved by simply setting the source frame buffer pitch value to twice the value it would normally be set to for the equivalent progressive frame. The output parameters also need to be consistent with the desired processing effect. For example, the vertical resolution would be set to account for the reduced resolution to process the interlaced input buffers.

52.3.1.19 LCDIF Handshake

The PXP and LCDIF support a mode where the internal SRAM can be used for the frame buffer to minimize external memory bandwidth required.

This is accomplished by creating two buffers in SRAM, a double buffer row of blocks, where each correspond to 8/16-lines of the frame buffer. The buffers must be consecutive and allocated as a single block of data.

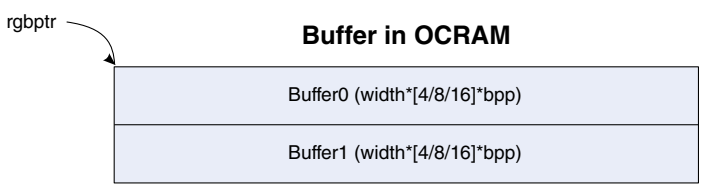

Figure 52-13. Buffer in OCRAM

The storage required can be calculated for an 8x8 block size as

- storage = 16 (lines) * rotated_row_length * pixel_size

and for 16x16 block size as

- storage = 32 (lines) * rotated_row_length * pixel_size

where pixel_size = 4 for 32bpp or 2 for 16bpp modes. The following table lists the storage requirements for common image sizes using 8x8 block size:

Image Size	Storage (16bpp)	Storage (24bpp)	Storage (32bpp)
320x240 (QVGA) - 0/180 rotation	10KB	15KB	20KB
320x240 (QVGA) - 90/270 rotation	7.5KB	11.5KB	15KB
640x480 (VGA) - 0/180 rotation	20KB	30KB	40KB

Table continues on the next page...

640x480 (VGA) - 90/270 rotation	15KB	22.5KB	30KB

The following diagram shows how the minimal rotation buffer would be organized. As the engine and LCD progress down the image, they continually swap roles of filling and emptying each eight-line buffer.

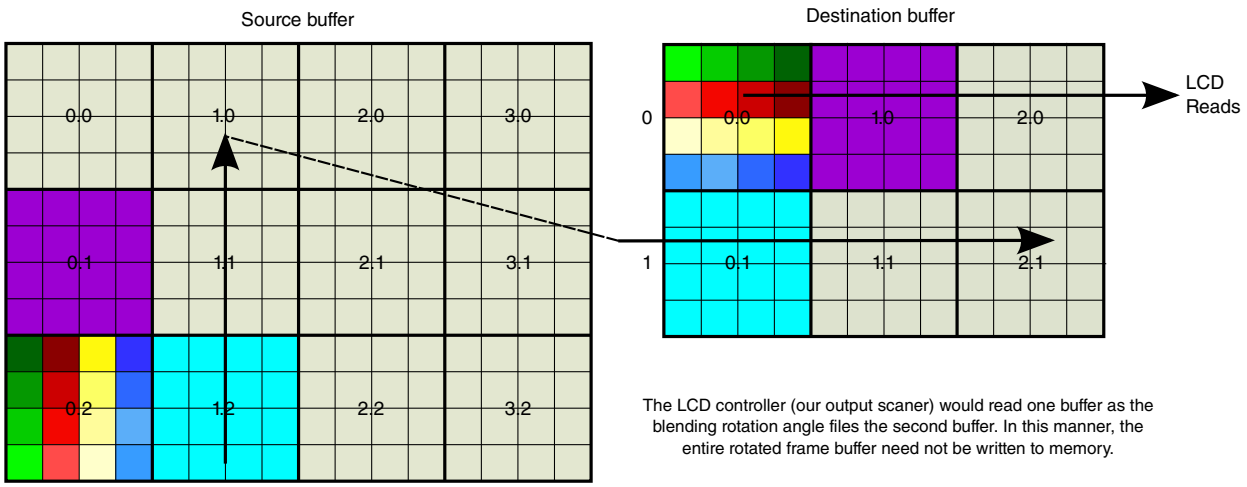

Figure 52-14. Minimal Rotation Buffer Organization

When this mode is enabled, the PXP will process one row of pixel blocks and write the results to the first SRAM buffer (buffer 0). The PXP will then alternate between writing subsequent rows to buffer 0 and buffer 1. After the PXP generates the data for one buffer, the LCDIF will begin reading that buffer and send the contents to the display device. After the LCDIF finishes reading a buffer, it will start displaying from the other buffer while the PXP continues filling the previously processed buffer.

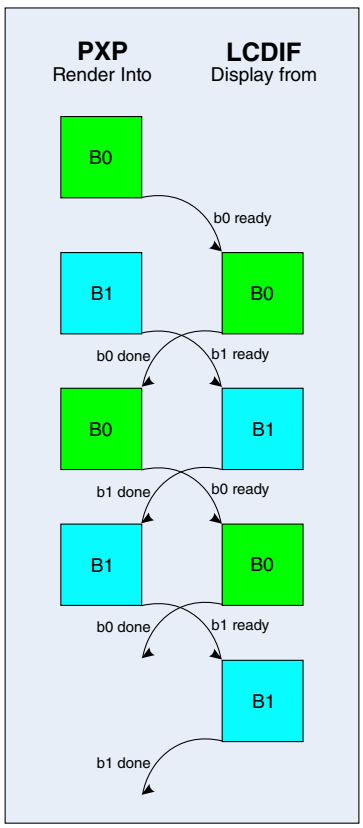

Figure 52-15. PXP and LCDIF Buffer Sharing

To accomplish the buffer sharing, the PXP and LCDIF will maintain buffer status using a pair of handshake signals. When a buffer is filled by the PXP, it will assert the pxp_lcdif_bx_ready (where x is 0 or 1) signal to indicate to the LCDIF that the buffer has valid data. The LCDIF will then release the buffer by asserting the lcdif_pxp_bx_done signal.

The basic protocol is shown in the diagram below:

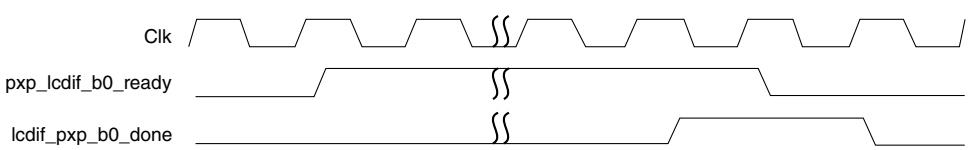

Figure 52-16. Buffer Sharing Protocol

The PXP will continue to assert the bx_ready signal until the corresponding bx_done signal is sampled high for one clock cycle. It will then deassert the bn_ready until the next time the buffer has been filled. After the PXP samples the bx_done signal asserted, it is free to begin filling the buffer with the next block size lines of display data. If a buffer has not been released when the PXP is ready to process data for that buffer, it will suspend rendering operations until the buffer has been released by the LCDIF.

52.3.1.20 LCDIF Abort

When the memory subsystem is not loaded, the PXP should be able to render the buffers faster than the LCDIF can drain the buffers.

It is possible under some scenarios (high LCDIF output rates with high memory latency) that the PXP may not be able to keep up with the LCDIF, even in the SRAM mode of operation. When this happens, the LCDIF will signal that it has completed one of the buffers before the other has been rendered by the PXP. This condition will be detected by the PXP's control logic as an "LCDIF Abort", which will cause the PXP to abort processing in the current row and proceed to the following row. It will acknowledge the abort to the LCDIF by raising the buffer_ready signal for the current buffer to enable the LCDIF to begin displaying the partially-filled buffer. While an abort will create artifacts in the video display, it does minimize the artifacts by limiting them to the remaining pixels blocks in the current row versus ruining the entire frame buffer.

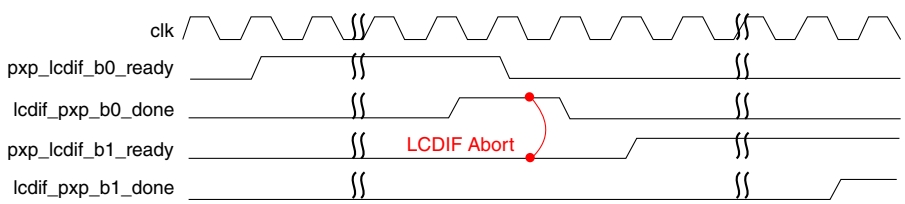

Figure 52-17. LCDIF Abort

52.3.1.21 Theory of Operation

The PXP can be used to accelerate graphics operations by offloading graphics processing from the processor. The block can perform alpha blending and color key substitution on two RGB graphics buffers.

The PXP is organized as having a processed surface (PS) and an alpha surface (AS) that can be blended with the processed surface. There are no restrictions on the location of the AS or PS within the output surface (OS). As the PXP processes NxN blocks, operations

are performed on a pixel by pixel basis. The AS and PS pixels are alpha blended, color keyed, process by CSC resources as individual pixel components. This allows efficient block processing with supporting arbitrary alignment for both the AS and PS surfaces. The resulting pixel block is then written to the corresponding block in the output buffer.

52.3.1.22 Pixel Handling

All pixels are internally represented as 32-bit values regardless of input or output pixel formats. The pixels get converted in the AS and PS buffer engines to 24-bit pixel values. There is also an 8-bit alpha value at stages up to the alpha blender within the PXP for blending within the RGB color space. Compositing of AS and PS images can only occur in the RGB color space. If compositing is not required, then YUV pixels can be transferred and processed at all PXP pixel resource components.. The color orientation of pixels within the PXP can be controlled by the CSC1 resource.

For RGB, input pixels are converted into 32-bit pixel values using the following rules for both AS and PS:

1. 32-bit ARGB8888 pixels are read directly with no conversion.
2. 32-bit RGB888 pixels are assumed to have an alpha value of 0xFF (full opaque).
3. 6-bit RGB565 and RGB555 values are expanded into the corresponding 24-bit color space and assigned an alpha value of 0xFF (opaque). The expansion process replicates the upper pixel bits into the lower pixel bits (for instance a 16-bit RGB555 triplet of 0x1F/0x10/0x07 would be expanded to 0xFF/0x84/0x39).
4. 16-bit RGB1555 values are expanded into the corresponding 24-bit color space and assigned an alpha value of either 0x00 or 0xFF, based on the 1-bit alpha value in the pixel. The ALPHA_MULTIPLY function is useful in this scenario to allow scaling of the opaque pixels to a semi-transparent value.

Alpha values can be passed through the entire PXP data path and output in ARGB8888 or ARGB1555 pixel modes. Also, output pixels can be assigned an alpha value using the OUT_CTRL[ALPHA] register. 16-bit pixels values are formed from the most significant bits of the 24-bit pixel values.

When YUV/YCbCr output formats are selected, all pixels are internally represented as either RGB or YUV pixels values.

52.3.1.23 Output Buffer Composition

The output buffer will be rendered by composing each pixel block from the associated PS and AS buffers.

The AS pixel buffer can be blended or color-keyed with the associated data from the PS buffer (either the PS image pixels or PS_BACKGROUND register based on PS programmed coordinates).

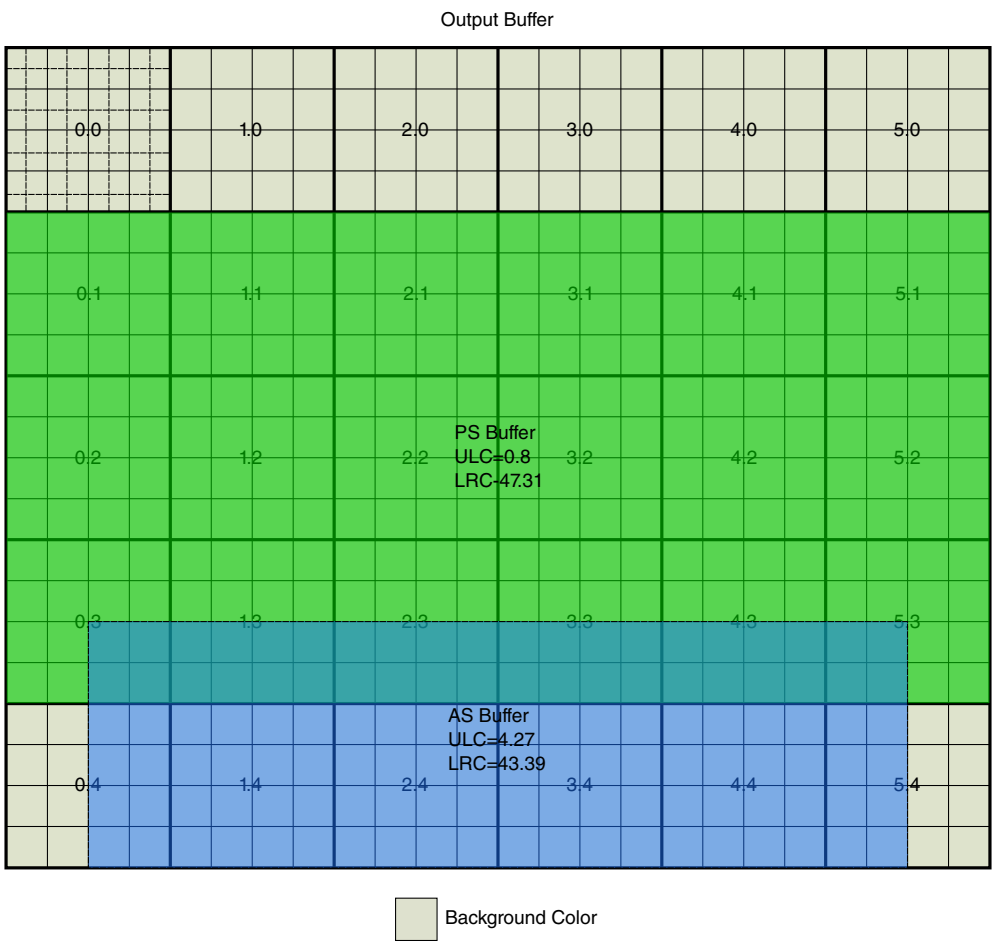

Figure 52-18. Output Buffer Composition

52.3.1.24 PS Image Processing

As the PXP processes image buffers, it iterates over the output buffer by fetching the corresponding input buffer blocks and processing the pixels embedded in these.

52.3.1.25 Letterboxing

At each pixel coordinate, the control logic determines if the PS pixel (argument also applies to AS pixels) will be used in rendering the output pixel.

This is determined by checking the output pixel's coordinates against the REG_OUT_PS_ULC and REG_OUT_PS_LRC (ULC and LRC in short) register contents. For pixels outside this region, the PS pixel will be loaded with the pixel value from REG_PS_BACKGROUND, which can be used to effectively control the letterboxing color. There are no block size or block boundary restrictions when setting the ULC or LRC for either the AS or PS. The only restriction is that the ULC and LRC are within the OUT LRC extents.

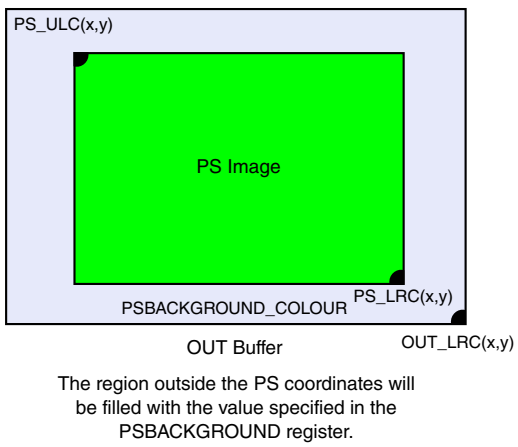

Figure 52-19. OUT Buffer

52.3.1.26 Clipping source images

A subset of the PS buffer can be used in rendering the output buffer. The PXP_PS_BUF register can indicate an offset into the PS buffer that will be used for display within the OUTPUT buffer.

The pixel at the address defined in the PXP_PS_BUF register will be the pixel that is displayed at the pixel coordinate indicated by PXP_OUT_PS_ULC within the output buffer. Essentially, the PXP_PS_BUF register can be used to establish an offset into the PS buffer thus clipping all PS buffer pixels that are at a lower address. The PXP_PS_PITCH will always indicate the number of bytes that are vertically adjacent in the PS buffer. The settings in the PXP_PS_BUF, PXP_OUT_PS_ULC, and PXP_OUT_PS_LRC will determine the subset of the PS buffer, or clipped PS source buffer, that will be used in the output buffer.

It is important to note that when scaling the PS buffer, the coordinates of the PS buffer within the output buffer need to be consistent with the scaling factors and original PS buffer size.

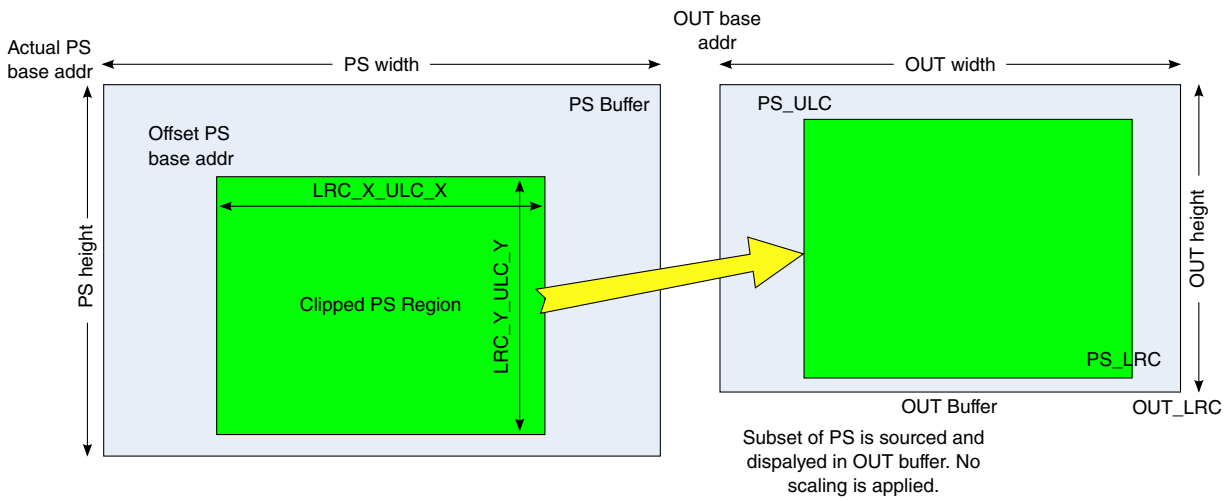

Figure 52-20. PS Buffer Scaling

When sourcing a subset of the PS image, it should fall completely within the PS buffer to avoid displaying incorrect data. The following conditions should be met:

x_base_addr_offset + x_scale * (LRC_X-ULC_X) <= PS_pitch

y_base_addr_offset + y_scale * (LRC_Y-ULC_Y) <= PS_size

The PXP hardware does not check for these conditions and will render the image as programmed. The following case could indicate invalid programming parameters for the PXP:

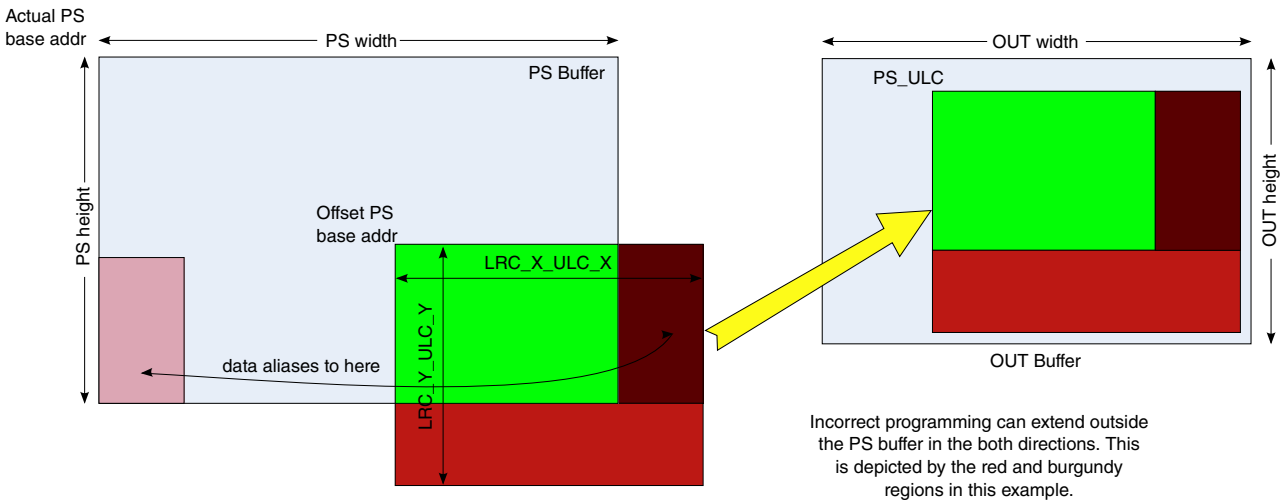

Figure 52-21. Example with Invalid Parameters

52.3.1.27 Color Key Processing

Pixels may be made transparent to the corresponding AS by using the PS color key registers.

If a PS pixel matches the range specified by the REG_PS_COLORKEYLOW and REG_PS_COLORKEYHIGH registers, the pixel from the associated AS will be displayed. If no AS is present for the pixel, a black pixel will be generated since the default AS pixel is 0x00000000 (transparent black pixel).

The most common use for this is when a bitmap does not support an alpha-field or for applications such as "green screen" where an image is substituted for a solid background color .

Figure 52-22. The PS image (player) and AS image (stadium)

The green portion of the background image can be color keyed to display the contents of the AS buffer for locations that match the color range. For this example, the color range is:

PS Colorkey: 00<R<80 70<G<ff 00<B<80

The resulting image becomes:

Figure 52-23. Resulting Image

52.3.1.28 In Place Processing (PS buffer is destination buffer)

The PXP also has the ability to process an image and write the resulting buffer back to the original PS buffer. This is referred to as "in place" rendering.

This could be useful for basic blit operations into the PS buffer. IN_PLACE operations are achieved by programming the OUT base address to the pixel location in the PS buffer that marks the upper left pixel of the update region. The actual region that is updated should be indicated by programming the ULC = (0,0) and the LRC = (X,Y). The region bounded by the coordinates will be updated, and the rest of the PS buffer will not be modified.

52.3.1.29 Alpha Surface (AS) Processing

The AS surface has a complete set of registers that determines how the AS effects the final OUT surface.

Most of the registers that exist for the PS surface also are defined for the AS surface where applicable. This is provided to replicate the SW interface for each PS and AS processes.

52.3.1.30 Alpha Handling

Alpha values in the AS are embedded in the source image pixels. For AS pixel formats that do not support an alpha value, the pixel is assigned an alpha value of 0xFF (opaque).

This can be modified by the AS control by setting either the ALPHA_MULTIPLY or ALPHA_OVERRIDE bit in the associated AS_CTRL register. If ALPHA_MULTIPLY is enabled, the 8-bit ALPHA value from the AS_CTRL register is multiplied by the source alpha before blending with the PS image. If the ALPHA_OVERRIDE bit is set, the 8-bit ALPHA value is simply substituted for the pixel.

52.3.1.31 Color Key Processing (AS_CTRL)

The AS_CTRL[ENABLE_COLORKEY] bit that can be used to enable or disable color key substitution for the AS.

When enabled, the pixel values are compared to the AS_COLORKEYLOW and AS_COLORKEYHIGH registers to determine if a match has occurred. When an AS pixel matches the color key range, the pixel from the AS image is considered transparent and the corresponding PS pixel is rendered.

AS color keys are handled in a manner similar to PS color keys. The same images used in the PS color key example could be used with the images swapped. In this case, matches on the AS image to the AS_COLORKEY register would display the PS pixels.

52.3.2 Output Image Processing

Several PXP options affect the resulting output image.

52.3.2.1 Output Image Size

The PXP generates an output image in the resolution programmed by the OUT_LRC register. As the PXP processes pixels, it iterates over the NxN blocks (in output scan-block order) based on the final image resolution.

52.3.2.2 Output Format

The result of PXP operations are written to the buffer pointed to by the OUT_BUF/ OUT_BUF2 registers. The pixel format is controlled by the OUT_CTRL[FORMAT] bit-field.

32-bit pixels are formed directly from the internal 24-bit representations and 16-bit pixel formats are generated by truncating the internal 24-bit values to the appropriate number of bits. For formats supporting an alpha value, the PXP assigns the alpha using the 8-bit value in the OUT_CTRL[ALPHA] field. For ARGB1555, the most significant alpha bit is appended to the output pixel. Also, for ARGB4444, the most significant nibble is appended to the output pixel. Single and dual buffer YUV output formats are also available. Since each pixel in the data path is represented by a full YUV444 24bpp value, decimation reduces the output in cases of YUV422/420 output formats.

52.3.2.3 Rotation/Flip operations

The PXP supports four rotation angles in conjunction with vertical and horizontal flip options. The flip operations effectively take place before the rotation.

Rotations of 0, 90, 180, and 270 degrees are supported and any combination of rotation and flip are supported. There is no performance difference between any of these modes of operation.

52.3.3 Queuing PXP transactions

The PXP supports a primitive ability to queue up one operation while the current operation is running. This is enabled through the use of the NEXT register.

When this register is written, it enables the PXP to reload its current register contents with the data found at the location pointed to by this address when it completes processing of the current frame. This feature may be useful in helping to reduce the interrupt latency in servicing the PXP, especially in cases where the PXP and eLCDIF are using the on-chip SRAM buffer handshake (since the PXP must begin generating next frame data immediately).

If the PXP is idle when the NEXT register is written, the PXP treats this as an indication that it should immediately load the values at the pointer and begin processing the frame. This ability should allow software to use the same routines when programming the PXP (so that the first frame doesn't differ from subsequent frames).

When loading values from the NEXT register, all registers in the PXP are reloaded. Some register loads have no effect

After writing the NEXT register, the PXP will set the NEXT[ENABLED] bit of the NEXT register to indicate that the next command has been queued. Software should first check the status of this bit to ensure that a previous command has not been enabled. Likewise, after programming the first frame in a sequence of frames, software should poll this bit until it is sampled logic 1'b0 before queuing the next operation.

The PXP will issue interrupts from frames as they complete, regardless of whether they were started by writing the control registers directly or using the NEXT register. When software receives an interrupt, it should check/clear the PXP's status register as normal, poll the NEXT[ENABLED] bit, and then issue the next operation. A queued operation may be cancelled by issuing a CLEAR operation to the NEXT[ENABLED] register bit. The SET and TOGGLE operations should never be used with this register.

52.3.4 Error Handling

The PXP does minimal checking on the control registers, so it is important that these are correctly specified. The PXP does monitor the bus transactions for errors and will report errors in the status register.

Upon receipt of a bus error, the PXP will set the ERROR interrupt and abort any further operations. Bus errors can be generated from any system access that results in an error response returned from the internal SIM Bus errors in the PXP are signaled as either a read or a write error, but do not indicate the failing address. Software may deduce the failing address from the current block status indicators.

52.3.4.1 Known PXP Limitations/Issues

The PXP has the following known limitations:

1. When using the NEXT register, the interrupt enable setting should remain the same for all frames. If not, the PXP will change the interrupt enable register value and possible cause the loss of an interrupt.
2. Rotations of 180/270 are not supported when performing LCD handshakes
3. PS buffer rotation and decimation does not function at the same time
4. No combination of rotate with flip, scaling or decimation is possible if buffer is unaligned.

52.3.5 Clocks

The following table describes the clock sources for PXP. Please see Clock Controller Module (CCM) for clock setting, configuration and gating information.

Table 52-2. PXP Clocks

Clock name	Clock Root	Description
clk	ipg_clk_root	PXP clock

52.3.6 Interrupts

The PXP consists of the following interrupts. Refer to the STAT register for details.

- Current PXP status interrupt (STAT[IRQ])
- LUT DMA transfer interrupt (STAT[LUT_DMA_LOAD_DONE_IRQ]
- Next Command issued interrupt (STAT[NEXT_IRQ])
- AXI ID error interrupt (STAT[AXI_ERROR_ID])
- AXI read error interrupt (STAT[AXI_READ_ERROR])
- AXI write error interrupt (STAT[AXI_WRITE_ERROR])

52.4 External Signals

PXP does not contain external signals.

52.5 Initialization

To initialize PXP, follow the steps:

1. Set CTRL[SFTRST] initially. Subsequently clear CTRL[SFTRST] and CTRL[CLKGATE] to reset PXP.
2. Configure the PXP registers
3. Set CTRL[ENABLE] = 1 to start PXP processing
4. Monitor STAT register to check if the processing is complete

Repeat steps 2-4 for the next fetch.

52.6 PXP Memory Map/Register Definition

PXP Hardware Register Format Summary

PXP memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4081_4000	Control Register 0 (PXP_CTRL)	32	R/W	C000_0000h	52.6.1/3295
4081_4004	Control Register 0 (PXP_CTRL_SET)	32	R/W	C000_0000h	52.6.1/3295
4081_4008	Control Register 0 (PXP_CTRL_CLR)	32	R/W	C000_0000h	52.6.1/3295
4081_400C	Control Register 0 (PXP_CTRL_TOG)	32	R/W	C000_0000h	52.6.1/3295
4081_4010	Status Register (PXP_STAT)	32	R/W	0000_0000h	52.6.2/3298
4081_4014	Status Register (PXP_STAT_SET)	32	R/W	0000_0000h	52.6.2/3298
4081_4018	Status Register (PXP_STAT_CLR)	32	R/W	0000_0000h	52.6.2/3298
4081_401C	Status Register (PXP_STAT_TOG)	32	R/W	0000_0000h	52.6.2/3298
4081_4020	Output Buffer Control Register (PXP_OUT_CTRL)	32	R/W	0000_0000h	52.6.3/3300
4081_4024	Output Buffer Control Register (PXP_OUT_CTRL_SET)	32	R/W	0000_0000h	52.6.3/3300
4081_4028	Output Buffer Control Register (PXP_OUT_CTRL_CLR)	32	R/W	0000_0000h	52.6.3/3300
4081_402C	Output Buffer Control Register (PXP_OUT_CTRL_TOG)	32	R/W	0000_0000h	52.6.3/3300
4081_4030	Output Frame Buffer Pointer (PXP_OUT_BUF)	32	R/W	0000_0000h	52.6.4/3302

Table continues on the next page...

PXP memory map (continued)

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4081_4040	Output Frame Buffer Pointer #2 (PXP_OUT_BUF2)	32	R/W	0000_0000h	52.6.5/3303
4081_4050	Output Buffer Pitch (PXP_OUT_PITCH)	32	R/W	0000_0000h	52.6.6/3303
4081_4060	Output Surface Lower Right Coordinate (PXP_OUT_LRC)	32	R/W	0000_0000h	52.6.7/3304
4081_4070	Processed Surface Upper Left Coordinate (PXP_OUT_PS_ULC)	32	R/W	0000_0000h	52.6.8/3305
4081_4080	Processed Surface Lower Right Coordinate (PXP_OUT_PS_LRC)	32	R/W	0000_0000h	52.6.9/3306
4081_4090	Alpha Surface Upper Left Coordinate (PXP_OUT_AS_ULC)	32	R/W	0000_0000h	52.6.10/ 3307
4081_40A0	Alpha Surface Lower Right Coordinate (PXP_OUT_AS_LRC)	32	R/W	0000_0000h	52.6.11/ 3308
4081_40B0	Processed Surface (PS) Control Register (PXP_PS_CTRL)	32	R/W	0000_0000h	52.6.12/ 3309
4081_40B4	Processed Surface (PS) Control Register (PXP_PS_CTRL_SET)	32	R/W	0000_0000h	52.6.12/ 3309
4081_40B8	Processed Surface (PS) Control Register (PXP_PS_CTRL_CLR)	32	R/W	0000_0000h	52.6.12/ 3309
4081_40BC	Processed Surface (PS) Control Register (PXP_PS_CTRL_TOG)	32	R/W	0000_0000h	52.6.12/ 3309
4081_40C0	PS Input Buffer Address (PXP_PS_BUF)	32	R/W	0000_0000h	52.6.13/ 3311
4081_40D0	PS U/Cb or 2 Plane UV Input Buffer Address (PXP_PS_UBUF)	32	R/W	0000_0000h	52.6.14/ 3312
4081_40E0	PS V/Cr Input Buffer Address (PXP_PS_VBUF)	32	R/W	0000_0000h	52.6.15/ 3312
4081_40F0	Processed Surface Pitch (PXP_PS_PITCH)	32	R/W	0000_0000h	52.6.16/ 3313
4081_4100	PS Background Color (PXP_PS_BACKGROUND)	32	R/W	0000_0000h	52.6.17/ 3314
4081_4110	PS Scale Factor Register (PXP_PS_SCALE)	32	R/W	1000_1000h	52.6.18/ 3314
4081_4120	PS Scale Offset Register (PXP_PS_OFFSET)	32	R/W	0000_0000h	52.6.19/ 3316
4081_4130	PS Color Key Low (PXP_PS_CLRKEYLOW)	32	R/W	00FF_FFFFh	52.6.20/ 3317
4081_4140	PS Color Key High (PXP_PS_CLRKEYHIGH)	32	R/W	0000_0000h	52.6.21/ 3318
4081_4150	Alpha Surface Control (PXP_AS_CTRL)	32	R/W	0000_0000h	52.6.22/ 3318
4081_4160	Alpha Surface Buffer Pointer (PXP_AS_BUF)	32	R/W	0000_0000h	52.6.23/ 3321
4081_4170	Alpha Surface Pitch (PXP_AS_PITCH)	32	R/W	0000_0000h	52.6.24/ 3321

Table continues on the next page...

PXP memory map (continued)

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4081_4180	Overlay Color Key Low (PXP_AS_CLRKEYLOW)	32	R/W	00FF_FFFFh	52.6.25/ 3322
4081_4190	Overlay Color Key High (PXP_AS_CLRKEYHIGH)	32	R/W	0000_0000h	52.6.26/ 3322
4081_41A0	Color Space Conversion Coefficient Register 0 (PXP_CSC1_COEF0)	32	R/W	0400_0000h	52.6.27/ 3323
4081_41B0	Color Space Conversion Coefficient Register 1 (PXP_CSC1_COEF1)	32	R/W	0123_0208h	52.6.28/ 3325

4081_4320	PXP Power Control Register (PXP_POWER)	32	R/W	0000_0000h	52.6.30/ 3327
4081_4400	Next Frame Pointer (PXP_NEXT)	32	R/W	0000_0000h	52.6.31/ 3327
4081_4440	PXP Alpha Engine A Control Register. (PXP_PORTER_DUFF_CTRL)	32	R/W	0000_0000h	52.6.32/ 3329

52.6.1 Control Register 0 (PXP_CTRL*n*)

The CTRL register contains controls for the PXP module.

PXP_CTRL: 0x000

PXP_CTRL_SET: 0x004

PXP_CTRL_CLR: 0x008

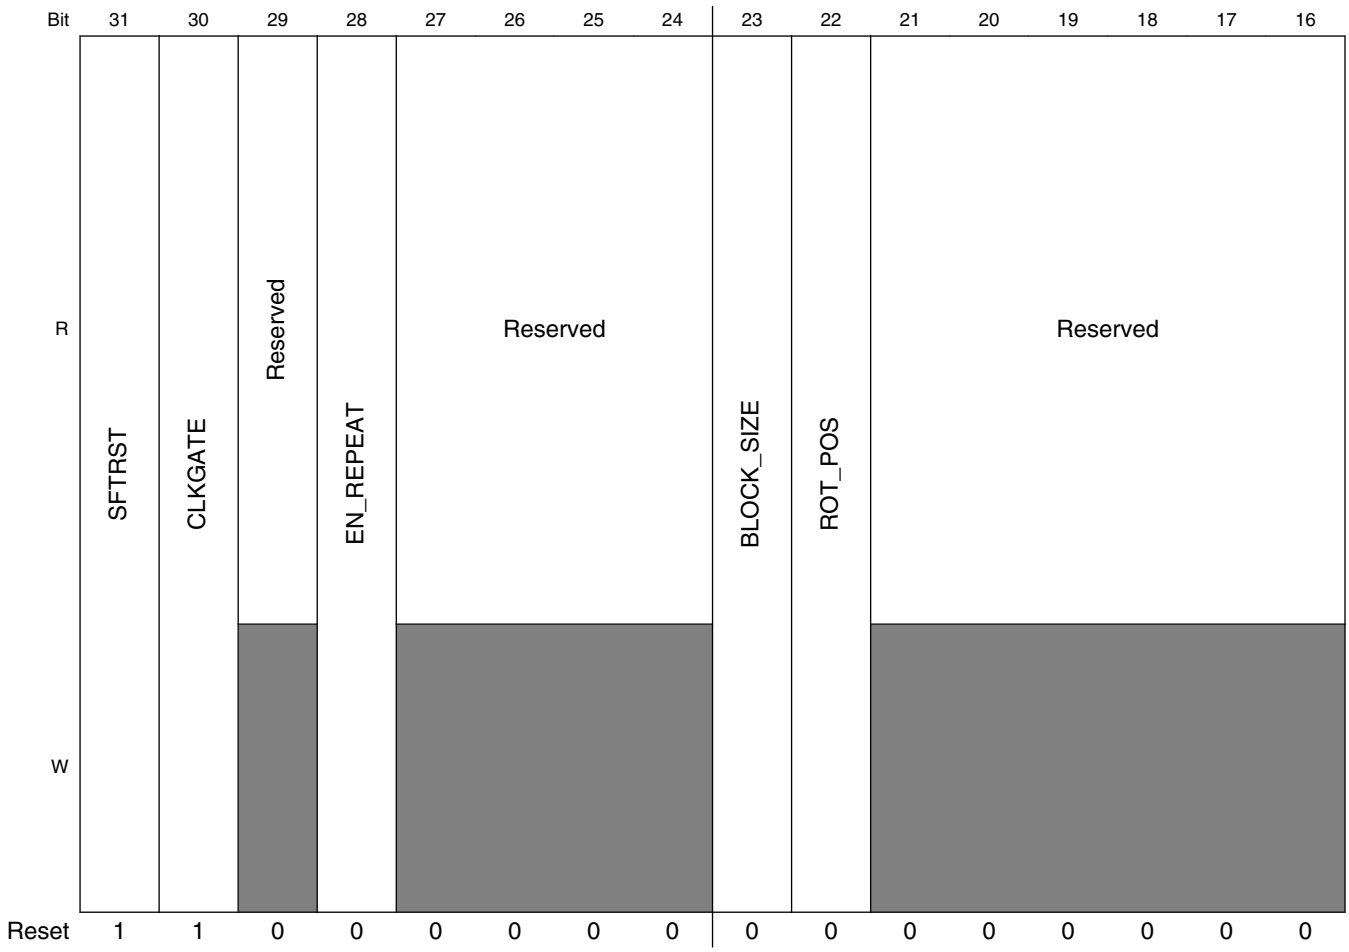
PXP_CTRL_TOG: 0x00C

The Control register contains the primary controls for the PXP block. The present bits indicate which of the sub-features of the block are present in the hardware.

EXAMPLE

```
PXP_CTRL_SET(BM_PXP_CTRL_SFTRST);
PXP_CTRL_CLR(BM_PXP_CTRL_SFTRST | BM_PXP_CTRL_CLKGATE);
```

Address: 4081_4000h base + 0h offset + (4d × i), where i=0d to 3d



PXP_CTRL*n* field descriptions

Field	Description
31 SFTRST	This bit can be turned on and then off to reset the PXP block to its default state. 0x0 **Enabled** — Normal PXP operation is enabled 0x1 **Disabled** — Clocking with PXP is disabled and held in its reset (lowest power) state. This is the default value.
30 CLKGATE	This bit must be set to zero for normal operation. When set to one it gates off the clocks to the block. 0x0 **Normal** — Normal operation 0x1 **Gated** — All clocks to PXP is gated-off
29 Reserved	This field is reserved. Always set to zero.
28 EN_REPEAT	Enable the PXP to run continuously. This bit should be set when the LCDIF handshake mode is enabled so that the next frame is automatically generated for the next screen refresh cycle. If it not set and the handshake mode is enabled, the CPU will have to initiate the PXP for the next refresh cycle. When the PXP NEXT feature is used, it has priority over the REPEAT mode, in that the new register settings are fetched first, and then the next PXP operation will continue. 0x1 **Repeat** — PXP will repeat based on the current configuration register settings 0x0 **Complete** — PXP will complete the process and enter the idle state ready to accept the next frame to be processed
27–24 Reserved	This field is reserved. Always set to zero.
23 BLOCK_SIZE	Select the block size to process. 0x0 **8X8** — Process 8x8 pixel blocks. 0x1 **16X16** — Process 16x16 pixel blocks.
22 ROT_POS	This bit controls where rotation will occur in the PXP datapath. Setting this bit to 1'b0 will place the rotation resources at the output stage of the PXP data path. Image compositing will occur before pixels are processed for rotation. Setting this bit to a 1'b1 will place the rotation resources before image composition. Only the PS can be rotated in this configuration and AS will not be rotated.
21–12 Reserved	This field is reserved. Always set to zero.
11 VFLIP	Indicates that the output buffer should be flipped vertically (effect applied before rotation). 0x0 **Disabled** — Vertical Flip is disabled 0x1 **Enabled** — Vertical Flip is enabled
10 HFLIP	Indicates that the output buffer should be flipped horizontally (effect applied before rotation). 0x0 **Disabled** — Horizontal Flip is disabled 0x1 **Enabled** — Horizontal Flip is enabled
9–8 ROTATE	Indicates the clockwise rotation to be applied at the output buffer. The rotation effect is defined as occurring after the FLIP_X and FLIP_Y permutation. 0x0 **ROT_0** — 0x1 **ROT_90** — 0x2 **ROT_180** — 0x3 **ROT_270** —
7–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

PXP_CTRL*n* field descriptions (continued)

Field	Description
4 ENABLE_LCD_ HANDSHAKE	Enable handshake with LCD controller. When this is set, the PXP will not process an entire framebuffer, but will instead process rows of NxN blocks in a double-buffer handshake with the LCDIF. This enables the use of the onboard SRAM for a partial frame buffer.
3 Reserved	This field is reserved.
2 NEXT_IRQ_ ENABLE	Next command interrupt enable. When set, the PXP will issue an interrupt when a queued command initiated by a write to the PXP_NEXT register has been loaded into the PXP's registers. This interrupt also indicates that a new command may now be queued. 0x0 **Disabled** — 0x1 **Enabled** —
1 IRQ_ENABLE	Interrupt enable **NOTE:** When using the PXP_NEXT functionality to reprogram the PXP, the new value of this bit will be used and may therefore enable or disable an interrupt unintentionally. 0x1 **Enabled** — PXP interrupt is enabled 0x0 **Disabled** — PXP interrupt is disabled
0 ENABLE	Enables PXP operation with specified parameters. The ENABLE bit will remain set while the PXP is active and will be cleared after the current operation completes. Software should use the IRQ bit in the PXP_STAT when polling for PXP completion. 0x1 **Enabled** — PXP is enabled 0x0 **Disabled** — PXP is disabled

52.6.2 Status Register (PXP_STAT*n*)

The PXP Interrupt Status register provides interrupt status information.

PXP_STAT: 0x010

PXP_STAT_SET: 0x014

PXP_STAT_CLR: 0x018

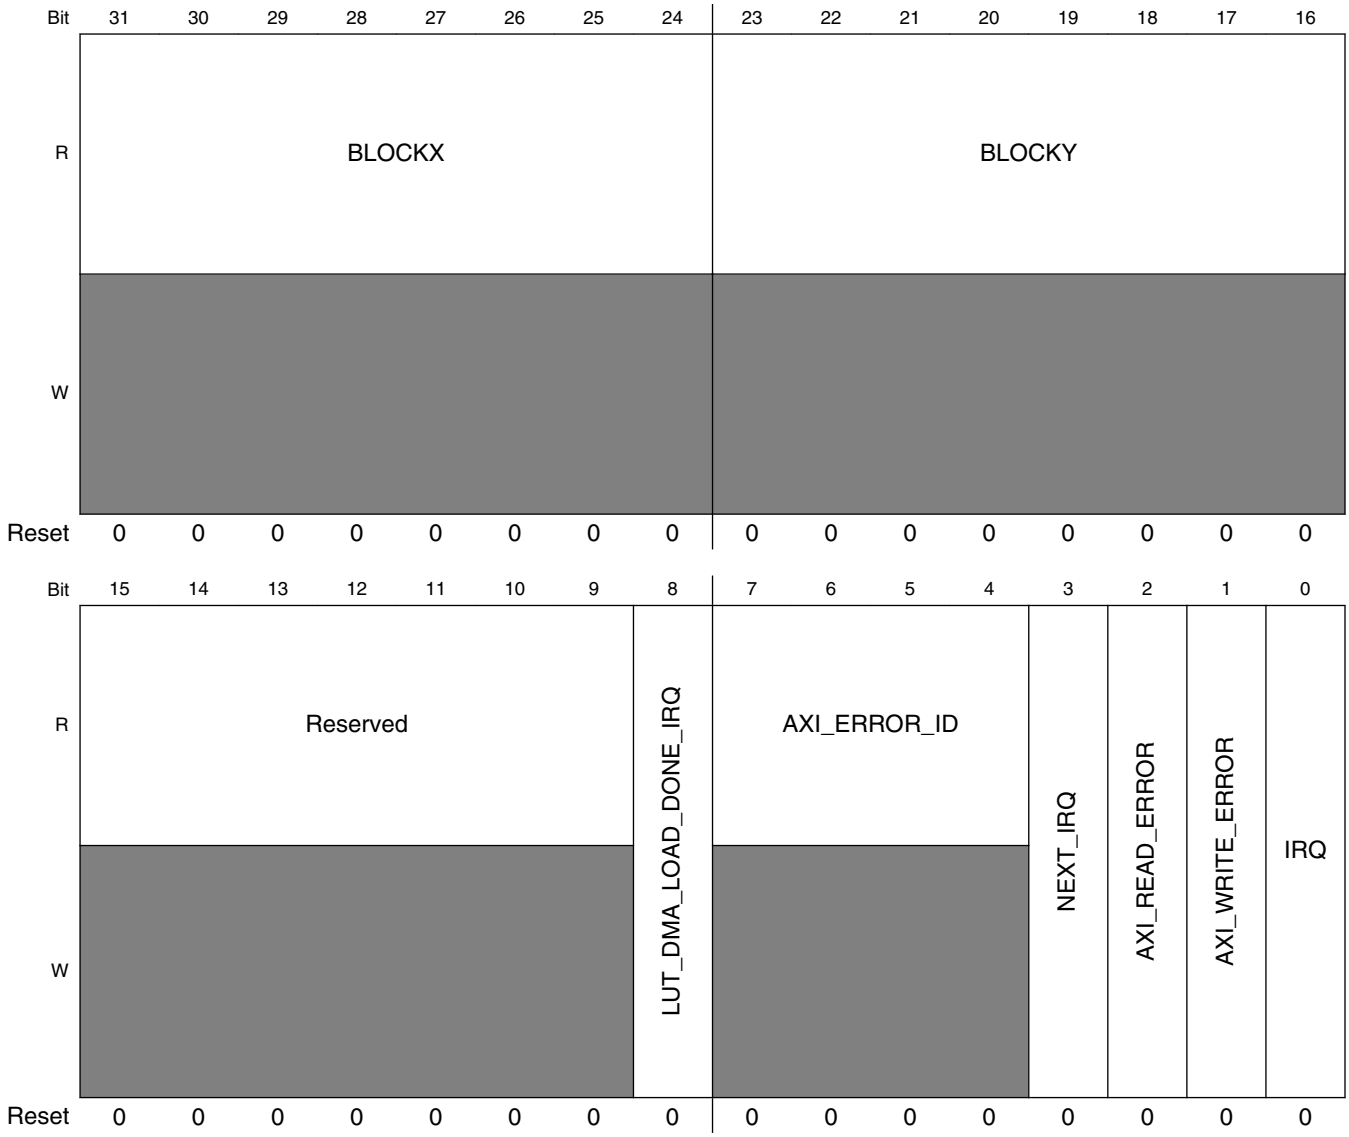
PXP_STAT_TOG: 0x01C

This register provides PXP interrupt status and the current X/Y block coordinate that is being processed.

EXAMPLE

```
PXP_STAT_CLR(BM_PXP_STAT_IRQ);  // clear CSC interrupt
```

Address: 4081_4000h base + 10h offset + (4d × i), where i=0d to 3d



PXP_STAT*n* field descriptions

Field	Description
31–24 BLOCKX	Indicates the X coordinate of the block currently being rendered.
23–16 BLOCKY	Indicates the X coordinate of the block currently being rendered.
15–9 Reserved	This field is reserved. Always set to zero.
8 LUT_DMA_ LOAD_DONE_ IRQ	Indicates that the LUT DMA transfer has completed. 0x0 **Active** — LUT DMA LOAD transfer is active 0x1 **Complete** — LUT DMA LOAD transfer is complete
7–4 AXI_ERROR_ID	Indicates the AXI ID of the failing bus operation.

Table continues on the next page...

PXP_STAT*n* field descriptions (continued)

Field	Description
3 NEXT_IRQ	Indicates that a command issued with the "Next Command" functionality has been issued and that a new command may be initiated with a write to the PXP_NEXT register.
2 AXI_READ_ ERROR	Indicates PXP encountered an AXI read error and processing has been terminated. 0x0 **Normal** — AXI read is normal 0x1 **Error** — AXI read error has occurred
1 AXI_WRITE_ ERROR	Indicates PXP encountered an AXI write error and processing has been terminated. 0x0 **Normal** — AXI write is normal 0x1 **Error** — AXI write error has occurred
0 IRQ	Indicates current PXP interrupt status. The IRQ is routed through the pxp_irq when the IRQ_ENABLE bit in the control register is set. 0x0 **No interrupt** — PXP interrupt not generated 0x1 **Interrupt generated** — PXP interrupt is generated

52.6.3 Output Buffer Control Register (PXP_OUT_CTRL*n*)

The OUT_CTRL register contains controls for the Output Buffer.

PXP_OUT_CTRL: 0x020

PXP_OUT_CTRL_SET: 0x024

PXP_OUT_CTRL_CLR: 0x028

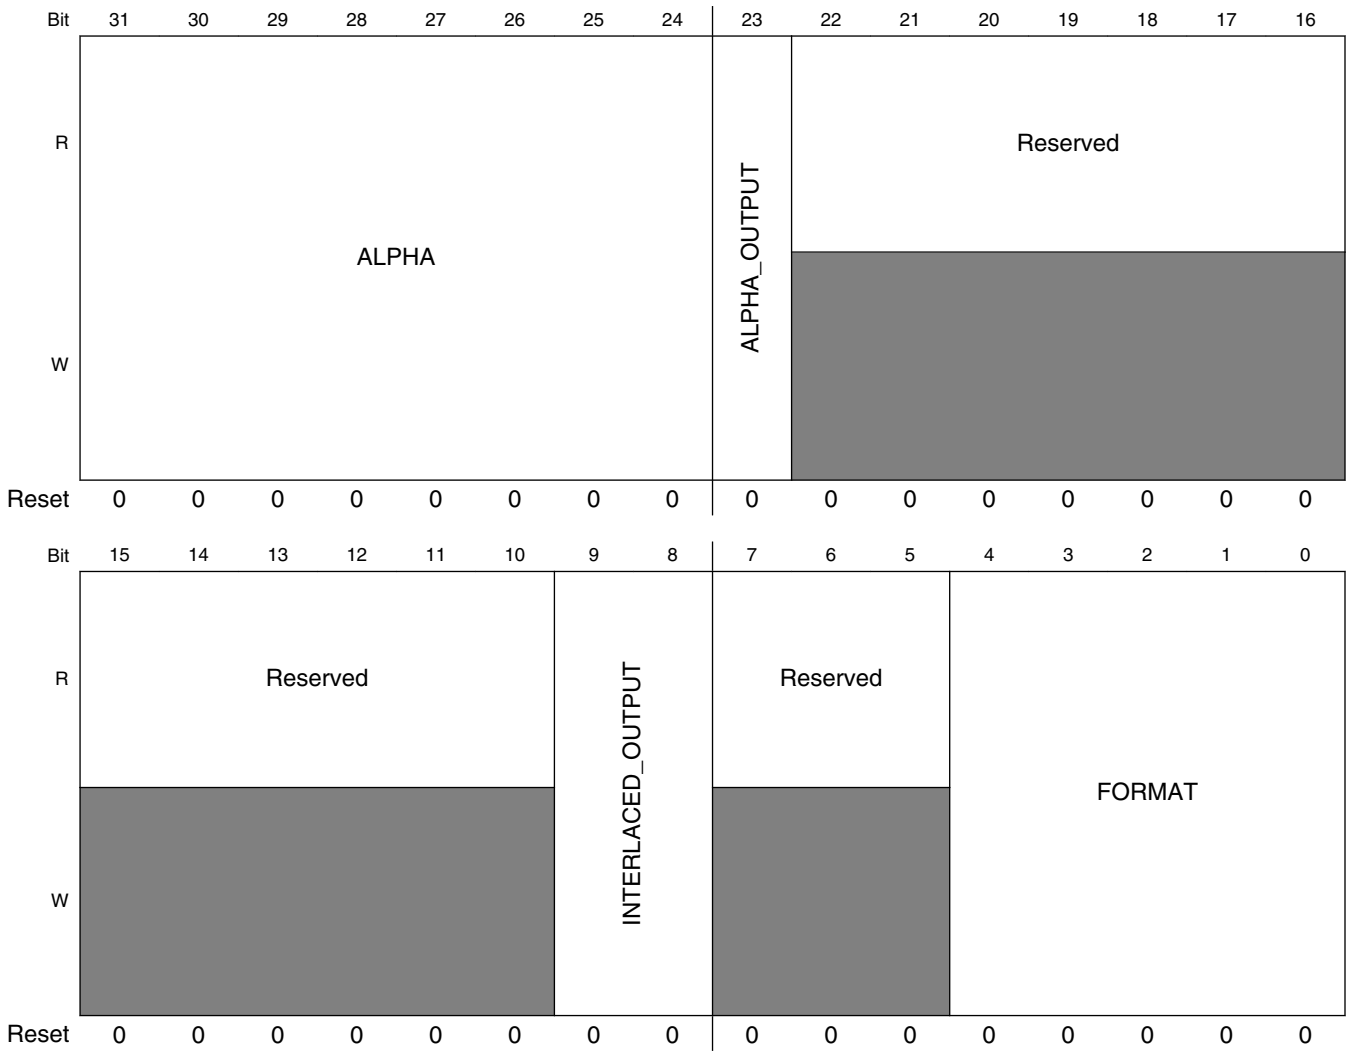
PXP_OUT_CTRL_TOG: 0x02C

The Control register contains the primary controls for the PXP block. The present bits indicate which of the sub-features of the block are present in the hardware.

EXAMPLE

```
PXP_CTRL_SET(BM_PXP_CTRL_SFTRST);
PXP_CTRL_CLR(BM_PXP_CTRL_SFTRST | BM_PXP_CTRL_CLKGATE);
```

Address: 4081_4000h base + 20h offset + (4d × i), where i=0d to 3d



PXP_OUT_CTRL*n* field descriptions

Field	Description
31–24 ALPHA	When generating an output buffer with an alpha component, the value in this field will be used when enabled to override the alpha passed through the pixel data pipeline.
23 ALPHA_ OUTPUT	Indicates that alpha component in output buffer pixels should be overwritten by PXP_OUT_CTRL[ALPHA]. If 0, retain their alpha value from the computed alpha for that pixel. 0x0 **Retain** — 0x1 **Overwritten** —
22–10 Reserved	This field is reserved. Always set to zero.
9–8 INTERLACED_ OUTPUT	Determines how the PXP writes it's output data. Output interlacing should not be used in conjunction with input interlacing. Splitting frames into fields is most efficient using output interlacing. 2-plane output formats AND interlaced output is NOT supported. 0x0 **PROGRESSIVE** — All data written in progressive format to the OUTBUF Pointer. 0x1 **FIELD0** — Interlaced output: only data for field 0 is written to the OUTBUF Pointer.

Table continues on the next page...

PXP_OUT_CTRL*n* field descriptions (continued)

Field	Description
	0x2 **FIELD1** — Interlaced output: only data for field 1 is written to the OUTBUF2 Pointer. 0x3 **INTERLACED** — Interlaced output: data for field 0 is written to OUTBUF and data for field 1 is written to OUTBUF2.
7–5 Reserved	This field is reserved. Always set to zero.
FORMAT	Output framebuffer format. The UV byte lanes are synonymous with CbCr byte lanes for YUV output pixel formats. For example, the YUV2P420 format should be selected when the output is YCbCr 2-plane 420 output format. 0x0 **ARGB8888** — 32-bit pixels 0x4 **RGB888** — 32-bit pixels (unpacked 24-bit pixel in 32 bit DWORD.) 0x5 **RGB888P** — 24-bit pixels (packed 24-bit format) 0x8 **ARGB1555** — 16-bit pixels 0x9 **ARGB4444** — 16-bit pixels 0xC **RGB555** — 16-bit pixels 0xD **RGB444** — 16-bit pixels 0xE **RGB565** — 16-bit pixels 0x10 **YUV1P444** — 32-bit pixels (1-plane XYUV unpacked) 0x12 **UYVY1P422** — 16-bit pixels (1-plane U0,Y0,V0,Y1 interleaved bytes) 0x13 **VYUY1P422** — 16-bit pixels (1-plane V0,Y0,U0,Y1 interleaved bytes) 0x14 **Y8** — 8-bit monochrome pixels (1-plane Y luma output) 0x15 **Y4** — 4-bit monochrome pixels (1-plane Y luma, 4 bit truncation) 0x18 **YUV2P422** — 16-bit pixels (2-plane UV interleaved bytes) 0x19 **YUV2P420** — 12-bit pixels (2-plane UV) 0x1A **YVU2P422** — 16-bit pixels (2-plane VU interleaved bytes) 0x1B **YVU2P420** — 12-bit pixels (2-plane VU)

52.6.4 Output Frame Buffer Pointer (PXP_OUT_BUF)

Output Framebuffer Pointer. This register points to the beginning of the output frame buffer. This pointer is used for progressive format and field 0 when generating interlaced output.

This register is used by the logic to point to the current output location for the output frame buffer.

EXAMPLE

```
PXP_OUT_BUF_WR( buffer );
```

Address: 4081_4000h base + 30h offset = 4081_4030h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	ADDR																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PXP_OUT_BUF field descriptions

Field	Description
ADDR	Current address pointer for the output frame buffer. The address can have any byte alignment. 64B alignment is recommended for optimal performance.

52.6.5 Output Frame Buffer Pointer #2 (PXP_OUT_BUF2)

Output Framebuffer Pointer #2. This register points to the beginning of the output frame buffer for either field 1 when generating interlaced output or for the UV buffer when in YUV 2-plane output modes. Both interlaced output AND 2-plane output modes are not supported in a single PXP operation. This register is not used as the pointer to the second buffer when in LCDIF_HANDSHAKE mode.

This register is used by the logic to point to the current output location for the field 1 or UV output frame buffer.

EXAMPLE

```
PXP_OUT_BUF_WR( field0 );  // buffer for interlaced field 0
PXP_OUT_BUF2_WR( field1 ); // buffer for interlaced field 1
```

Address: 4081_4000h base + 40h offset = 4081_4040h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	ADDR																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PXP_OUT_BUF2 field descriptions

Field	Description
ADDR	Current address pointer for the output frame buffer. The address can have any byte alignment. 64B alignment is recommended for optimal performance.

52.6.6 Output Buffer Pitch (PXP_OUT_PITCH)

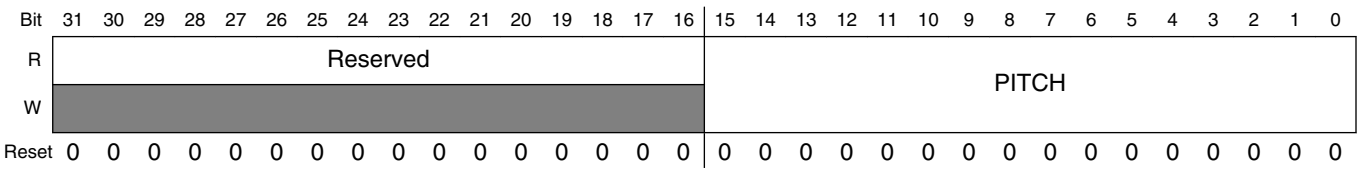
This register contains the output buffer pitch in bytes.

Any byte value will indicate the vertical pitch. This value will be used in output pixel address calculations.

EXAMPLE

```
PXP_OUT_PITCH_WR( 68 * 4 );  // The output buffer pitch is 68 pixels times 32 bits per pixel
```

Address: 4081_4000h base + 50h offset = 4081_4050h



PXP_OUT_PITCH field descriptions

Field	Description
31–16 Reserved	This field is reserved. Always set to zero.
PITCH	Indicates the number of bytes in memory between two vertically adjacent pixels.

52.6.7 Output Surface Lower Right Coordinate (PXP_OUT_LRC)

This register contains the size, or lower right coordinate, of the output buffer NOT rotated. It is implied that the upper left coordinate of the output surface is always [0,0]. When rotating the framebuffer, the PXP will automatically swap the X/Y, or WIDTH/HEIGHT, to accomodate the rotated size.

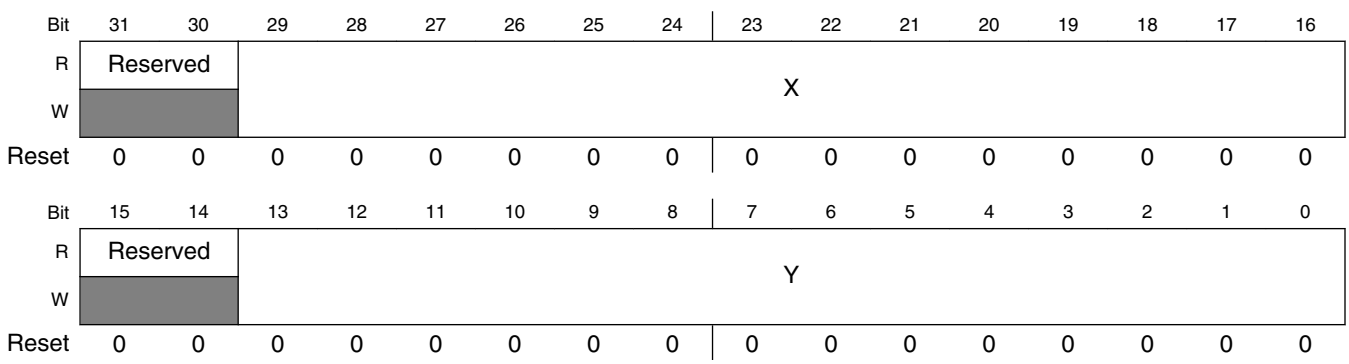
This register sets the size of the output frame buffer in pixels, not blocks. The frame buffer need not be a multiple of NxN pixels. Partial blocks will be written for output frame buffer sizes that are not divisable by N pixels in either dimension.

EXAMPLE

```
PXP_OUT_LRC[X]=319;   // set width of output frame buffer to 320 pixels
PXP_OUT_LRC[Y]=243;  // set height of output frame buffer to 244 pixels which is not
divisible by block size N

PXP_OUT_LRC_WR( BF_PXP_OUT_LRC_X(319)   |   BF_PXP_OUT_LRC_Y(243) );
```

Address: 4081_4000h base + 60h offset = 4081_4060h



PXP_OUT_LRC field descriptions

Field	Description
31–30 Reserved	This field is reserved. Always set to zero.
29–16 X	Indicates number of horizontal PIXELS in the output surface (non-rotated). The output buffer pixel width minus 1 should be programmed. The image size is not required to be a multiple of 8 pixels. The PXP will clip the pixel output at this boundary.
15–14 Reserved	This field is reserved. Always set to zero.
Y	Indicates the number of vertical PIXELS in the output surface (non-rotated). The output buffer pixel height minus 1 should be programmed. The image size is not required to be a multiple of 8 pixels. The PXP will clip the pixel output at this boundary.

52.6.8 Processed Surface Upper Left Coordinate (PXP_OUT_PS_ULC)

This register contains the upper left pixel coordinate for the Processed Surface in the OUTPUT buffer.

This register contains the upper left coordinate of the Processed Surface in the output frame buffer (in pixels). Values that are within the PXP_OUT_LRC X,Y extents are valid. The lowest valid value for these fields is 0,0. If the value of the PXP_OUT_PS_ULC is greater than the PXP_OUT_LRC, then no PS pixels will be fetched from memory, but only PXP_PS_BACKGROUND pixels will be processed by the PS engine. Pixel locations that are greater than or equal to the PS upper left coordinates, less than or equal to the PS lower right coordinates, and within the PXP_OUT_LRC extents will use the PS to render pixels into the output buffer.

EXAMPLE

```
PXP_OUT_PS_ULC_WR(0,0x0002_0002); // Processed Surface upper left coordinate at (X,Y) =
2,2.  The PS surface will not effect pixels in the first and second row and column of the
output buffer.
```

Address: 4081_4000h base + 70h offset = 4081_4070h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved		X

PXP_OUT_PS_ULC field descriptions

Field	Description
31–30 Reserved	This field is reserved. Always set to zero.
29–16 X	This field indicates the upper left X-coordinate (in pixels) of the processed surface (PS) in the output buffer.
15–14 Reserved	This field is reserved. Always set to zero.
Y	This field indicates the upper left Y-coordinate (in pixels) of the processed surface in the output buffer.

52.6.9 Processed Surface Lower Right Coordinate (PXP_OUT_PS_LRC)

This register contains the lower right extent for the Processed Surface in the OUTPUT buffer.

This register contains the lower right coordinate of the Processed Surface in the output frame buffer (in pixels). Values that are within the PXP_OUT_LRC X,Y extents are valid. The lowest valid value for these fields is 0,0. Pixel locations that are greater than or equal to the PS upper left coordinates, less than or equal to the PS lower right coordinates, and within the PXP_OUT_LRC extents will use the PS to render pixels into the output buffer.

EXAMPLE

```
PXP_OUT_PS_ULC_WR(0,0x03FF_03FF); // With this UL/LR pair of pixel coordinates, only one
pixel at OUT[X,Y]=1023,1023 will use the PS to contribute to its value.
PXP_OUT_PS_LRC_WR(0,0x03FF_03FF);
```

Address: 4081_4000h base + 80h offset = 4081_4080h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Description
31–30 Reserved	This field is reserved. Always set to zero.
29–16 X	This field indicates the lower right X-coordinate (in pixels) of the processed surface (PS) in the output frame buffer.
15–14 Reserved	This field is reserved. Always set to zero.
Y	This field indicates the lower right Y-coordinate (in pixels) of the processed surface in the output frame buffer.

52.6.10 Alpha Surface Upper Left Coordinate (PXP_OUT_AS_ULC)

This register contains the upper left location for the Alpha Surface in the output buffer.

This register contains the upper left coordinate of AS in the output frame buffer (in pixels). Values that are within the PXP_OUT_LRC X,Y extents are valid. The lowest valid value for these fields is 0,0. Pixel locations that are greater than or equal to the upper left coordinates will use the AS to render pixels in the output buffer.

EXAMPLE

```
PXP_OUT_AS_ULC_WR(0,0x0001_0001); // Alpha Surface upper left coordinate at (X,Y) = 1,1.
The AS surface will not effect pixels in the first row or first column of the output buffer.
```

Address: 4081_4000h base + 90h offset = 4081_4090h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Description
15–14 Reserved	This field is reserved. Always set to zero.
Y	This field indicates the upper left Y-coordinate (in pixels) of the alpha surface in the output frame buffer.

52.6.11 Alpha Surface Lower Right Coordinate (PXP_OUT_AS_LRC)

This register contains the lower right extent for Alpha Surface in the output buffer.

This register contains the lower right coordinate of AS in the output frame buffer (in pixels). Values that are within the PXP_OUT_LRC X,Y extents are valid. The lowest valid value for these fields is 0,0. Pixel locations that are less than or equal to the lower right coordinates will use the AS to render pixels in the output buffer.

EXAMPLE

```
PXP_AS_LRC_WR(0,0x03FF_03FF); // Alpha Surface lower right coordinate at (X,Y) = 1023,1023.
```

Address: 4081_4000h base + A0h offset = 4081_40A0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

PXP_OUT_AS_LRC field descriptions

Field	Description
31–30 Reserved	This field is reserved. Always set to zero.
29–16 X	This field indicates the lower right X-coordinate (in pixels) of the alpha surface (AS) in the output frame buffer.
15–14 Reserved	This field is reserved. Always set to zero.
Y	This field indicates the lower right Y-coordinate (in pixels) of the alpha surface in the output frame buffer.

52.6.12 Processed Surface (PS) Control Register (PXP_PS_CTRL*n*)

The PS_CTRL register contains controls for the Processed Surface Buffer.

PXP_PS_CTRL: 0x0B0

PXP_PS_CTRL_SET: 0x0b4

PXP_PS_CTRL_CLR: 0x0B8

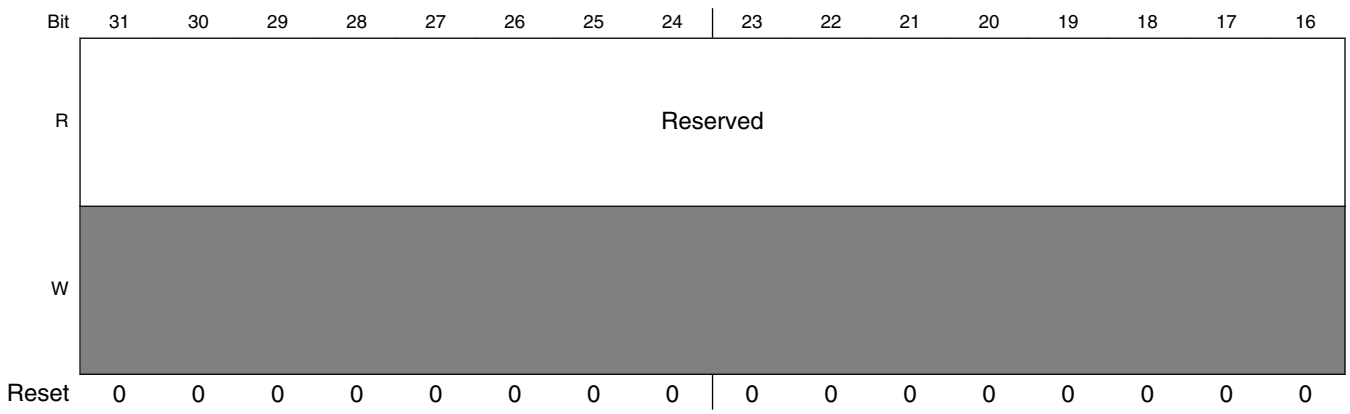
PXP_PS_CTRL_TOG: 0x0BC

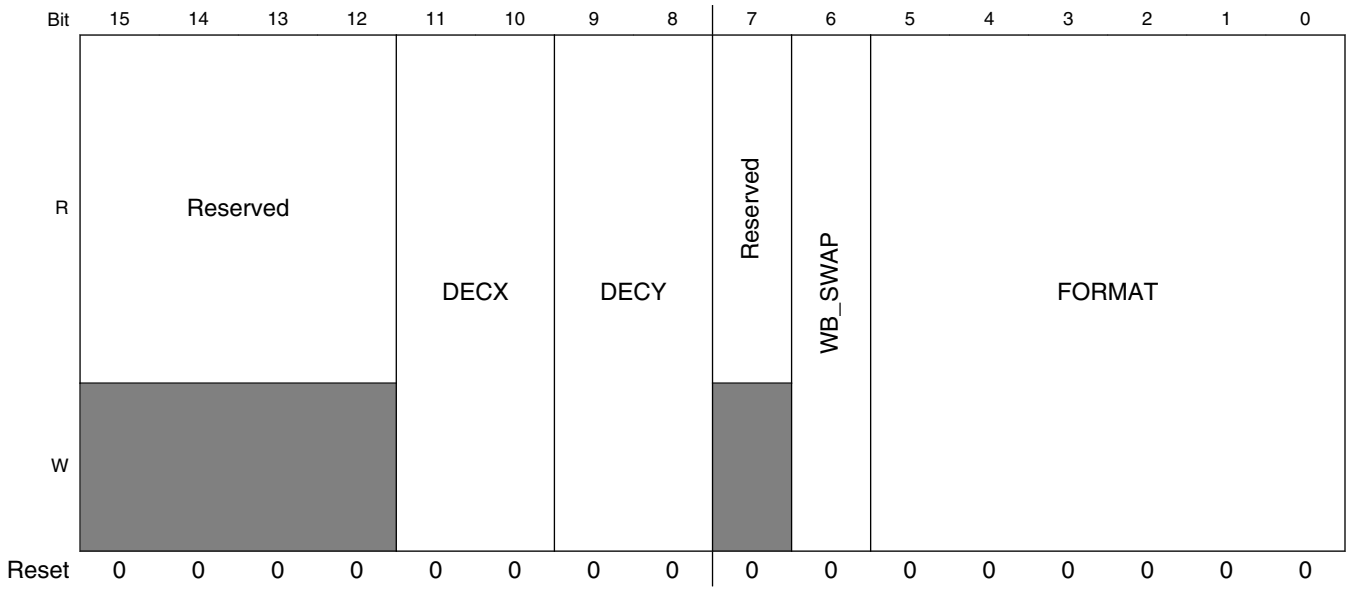
The Control register contains the primary controls for the PXP block. The present bits indicate which of the sub-features of the block are present in the hardware.

EXAMPLE

```
PXP_CTRL_SET(BM_PXP_CTRL_SFTRST);
PXP_CTRL_CLR(BM_PXP_CTRL_SFTRST | BM_PXP_CTRL_CLKGATE);
```

Address: 4081_4000h base + B0h offset + (4d × i), where i=0d to 3d





PXP_PS_CTRL*n* field descriptions

Field	Description
31–12 Reserved	This field is reserved. Always set to zero.
11–10 DECX	Horizontal pre decimation filter control. 0x0 **DISABLE** — Disable pre-decimation filter. 0x1 **DECX2** — Decimate PS by 2. 0x2 **DECX4** — Decimate PS by 4. 0x3 **DECX8** — Decimate PS by 8.
9–8 DECY	Verticle pre decimation filter control. 0x0 **DISABLE** — Disable pre-decimation filter. 0x1 **DECY2** — Decimate PS by 2. 0x2 **DECY4** — Decimate PS by 4. 0x3 **DECY8** — Decimate PS by 8.
7 Reserved	This field is reserved. Always set to zero.
6 WB_SWAP	Swap bytes in words. For each 16 bit word, the two bytes will be swapped. 0x0 **Disabled** — Byte swap is disabled 0x1 **Enabled** — Byte swap is enabled
FORMAT	PS buffer format. To select between YUV and YCbCr formats, see bit 31 of the CSC1_COEF0 register. 0x4 **RGB888_ARGB8888** — 32-bit pixels (unpacked 24-bit format with/without alpha at high 8bits) 0xC **RGB555_ARGB1555** — 16-bit pixels with/without alpha at high 1bit 0xD **RGB444_ARGB4444** — 16-bit pixels with/without alpha at high 4 bits 0xE **RGB565** — 16-bit pixels 0x10 **YUV1P444** — 32-bit pixels (1-plane XYUV unpacked) 0x12 **UYVY1P422** — 16-bit pixels (1-plane U0,Y0,V0,Y1 interleaved bytes) 0x13 **VYUY1P422** — 16-bit pixels (1-plane V0,Y0,U0,Y1 interleaved bytes)

Table continues on the next page...

PXP_PS_CTRL*n* field descriptions (continued)

Field	Description
	0x14 **Y8** — 8-bit monochrome pixels (1-plane Y luma output) 0x15 **Y4** — 4-bit monochrome pixels (1-plane Y luma, 4 bit truncation) 0x18 **YUV2P422** — 16-bit pixels (2-plane UV interleaved bytes) 0x19 **YUV2P420** — 12-bit pixels (2-plane UV) 0x1A **YVU2P422** — 16-bit pixels (2-plane VU interleaved bytes) 0x1B **YVU2P420** — 12-bit pixels (2-plane VU) 0x1E **YUV422** — 16-bit pixels (3-plane format) 0x1F **YUV420** — 12-bit pixels (3-plane format) 0x24 **RGBA8888** — 32-bit pixels with alpha at the low 8 bits 0x2C **RGBA5551** — 16-bit pixels with alpha at the low 1bits 0x2D **RGBA4444** — 16-bit pixels with alpha at the low 4 bits

52.6.13 PS Input Buffer Address (PXP_PS_BUF)

PS Input Buffer Address. This should be programmed to the starting address of the RGB data or Y (luma) data for the PS plane.

This register contains the pointer to the Luma/RGB buffer. If the application requires an offset into the PS buffer, then this address can be set so that the desired offset is achieved. Any byte address is valid. For best performance, 64B alignment is recommended.

EXAMPLE

```
PXP_PS_BUF_WR(image_rgb); // RGB image
PXP_PS_BUF_WR(image_y);   // Y (luma) image data
PXP_PS_UBUF_WR(image_u);  // U (Cb) image data
PXP_PS_VBUF_WR(image_v);  // V (Cr) image data
```

Address: 4081_4000h base + C0h offset = 4081_40C0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	ADDR																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PXP_PS_BUF field descriptions

Field	Description
ADDR	Address pointer for the PS RGB or Y (luma) input buffer.

52.6.14 PS U/Cb or 2 Plane UV Input Buffer Address (PXP_PS_UBUF)

PS Chroma (U/Cb/UV) Input Buffer Address. This register points to the beginning of the PS U/Cb input buffer. In two plane operation, this register points to the beginning of the PS UV chroma input buffer.

This register contains the pointer to the Chroma U/Cb or 2 plane UV buffer. This register is unused when processing 1-plane buffer formats. If the application requires an offset into the PS buffer, then this address can be set so that the desired offset is achieved. Any byte address is valid. For best performance, 64B alignment is recommended.

EXAMPLE

```
PXP_PS_BUF_WR(image_y);   // Y (luma) image data
PXP_PS_UBUF_WR(image_u);  // U (Cb) image data
PXP_PS_VBUF_WR(image_v);  // V (Cr) image data
```

Address: 4081_4000h base + D0h offset = 4081_40D0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	ADDR																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PXP_PS_UBUF field descriptions

Field	Description
ADDR	Address pointer for the PS U/Cb or 2 plane UV Chroma input buffer.

52.6.15 PS V/Cr Input Buffer Address (PXP_PS_VBUF)

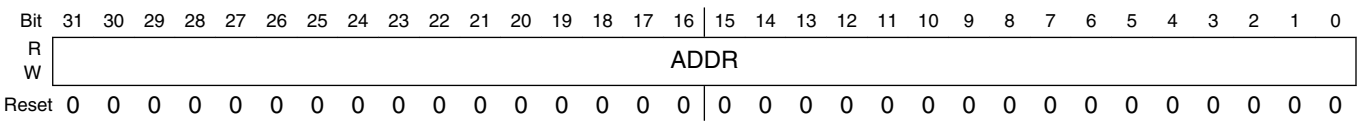
PS Chroma (V/Cr) Input Buffer Address. This register points to the beginning of the PS V/Cr input buffer. In one or two plane operation, this register is not used. In monochrome modes Y8 and Y4, the low 16 bits are used as the U/V data in the datapath instead of sourcing U/V data from external buffers. In this case, it represents a fixed value for U/V data.

This register contains the pointer to the Chroma V/Cr buffer. For Y8/Y4 modes, the low 16 bits are used as the monochrome U and V values in the data path. Bits [15:8] represent the U data byte, and bits]7:0] represent the V data byte. Other than with Y8/Y4 input buffer formats, this register is unused when processing 1 or 2-plane buffer formats. If the application requires an offset into the PS buffer, then this address can be set so that the desired offset is achieved. Any byte address is valid. For best performance, 64B alignment is recommended.

EXAMPLE

```
PXP_PS_BUF_WR(image_y);   // Y (luma) image data
PXP_PS_UBUF_WR(image_u);  // U (Cb) image data
PXP_PS_VBUF_WR(image_v);  // V (Cr) image data
```

Address: 4081_4000h base + E0h offset = 4081_40E0h



PXP_PS_VBUF field descriptions

Field	Description
ADDR	Address pointer for the PS V/Cr Chroma input buffer.

52.6.16 Processed Surface Pitch (PXP_PS_PITCH)

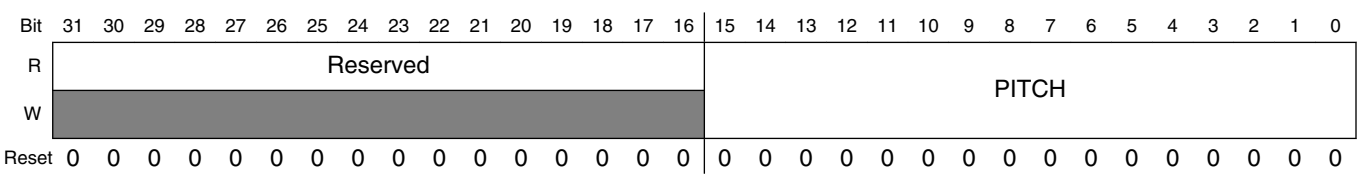
This register contains the processed surface pitch in bytes.

Any byte value will indicate the vertical pitch of the PS source frame buffer. This value will be used in PS pixel address calculations. This value has no relation to the UL and LR registers. It specifies how many bytes are between two vertically adjacent pixels in the input PS surface. For multi-plane formats, the Y buffer pitch should be programmed. For 2-plane YUV422, the UV pitch is the same as the Y pitch. For 3-plane YUV422, the U and V pitch is 1/2 the Y pitch. For 2-plane YUV420, the UV pitch is 1/2 the Y pitch. For 3-plane YUV420, the U and V pitch is 1/4 the Y pitch. All source buffers should comply with these U and V resolution reductions with respect to their Y source buffers.

EXAMPLE

```
PXP_PS_PITCH_WR( 64 * 4 );  // The output buffer pitch is 64 pixels times 32 bits per pixel
```

Address: 4081_4000h base + F0h offset = 4081_40F0h



PXP_PS_PITCH field descriptions

Field	Description
31–16 Reserved	This field is reserved. Always set to zero.
PITCH	Indicates the number of bytes in memory between two vertically adjacent pixels.

52.6.17 PS Background Color (PXP_PS_BACKGROUND)

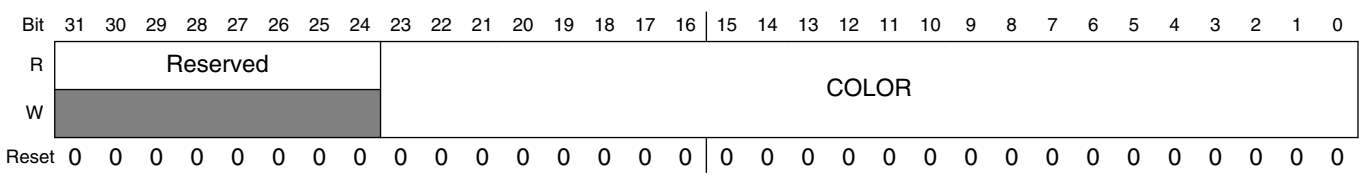
PS Background Pixel Color. This register provides a pixel value used when processing pixels outside of the region specified by the PS Coordinate registers. This value can effectively be used to set the color of the letterboxing region around the PS image.

This register contains a pixel value to be used for any PS pixels that fall outside the PS extents. This is effectively a background or letterbox color. The CSC1 control and datapath pixel format should be considered when selecting the background color.

EXAMPLE

```
PXP_PS_BACKGROUND_WR(0x00000000);  // letterbox is black
PXP_PS_BACKGROUND_WR(0x00800000);  // letterbox is dark red
PXP_PS_BACKGROUND_WR(0x00008000);  // letterbox is dark green
PXP_PS_BACKGROUND_WR(0x00000080);  // letterbox is dark blue
```

Address: 4081_4000h base + 100h offset = 4081_4100h



PXP_PS_BACKGROUND field descriptions

Field	Description
31–24 Reserved	This field is reserved. Always set to zero.
COLOR	Background color (in 24bpp format) for any pixels not within the buffer range specified by the PS ULC/ LRC.

52.6.18 PS Scale Factor Register (PXP_PS_SCALE)

PS Scale Factor. This register provides the scale factor for the PS buffer.

The maximum down scaling factor is 1/2 such that the output image in either axis is 1/2 the size of the source. The maximum up scaling factor is 2^12 for either axis. The reciprocal of the scale factor should be loaded into this register. To reduce the PS buffer by a factor of two in the output frame buffer, a value of 10.0000_0000_0000 should be loaded into this register. To scale up by a factor of 4, the value of 1/4, or 00.0100_0000_0000, should be loaded into this register. To scale up by 8/5, the value of 00.1010_0000_0000 should be loaded.

EXAMPLE

```
PXP_PS_SCALE_WR(0x10001000);  // 1:1  scaling (0x1.000)
PXP_PS_SCALE_WR(0x08000800);  // 2x   scaling (0x0.800)
PXP_PS_SCALE_WR(0x20002000);  // 1/2x scaling (0x2.000)
```

Address: 4081_4000h base + 110h offset = 4081_4110h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved								YSCALE							
W																
Reset	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved								XSCALE							
W																
Reset	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0

PXP_PS_SCALE field descriptions

Field	Description
31 Reserved	This field is reserved. Always set to zero.
30–16 YSCALE	This is a two bit integer and 12 bit fractional representation (##.####_####_####) of the Y scaling factor for the PS source buffer. The maximum value programmed should be 2 since scaling down by a factor greater than 2 is not supported with the bilinear filter. Decimation and the bilinear filter should be used together to achieve scaling by more than a factor of 2.
15 Reserved	This field is reserved. Always set to zero.
XSCALE	This is a two bit integer and 12 bit fractional representation (##.####_####_####) of the X scaling factor for the PS source buffer. The maximum value programmed should be 2 since scaling down by a factor greater than 2 is not supported with the bilinear filter. Decimation and the bilinear filter should be used together to achieve scaling by more than a factor of 2.

52.6.19 PS Scale Offset Register (PXP_PS_OFFSET)

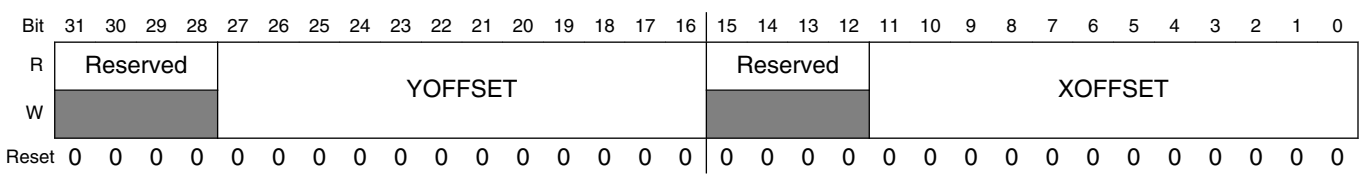
PS Scale Offset. This register provides the initial scale offset for the PS buffer.

The X and Y offset provides the ability to access the source image with a per sub-pixel granularity. This provides the capability to use all source pixels to effect the output PS image. The fixed offset values can be used for sub-pixel adjustments in the bilinear scaling filter. For example, when scaling an image down by a factor of 2, an initial offset of 0x0 would result in sub-sampling every other pixel. If a fixed offset of 0x800 (1/2), all pixels are used in scaling the final output pixel value. In this case, the first output pixel would be the sum of (1/2*P0) + (1/2*P1). This fixed offset is applied after the decimation filter stage, and before the bilinear filter stage.

EXAMPLE

```
PXP_PS_SCALE_WR(0x2000_2000);   // 1/2x scaling (0x2.000)
PXP_PS_OFFSET_WR(0x0800_0800);  // half-pixel offset in both X and Y to ensure averaging
versus pixel decimation
```

Address: 4081_4000h base + 120h offset = 4081_4120h



PXP_PS_OFFSET field descriptions

Field	Description
31–28 Reserved	This field is reserved. Always set to zero.
27–16 YOFFSET	This is a 12 bit fractional representation (0.####_####_####) of the Y scaling offset. This represents a fixed pixel offset which gets added to the scaled address to determine source data for the scaling engine.
15–12 Reserved	This field is reserved. Always set to zero.
XOFFSET	This is a 12 bit fractional representation (0.####_####_####) of the X scaling offset. This represents a fixed pixel offset which gets added to the scaled address to determine source data for the scaling engine.

52.6.20 PS Color Key Low (PXP_PS_CLRKEYLOW)

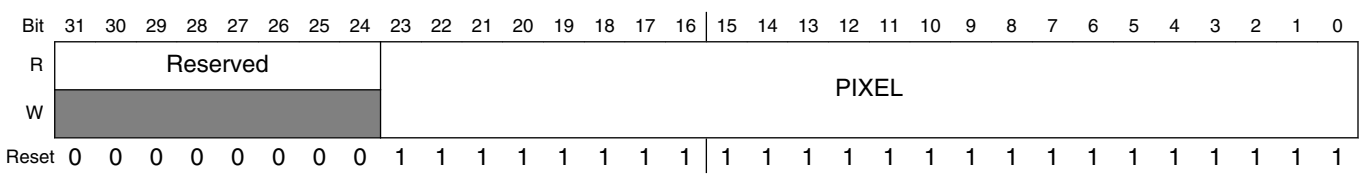
This register contains the color key low value for the PS buffer.

When processing an image, if the PXP finds a pixel in the PS buffer with a color that falls in the range between PXP_PS_CLRKEYLOW and PXP_PS_CLRKEYHIGH, it will insert the pixel from the AS channel. If the current AS pixel is letterboxed or if the AS also matches its colorkey range, the PXP_PS_BACKGROUND color is passed down the pixel pipeline.

EXAMPLE

```
                                    // colorkey values between
PXP_PS_CLRKEYLOW_WR (0x008000); // medium green and
PXP_PS_CLRKEYHIGH_WR(0x00FF00); // light green
```

Address: 4081_4000h base + 130h offset = 4081_4130h



PXP_PS_CLRKEYLOW field descriptions

Field	Description
31–24 Reserved	This field is reserved. Always set to zero.
PIXEL	Low range of color key applied to PS buffer. To disable PS colorkeying, set the low colorkey to 0xFFFFFF and the high colorkey to 0x000000.

52.6.21 PS Color Key High (PXP_PS_CLRKEYHIGH)

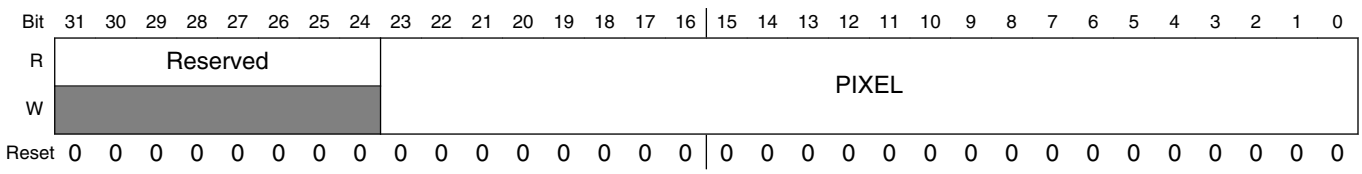
This register contains the color key high value for the PS buffer.

When processing an image, if the PXP finds a pixel in the PS buffer with a color that falls in the range between PXP_PS_CLRKEYLOW and PXP_PS_CLRKEYHIGH, it will insert the pixel from the AS channel. If the current AS pixel is letterboxed or if the AS also matches its colorkey range, the PXP_PS_BACKGROUND color is passed down the pixel pipeline.

EXAMPLE

```
                                    // colorkey values between
PXP_PS_CLRKEYLOW_WR (0x008000); // medium green and
PXP_PS_CLRKEYHIGH_WR(0x00FF00); // light green
```

Address: 4081_4000h base + 140h offset = 4081_4140h



PXP_PS_CLRKEYHIGH field descriptions

Field	Description
31–24 Reserved	This field is reserved. Always set to zero.
PIXEL	High range of color key applied to PS buffer. To disable PS colorkeying, set the low colorkey to 0xFFFFFF and the high colorkey to 0x000000.

52.6.22 Alpha Surface Control (PXP_AS_CTRL)

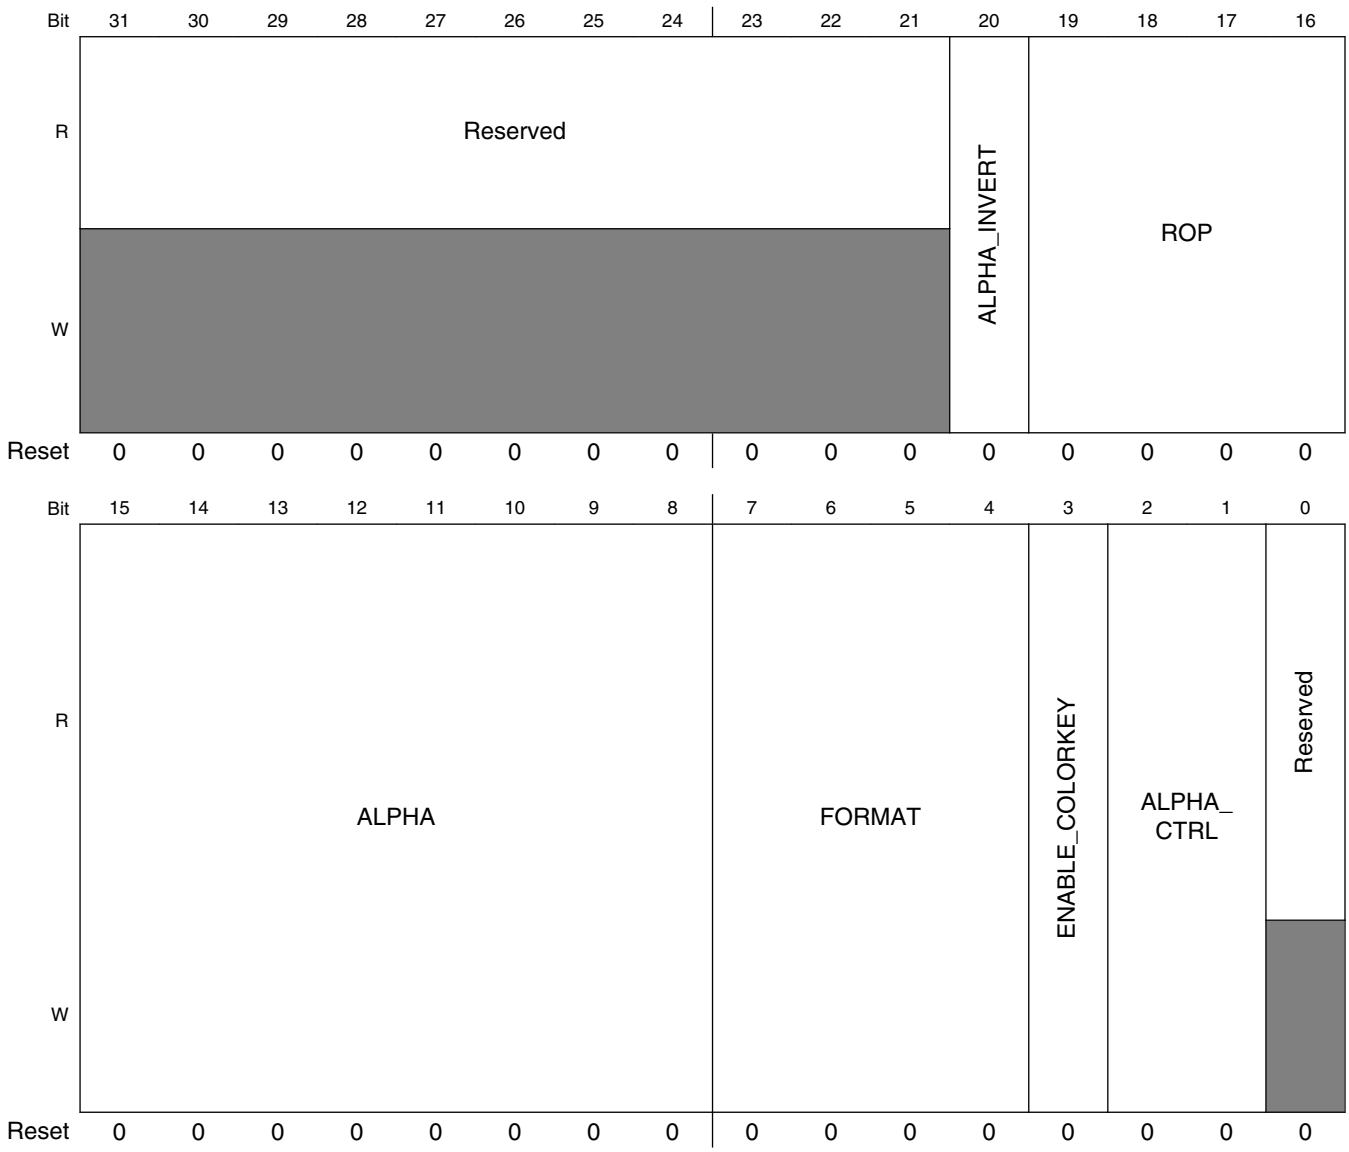
This register contains buffer control for the Alpha Surface 0 input buffer.

The Alpha Surface Parameter register provides additional controls for AS.

EXAMPLE

```
u32 asparam;
      asparam  = BF_PXP_ASPARAM_ENABLE    (1);
      asparam |= BF_PXP_ASPARAM_ALPHA_CTRL(BV_PXP_ASPARAM_ALPHA_CTRL__ROPs);
      asparam |= BF_PXP_ASPARAM_FORMAT    (BV_PXP_ASPARAM_FORMAT__ARGB8888);
      asparam |= BF_PXP_ASPARAM_ROP       (BV_PXP_ASPARAM_ROP__XORAS);
PXP_ASPARAM_WR(0,asparam);  // enable alpha surface to perform XOR ROP using RGB8888 AS
pixel format
```

Address: 4081_4000h base + 150h offset = 4081_4150h



PXP_AS_CTRL field descriptions

Field	Description
31–21 Reserved	This field is reserved. Always set to zero.
20 ALPHA_INVERT	Setting this bit to logic 0 will not alter the alpha value. A logic 1 will invert the alpha value and apply (1-alpha) for image composition. 0x0 **Not inverted** — 0x1 **Inverted** —
19–16 ROP	Indicates a raster operation to perform when enabled. Raster operations are enabled through the ALPHA_CTRL field. 0x0 **MASKAS** — AS AND PS 0x1 **MASKNOTAS** — nAS AND PS

Table continues on the next page...

PXP_AS_CTRL field descriptions (continued)

Field	Description
	0x2 **MASKASNOT** — AS AND nPS 0x3 **MERGEAS** — AS OR PS 0x4 **MERGENOTAS** — nAS OR PS 0x5 **MERGEASNOT** — AS OR nPS 0x6 **NOTCOPYAS** — nAS 0x7 **NOT** — nPS 0x8 **NOTMASKAS** — AS NAND PS 0x9 **NOTMERGEAS** — AS NOR PS 0xA **XORAS** — AS XOR PS 0xB **NOTXORAS** — AS XNOR PS
15–8 ALPHA	Alpha modifier used when the ALPHA_MULTIPLY or ALPHA_OVERRIDE values are programmed in PXP_AS_CTRL[ALPHA_CTRL]. The output alpha value will either be replaced (ALPHA_OVERRIDE) or scaled (ALPHA_MULTIPLY) when selected.
7–4 FORMAT	Indicates the input buffer format for AS. 0x0 **ARGB8888** — 32-bit pixels with alpha 0x1 **RGBA888** — 2-bit pixel with alpha at low 8 bits 0x4 **RGB888** — 32-bit pixels without alpha (unpacked 24-bit format) 0x8 **ARGB1555** — 16-bit pixels with alpha 0x9 **ARGB4444** — 16-bit pixels with alpha 0xA **RGBA5551** — 16-bit pixel with alpha at low 1 bit 0xB **RGBA4444** — 16-bit pixel with alpha at low 4 bits 0xC **RGB555** — 16-bit pixels without alpha 0xD **RGB444** — 16-bit pixels without alpha 0xE **RGB565** — 16-bit pixels without alpha
3 ENABLE_ COLORKEY	Indicates that colorkey functionality is enabled for this alpha surface. Pixels found in the alpha surface colorkey range will be displayed as transparent (the PS pixel will be used). 0x0 **Disabled** — 0x1 **Enabled** —
2–1 ALPHA_CTRL	Determines how the alpha value is constructed for this alpha surface. Indicates that the value in the ALPHA field should be used instead of the alpha values present in the input pixels. 0x0 **Embedded** — Indicates that the AS pixel alpha value will be used to blend the AS with PS. The ALPHA field is ignored. 0x1 **Override** — Indicates that the value in the ALPHA field should be used instead of the alpha values present in the input pixels. 0x2 **Multiply** — Indicates that the value in the ALPHA field should be used to scale all pixel alpha values. Each pixel alpha is multiplied by the value in the ALPHA field. 0x3 **ROPs** — Enable ROPs. The ROP field indicates an operation to be performed on the alpha surface and PS pixels.
0 Reserved	This field is reserved. Always set to zero.

52.6.23 Alpha Surface Buffer Pointer (PXP_AS_BUF)

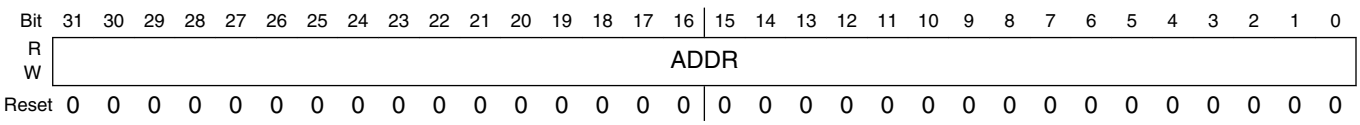
Alpha Surface 0 Buffer Address Pointer. This register points to the beginning of the Alpha Surface 0 input buffer.

This register is used to indicate the base address of the AS buffer.

EXAMPLE

```
u32* alpha_ptr;
PXP_ASn_WR(0,alpha_ptr);
```

Address: 4081_4000h base + 160h offset = 4081_4160h



PXP_AS_BUF field descriptions

Field	Description
ADDR	Address pointer for the alpha surface 0 buffer.

52.6.24 Alpha Surface Pitch (PXP_AS_PITCH)

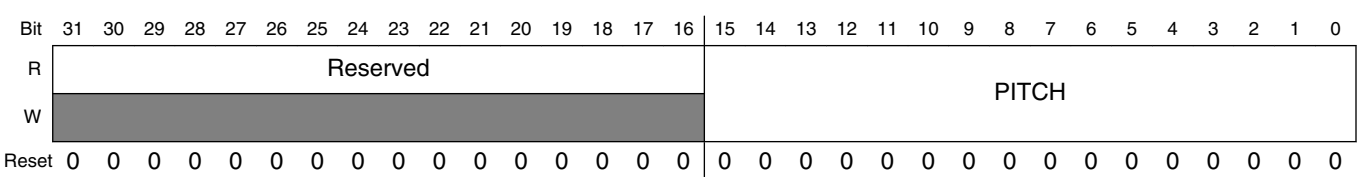
This register contains the alpha surface pitch in bytes.

Any byte value will indicate the vertical pitch. This value will be used in AS pixel address calculations. This value has no relation to the UL and LR registers. It specifies how many bytes are between two vertically adjacent pixels in the input AS surface.

EXAMPLE

```
PXP_AS_PITCH_WR( 1920 * 4 );  // The output buffer pitch is HD resolution at 32 bits per
pixel
```

Address: 4081_4000h base + 170h offset = 4081_4170h



PXP_AS_PITCH field descriptions

Field	Description
31–16 Reserved	This field is reserved. Always set to zero.
PITCH	Indicates the number of bytes in memory between two vertically adjacent pixels.

52.6.25 Overlay Color Key Low (PXP_AS_CLRKEYLOW)

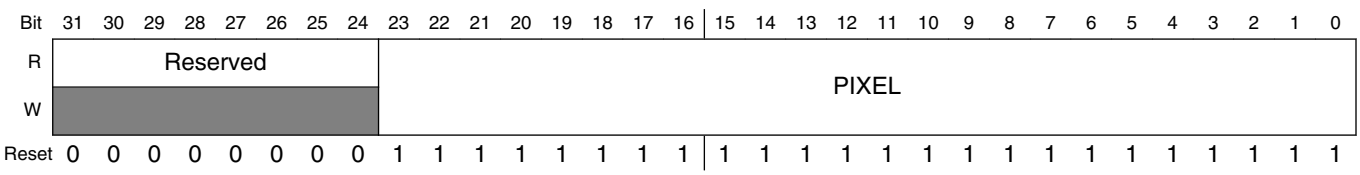
This register contains the color key low value for the AS buffer.

When processing an image, the if the PXP finds a pixel in the current overlay image with a color that falls in the range from the ASCOLORKEYLOW to ASCOLORKEYHIGH range, it will use the PS pixel value for that location. If no PS image is present or if the PS image also matches its colorkey range, the PS background color is used. Colorkey operations are higher priority than alpha or ROP operations.

EXAMPLE

```
                                    // colorkey values between
PXP_AS_CLRKEYLOW_WR (0x000000); // black and
PXP_AS_CLRKEYHIGH_WR(0x800000); // medium red
```

Address: 4081_4000h base + 180h offset = 4081_4180h



PXP_AS_CLRKEYLOW field descriptions

Field	Description
31–24 Reserved	This field is reserved. Always set to zero.
PIXEL	Low range of RGB color key applied to AS buffer. Each overlay has an independent colorkey enable.

52.6.26 Overlay Color Key High (PXP_AS_CLRKEYHIGH)

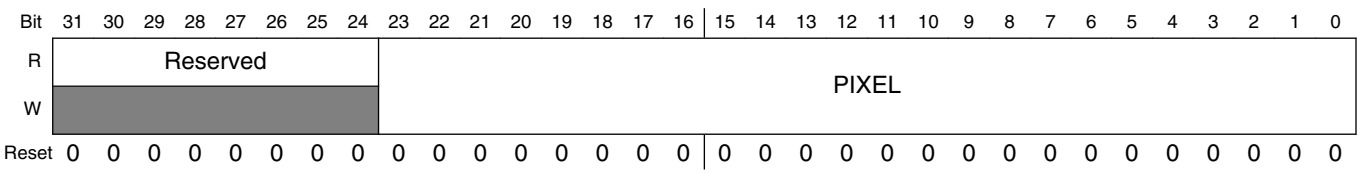
This register contains the color key high value for the AS buffer.

When processing an image, the if the PXP finds a pixel in the current overlay image with a color that falls in the range from the ASCOLORKEYLOW to ASCOLORKEYHIGH range, it will use the PS pixel value for that location. If no PS image is present or if the PS image also matches its colorkey range, the PS background color is used. Colorkey operations are higher priority than alpha or ROP operations.

EXAMPLE

```
                                    // colorkey values between
PXP_AS_CLRKEYLOW_WR (0x000000); // black and
PXP_AS_CLRKEYHIGH_WR(0x800000); // medium red
```

Address: 4081_4000h base + 190h offset = 4081_4190h



PXP_AS_CLRKEYHIGH field descriptions

Field	Description
31–24 Reserved	This field is reserved. Always set to zero.
PIXEL	High range of RGB color key applied to AS buffer. Each overlay has an independent colorkey enable.

52.6.27 Color Space Conversion Coefficient Register 0 (PXP_CSC1_COEF0)

This register contains color space conversion coefficients in two's compliment notation.

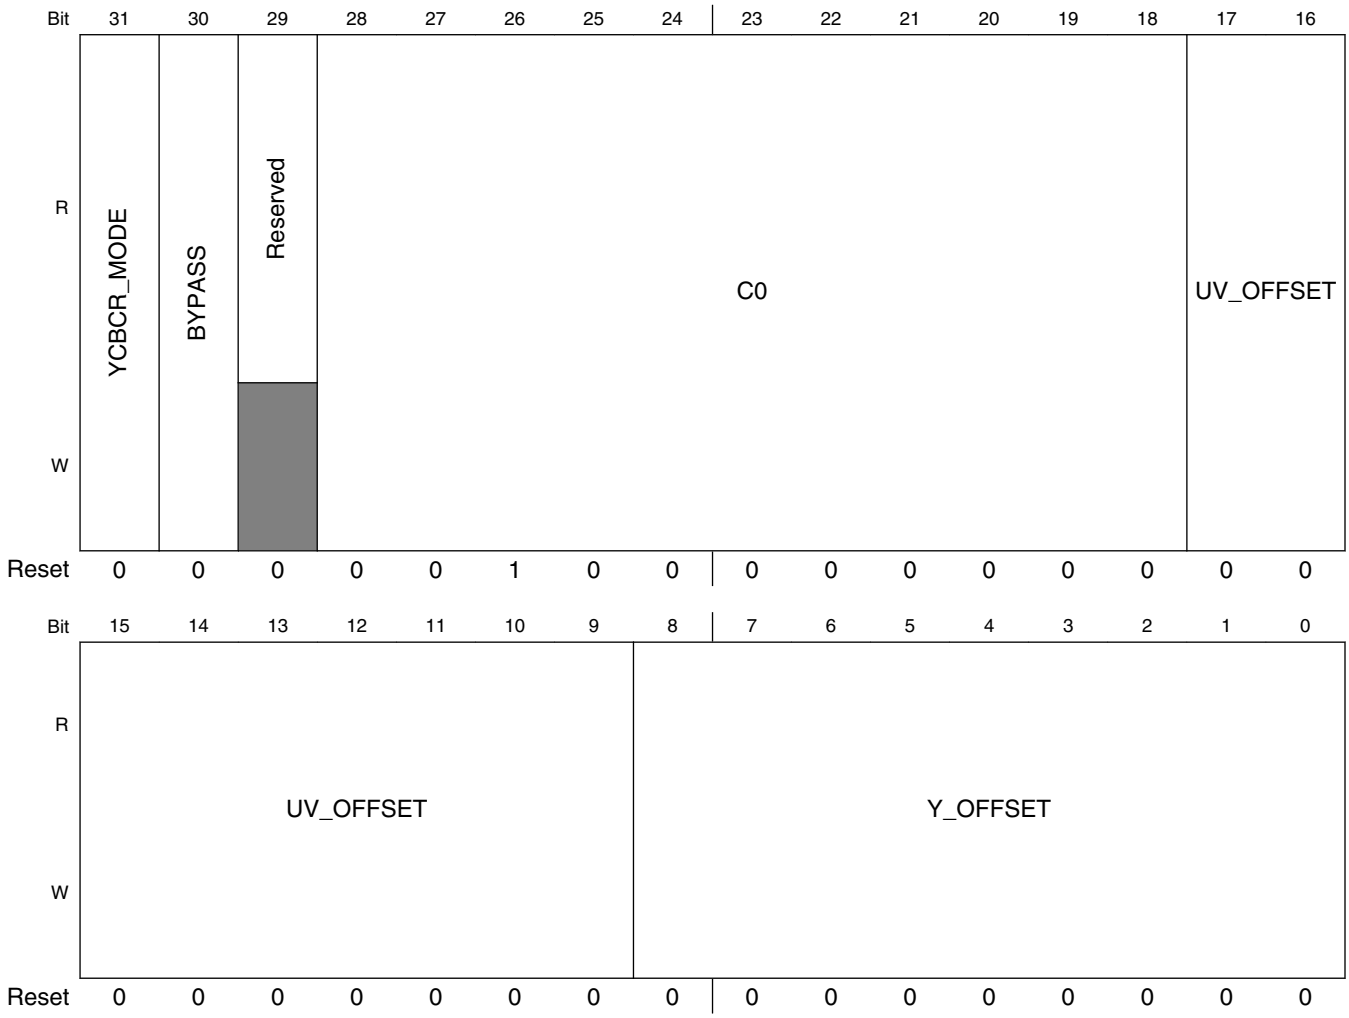
The coefficient 0 register contains coefficients used in the color space conversion algorithm. The Y and UV offsets are added to the source buffer to normalize them before the conversion. C0 is the coefficient that is used to multiply the luma component of the data for all three RGB components.

EXAMPLE

```
//  The equations used for Colorspace conversion are:
//     R = C0*(Y+YOFFSET)                    + C1(V+UV_OFFSET)
//     G = C0*(Y+YOFFSET) + C3(U+UV_OFFSET) + C2(V+UV_OFFSET)
//     R = C0*(Y+YOFFSET) + C4(U+UV_OFFSET)

   PXP_CSCCOEF0_WR(0x04030000); // YUV coefficients: C0, Yoffset, UVoffset
   PXP_CSCCOEF1_WR(0x01230208); // YUV coefficients: C1, C4
   PXP_CSCCOEF2_WR(0x076B079b); // YUV coefficients: C2, C3
```

Address: 4081_4000h base + 1A0h offset = 4081_41A0h



PXP_CSC1_COEF0 field descriptions

Field	Description
31 YCBCR_MODE	Set to 1 when performing YCbCr conversion to RGB. This bit changes the behavior of the scaler when performing U/V scaling. 0 YUV to RGB 1 YCbCr to RGB **NOTE:** This bit should be configured correctly for YUV/YCbCr input even CSC is bypassed.
30 BYPASS	Bypass the CSC unit in the scaling engine. When set to logic 1, bypass is enabled and the output pixels will be in the YUV/YCbCr color space. When set to logic 0, the CSC unit is enabled and the pixels will be converted based on the programmed coefficients.
29 Reserved	This field is reserved. Always set to zero.
28–18 C0	Two's compliment Y multiplier coefficient. YUV=0x100 (1.000) YCbCr=0x12A (1.164)
17–9 UV_OFFSET	Two's compliment phase offset implicit for CbCr data. Generally used for YCbCr to RGB conversion. YCbCr=0x180, YUV=0x000 (typically -128 or 0x180 to indicate normalized -0.5 to 0.5 range)

Table continues on the next page...

PXP_CSC1_COEF0 field descriptions (continued)

Field	Description
Y_OFFSET	Two's compliment amplitude offset implicit in the Y data. For YUV, this is typically 0 and for YCbCr, this is typically -16 (0x1F0)

52.6.28 Color Space Conversion Coefficient Register 1 (PXP_CSC1_COEF1)

This register contains color space conversion coefficients in two's compliment notation.

The Coeffient 1 register contains coefficients used in the color space conversion algorithm. C1 is the coefficient that is used to multiply the chroma (Cr/V) component of the data for the red component. C4 is the coefficient that is used to multiply the chroma (Cb/U) component of the data for the blue component. Both values should be coded as a two's compliment fixed point number with 8 bits right of the decimal.

EXAMPLE

```
PXP_CSCCOEF0_WR(0x04030000); // YUV coefficients: C0, Yoffset, UVoffset
PXP_CSCCOEF1_WR(0x01230208); // YUV coefficients: C1, C4
PXP_CSCCOEF2_WR(0x076B079b); // YUV coefficients: C2, C3
```

Address: 4081_4000h base + 1B0h offset = 4081_41B0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

PXP_CSC1_COEF1 field descriptions

Field	Description
31–27 Reserved	This field is reserved. Always set to zero.
26–16 C1	Two's compliment Red V/Cr multiplier coefficient. YUV=0x123 (1.140) YCbCr=0x198 (1.596)
15–11 Reserved	This field is reserved. Always set to zero.
C4	Two's compliment Blue U/Cb multiplier coefficient. YUV=0x208 (2.032) YCbCr=0x204 (2.017)

52.6.29 Color Space Conversion Coefficient Register 2 (PXP_CSC1_COEF2)

This register contains color space conversion coefficients in two's compliment notation.

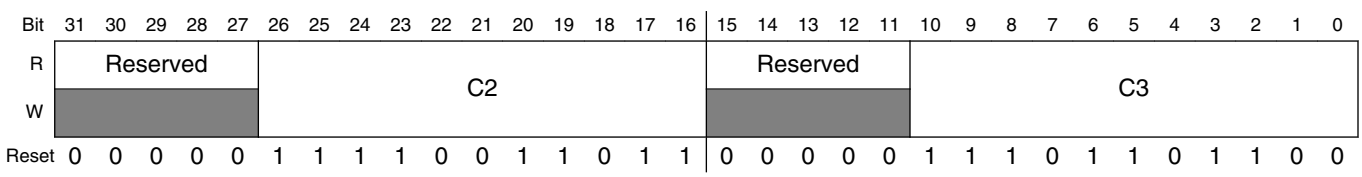
The Coefficient 2 register contains coefficients used in the color space conversion algorithm. C2 is the coefficient that is used to multiply the chroma (Cr/V) component of the data for the green component. C3 is the coefficient that is used to multiply the chroma (Cb/U) component of the data for the green component. Both values should be coded as a two's compliment fixed point number with 8 bits right of the decimal.

EXAMPLE

```
// NOTE: The default values for the CSCCOEF2 register are incorrect.  C2 should be 0x76B and
C3 should be 0x79C for proper operation.

   PXP_CSCCOEF0_WR(0x04030000); // YUV coefficients: C0, Yoffset, UVoffset
   PXP_CSCCOEF1_WR(0x01230208); // YUV coefficients: C1, C4
   PXP_CSCCOEF2_WR(0x076B079b); // YUV coefficients: C2, C3
```

Address: 4081_4000h base + 1C0h offset = 4081_41C0h



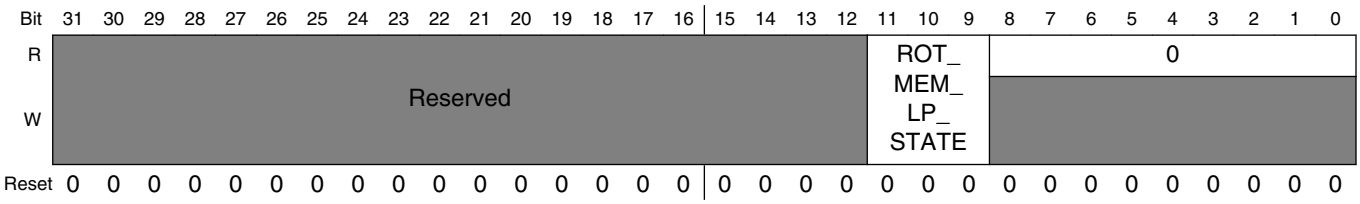
PXP_CSC1_COEF2 field descriptions

Field	Description
31–27 Reserved	This field is reserved. Always set to zero.
26–16 C2	Two's complement Green V/Cr multiplier coefficient. YUV=0x76B (-0.581) YCbCr=0x730 (-0.813)
15–11 Reserved	This field is reserved. Always set to zero.
C3	Two's complement Green U/Cb multiplier coefficient. YUV=0x79C (-0.394) YCbCr=0x79C (-0.392)

52.6.30 PXP Power Control Register (PXP_POWER)

This register controls power states for PXP memories.

Address: 4081_4000h base + 320h offset = 4081_4320h



PXP_POWER field descriptions

Field	Description
31–12 Reserved	This field is reserved.
11–9 ROT_MEM_LP_ STATE	Select the low power state of the Rotation (ROT) memory. 0x0 **NONE** — Memory is not in low power state. 0x1 **LS** — Light Sleep Mode. Low leakage mode, maintain memory contents. 0x2 **DS** — Deep Sleep Mode. Low leakage mode, maintain memory contents. 0x4 **SD** — Shut Down Mode. Shut Down periphery and core, no memory retention.
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

52.6.31 Next Frame Pointer (PXP_NEXT)

This register contains a pointer to a data structure used to reload the PXP registers at the end of the current frame.

To enable this functionality, software must write this register while the PXP is processing the current data frame (if the PXP is currently idle, this will also initiate an immediate load of registers from the pointer). The process of writing this register (WRITE operation) will set a semaphore in hardware to notify the control logic that a register reload operation must be performed when the current frame processing is complete. At the end of a frame, the PXP will fetch the register settings from this location, signal an interrupt to software, then proceed with rendering the next frame of data. Software may cancel the reload operation by issuing a CLEAR operation to this register. SET and TOGGLE operations should not be used when addressing this register. All registers will be reloaded with the exception of the following: STAT, CSCCOEFn, NEXT. All other registers will be loaded in the order they appear in the register map. After the pointer's contents have been loaded into the PXP's registers, the NEXT_IRQ interrupt will be issued (see the PXP_STATUS register).

EXAMPLE

```
// create register command structure in memory
  u32* pxp_commands0[48], pxp_commands1;
  u32  rc;

// initialize control structure for frame 0
  pxp_commands0[0] = ...; // CTRL
  pxp_commands0[1] = ...; // OUT Buffer
  ...
  pxp_commands0[47] = ..; // Overlay7 param2

// initialize control structure for frame 1
  pxp_commands1[0] = ...; // CTRL
  pxp_commands1[1] = ...; // OUT Buffer
  ...
  pxp_commands1[47] = ..; // Overlay7 param2

// poll until a command isn't queued
  while (rc=PXP_NEXT_RD() & BM_PXP_NEXT_ENABLED );
  PXP_NEXT_WR(pxp_commands0);  // enable PXP operation 0 via command pointer

// poll until first command clears
  while (rc=PXP_NEXT_RD() & BM_PXP_NEXT_ENABLED );
  PXP_NEXT_WR(pxp_commands1);  // enable PXP operation 1 via command pointer
```

Address: 4081_4000h base + 400h offset = 4081_4400h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Chapter 53
Graphics Processing Unit (GPU2D)

53.1 Chip-specific GPU information

Table 53-1. Reference links to related information

Topic	Related module(s)	Reference
System memory map	-	System Memory Map
Clocking	CCM	Clock Management Clock Control Module (CCM)
Power management	PMU	Power Management Power Management Unit
Signal multiplexing	IOMUX	External Signals and Pin Multiplexing IOMUX
Interrupts, DMA Events and XBAR Assignments	-	Interrupts, DMA Events and XBAR Assignments

53.2 Overview

The Graphics Processing Unit (GPU) provides high performance, low power consumption, and high quality graphics. It supports raster, vector graphics encompassing the majority of the embedded graphics use-case scenarios.

53.2.1 Block diagram

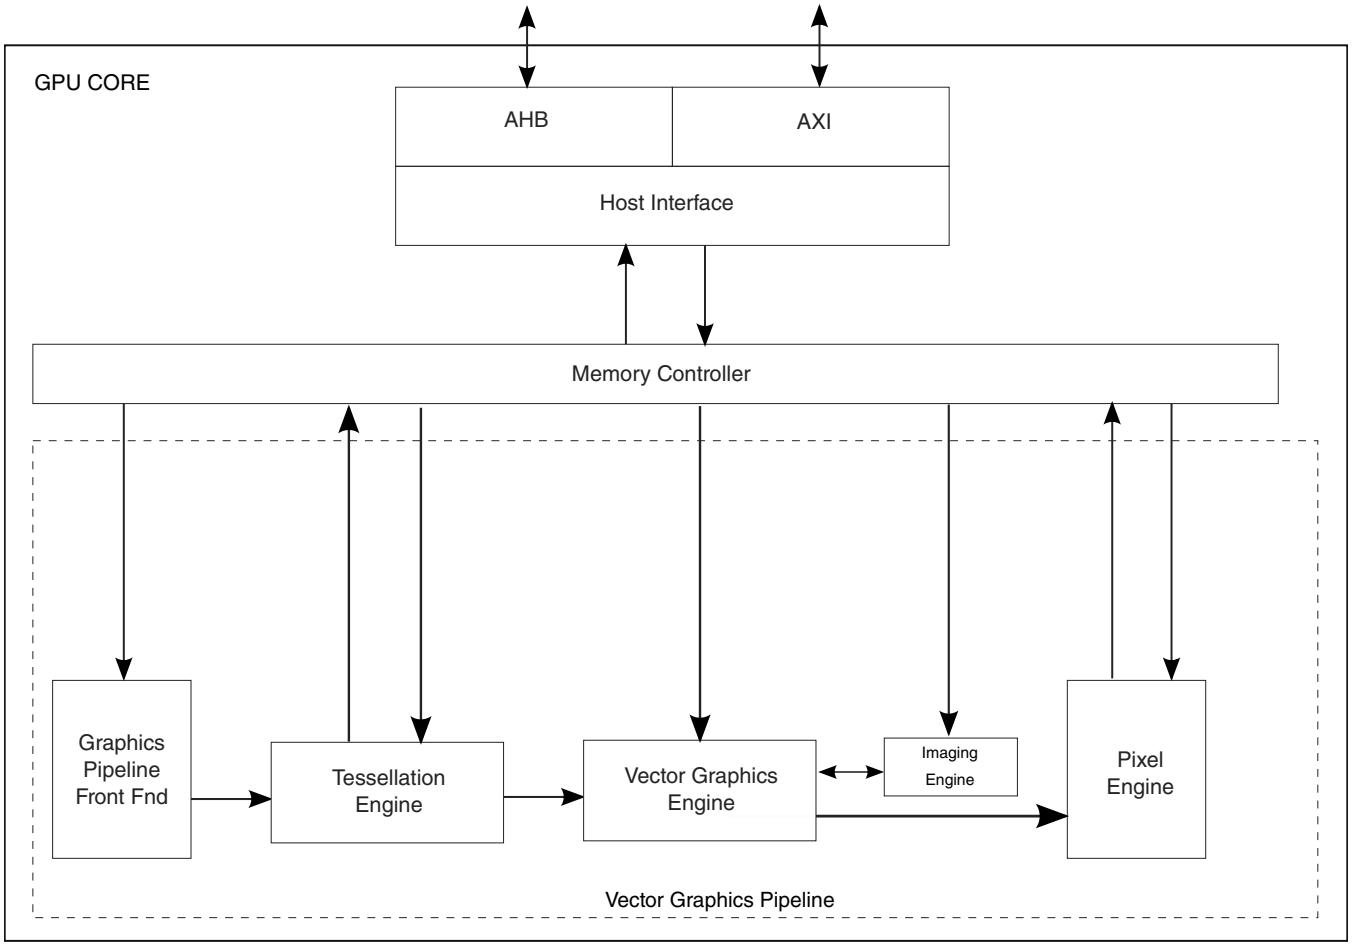

Figure 53-1. GPU block diagram

- Host Interface: Allows the GPU core to communicate with external memory and the CPU through the AXI or AHB bus. In this block, data crosses clock domain boundaries.
- Memory Controller: Internal memory management unit that controls the block-to-host memory request interface.
- Graphics Pipeline Front End: Inserts high level primitives and commands into the graphics pipeline.
- Tessellation Engine: Transforms vertices, and control points and tessellates lines, quadratic, and cubic Bezier curves.
- Vector Graphics Engine: Rasterizer that converts primitives to pixels.
- Imaging Engine: Paint and Image generator that colors each pixel.
- Pixel Engine: Renderer that combines different sources into the final pixel value.

53.2.2 Features

The following features are supported by the GPU 2D unit:

- OpenVG 1.1
- Hardware Tessellation
- High Quality 16x FSAA rendering
- Configurable Co-ordinate systems and transformations (3x3 matrix)
- Blending including 8 Porter Duff blending modes
- Rotation to any angle
- Odd/even and non-zero fill rules
- Linear and curved paint paths (linear and gradient)
- Solid and linear pattern for paints
- Supports 14 pixel formats for image interpolation
- Support for various VG input formats including A4,A8, L8, YV, NV, YUV2 Etc.

The table below describes the Graphics Hardware features:

Table 53-2. Graphics Hardware Features

Feature	Description
Coordinate systems and transformations	Image drawing uses a 3x3 perspective transformation matrix
Scissoring and viewport clipping	-
Porter-Duff blending	-
Blending	Surface (alpha) masking for variable transparency Porter Duff blending plus additional blend modes
Rotation	To any angle
Fill rules	Odd/even and non-zero
Paint paths	Linear and radial gradient paint paths
Paints	Solid, linear, radial gradient and pattern
Pixel formats for image interpolation	14 pixel formats for image interpolation, including A4/A8
Image filters and interpolations	Point, Linear and Bi-linear blends
Transformations	sRGBA color transformation

53.3 Functional description

The following sections describe functional details of the GPU2D module.

53.3.1 VG Format Support

The following tables describes the available graphic formats:

Table 53-3. VG Format Support

<table>
<tr><th>Feature</th><th colspan="4">GPU Support</th></tr>
<tr><td>Image formats

The graphics engine supports these formats for source image and destination render targets.</td><td colspan="4"><table>

53.3.2 Clocks

Table 53-4. Clocks

Clock name	Description
aclk	AXI interface clock
hclk	AHB interface clock
clk2x	Functional 2X GPU core clock for the core logic. Also used internally, divided by 2.

53.4 Software Application Programming Interface (API)

There following software APIs are supported by the GPU:

- OpenVG 1.1 API Standard for Vector Graphics Acceleration
- VGLite Graphics API

53.4.1 OpenVG 1.1 API Standard for Vector Graphics Acceleration

OpenVG provides a low-level hardware acceleration interface for vector graphics libraries such as Flash and SVG. It is used for acceleration of high-quality vector graphics for user interfaces and text on small screen devices.

53.4.1.1 Core API features of OpenVG

Vector GPU supports the following key features of OpenVG:

- Coordinate Systems and Transformations (Image drawing uses a 3x3 perspective transformation matrix)
- Viewport Clipping, Scissoring and Alpha Masking
- Paths
- Images
- Image Filters
- Paint (gradient and pattern)
- Blending
- Dithering

53.4.1.2 OpenVG Rendering Pipeline

- Stage 1: Path, Transformation, Stroke, and Paint
- Stage 2: Stroked Path Generation
- Stage 3: Transformation
- Stage 4: Rasterization
- Stage 5: Clipping and Masking
- Stage 6: Paint Generation
- Stage 7: Image Interpolation
- Stage 8: Blending and Anti-aliasing

53.4.2 VGLite Graphics API

The GPU can also be used with the VGLite Graphics API. It is designed to support menu-driven user interfaces optimized for a system's overall resource requirements. The goal is to provide maximum performance, while keeping the memory footprint to a minimum.

The VGLite API is partitioned to provide controls for three main areas of functionality:

- Initialization: For Hardware and Software initialization
- Blit: For Raster rendering
- Draw: For Draw operations

The table below describes the Hardware supported Blit and/or Draw capabilities available for software control through the API:

Table 53-5. Blit and Draw Controls in VGLite API

Capability	GPU with VGLite API Support
Fill	Non-zero or Even-Odd
Path coordinate formats	S8, S16, S32, FP32
HW Anti-alias levels	Low, Medium, High
Blending	SrcOver, DstOver, SrcIn, DstIn, Screen, Multiply, Additive, Subtractive
Data Formats	ARGB4/8, RGB565, A4/8, L8 and BRGA variants
Path definitions	bounding box, path quality, coordinate format, buffer pointer, path length, path data

NOTE

The VGLite Graphics API document will be available as a part of the Software Development Kit (SDK).

Chapter 54
Audio Overview

54.1 Audio Overview

The audio subsystem consists of the following modules: SAI-1, SAI-2, SAI-3,SAI-4, PDM, ASRC, SPDIF and MQS. In addition, the IOMUX must be appropriately configured to get signals in and out of the chip.

Audio Module Overview provides an overview of each of the audio modules, followed by a module-specific section.

54.1.1 Audio Module Overview

The following figure shows a high level block diagram of the audio subsystem.

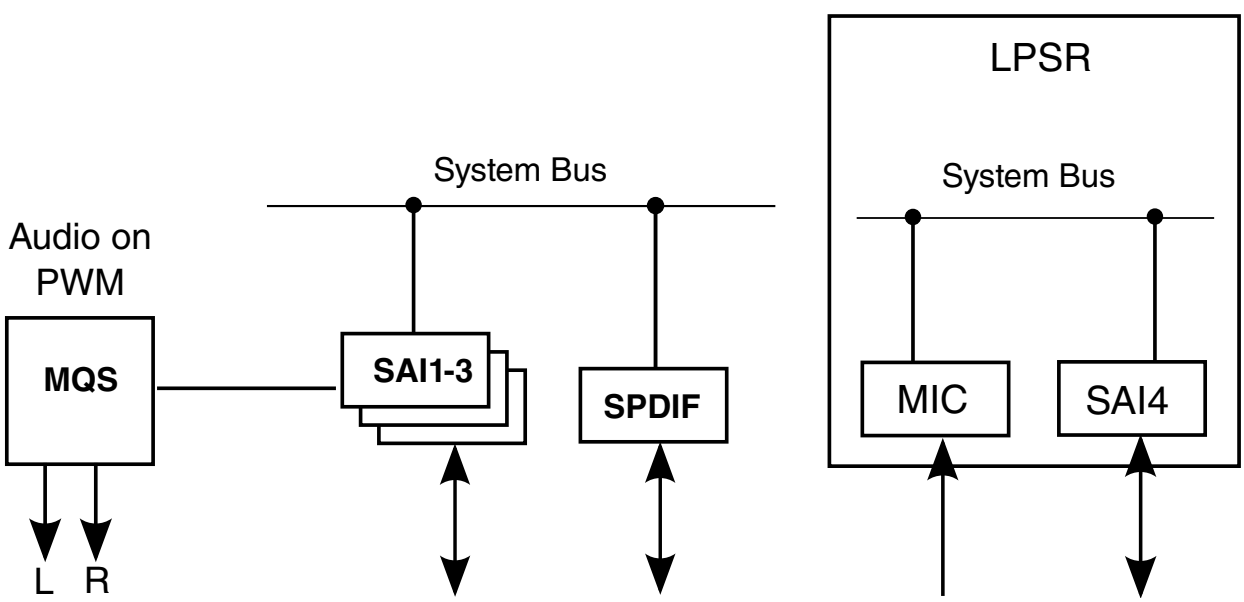

Figure 54-1. Audio peripherals block diagram

SAI*n* are synchronous serial interfaces used to transfer audio data. They can be accessed by both the eDMA and Arm CPUs. Their input/output are connected to the pads through IOMUX.

The PDM Microphone Interface (PDM) is used to receive audio from microphone. It supports 8-channel input with individual enable control for full or partial set of channels.

Asynchronous Sample Rate Converter (ASRC) is used for PCM sample rate conversion from one audio sampling clock domain to another.

MQS (medium quality speaker) is used to convert the I2S audio data from SAI to PWM signals that can drive external speaker directly. Its audio source comes from SAI-3 and its output is connected to pads through IOMUX.

The Sony/Philips digital interface (SPDIF) audio module is a stereo transceiver that allows the processor to receive and transmit digital audio over it. The SPDIF receiver section includes a frequency measurement block that allows the precise measurement of an incoming sampling frequency. A recovered clock is provided by the SPDIF receiver section and may be used to drive both internal and external components in the system.

The audio interfaces are summarized as the table below.

Table 54-1. Audio Interface Summary

Interface	Function	Configuration	
		RX Data Line	TX Data Line
SAI-1	External audio	4	4
SAI-2	External audio	1	1
SAI-3	External audio	1	1
SAI-4	External audio	1	1
MQS	External audio	0	2
SPDIF	External audio	1	1
PDM	PDM microphone interface	Four-pair inputs	
ASRC	Asynchronous Sample Rate Converter	-	

SAI-1 is used for multi-channel audio interface, which supports up to 8-channels audio input or 8-channels audio output at 384 kHz/32-bit. SAI-2, SAI-3 and SAI-4 can be used for stereo audio input and output up to 384 kHz/32-bit. Also SAI-3 is able to drive MQS directly as a low-cost audio output.

To reduce IO count and keep the flexibilities of supporting multiple RX and TX data lines application, SAI-1 has following options on data pin multiplexing. The multiplexing is done in the IOMUX. The following table is not an exhastive list of options, but does show that there can be up to 5 SAI-1 RX/TX data pins.

Table 54-2. SAI-1 TX/RX Data Pin Multiplexing

Options	Number of RX Data Pins	Number of TX Data Pins
0	1	4
1	2	3
2	3	2
3	4	1

SAI-1 to IOMUXC connection is implemented as shown in the diagram below.

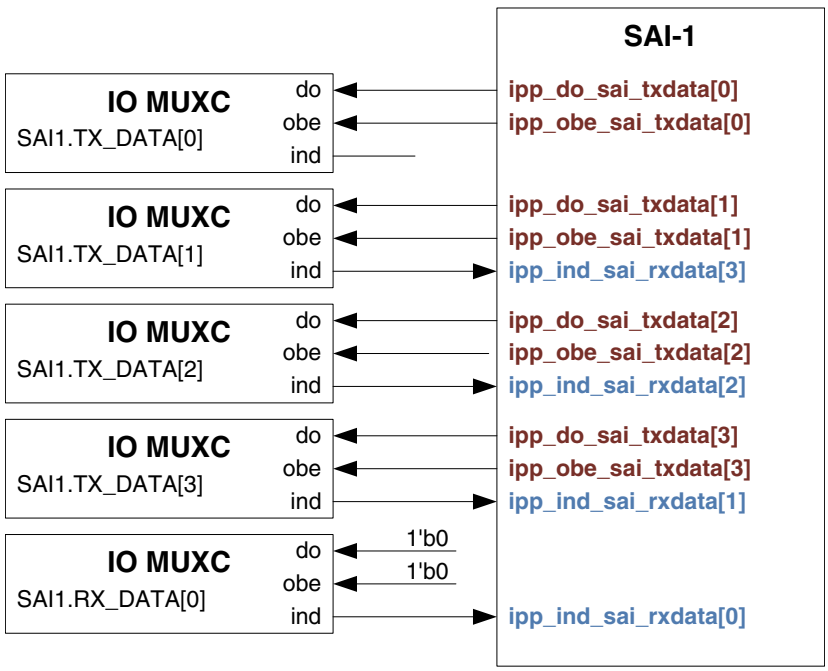

Figure 54-2. SAI-1 TX/RX Data Multiplexing

In the SAI-1 TX/RX Data Multiplexing figure:

- 'do' in the signal names indicate data transmitted to the PAD from SAI
- 'ind' in the signal name indicate data sensed from PAD and received by SAI
- 'obe' in the signal name indicate transmit enable

For example, if a pin is configured to use SAI-1 TXD3, then the PAD level is driven from SAI-1 TXD3 when transmit is enabled (obe=1). When the signal works as a receive function, the PAD level is sensed and sent to SAI-1 RXD1.

Detailed clock multiplexing scheme is shown in the following figure.

Please note that SAI-4 is a standalone SAI module and is not shown in the Audio subsystem clocking diagram below.

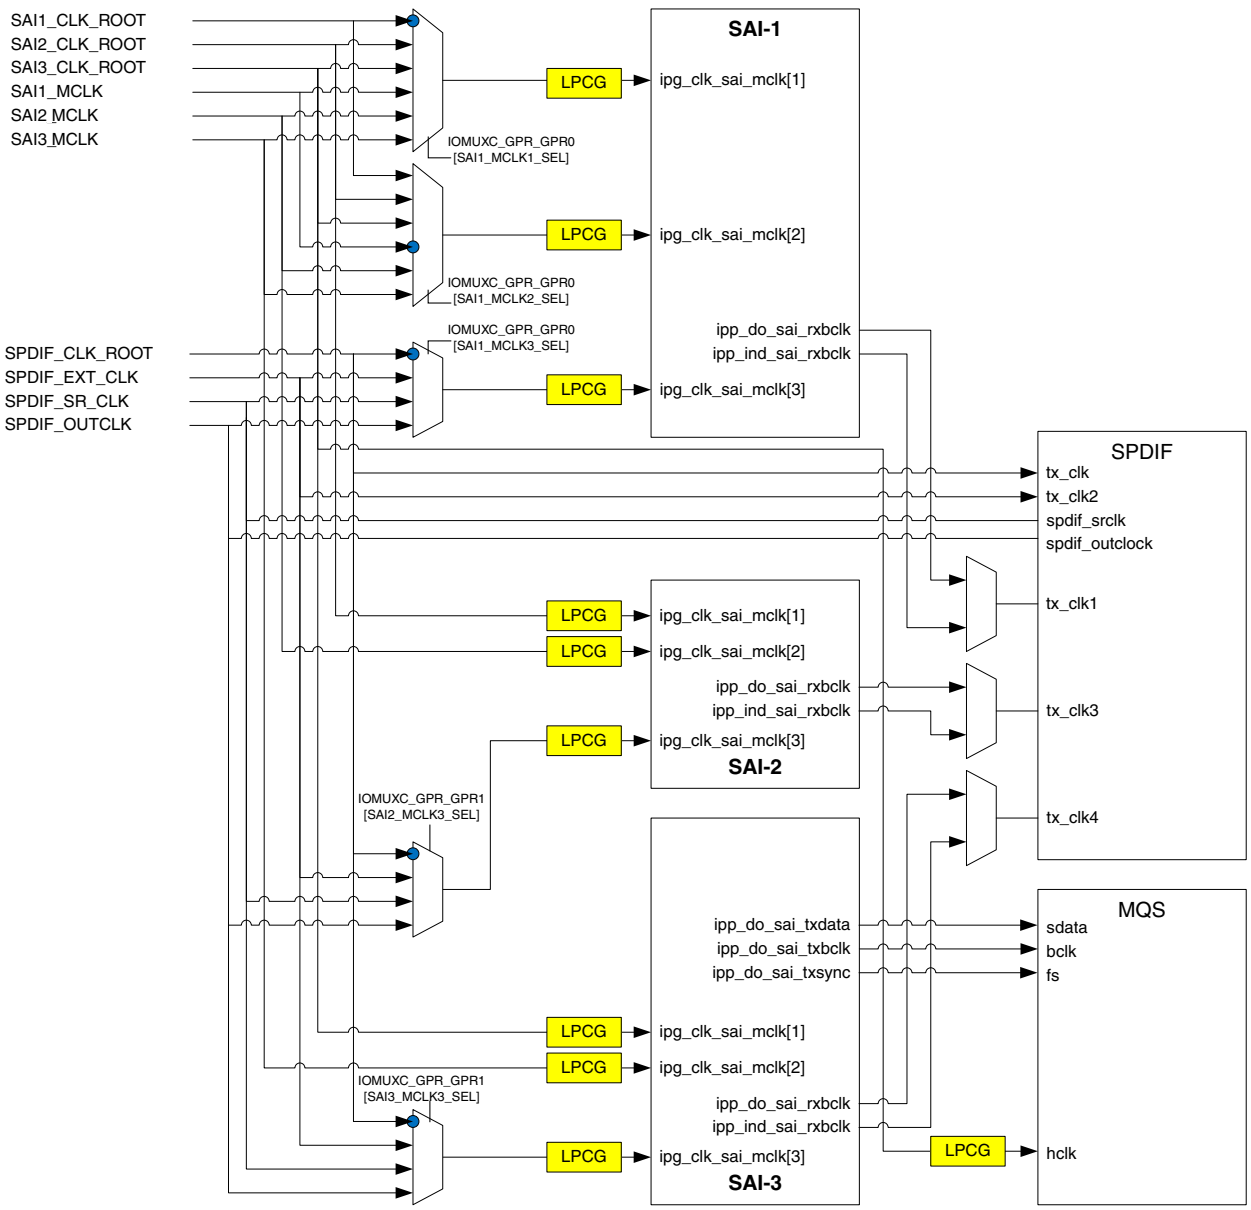

Figure 54-3. Audio subsystem clocking diagram

NOTE

SPDIF tx_clk1, tx_clk3, and tx_clk4 inputs are selected inside the SAI-1, SAI-2, and SAI-3, respectively.

54.1.2 Medium Quality Sound (MQS)

MQS is used to generate medium quality audio via a standard GPIO in the pinmux. The user can connect stereo speakers or headphones to a power amplifier without an additional DAC chip.

- 2-channel, LSB-valid 16 bit, MSB shift-out first serial data (sdata)

- Frame sync aligned with the left channel data
- 44.1 kHz or 48 kHz I2S signals from SAI3
- SNR target as no more than 20 dB for the signals below 10 kHz
- Signals over 10 kHz have worse THD+N values

54.1.3 Synchronous Audio Interface (SAI)

- Transmitter with independent Bit Clock and Frame Sync supporting up to 4 data lines
- Receiver with independent Bit Clock and Frame Sync supporting up to 4 data lines
- Maximum Frame Size of 32 Words
- Word size programmable from 8-bits to 32-bits
- Word size configured separately for first word and remaining words in frame
- Asynchronous FIFO for each Transmit and Receive data line
- Graceful restart after FIFO Error

54.1.4 Sony/Philips Digital Interface (SPDIF)

The Sony/Philips Digital Interface (SPDIF) module is a stereo transceiver that allows the processor to receive and transmit digital audio over it using the IEC60958 standard, consumer format. The chip provides a single SPDIF receiver with one input, and one SPDIF transmitter with one output.

The SPDIF transceiver allows the handling of both SPDIF channel status (CS) and User (U) data and features a frequency measurement block that allows the precise measurement of the incoming sampling frequency.

The clock recovered by the SPDIF receiver is provided to drive both internal and external components in the system such as the SPDIF transmitter, SAI ports, as well as external A/Ds or D/As, with clocking control provided via related registers.

The SPDIF is composed of two parts: SPDIF Receiver and SPDIF Transmitter. The SPDIF receiver extracts the audio data from each SPDIF frame and places the data in two 16-word-deep FIFOs, one FIFO for the left channel, the other FIFO for the right channel. The FIFOs support programmable watermark levels so that FIFO Full service request can be triggered when the combined number of data words stored in both FIFOs is 2, 8, 16 or 32 words. It is recommended to program the watermark level to trigger a FIFO Full service request when 16 word locations are filled. For optimal performance when servicing the FIFO Full service request, the FIFOs should be read alternately, starting

with the left channel FIFO. The Channel Status and User Bits are also extracted from each frame and placed in the corresponding registers. The SPDIF receiver provides a bypass option for direct transfer of the SPDIF input signal to the SPDIF transmitter.

For the SPDIF transmitter, the audio data is provided by the processor via the SPDIFTxLeft and SPDIFTxRight registers, and the data is stored in two 16-word-deep FIFOs, one for the right channel, the other for the left channel. The FIFOs support programmable watermark levels so that FIFO Empty service request can be triggered when the combined number of empty data words locations in both FIFOs is 8, 16, 24 or 32 words. It is recommended to program the watermark level to trigger a FIFO Empty service request when 16 word locations are empty. For optimal performance when servicing the FIFO Empty service request, the FIFOs should be written alternately, starting with the left channel FIFO. The Channel Status bits are also provided via the corresponding registers. The SPDIF transmitter generates an SPDIF output bitstream in the biphase mark format (IEC 60958), which consists of audio data, channel status and user bits.

The data handled by the SPDIF module is 24-bit wide. The 24-bit SPDIF data is aligned in the 24 least significant bits of the 32-bit shared peripheral bus data word. The 8 most significant bits of the 32-bit word are ignored by the SPDIF Transmitter when data is being stored in the Transmit FIFOs from the peripheral bus. The 8 most significant bits of the 32-bit word are zeroed by the SPDIF Receiver module when the data is being read from the Receiver FIFOs to the peripheral bus.

Note that 16-bit data is left-aligned in the 24-bit word format of the SPDIF. This means that when receiving 16-bit data, it will be located in the middle two bytes of the 32-bit peripheral bus data word, while the 8 bits of the MSB and the 8 bits of the LSB will be zero. When 16-bit data is to be transmitted, the 32-bit word to be written to the SPDIF Transmit FIFOs should be created as follows: the 16-bit data should be located in the middle two bytes of the 32-bit data word and the 8 bits of the LSB must be set to zero, while the 8 bits of the MSB will be ignored.

The SPDIF Transmit clock is generated by the SPDIF internal clock generator module and the clock sources are from outside of the SPDIF block. The clock sources should provide a clock that is at least 64 x Fs, where Fs is the sampling frequency. The external clock source should provide at least 128 x Fs. Clocks of higher frequency may be provided as long as the multiplication factor is a power of 2 (for example, 128x, 256x or 512x). Also, clock frequency precision of 100ppm or better should be provided.

54.1.5 PDM Microphone Interface (PDM)

The PDM module receives audio from a microphone. It includes the following features:

- Fixed filtering characteristics for audio application
- Full or partial set of channels operation with individual enable control
- Programmable PDM clock generator
- Programmable decimation rate
- 16-bit signed output result
- Overall stopband attenuation more than 80dB
- Overall passband ripple less than 0.2dB
- CIC filter
- DC remover
- Half Band filter
- FIR filter
- FIFOs with DMA capability
- Hardware Voice Activity Detector (HWVAD)
- 4 lines, 8 channels

Chapter 55
Asynchronous Sample Rate Converter (ASRC)

The below figure shows the ASRC System Overview for this chip.

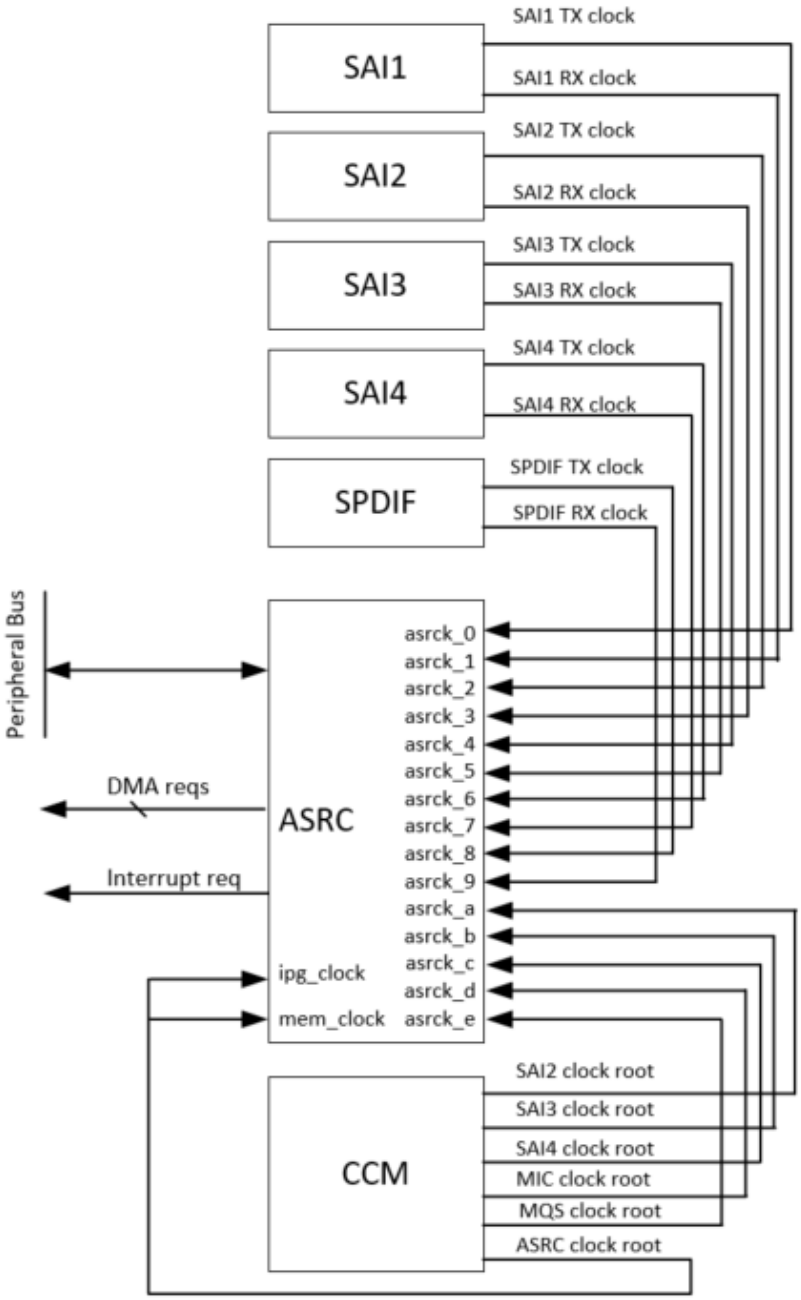

Figure 55-1. ASRC System Overview

55.2 Overview

The Asynchronous Sample Rate Converter (ASRC) converts the sampling rate of a signal associated with an input clock into a signal associated with a different output clock.

The ASRC supports concurrent sample rate conversion of up to 10 channels of about -120dB THD+N. The ASRC supports up to three sampling rate pairs.

The incoming audio data to this chip may be received from various sources at different sampling rates. The outgoing audio data of this chip may have different sampling rates and it can also be associated with output clocks that are asynchronous to the input clocks.

The ASRC is implemented as a co-processor in hardware, with minimal ARM Platform intervention required.

The ASRC Filter Processor (FP) handles the main signal processing algorithm. It has its own simplified instructions. The FP resources (MIPS,RAM,ROM ALU etc) are shared among the different conversation pairs.

55.2.1 Block Diagram

The following figure is the ASRC block diagram.

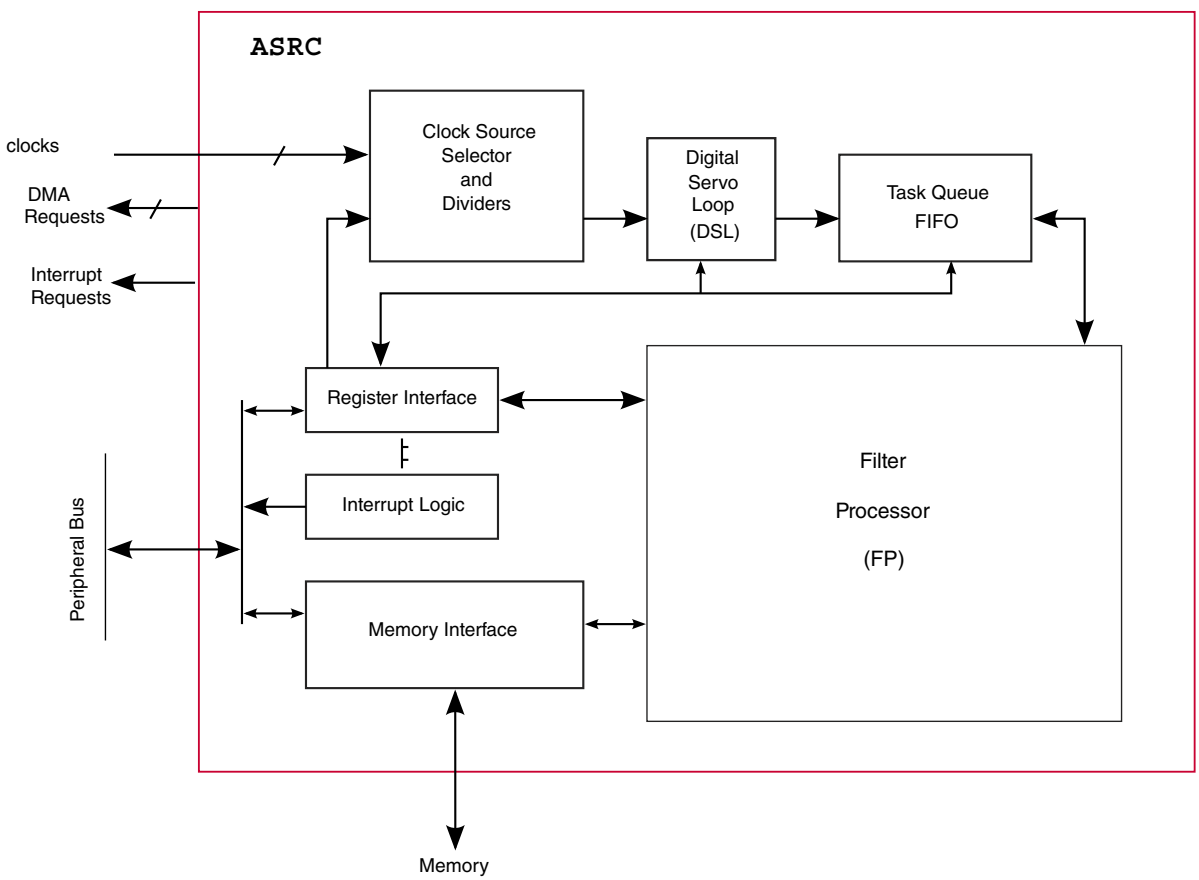

Figure 55-2. ASRC block diagram

55.2.2 Features

The ASRC features are listed below:

- Any number (0-10) of contiguous channels can be associated to one of the sampling rate pairs
- Support user-programmable threshold for the input/output FIFOs
- Support flexible 8/16/24-bit width of input data, and 16/24-bit width of output data
- Designed for rate conversion between 32 kHz, 44.1 kHz, 48 kHz, 96 kHz, and 192 kHz. The useful signal bandwidth is below 24 kHz
- Other input sampling rates in the range of 8 kHz to 200 kHz is also supported[1]
- Other output sampling rates in the range of 30 kHz to 200 kHz is also supported[1]
  - The limitation is the supported ratio (Fsin/Fsout) range (between 1/24 to 8)
- Automatic accommodation to slow variations in the incoming and outgoing sampling rates.
- Linear phase
- Tolerant to sample clock jitter
- Designed for real-time streaming audio usage. The output sampling clock must be always physically available in the system.

Clock/Data Connections

- The sampling rate clocks are directly connected to the ASRC block. The ratio estimation of the input clocks with output clocks are done in ASRC hardware when both input/output sampling clocks are physically available.
- When both the input sampling clock and the output sampling clock are physically available, the rate conversion can work by configuring the physical clocks.
- When the input sampling clock is not physically available, the rate conversion can still work by setting ideal-ratio values into ASRC interface registers.
- The clock signals come from the following blocks:
  - SAI, receiving bit clock and transmitting bit clock
  - SPDIF, receiving bit clock and transmitting bit clock
  - other audio peripherals etc.
- The Digital Servo Loop (DSL) is a digital PLL for tracking the relationship between input/output sampling clocks. It is shared among all pairs in a first-come-first-serve form
- The exchange of audio data is done by the processor accessing ASRC block through registers defined on shared peripheral bus

1. The ASRC designed input and output sampling rate are between 44.1 kHz, 32 kHz, 48 kHz, 96 kHz, and 192kHz. Useful signal bandwidth is below 24 kHz.

55.3 Functional Description

This section provides a complete functional description of the block.

55.3.1 Operating Modes

The ASRC supports modes described in the following sections:

- Data Transfer Schemes
- Word Alignment Supported

55.3.1.1 Data Transfer Schemes

55.3.1.1.1 Data Input Modes

The input mode for each of the three channel sets may be set independently. Three modes of supplying data to the ASRC input FIFOs are available:

- Polling
- Interrupt
- DMA

In all input-data transfer schemes, the ASRC fetches data from each enabled FIFO and processes the data sample-by-sample after each rising edge of the associated input sampling clock until the FIFO level reaches a threshold.

After the threshold is reached, the ASRC requests data. The FIFO size for each channel set is 64 samples and the threshold is set at 32 samples.

The threshold can be defined by interface registers ASRMCRx, x = A, B or C.

If the ASRC attempts to fetch data from an empty FIFO, an error is generated and the ASRSTR[AOLE] bit is set. If the ASRC overload interrupt is enabled (ASRIER[AOLIE] bit is set), an interrupt is generated.

When writing data to an input FIFO, you must ensure that it is in a predefined sequence. For example, when writing to an input FIFO, the sequence should be: channel_0, channel_1, channel_2,..., channel_n, channel_0, channel_1, channel_2, etc. Here channel_n stands for the data intended for the n-th channel. The hardware re-allocates each data to its corresponding channel FIFO. The channel being re-allocated is shown by ASRCCR[ACIx], x=A,B or C.

55.3.1.1.1.1 Data Input Polling Mode

Polling mode is the default mode following power-on or individual reset, and is selected by clearing the associated channel set A, B, or C data-input interrupt enable bit (ASRIER[ADIEx], where x=A, B or C). In this mode, data-input interrupts are disabled. When the FIFO level is below the threshold, the associated status bit (ASRSTR[AIDEx], where x=A, B, or C) is set. To clear the status bit, the FIFO must be written with enough data to raise the level above the threshold.

55.3.1.1.1.2 Data Input Interrupt Mode

The ASRC input FIFOs can also be serviced by interrupts. To enable interrupts, the corresponding data-input interrupt enable bits (ASRIER[ADIEx], where x=A, B, or C) should be set. An interrupt is automatically generated any time the input FIFO level is below the threshold. The interrupt is cleared when enough data is written to the FIFO to raise the level above the threshold.

55.3.1.1.1.3 Data Input DMA Mode

The ASRC input FIFOs can also be filled using DMA. In this mode, the data-input interrupt-enable bits (ASRIER[ADIEx], where x=A, B, or C) should be cleared and the DMA controller should be configured to use the ASRC as a request source.

55.3.1.1.2 Data Output Modes

The output mode for each of the 3 channel sets (A, B, and C) may be set independently.

Three modes of retrieving data from the ASRC output FIFOs are available:

- Polling
- Interrupt
- DMA

In all output-data transfer schemes, the ASRC places a processed sample into the associated output FIFO. After a threshold is reached, the ASRC requests that data be transferred out of the FIFO.

The FIFO size for each channel set is 64 samples and the threshold is set at 32 samples. The threshold can be defined by interface registers ASRMCRx, x = A, B or C.

If the ASRC attempts to place data into a FIFO that is already full, an error is generated and the ASRSTR[AOLE] bit is set. If the ASRC overload interrupt is enabled (ASRIER[AOLIE] bit is set), an interrupt is generated.

Each output FIFO is organized in the same channel order in which the associated input FIFO was written.

Three transfer modes are supported by Interface Block.

55.3.1.1.2.1 Data Output Polling Mode

The ASRC output FIFOs can be serviced by polling. In this mode, ensure the associated output-data interrupt enable bit (ASRIER[ADOEx], where x=A, B, or C) is cleared. In this mode, all output-data interrupts are disabled. Any time the output FIFO exceeds the threshold the associated status bit (ASRSTR[AODFx], where x=A, B, or C) is set. To clear the status bit, enough data must be read from the associated output FIFO to lower the level below the threshold.

55.3.1.1.2.2 Data Output Interrupt Mode

The ASRC output FIFOs may also be serviced using interrupts. To enable this mode, the corresponding output-data interrupt-enable bits (ASRIER[ADOEx], where x=A, B, or C) should be set. Any time the output FIFO level exceeds the threshold, an interrupt is automatically generated. The interrupt is cleared when enough data is read from the FIFO to lower the level below the threshold.

55.3.1.1.2.3 Data Output DMA Mode

The ASRC output FIFOs can also be read using DMA. In this mode, the output-data interrupt-enable bits (ASRIER[ADOEx], where x=A, B, or C) should be cleared and the DMA controller should be configured to use the ASRC as a request source.

55.3.1.2 Word Alignment Supported

55.3.1.2.1 Input Data Alignment Modes

The position and length of input data word to the input data FIFOs ASRDIA, ASRDIB, ASRDIC are programmable. The control bits are defined in ASRMCR1x {x=A, B, or C}. It supports the following modes:

Table 55-2. Input Data Alignment

55.3.2 Algorithm Description

55.3.2.1 Signal processing flow

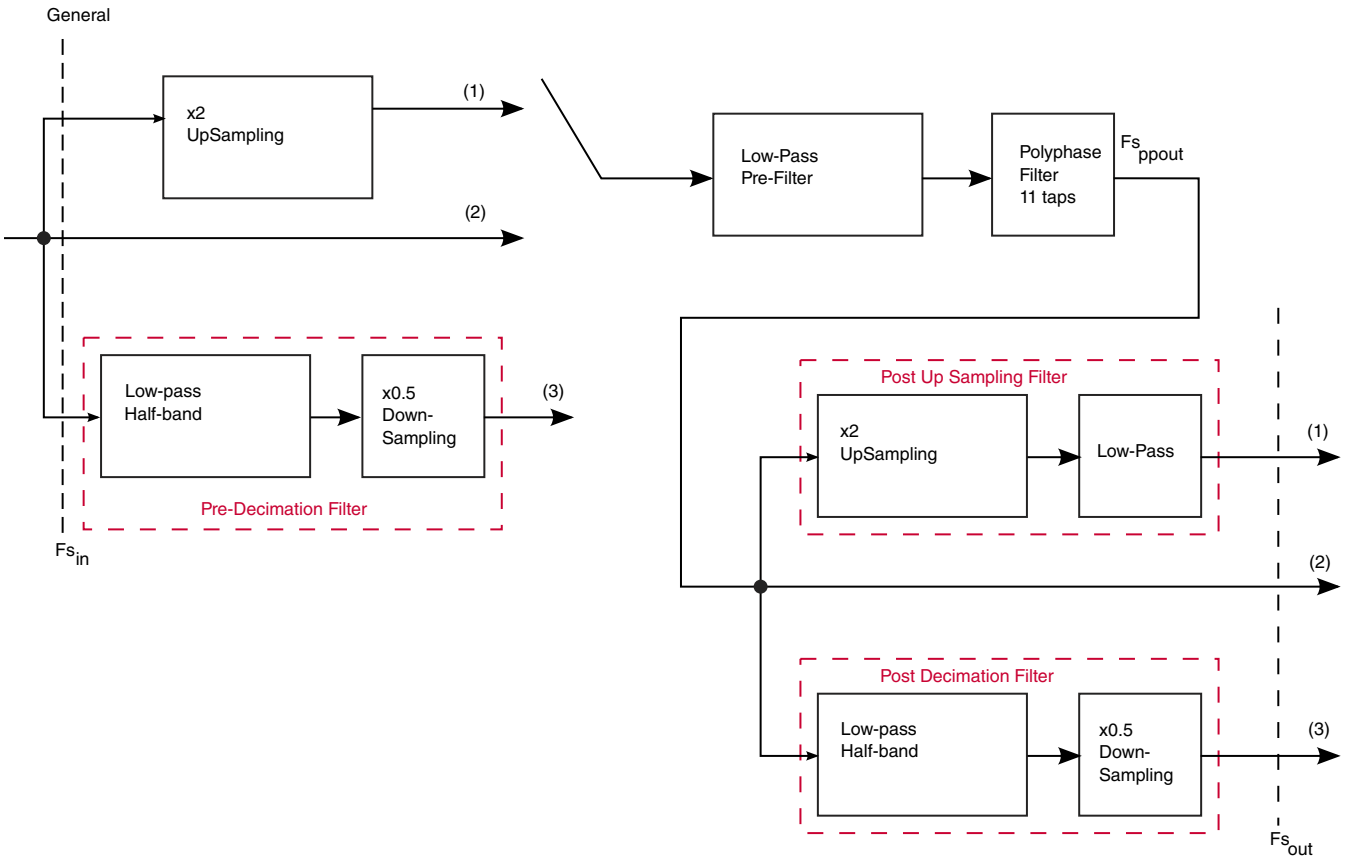

Figure 55-3. Signal processing configurations

The figure above shows the possible configurations of the ASRC. Each configuration consists of 2 to 4 stages.

- x2 up-sampling rate expander (zero insertion only) (input branch 1), direct connection (input branch 2), or low-pass pre decimation filter (consisting of a low-pass half-band FIR filter with x0.5 downsampling rate decimator) (input branch 3),
- low-pass pre-filter, the low-pass bandwidth is at most 0.25 x Fs, where Fs is the sampling rate of the input signal to this low-pass pre-filter,
- polyphase filter,
- x2 post upsampling filter (consisting of a x2 up-sampling rate expander (zero insertion only) with low-pass half-band FIR filter) (output branch 1), direct connection (output branch 2), or low-pass post decimation filter (consisting of a low-pass half-band FIR filter with x0.5 downsampling rate decimator) (output branch 3).

By flowing through different processing branches and different setups of the pre-filter, this ASRC scheme can be used to handle different rate conversion requirements.

Table 55-4. ASRC Rate Conversion Configurations

Configuration	Max Signal Bandwidth before polyphase filter	Signal Sampling Rate of polyphase filter output
a: Input Branch 1 + Output Branch 1	$BW_{in} = Fs_{in}/2$	$Fs_{ppout} = Fs_{out}/2$
b: Input Branch 1 + Output Branch 2	$BW_{in} = Fs_{in}/2$	$Fs_{ppout} = Fs_{out}$
c: Input Branch 1 + Output Branch 3	$BW_{in} = Fs_{in}/2$	$Fs_{ppout} = 2Fs_{out}$
d: Input Branch 2 + Output Branch 1	$BW_{in} = Fs_{in}/4$	$Fs_{ppout} = Fs_{out}/2$
e: Input Branch 2 + Output Branch 2	$BW_{in} = Fs_{in}/4$	$Fs_{ppout} = Fs_{out}$
f: Input Branch 2 + Output Branch 3	$BW_{in} = Fs_{in}/4$	$Fs_{ppout} = 2Fs_{out}$
g: Input Branch 3 + Output Branch 1	$BW_{in} = Fs_{in}/8$	$Fs_{ppout} = Fs_{out}/2$
h: Input Branch 3 + Output Branch 2	$BW_{in} = Fs_{in}/8$	$Fs_{ppout} = Fs_{out}$
i: Input Branch 3 + Output Branch 3	$BW_{in} = Fs_{in}/8$	$Fs_{ppout} = 2Fs_{out}$

Table 55-5 lists some typical settings for typical sample rate conversation pairs to achieve less MIPS. ASRC can be set to automatically fill these settings depending on input/ouptut sample rate or users can configure the fields manually to achieve better filter bandwidth performance.

Table 55-5. Pre-processing, post-processing options

{Pre_Proc, Post_Proc}		Fsout (KHz)											
		8	12	16	24	32	44.1	48	64	88.2	96	128	192
Fsin (KHz)	8	{0,1}	{0,1}	{0,1}	{0,0}	{0,0}	{0,0}	{0,0}	{0,0}	{0,0}	{0,0}	{0,0}	{0,0}
	12	{0,2}	{0,1}	{0,1}	{0,1}	{0,1}	{0,0}	{0,0}	{0,0}	{0,0}	{0,0}	{0,0}	{0,0}
	16	{1,2}	{0,2}	{0,1}	{0,1}	{0,1}	{0,1}	{0,1}	{0,0}	{0,0}	{0,0}	{0,0}	{0,0}
	24	{1,2}	{1,2}	{0,2}	{0,1}	{0,1}	{0,1}	{0,1}	{0,1}	{0,0}	{0,0}	{0,0}	{0,0}
	32	{1,2}	{1,2}	{1,2}	{0,2}	{0,1}	{0,1}	{0,1}	{0,1}	{0,1}	{0,0}	{0,0}	{0,0}
	44.1	{2,2}	{1,2}	{1,2}	{0,2}	{0,2}	{0,1}	{0,1}	{0,1}	{0,1}	{0,1}	{0,0}	{0,0}
	48	{2,2}	{1,2}	{1,2}	{1,2}	{0,2}	{0,2}	{0,1}	{0,1}	{0,1}	{0,1}	{0,1}	{0,0}
	64	{2,2}	{2,2}	{1,2}	{1,2}	{0,2}	{0,2}	{0,2}	{0,1}	{0,1}	{0,1}	{0,1}	{0,0}
	88.2	NA	{2,2}	{2,2}	{1,2}	{1,2}	{1,2}	{1,2}	{1,1}	{1,1}	{1,1}	{1,1}	{1,1}
	96	NA	{2,2}	{2,2}	{1,2}	{1,2}	{1,2}	{1,2}	{1,1}	{1,1}	{1,1}	{1,1}	{1,1}
	128	NA	NA	{2,2}	{2,2}	{1,2}	{1,2}	{1,2}	{1,1}	{1,1}	{1,1}	{1,1}	{1,1}
	192	NA	NA	NA	{2,2}	{2,2}	{2,2}	{2,2}	{2,1}	{2,1}	{2,1}	{2,1}	{2,1}

NOTE: In the {Pre_Proc, Post_Proc} pair, the meaning of the values are:

Pre_Proc:

- 0 --- Pre-processing Branch 1 as shown in Figure 55-3
- 1 --- Pre-processing Branch 2 as shown in Figure 55-3
- 2 --- Pre-processing Branch 3 as shown in Figure 55-3, decimation-by-2

Post_Proc:

- 0 --- Post-processing Branch 1 as shown in Figure 55-3
- 1 --- Post-processing Branch 2 as shown in Figure 55-3
- 2 --- Post-processing Branch 3 as shown in Figure 55-3

The latencies of the different option can be roughly calculated as follows:

- For PreProc = 0, PostProc = 1 : min latency = constant_A / input-sample-rate + constant_B / output-sample-rate
- For PreProc = 0, PostProc = 0 : min latency = constant_A / input-sample-rate + constant_C / output-sample-rate
- For PreProc = 1, PostProc = 1 : min latency = constant_D / input-sample-rate + constant_B / output-sample-rate

The constants above (e.g., constant_A means the Constant for Preproc = 0, constant_B means the Constant for Postproc = 1, ...) are only influenced by the PreProc/PostProc and (input/output) sampling rate to which they are connected. Input latencies have no relationship with the output latencies, but both elements add together to form the total latencies.

For a rough estimation, the constants can be set as:

- Constant for Preproc = 0: 39
- Constant for Preproc = 1: 78.5
- Constant for Preproc = 2: 235
- Constant for Postproc = 0: 42.5
- Constant for Postproc = 1: 8.5
- Constant for Postproc = 2: 172

The max latency can be derived from this value by using the following formula (where 32 means the input/output FIFO depth that initiates data transfer):

- max latency = min latency + 32 / input-sample-rate + 32 / output-sample-rate

55.3.2.2 Operation of the Filter

55.3.2.2.1 Support of Physical Clocks

This design supports physical sampling clocks. The clocks can be provided by:

- Sony/Phillips digital interface (SPDIF)
- Serial Audio Interface (SAI)
- Core master clock derivative as ASRCK1

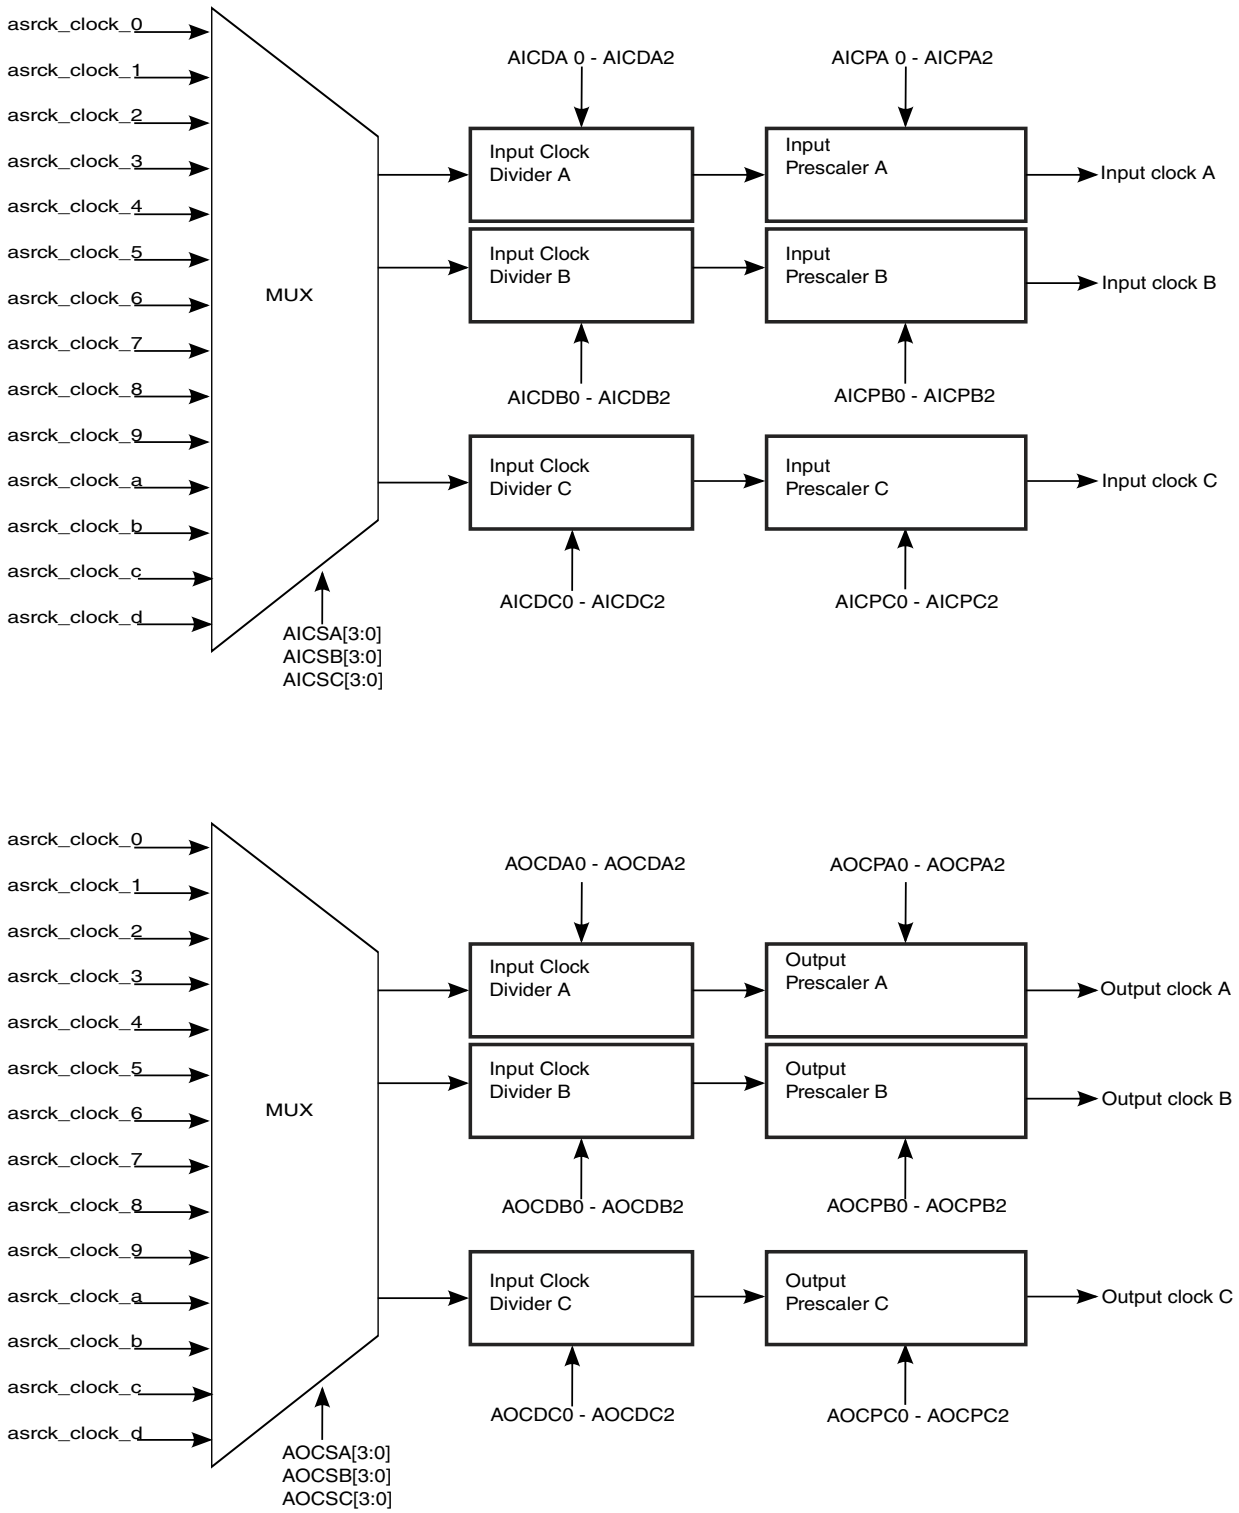

Figure 55-4. Clock Source Selector and Divider

Software can set the ASRC Clock Source Register (ASRCSR) and the Clock Divider Register to select the desired clock source and divide it to the needed sample rate clock for use by the ASRC.

The following is the description of the Clock Source Selector and Divider figure above (x refers to A, B or C):

- If the input clock is available, Pair x divider and prescaler depends on the input clock and input sample rate, which can be calculated by:
  - Input Clock x = (Input Sample Rate x) * AICDx * (2^(AICPx))
  - Where the Input Sample Clock Source x is determined by ASRCSR[AICSx]
- If the output clock is available, Pair x divider and prescaler depends on the output clock and output sample rate, which can be calculated by:
  - Output Clock x = (Output Sample Rate x) * AOCDx * (2^(AOCPx))
  - Where the Output Sample Clock Source x is determined by ASRCSR[AOCSx]

NOTE

The clocks have the following restriction: If the prescaler is set to 1, the clock divider can only be set to 1 and the clock source must have a 50% duty cycle.

55.3.3 Clocks

The table below describes the clock sources for ASRC. Please see clock control block for clock setting, configuration and gating information.

Table 55-6. ASRC Clocks

Clock name	Description
asrck_clock_d	ASRC module clock
ipg_clk	Peripheral clock
mem_clk	Peripheral access clock

55.3.4 Interrupts

ASRC has several interrupts events.

The priorities are shown in the following table.

Table 55-7. Interrupt Priorities/Vector

Priority	Offset	Description
lowest	0x0	ASRC Pair A input data needed
	0x2	ASRC Pair B input data needed
	0x4	ASRC Pair C input data needed
	0x6	ASRC Pair A output data ready

Table continues on the next page...

Table 55-7. Interrupt Priorities/Vector (continued)

Priority	Offset	Description
	0x8	ASRC Pair B output data ready
	0xA	ASRC Pair C output data ready
highest	0xC	ASRC Overload

55.3.5 DMA requests

ASRC has six DMA requests. They are directly connected to the lowest six status bits in the ASRSTR register. For some ARM platforms, the six status bits are directly connected to the DMA peripheral as DMA event signals.

Table 55-8. DMA requests

Type	Description
0	ASRC Pair A input data needed
1	ASRC Pair B input data needed
2	ASRC Pair C input data needed
3	ASRC Pair A output data ready
4	ASRC Pair B output data ready
5	ASRC Pair C output data ready

55.4 External Signals

The ASRC does not have external signals pinned out.

The following table shows the bit definitions that are used by the ASRCSR register to control the sources of the input and output clocks of the ASRC.

Table 55-9. ASRC Bit Clock Definitions

Bit Clk Name	Definition	Description
bit clock 0	SAI1_TX_BCLK	SAI1 Transmitter serial bit clock
bit clock 1	SAI1_RX_BCLK	SAI1 Receiver serial bit clock
bit clock 2	SAI2_TX_BCLK	SAI2 Transmitter serial bit clock
bit clock 3	SAI2_RX_BCLK	SAI2 Receiver serial bit clock
bit clock 4	SAI3_TX_BCLK	SAI3 Transmitter serial bit clock
bit clock 5	SAI3_RX_BCLK	SAI3 Receiver serial bit clock
bit clock 6	SAI4_TX_BCLK	SAI4 Transmitter serial bit clock

Table continues on the next page...

Table 55-9. ASRC Bit Clock Definitions (continued)

Bit Clk Name	Definition	Description
bit clock 7	SAI4_RX_BCLK	SAI4 Receiver serial bit clock
bit clock 8	SPDIF_TX_BCLK	SPDIF Transmitter serial bit clock
bit clock 9	SPDIF_RX_BCLK	SPDIF Receiver serial bit clock
bit clock A	SAI2_CLK_ROOT	SAI2 Clock Root
bit clock B	SAI3_CLK_ROOT	SAI3 Clock Root
bit clock C	SAI4_CLK_ROOT	SAI4 Clock Root
bit clock D	MIC_CLK_ROOT	MIC Clock Root
bit clock E	MQS_CLK_ROOT	MQS Clock Root

55.5 Application Information

The following outlines an **example** setup procedure for the ASRC block:

1. Configure and enable the ASRC clock source. See this device's clocking chapter for more information
2. Disable the ASRC (write 0x00000000 to ASRCTR)
3. Enable the peripheral that is connected to the ASRC. See this device's clocking chapter and the ASRC chip specific section for more information
4. Configure the following:
   a. Enable ASRC function(ASRCTR[ASRCEN]=1)
   b. Enable Use of Ideal Ratio for Pair A (ASRCTR[IDRA]=1)
   c. Enable Use of Ratio for Pair A (ASRCTR[URSA]=1)
   d. Assign 2 channels to Pair A (ASRCNCR[ANCA]=2)
   e. Configure Post-Processing Configuration and Pre-Processing Configuration for Conversion Pair A. See Signal processing flow
   f. Set ASRC Clock Divider 1 (ASRCDR1) and ASRC Clock Divider 2 (ASRCDR2. See Support of Physical Clocks for more information
   g. Set the Input Clock Source A (ASRCSR[AICSA]) and Output Clock Source A (ASRCSR[AOCSA]) both to Bit Clock D (0x0000d00d)
   h. Set the Ideal Ratio for Pair A. The ratio depends on input sample rate and output sample rate. See the ASRC Ideal Ratio for Pair A-High Part (ASRIDRHA) and ASRC Ideal Ratio for Pair A -Low Part (ASRIDRLA) register descriptions. If the input sample rate is equal to the output sample rate, Ideal Ratio is 1:
      - Ideal Ratio for Pair A-High Part (ASRIDRHA = 0x4)
      - Ideal Ratio for Pair A-Low Part (ASRIDRLA = 0x0)
5. For Pair A - Set input threshold to 32 and output threshold to 8 (ASRMCRA[INFIFO_THRESHOLDA], ASRMCRA[OUTFIFO_THRESHOLDA])
7. Zeroize Pair A buffers(ASRMCRA[ZEROBUFA]=1)

8. Do not bypass polyA filter (ASRMCRA[BYPASSPOLYA]=0)
9. Set Pair A data width (ASRMCR1A[IWD]) and data alignment(ASRMCR1A[IMSB] and ASRC_ASRMCR1A[OMSB]) depends on the audio data format
10. Disable interrupt handler (ASRIER = 0x00000000)
11. After configuration is done, enable the ASRC pair(ASRCTR[ASREA]=1)
12. Poll until the initialization is done (ASRCFG and ASRCFG[INIRQA]) == 0)
13. Feed Input Data (ASRDIA)
14. Get Output Data (ASRDOA)
15. Disable ASRC (ASRCTR[ASRCEN] = 0)

55.6 ASRC Memory Map/Register Definition

55.6.1 ASRC register descriptions

All useful registers are listed in the memory map below. The access of undefined registers behaves as normal registers.

All the interface registers are LSB aligned except the input FIFOs and the output FIFOs, and each register has only 24 effective bits.

The input FIFO and output FIFO word alignment can be defined using ASRMCR1{A,B,C} registers in 32-bit interface system.

55.6.1.1 ASRC memory map

ASRC0 base address: 4041_4000h

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)

55.6.1.2.3 Fields

Field	Description
31-24 —	- Reserved
23 —	- Reserved. Should be written as zero for compatibility.
22 ATSC	ATSC ASRC Pair C Automatic Selection For Processing Options When this bit is 1, pair C automatically updates its pre-processing and post-processing options (ASRCFG[PREMODC], ASRCFG[POSTMODC] see ASRC Filter Configuration Status Register for Pair C) based on the frequencies it detected. To use this option, the two parameter registers(ASR76K and ASR56K) should be set correctly (see ASRC 76 kHz Period in terms of ASRC processing clock and ASRC 56 kHz Period in terms of ASRC processing clock). When this bit is 0, the user is responsible for choosing the proper processing options for pair C. This bit should be disabled when {USRC, IDRC}={1,1}. 0 - Pair C does not automatically update its pre-processing and post-processing options 1 - Pair C automatically updates its pre-processing and post-processing options
21 ATSB	ATSB ASRC Pair B Automatic Selection For Processing Options When this bit is 1, pair B automatically updates its pre-processing and post-processing options (ASRCFG[PREMODB], ASRCFG[POSTMODB] see ASRC Filter Configuration Status Register for Pair B) based on the frequencies it detected. To use this option, the two parameter registers(ASR76K and ASR56K) should be set correctly (see ASRC 76 kHz Period in terms of ASRC processing clock and ASRC 56 kHz Period in terms of ASRC processing clock). When this bit is 0, the user is responsible for choosing the proper processing options for pair B. This bit should be disabled when {USRB, IDRB}={1,1}.

Table continues on the next page...

Field	Description
	0 - Pair B does not automatically update its pre-processing and post-processing options 1 - Pair B automatically updates its pre-processing and post-processing options
20 ATSA	ATSA ASRC Pair A Automatic Selection For Processing Options When this bit is 1, pair A automatically updates its pre-processing and post-processing options (ASRCFG[PREMODA], ASRCFG[POSTMODA] see ASRC Filter Configuration Status Register for Pair A) based on the frequencies it detected. To use this option, the two parameter registers(ASR76K and ASR56K) should be set correctly (see ASRC 76 kHz Period in terms of ASRC processing clock and ASRC 56 kHz Period in terms of ASRC processing clock). When this bit is 0, the user is responsible for choosing the proper processing options for pair A. This bit should be disabled when {USRA, IDRA}={1,1}. 0 - Pair A does not automatically update its pre-processing and post-processing options 1 - Pair A automatically updates its pre-processing and post-processing options
19 —	- Reserved. Should be written as zero for compatibility.
18 USRC	USRC Use Ratio for Pair C Use ratio as the input to ASRC. This bit is used in conjunction with IDRC control bit. 0 - Do not use ratio as the input to ASRC for pair C 1 - Use ratio as the input to ASRC for pair C
17 IDRC	IDRC Use Ideal Ratio for Pair C When USRC=0, this bit has no usage. When USRC=1 and IDRC=0, ASRC internal measured ratio is used. When USRC=1 and IDRC=1, the idea ratio from the interface register ASRIDRHC, ASRIDRLC is used. It is suggested to manually set ASRCFG[POSTMODC], ASRCFG[PREMODC] according to Table 55-5 in this case. 0 - ASRC internal measured ratio is used 1 - Ideal ratio from the interface register ASRIDRHC, ASRIDRLC is used
16 USRB	USRB Use Ratio for Pair B Use ratio as the input to ASRC. This bit is used in conjunction with IDRB control bit. 0 - Do not use ratio as the input to ASRC for pair B 1 - Use ratio as the input to ASRC for pair B
15 IDRB	IDRB Use Ideal Ratio for Pair B When USRB=0, this bit has no usage. When USRB=1 and IDRB=0, ASRC internal measured ratio is used. When USRB=1 and IDRB=1, the idea ratio from the interface register ASRIDRHB, ASRIDRLB is used.It is suggested to manually set ASRCFG[POSTMODB], ASRCFG[PREMODB] according to Table 55-5 in this case.

Table continues on the next page...

Field	Description
	0 - ASRC internal measured ratio is used 1 - Ideal ratio from the interface register ASRIDRHB, ASRIDRLB is used
14 USRA	USRA Use Ratio for Pair A Use ratio as the input to ASRC. This bit is used in conjunction with IDRA control bit. 0 - Do not use ratio as the input to ASRC for pair A 1 - Use ratio as the input to ASRC for pair A
13 IDRA	IDRA Use Ideal Ratio for Pair A When USRA=0, this bit has no usage. When USRA=1 and IDRA=0, ASRC internal measured ratio is used. When USRA=1 and IDRA=1, the ideal ratio from the interface register ASRIDRHA, ASRIDRLA is used. It is suggested to manually set ASRCFG[POSTMODA], ASRCFG[PREMODA] according to Table 55-5 in this case. 0 - ASRC internal measured ratio is used 1 - Ideal ratio from the interface register ASRIDRHA, ASRIDRLA is used
12-5 —	- Reserved. Should be written as zero for compatibility.
4 SRST	SRST Software Reset This bit is self-clear bit. Once it is been written as 1, it generates a software reset signal inside ASRC. After 9 cycles of the ASRC processing clock, this reset process stops, and this bit is cleared automatically. 0 - ASRC Software reset cleared 1 - ASRC Software reset generated. NOTE: This is a self-clear bit
3 ASREC	ASREC ASRC Enable C Enable the operation of the conversion C of ASRC. 0 - operation of conversion C is disabled 1 - operation of conversion C is enabled
2 ASREB	ASREB ASRC Enable B Enable the operation of the conversion B of ASRC. 0 - operation of conversion B is disabled 1 - operation of conversion B is enabled
1 ASREA	ASREA ASRC Enable A Enable the operation of the conversion A of ASRC. 0 - operation of conversion A is disabled 1 - operation of conversion A is enabled

Table continues on the next page...

Field	Description
0 ASRCEN	ASRCEN ASRC Enable Enable the operation of ASRC. 0 - operation of ASRC disabled 1 - operation ASRC is enabled

55.6.1.3 ASRC Interrupt Enable Register (ASRIER)

The ASRC Interrupt Enable Register (ASRIER) is a read/write register that enables ASRC data input, data output, overload, and wait state interrupts.

55.6.1.3.1 Offset

Register	Offset
ASRIER	4h

ADIEA	Pair A Data Input Interrupt Enable Enables the data input A Interrupt. 0 - interrupt disabled 1 - interrupt enabled

55.6.1.4 ASRC Channel Number Configuration Register (ASRCNCR)

The ASRC channel number configuration register (ASRCNCR) is a read/write register that sets the number of channels used by each ASRC conversion pair.

There are 10 channels available for distribution among 3 conversion pairs, they are ordered as 0,1,...,9. The bottom [0, ANCA-1] channels are used for pair A, the top [10-ANCC, 9] channels are used for pair C, and the [ANCA, ANCA+ANCB-1] channels are allocated for pair B. In case that ANCA=0, then the [0, ANCB-1] channels are assigned for pair B.

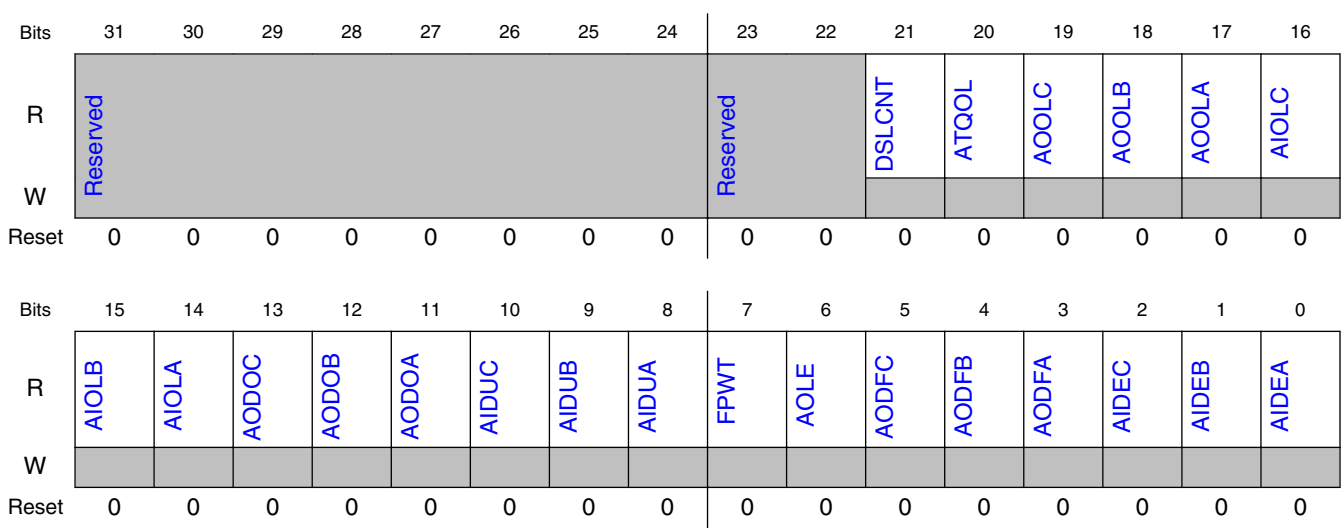
55.6.1.9 ASRC Status Register (ASRSTR)

The ASRC status register (ASRSTR) is a read/write register used by the processor core to examine the status of the ASRC block and clear the overload interrupt request and AOLE flag bit. Read of the status register returns the current state of ASRC.

55.6.1.9.1 Offset

Register	Offset
ASRSTR	20h

55.6.1.9.2 Diagram



55.6.1.9.3 Fields

Field	Description
31-24 —	- Reserved
23-22 —	- Reserved. Should be written as zero for compatibility.
21 DSLCNT	DSLCNT Digital Servo Loop (DSL) Counter Input to FIFO ready When set, this bit indicates that new DSL counter information is stored in the internal ASRC FIFO. When clear, this bit indicates that new DSL counter information is in the process of storage into the internal ASRC FIFO. When ASRIER[AFPWE]=1, the rising edge of this signal proposes an interrupt request. Writing any value with this bit set clears the interrupt request proposed by the rising edge of this bit. 0 - New DSL counter information is in the process of storage into the internal ASRC FIFO 1 - New DSL counter information is stored in the internal ASRC FIFO
20 ATQOL	ATQOL Task Queue FIFO overload When set, this bit indicates that task queue FIFO logic is oveloaded. This may help to check the reason why overload interrupt happens. The bit is cleared when writing ASRSTR[AOLE] as 1. 0 - Task queue FIFO logic is not oveloaded 1 - Task queue FIFO logic is oveloaded
19 AOOLC	AOOLC Pair C Output Task Overload When set, this bit indicates that pair C output task is oveloaded. This may help to check the reason why overload interrupt happens. The bit is cleared when writing ASRSTR[AOLE] as 1. 0 - Pair C output task is not oveloaded 1 - Pair C output task is oveloaded
18 AOOLB	AOOLB Pair B Output Task Overload When set, this bit indicates that pair B output task is oveloaded. This may help to check the reason why overload interrupt happens. The bit is cleared when writing ASRSTR[AOLE] as 1. 0 - Pair B output task is not oveloaded 1 - Pair B output task is oveloaded
17 AOOLA	AOOLA Pair A Output Task Overload When set, this bit indicates that pair A output task is oveloaded. This may help to check the reason why overload interrupt happens. The bit is cleared when writing ASRSTR[AOLE] as 1.

Table continues on the next page...

Field	Description
	0 - Pair A output task is not oveloaded 1 - Pair A output task is oveloaded
16 AIOLC	AIOLC Pair C Input Task Overload When set, this bit indicates that pair C input task is oveloaded. This may help to check the reason why overload interrupt happens. The bit is cleared when writing ASRSTR[AOLE] as 1. 0 - Pair C input task is not oveloaded 1 - Pair C input task is oveloaded
15 AIOLB	AIOLB Pair B Input Task Overload When set, this bit indicates that pair B input task is oveloaded. This may help to check the reason why overload interrupt happens. The bit is cleared when writing ASRSTR[AOLE] as 1. 0 - Pair B input task is not oveloaded 1 - Pair B input task is oveloaded
14 AIOLA	AIOLA Pair A Input Task Overload When set, this bit indicates that pair A input task is oveloaded. This may help to check the reason why overload interrupt happens. The bit is cleared when writing ASRSTR[AOLE] as 1. 0 - Pair A input task is not oveloaded 1 - Pair A input task is oveloaded
13 AODOC	AODOC Output Data Buffer C has overflowed When set, this bit indicates that output data buffer C has overflowed. When clear, this bit indicates that output data buffer C has not overflowed The bit is cleared when writing ASRSTR[AOLE] as 1. 0 - No Overflow in Output data buffer C 1 - Overflow in Output data buffer C
12 AODOB	AODOB Output Data Buffer B has overflowed When set, this bit indicates that output data buffer B has overflowed. When clear, this bit indicates that output data buffer B has not overflowed The bit is cleared when writing ASRSTR[AOLE] as 1. 0 - No Overflow in Output data buffer B 1 - Overflow in Output data buffer B
11 AODOA	AODOA Output Data Buffer A has overflowed When set, this bit indicates that output data buffer A has overflowed. When clear, this bit indicates that output data buffer A has not overflowed

Table continues on the next page...

Field	Description
	The bit is cleared when writing ASRSTR[AOLE] as 1. 0 - No Overflow in Output data buffer A 1 - Overflow in Output data buffer A
10 AIDUC	AIDUC Input Data Buffer C has underflowed When set, this bit indicates that input data buffer C has underflowed. When clear, this bit indicates that input data buffer C has not underflowed. The bit is cleared when writing ASRSTR[AOLE] as 1. 0 - No Underflow in Input data buffer C 1 - Underflow in Input data buffer C
9 AIDUB	AIDUB Input Data Buffer B has underflowed When set, this bit indicates that input data buffer B has underflowed. When clear, this bit indicates that input data buffer B has not underflowed. The bit is cleared when writing ASRSTR[AOLE] as 1. 0 - No Underflow in Input data buffer B 1 - Underflow in Input data buffer B
8 AIDUA	AIDUA Input Data Buffer A has underflowed When set, this bit indicates that input data buffer A has underflowed. When clear, this bit indicates that input data buffer A has not underflowed. The bit is cleared when writing ASRSTR[AOLE] as 1. 0 - No Underflow in Input data buffer A 1 - Underflow in Input data buffer A
7 FPWT	FPWT FP is in wait states This bit is for debug only. When set, this bit indicates that ASRC is in wait states. When clear, this bit indicates that ASRC is not in wait states. 0 - ASRC is not in wait state 1 - ASRC is in wait state
6 AOLE	AOLE Overload Error Flag When set, this bit indicates that the task rate is too high for the ASRC to handle. The reasons for overload may be: - too high input clock frequency, - too high output clock frequency, - incorrect selection of the pre-filter, - low ASRC processing clock,

Table continues on the next page...

Field	Description
	- too many channels, - underrun, - or any combination of the reasons above. Since the ASRC uses the same hardware resources to perform various tasks, the real reason for the overload is not straight forward, and it should be carefully analyzed by the programmer. If ASRIER[AOLIE]=1, an interrupt is proposed when this bit is set. Write any value with this bit set as one into the status register clears this bit and the interrupt request proposed by this bit. 0 - No overload 1 - Task rate is too high
5 AODFC	AODFC Number of data in Output Data Buffer C is greater than threshold When set, this bit indicates that number of data already existing in ASRDOC is greater than threshold and the processor can read data from ASRDOC. A DMA request is always generated when the AODFC bit is set, but a DMA transfer takes place only if a DMA channel is active and triggered by this event. 0 - The threshold has not yet been met and no data output C interrupt is generated 1 - When AODFC is set, the ASRC generates data output C interrupt request to the processor if ASRIER[ADOEC] = 1
4 AODFB	AODFB Number of data in Output Data Buffer B is greater than threshold When set, this bit indicates that number of data already existing in ASRDOB is greater than threshold and the processor can read data from ASRDOB. A DMA request is always generated when the AODFB bit is set, but a DMA transfer takes place only if a DMA channel is active and triggered by this event. 0 - The threshold has not yet been met and no data output B interrupt is generated 1 - When AODFB is set, the ASRC generates data output B interrupt request to the processor if ASRIER[ADOEB] = 1
3 AODFA	AODFA Number of data in Output Data Buffer A is greater than threshold When set, this bit indicates that number of data already existing in ASRDOA is greater than threshold and the processor can read data from ASRDOA. A DMA request is always generated when the AODFA bit is set, but a DMA transfer takes place only if a DMA channel is active and triggered by this event. 0 - The threshold has not yet been met and no data output A interrupt is generated 1 - When AODFA is set, the ASRC generates data output A interrupt request to the processor if ASRIER[ADOEA] = 1
2 AIDEC	AIDEC Number of data in Input Data Buffer C is less than threshold When set, this bit indicates that the number of data still available in ASRDIC is less than the threshold and the processor can write data to ASRDIC. A DMA request is always generated when the AIDEC bit is set, but a DMA transfer takes place only if a DMA channel is active and triggered by this event. 0 - The threshold has been met and no data input C interrupt is generated 1 - When AIDEC is set, the ASRC generates data input C interrupt request to the processor if ASRIER[AIDEC] = 1
1	AIDEB

Table continues on the next page...

Field	Description
AIDEB	Number of data in Input Data Buffer B is less than threshold When set, this bit indicates that number of data still available in ASRDIB is less than threshold and the processor can write data to ASRDIB. A DMA request is always generated when the AIDEB bit is set, but a DMA transfer takes place only if a DMA channel is active and triggered by this event. 0 - The threshold has been met and no data input B interrupt is generated 1 - When AIDEB is set, the ASRC generates data input B interrupt request to the processor if ASRIER[AIDEB] = 1
0 AIDEA	AIDEA Number of data in Input Data Buffer A is less than threshold When set, this bit indicates that number of data still available in ASRDIA is less than the threshold and the processor can write data to ASRDIA. A DMA request is always generated when the AIDEA bit is set, but a DMA transfer takes place only if a DMA channel is active and triggered by this event. 0 - The threshold has been met and no data input A interrupt is generated 1 - When AIDEA is set, the ASRC generates data input A interrupt request to the processor if ASRIER[AIDEA] = 1

55.6.1.10 ASRC Parameter Register n (ASRPM1 - ASRPM5)

Parameter registers determine the performance of ASRC.

The parameter registers must be initialized by software before ASRC is enabled. Recommended values are given in the table below:

Table 55-10. ASRC Parameter Registers (ASRPM1~ASRPM5)

Register	Offset	Access	Reset Value	Recommend Value
ASRPM1	0x40	R/W	0x00_0000	0x7fffff
ASRPM2	0x44	R/W	0x00_0000	0x255555
ASRPM3	0x48	R/W	0x00_0000	0xff7280
ASRPM4	0x4C	R/W	0x00_0000	0xff7280
ASRPM5	0x50	R/W	0x00_0000	0xff7280

55.6.1.21 ASRC 76 kHz Period in terms of ASRC processing clock (ASR76K)

The register (ASR76K) holds the period of the 76 kHz sampling clock in terms of the ASRC processing clock with frequency Fs_{ASRC}. ASR76K = Fs_{ASRC}/Fs_{76k}. Reset value is 0x0A47 which assumes that Fs_{ASRC}=200 MHz. This register is used to help the ASRC internal logic to decide the pre-processing and the post-processing options automatically (see ASRC Control Register and ASRC Filter Configuration Status Register). In a system when Fs_{ASRC} = 133 MHz, the value should be assigned explicitly as 0x06D6 in user application code.

23 ZEROBUFA	ZEROBUFA Initialize buffer of Pair A when pair A is enabled. Always clear option. This bit is used to control whether the buffer is to be zeroized when pair A is enabled. 0 - Zeroize the buffer 1 - Don't zeroize the buffer
22 EXTTHRSHA	EXTTHRSHA Use external thresholds for FIFO control of Pair A This bit determines whether the FIFO thresholds externally defined in this register is used to control ASRC internal FIFO logic for pair A. 0 - Use default thresholds.

Table continues on the next page...

Field	Description
	1 - Use external defined thresholds.
21 BUFSTALLA	BUFSTALLA Stall Pair A conversion in case of Buffer Near Empty/Full Condition This bit determines whether the near empty/full FIFO condition stalls the rate conversion for pair A. This option can only work when external ratio is used. Near empty condition is the condition when input FIFO has less than 4 useful samples per channel. Near full condition is the condition when the output FIFO has less than 4 vacant sample words to fill per channel. 0 - Don't stall Pair A conversion even in case of near empty/full FIFO conditions. 1 - Stall Pair A conversion in case of near empty/full FIFO conditions.
20 BYPASSPOLYA	BYPASSPOLYA Bypass Polyphase Filtering for Pair A This bit determines whether the polyphase filtering part of Pair A conversion is bypassed. 0 - Don't bypass polyphase filtering. 1 - Bypass polyphase filtering.
19-18 —	- Reserved. Should be written as zero for future compatibility.
17-12 OUTFIFO_THRESHOLDA	OUTFIFO_THRESHOLDA The threshold for Pair A's output FIFO per channel These bits stand for the threshold for Pair A's output FIFO per channel. Possible range is [0,63]. When the value is n, it means that: when the number of output FIFO fillings of the pair is greater than n samples per channel, the output data ready flag is set; when the number of output FIFO fillings of the pair is less than or equal to n samples per channel, the output data ready flag is automatically cleared.
11 RSYNIFA	RSYNIFA Re-sync Input FIFO Channel Counter If bit set, force ASRCCR[ACIA]=0. If bit clear, untouch ASRCCR[ACIA]. 0 - Do not touch ASRCCR[ACIA] 1 - Force ASRCCR[ACIA]=0
10 RSYNOFA	RSYNOFA Re-sync Output FIFO Channel Counter If bit set, force ASRCCR[ACOA]=0. If bit clear, untouch ASRCCR[ACOA]. 0 - Do not touch ASRCCR[ACOA] 1 - Force ASRCCR[ACOA]=0
9-6 —	- Reserved. Should be written as zero for future compatibility.
5-0 INFIFO_THRESHOLDA	INFIFO_THRESHOLDA The threshold for Pair A's input FIFO per channel These bits stand for the threshold for Pair A's input FIFO per channel. Possible range is [0,63].

Field	Description
	When the value is n, it means that: when the number of input FIFO fillings of the pair is less than n samples per channel, the input data needed flag is set; when the number of input FIFO fillings of the pair is greater than or equal to n samples per channel, the input data needed flag is automatically cleared.

56.2 Overview

The Pulse Density Modulated Microphone Interface (PDM) is a popular way to deliver audio from microphones to the processor in several applications, such as mobile telephones. However, current digital-audio systems use multibit audio signal (also known as multibit PCM) to represent the signal. This block implements the required digital interface to provide a 24-bits audio signal from a PDM microphone bitstream in a configurable output sampling rate.

The implementation of this digital interface is based on the application of digital signal processing techniques in hardware. The PDM Microphone Interface architecture was designed to save gate count and minimize power consumption. It implements a series of filters to transform a PDM bitstream to a 24-bit PCM signal in the audio band.

The whole module is implemented to work in a multichannel mode. All channels have the same configuration but each input channel could be turned on/off independently.

56.2.1 Block Diagram

Figure 56-1 shows the block diagram for the PDM Microphone Interface module. It consists of the following:

- an input interface for each pair of PDM microphones.
- a decimation filter by channel.
- a FIFO by channel.
- a time generation unit.
- shared interfaces to DMA, interrupts and SoC.
- A Hardware Voice Activity Detector (HWVAD).

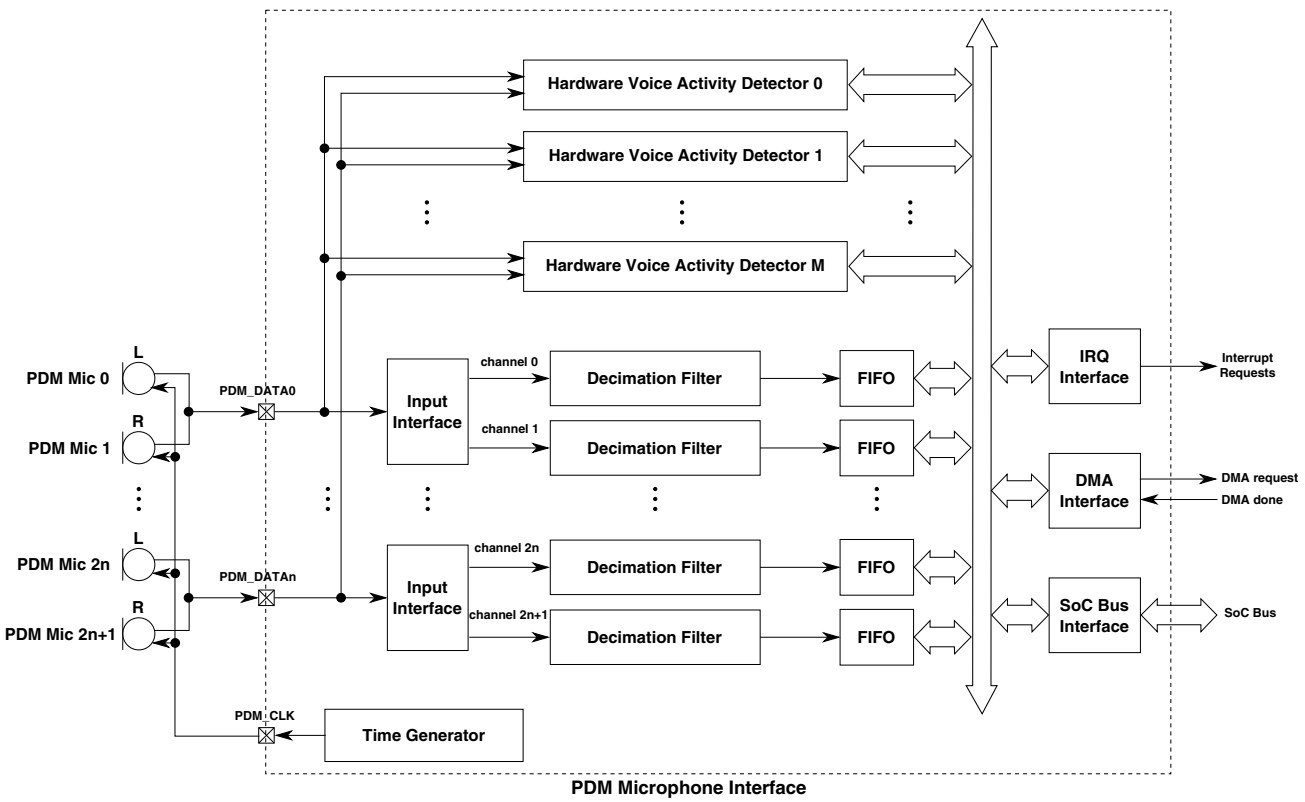

Figure 56-1. PDM Microphone Interface Block Diagram

The Time Generator unit delivers the PDM_CLK to all microphones. All microphones must operate at the same clock frequency. Each input interface receives a time multiplexed PDM bitstream from two PDM microphones and it separates the two audio information in two channels: left (0) and right (1). Each channel is processed separately.

The Decimation Filter is composed internally by a CIC filter, a DC remover and Half Band filters. The filtering results are stored in individual FIFOs; a FIFO by channel. The FIFOs have overflow and underflow detectors to deliver an error interrupt request.

An interrupt request or DMA request could be delivered by the PDM. Then the filters results stored in FIFOs could be accessed by the SoC or DMA respectively via the internal bus interface .

The HWVAD takes data from the input of a selected PDM microphone to detect if there is any voice activity. When a voice activity is detected, an interrupt could be delivered to the system.

56.2.2 Features

The PDM Microphone Interface (PDM) includes the following features:

- Decimation filters:
  - Fixed filtering characteristics for audio application.
  - 24-bit signed filter output.
  - Internal clock divider for a programmable PDM clock generation.
  - Full or partial set of channels operation with individual enable control.
  - Programmable decimation rate.
  - Programmable DC remover.
  - Range adjustement capability.
  - FIFOs with interrupt and DMA capability.
    - Each FIFO with 8 entries length.
- Hardware Voice Activity Detector (HWVAD).
  - Interrupt capability.
  - Zero-Crossing Detection (ZCD) option.

56.3 Functional Description

Figure 56-1 shows the PDM Microphone Interface (PDM) block diagram. Basically this module is composed by a Decimation Filter and a FIFO by channel, an Input Interface for each pair of microphones, a shared Time Generator unit, a shared bus interface, a shared DMA interface and a shared interrupt interface.

The Decimation Filter implements a low-pass filter in the audio band (20Hz-22.5kHz @48kHz output sampling rate by default) with a configurable decimation rate. It is implemented using a series of CIC, Half Band and DC remover filters.

The Time Generator unit generates the PDM_CLK to the microphones. This clock is the same for all the PDM microphones and it is active for all the microphones, i.e. there is not possiblity to turn off the PDM_CLK for one microphone only.

The output of each Decimation Filter is stored into a FIFO buffer. Each FIFO is mapped in the DATACHn registers. It is possible to generate either an interrupt or a DMA request when, in each FIFO of all enabled channels, the number of data stored surpasses a configured watermark.

Also, independently on decimation filters, there is a Hardware Voice Activity Detector(HWVAD) which implements voice-detection algorithms to generate wake-up interrupts.

56.3.1 Modes of operation

This section describes the PDM operation modes which depends on the SoC power mode , the SoC Doze mode , the SoC Debug mode and MDIS, DBGE, DBG and DOZEN bitfields as summarized in Table 56-2.

Table 56-2. Operation Mode Selection

<table>
<tr><th>Mode</th><th>MDIS</th><th>SoC Doze & DOZEN= 1</th><th>SoC Power Mode</th><th>DOZEN</th><th>SoC Debug | DBG</th><th>DBG E</th><th>CPU clock</th><th>PDM internal clock</th><th>Decimation Filter state</th><th>HWVAD[n] state</th></tr>
<tr><td>Normal</td><td rowspan="6">0</td><td rowspan="3">0</td><td rowspan="2">RUN</td><td rowspan="2">Any</td><td>0</td><td>Any</td><td rowspan="3">Enabled</td><td rowspan="3">Enabled</td><td>Run (Depends on PDMIEN and CHENn)</td><td>Run (Depends on PDMIEN and VADEN)</td></tr>
<tr><td>Debug</td><td rowspan="2">1</td><td>1</td><td>Stop</td><td>Stop</td></tr>
<tr><td>Low Power</td><td>SLEEP</td><td rowspan="2">0</td><td rowspan="4">Any</td><td rowspan="4">Any</td><td rowspan="3">Gated (Externally)</td><td>Run (Depends on PDMIEN and CHENn)</td><td rowspan="2">Run (Depends on PDMIEN and VADEN)[1]</td></tr>
<tr><td></td><td>DEEPSLEEP</td><td rowspan="3">Stop</td></tr>
<tr><td rowspan="3">Disable/Low Leakage</td><td>SLEEP/ DEEPSLEEP</td><td>1</td><td rowspan="2">Gated</td><td rowspan="2">Stop</td></tr>
<tr><td>1</td><td rowspan="2">Any</td><td rowspan="2">Any</td><td rowspan="2">Any</td><td>Enabled</td></tr>
<tr><td>1</td><td>Any</td><td>Gated (Internally)</td></tr>
</table>

1. HWVAD[n] will run in DEEPSLEEP only if it is placed on an always-on power domain in the SoC.

56.3.1.1 Normal mode

This is the default PDM operational mode. In this mode the channels can be enabled to perform filtering operation.

56.3.1.2 Low Power mode

In Low Power mode the PDM is able to filter the PDM microphone data and perform voice detection such as in Normal mode and can generate a wake up event through asynchronous DMA/IRQ requests depending on CHENn, VADEN and PDMIEN values.

The Low Power mode is entered when the SoC enters to SLEEP or DEEPSLEEP modes and DOZEN =0. In this mode the CPU clock is gated externally and PDM could be kept running.

In case a SoC SLEEP mode is requested, the decimation filter is kept running such as Normal mode and the SoC SLEEP mode is acknowledged immediately.

In case a SoC DEEPSLEEP mode is requested it is waited until the last input samples are processed to acknowledge the SoC mode and stop the decimation filter.

During this mode, VAD will continue running if it was previously enabled (VADEN=1) during Normal mode.

The DMA and IRQ requests can be generated asynchronously to wake up the CPU. .

NOTE

The asynchronous DMA or asynchronous interrupt requests are generated only in this mode.

56.3.1.3 Debug mode

This mode is used to check the status of the IP when requested. In this mode the PDM can be stopped after the remaining data processing has finished depending on the DBGE bit value. This mode can be actived by a SoC debug request or asserting the DBG bitfield.

In DBGE=0 case, if a debug request is received or DBG is asserted while the module is running, it will be stopped after finish to process the remaining data. Otherwise, if DBGE=1, the module will be kept running.

The PDM Microphone Interface cannot enter Debug mode once in Disable/Low Leakage or Low Power mode.

The Debug mode request affects all channels in the PDM. Access to output buffers remain operational, as well as their related flags.

NOTE

Once a debug request is issued, it can not be aborted.

56.3.1.4 Disable/Low Leakage mode

In this mode, PDM is stopped after the remaining data processing has finished. PDM is in Disable/Low Leakage (DLL) mode when:

- The SoC is in SLEEP and DEEPSLEEP modes and DOZEN=1.
- The SoC is in Doze and DOZEN bit is asserted.
- MDIS is asserted.

When Disable/Low Leakage (DLL) mode is requested while the module is running, it will be stopped after finish to process the remaining data.

Writes only to CTRL_1 and CTRL_2 registers are allowed with the exception of writes to the DBG and SRES bits, which are ignored, but read is still available for these bits.

56.3.2 Output Rate

The output rate is the sampling rate at the decimation filter output. It depends on the sampling rate of the microphone input and the configured quality mode (refer to Quality Modes) . Common audio sampling rates are 48kHz and 16kHz. On this document the output rate is referred sometimes as FS.

56.3.3 Quality Modes

Independently on the power mode selected, if the decimation filter is running, the PDM can operate in 6 different quality modes, those can be selected by the QSEL bitfield. The decimation and interpolation rates in internal blocks are shown in Table 56-3 where OSR depends on the CICOSR as shown in Equation 1 on page 3418.

$$OSR = 16\text{-}CICOSR$$

Equation 1. Oversampling Rate (OSR)

The quality selected can be configured dinamically when the Decimation Filter is running, the output rate is mantained in every quality selected.

The passband of the Decimation Filter depends on the quality mode, refer to Overall Passband for more information.

In order to mantain the same output rate in the Decimation Filter when the quality is changed, the PDM_CLK rate changes depending on the quality selected. For more details about the PDM_CLK, refer to Time Generator.

The Sampler and the Half Band filters are whether enabled or not depending on the quality selected, achieving a low power consumption when they are disabled. The CIC filter decimation rate is also whether doubled or not depending on the quality selected. For more information, refer to Decimation Filter.

NOTE

In order to get a better audio performance, the RANGEADJn bitfield need to be adjusted depending on the quality mode selected as pointed out on its description. For more information, refer to Overall Filter Gain.

Table 56-3. Quality Modes

Quality Mode	QSEL bitfield	Sampler Interpolation	CIC Filter Decimation	1st Half Band Filter Decimation	2nd Half Band Filter Decimation	PDM_CLK Rate	Passband
High Quality	001	-	:(2OSR)	:2	:2	Output Rate x 8 x OSR	To ~0.5 x Output Rate
Medium Quality	000	-	:OSR	:2	:2	Output Rate x 4 x OSR	To ~0.5 x Output Rate
Low Quality	111	x2	:OSR	:2	:2	Output Rate x 2 x OSR	To ~0.5 x Output Rate
Very Low Quality 0	110	-	:(2OSR)	:2	-	Output Rate x 4 x OSR	To ~0.25 x Output Rate
Very Low Quality 1	101	-	:OSR	:2	-	Output Rate x 2 x OSR	To ~0.25 x Output Rate
Very Low Quality 2	100	x2	:OSR	:2	-	Output Rate x OSR	To ~0.25 x Output Rate

56.3.4 Time Generator

The Time Generator is the responsible to generate the PDM_CLK to the microphones.

NOTE

The Time Generator is affected by soft-reset. The PDM_CLK starts with a rising edge after a soft reset is issued.

56.3.4.1 Clock divider

The sampling rate of the microphone input depends on the PDM_CLK rate. The PDM_CLK rate can be trimmed using an internal clock divider, configuring the quality mode (refer to Table 56-3) or trimming the PDM's root clock frequency (PDM_CLK_ROOT rate).

The internal clock divider frequency is defined by the CLKDIV bitfield value which must be configured following Equation 2 on page 3420.

$$CLKDIV = \frac{\text{PDM_CLK_ROOT rate}}{8(16\text{-CICOSR})(\text{Output Rate})}$$

Equation 2. CLKDIV bitfield value

Once calculated the CLKDIV value, the generated PDM_CLK rate can be estimated as shown in Equation 3 on page 3420, where the K factor value depends on the quality mode as shown in Table 56-4 and floor(x) is the function that takes as input a real number x and gives as output the greatest integer less than or equal to x.

$$\text{PDM_CLK rate} = \frac{\text{PDM_CLK_ROOT rate}}{2 \cdot \text{floor}(K \cdot CLKDIV)}$$

Equation 3. PDM_CLK rate

Table 56-4. K factor value

Quality mode	K factor
High Quality	1/2
Medium Quality, Very Low Quality 0	1
Low Quality, Very Low Quality 1	2
Very Low Quality 2	4

56.3.4.1.1 Minimum Required CLKDIV

NOTE

This minimum CLKDIV condition is required only if any decimation filter channel is enabled and the clock divider is enabled, otherwise this condition should be ignored.

To work properly the CLKDIV bitfield value must have a minimum value according to the quality mode configured (see Quality Modes), the number of enabled channels (EC), Equation 1 on page 3418 and K factor (see Input/Output Timing Requirements). When this condition is not met the LOWFREQF bit is asserted and an error interrupt can be issued (in case ERREN=1).

The equations to estimate the minimum required CLKDIV bitfield value depending on the configured quality mode are shown in Equation 4 on page 3421 (for medium, high and low quality modes) and Equation 5 on page 3421 (for very low quality modes), on these equations floor(x) is the function that takes as input a real number x and gives as output the greatest integer less than or equal to x.

$$\text{floor}(\text{K x CLKDIV}) >= \text{K x } \frac{10+93EC}{8 \text{ x OSR}}$$

Equation 4. Minimum required CLKDIV value in Medium, High and Low Quality modes

$$\text{floor}(\text{K x CLKDIV}) >= \text{K x } \frac{10+43EC}{8 \text{ x OSR}}$$

Equation 5. Minimum required CLKDIV value in Very Low Quality modes

56.3.4.2 PDM_CLK_ROOT rate and CLKDIV calculation examples

Example 1:

If it is required an output rate=16kHz and enable 4 channels (EC=4). A valid configuration is following:

1. Configure High Quality mode and CIC decimation by 32 (CICOSR =0, then OSR=16), .
2. Check the PDM_CLK rate for High Quality mode in Table 56-3. PDM_CLK rate = 16kHz x 8 x OSR = 16kHz x 8 x 16 = 2.048MHz.
3. Check the K factor value for High Quality mode in Table 56-4. K factor is 1/2.
4. Calculate minimum CLKDIV value (see Equation 4 on page 3421): floor(K x CLKDIV) >= K x (10 + 93EC)/(8 x OSR) then floor(K x CLKDIV) >= 2.984375. Finally, CLKDIV >= 5.96875.
5. Calculate the minimum PDM_CLK_ROOT rate:
   - From Equation 2 on page 3420 : PDM_CLK_ROOT rate = 8 x (16-CICOSR) x CLKDIV x (Output rate)
   - From step 4 result: CLKDIV>=4, then PDM_CLK_ROOT rate >= 8 x (16-CICOSR) x 5.96875 x 16kHz.
   - Finally: PDM_CLK_ROOT rate >= 12224kHz
   - Select the PDM_CLK_ROOT rate in that range.
6. Check if selected PDM_CLK_ROOT rate and CLKDIV value satisfies the Table 56-5.
7. Finally, check again if the selected PDM_CLK_ROOT rate satisfies Equation 2 on page 3420. If not, adjust CLKDIV or change PDM_CLK_ROOT rate accordingly.

Example 2:

If it is required an output rate=48kHz and enable 4 channels (EC=4). A valid configuration is following:

1. Configure Medium Quality mode and CIC decimation by 16 (CICOSR =0, then OSR=16), .
2. Check the PDM_CLK rate for Medium Quality mode in Table 56-3. PDM_CLK rate = 48kHz x 4 x OSR = 48kHz x 4 x 16 = 3.072MHz.
3. Check the K factor value for Medium Quality mode in Table 56-4. K factor is 1.
4. Calculate minimum CLKDIV value (see Equation 4 on page 3421): floor(K x CLKDIV) >= K x (10 + 93EC)/(8 x OSR) then floor(K x CLKDIV) >= 2.984375. Finally, CLKDIV >= 2.984375.
5. Calculate the minimum PDM_CLK_ROOT rate:
   - From Equation 2 on page 3420 : PDM_CLK_ROOT rate = 8 x (16-CICOSR) x CLKDIV x (Output rate)
   - From step 4 result: CLKDIV>=2.984375, then PDM_CLK_ROOT rate >= 8 x (16-CICOSR) x 2.984375 x 48kHz.
   - Finally: PDM_CLK_ROOT rate >= 18336kHz
   - Select the PDM_CLK_ROOT rate in that range.
6. Check if selected PDM_CLK_ROOT rate and CLKDIV value satisfies the Table 56-5.
7. Finally, check again if the selected PDM_CLK_ROOT rate satisfies Equation 2 on page 3420. If not, adjust CLKDIV or change PDM_CLK_ROOT rate accordingly.

56.3.4.3 Input/Output Timing Requirements

The PDM microphones must meet the setup and hold timing requirements shown in Table 56-5 and Figure 56-2. The "k" factor value in Table 56-5 depends on the selected quality mode as shown in Table 56-4.

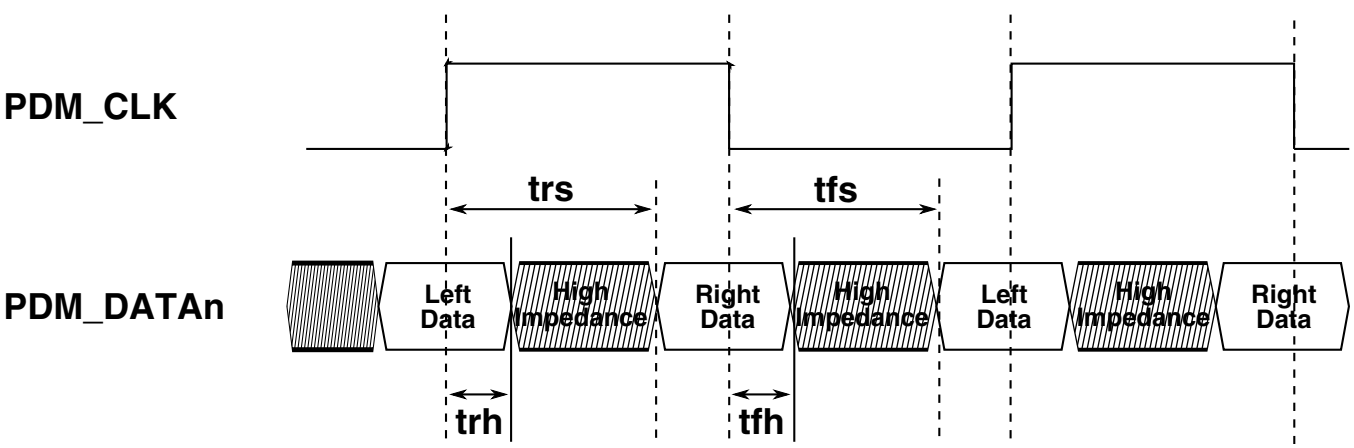

Figure 56-2. Input/Output TIming Requirements

Table 56-5. Timing parameters

Parameter	Value
trs, tfs	$<= \frac{\text{floor}(K \times CLKDIV) - 1}{\text{PDM_CLK_ROOT rate}}$ [1]
trh. tfh	>=0

1. Depending on K value, the user must make sure floor(K x CLKDIV) > 1 to avoid timing problems.

56.3.5 Decimation Filter

Figure 56-3 shows the block diagram of the Decimation Filter. This block is composed by a CIC filter, a DC remover, two Half Band filters for each channel.

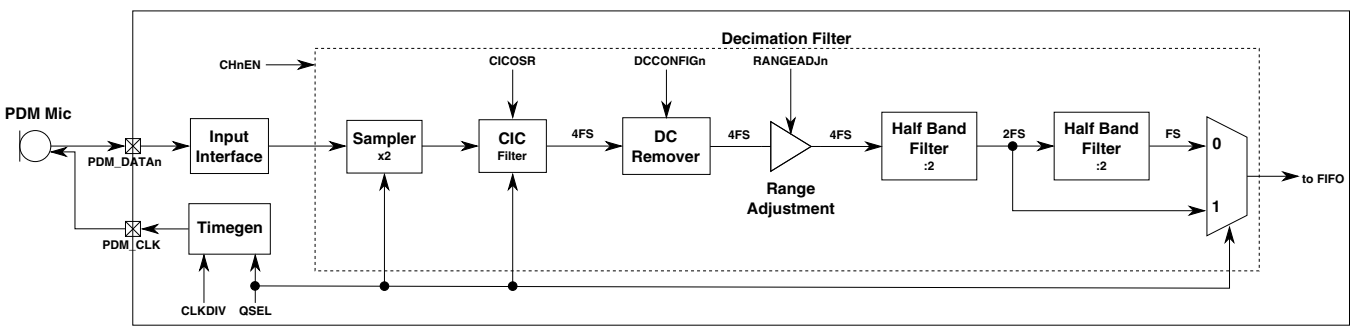

Figure 56-3. Decimation Filter Block Diagram

The Sampler block is activated depending on the quality mode selected (QSEL bitfield). This one samples twice the PDM_DATAn incoming from the Input Interface.

The CIC filter (Cascaded Integrator Comb filter) is a low pass filter commonly used to filter the sigma-delta modulator output signal.

The DC remover is a high pass filter used to remove the DC component of the processed signal with configurable cut-off frequency.

Each Half Band filter implements a low pass digital filter with decimation by 2. They are used to compensate the high CIC drop in passband and helps the FIR filter block to flat the overall passband response.

The Decimation Filter output depends on the quality mode selected by the QSEL bitfield, so it can come from any of the Half Band filters output. In case, the last Half Band filter stage is bypassed, power consumption should be reduced.

The range of each Decimation Filter can be adjusted by a Range Adjustment block so that, in case a adjustment overflows or underflows is detected. an error interrupt is raised.

56.3.5.1 Filter Performance

56.3.5.1.1 Overall Filter Gain

The overall filter gain depends on the quality mode, the Equation 8 on page 3425 and the RANGEADJn bitfield as shown in Equation 6 on page 3424.

$$OverallFilterGain\ (dB) = \begin{cases} 140 \cdot \log_{10}(32 - 2CICOSR) + 6.02RANGEADJn - 222.74 & ;if\ QSEL \in [HQ, VLQ0] \\ 140 \cdot \log_{10}(16 - CICOSR) + 6.02RANGEADJn - 222.74 & ;others \end{cases}$$

Equation 6. Overall Filter Gain

Finally, the input and output dBFS levels are related as shown in Equation 7 on page 3424.

$$Output(dBFS) = Input(dBFS) + OverallFilterGain(dB)$$

Equation 7. Filter input and output relationship

56.3.5.1.2 Overall Passband

The Decimation Filter passband depends on the quality mode and the output rate (FS). For instance, the overall filter passband for different output data rates when the PDM is in High, Medium and Low Quality modes is shown in Table 56-6.

Table 56-6. Filter Passband in HQ, MQ and LQ modes (DCCONFIGn=00)

Output Data Rate	Overall Filter Passband
FS	**0.0004FS - 0.4688FS**
16kHz	6.67Hz - 7.50kHz
48kHz	20Hz - 22.5kHz

The overall filter passband for different output data rates when the PDM is in Very Low Quality modes is shown in Table 56-7.

Table 56-7. Filter Passband in VLQn modes (DCCONFIGn=00)

Output Data Rate	Overall Filter Passband
FS	**0.0002FS - 0.2344FS**
16kHz	3.33Hz - 3.75kHz
48kHz	10.00Hz - 11.25kHz
96kHz	20Hz - 22.5kHz

56.3.5.2 Input Interface

The timing diagram of the input interface signals is shown in Figure 56-4. The bitstream incoming from the microphone data input "n" (PDM_DATAn) in the first half (Right microphone) of the PDM_CLK is directed to the Channel "2n+1" and the data generated during the last half (Left microphone) is directed to the Channel "2n".

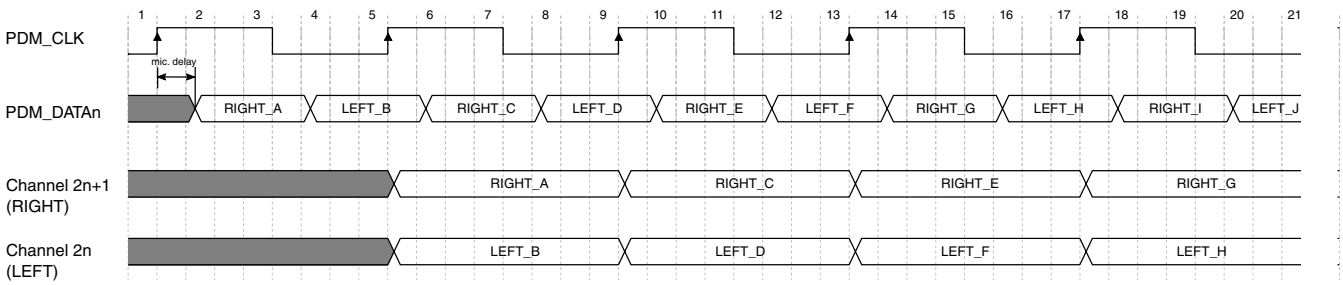

Figure 56-4. Input Interface signals

56.3.5.3 CIC Filter

The CIC filter is an optimized implementation of the low pass Sinc filter with multiple stages. It is widely used because it requires just adders and subtractors. The CIC filter is composed by sub-blocks called: integrator and comb. The CIC decimation rate is defined by the CICOSR bitfield and the selected quality mode as shown in Equation 8 on page 3425.

$$\text{CIC Decimation Rate} = \begin{cases} 2*(16-\text{CICOSR}) & ;\text{if HQ or VLQ0} \\ 16-\text{CICOSR} & ;\text{others} \end{cases}$$

Equation 8. CIC Decimation Rate

56.3.5.4 DC Remover

There are two DC removers in the filter chain, one in the input and another in the output. The former is integrated in the CIC filter, and the later is placed just before the FIFO. Both can be bypassed independently.

The block removes the DC level component of the signal using a high-pass filter with a very low cut-off frequency selected by the DCCONFIGn bitfield. This filter is bypassed when DCCONFIGn=11.

56.3.5.5 Half Band Filters

A half band filter divides the signal base-band into two equal subbands before to be decimated by 2. It also compensates the CIC filter drop in passband and helps to flatten the overall passband response. PDM has two half band filter stages, with the possibility of bypass the last one.

56.3.6 Hardware Voice Activity Detector

The Hardware Voice Activity Detector (HWVAD) is a block responsible for detect voice activity in a channel selected by the user as shown in the Figure 56-5 and Figure 56-6. It can be configured in Envelope-based or Energy-based mode and it should be configured as described in Initialization.

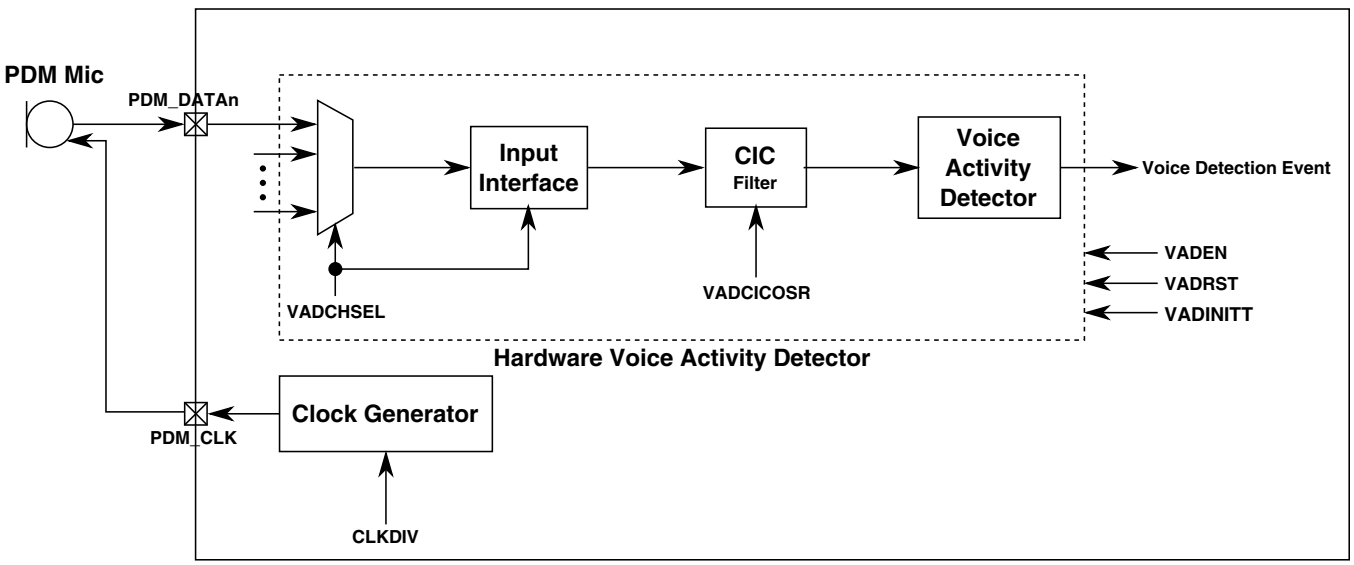

Figure 56-5. HWVAD Block Diagram

The HWVAD can divide the incoming PCM signal from its internal CIC in frames, the frame energy is used to estimate the background noise. Both frame energy and noise energy are examinated, a voice activity is detected when a specific delta between them is detected, then a interrupt will be issued. Optionally a Zero-Crossing Detection block (ZCD) could be enabled to avoid low energy voiced speech be missed, improving the voice detection performance.

The HWVAD detector can be enabled by the VADEN bit (VAD_CTRL_1 register) and could be reset by software through the VADRST bit (VAD_CTRL_1 register) . It is important to remark that the HWVAD detector could be enabled and/or reset only when the PDM isn't running i.e. when the BSY_FIL bit in STAT register is cleared.

To perform voice detection a Noise Filter and Signal Filter are used as shown Figure 56-6. In addition, a minimum block in the output of the Noise Filter and a maximum block in the ouput of the Signal Filter can be used. The result of both blocks can be scaled by gain blocks. Finally, the signal and noise estimated are compared, voice is detected when signal is greater than noise.

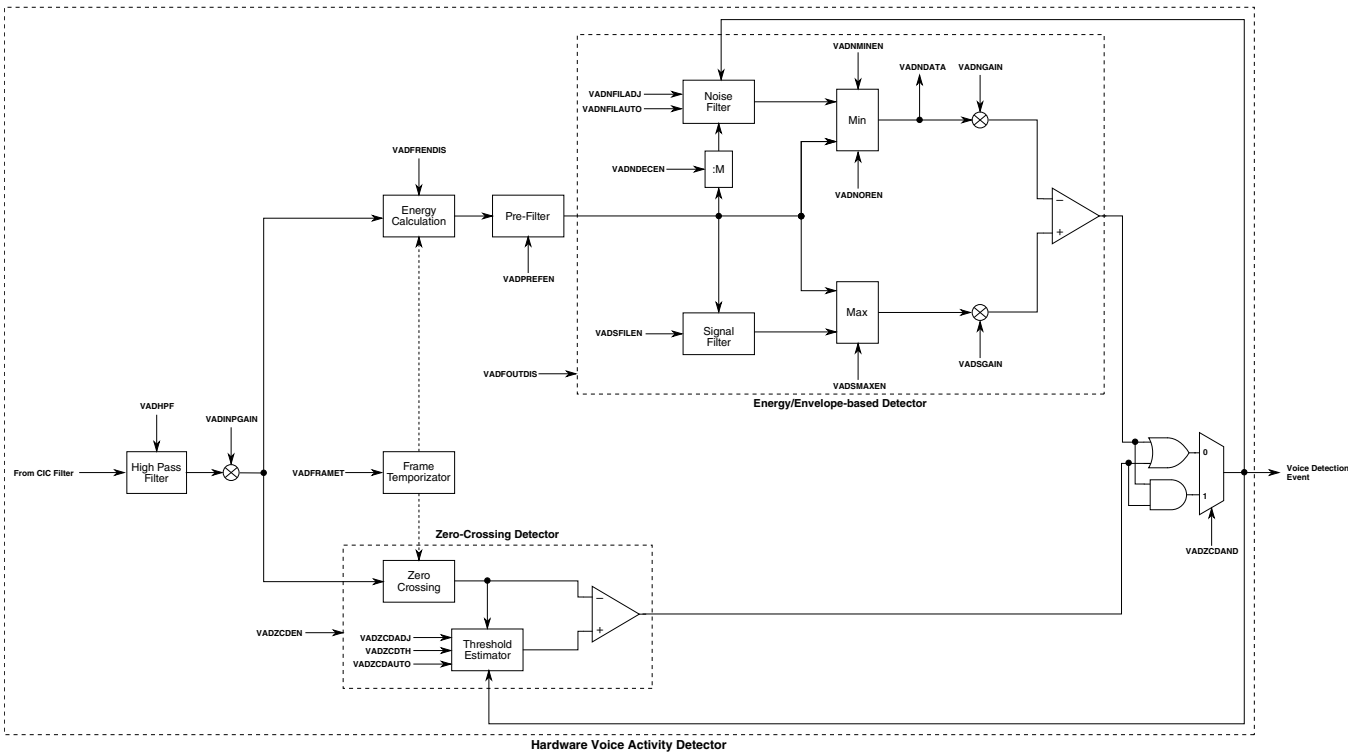

Figure 56-6. HWVAD Block Diagram (cont.)

56.3.6.1 High-Pass Filter

The purpose of the High-Pass Filter is to remove the low frequency components. The cut-off frequency is selected by the VADHPF bitfield. This filter is bypassed when VADHPF=00.

56.3.6.2 Input Setting

The HWVAD input has internally a user configurable High-Pass filter (see VADHPF bit description) and a user configurable gain (see VADINPGAIN). Both controls could be used to configure the module based on external noise conditions.

56.3.6.3 Frame Time Setting

In order to perform voice detection the signal frames incoming from the CIC filter can be divided in frames whose duration can be configured. The frame time will depend on the CIC output rate, the value of the VADFRAMET bitfield and a constant as is defined in Equation 9 on page 3428.

$$frame\ \ time = \frac{VADFRAMET \times 192}{CIC\ \ output\ \ rate}$$

Equation 9. Frame Time

For instance, in the typical case of the CIC filter output rate would be 192kHz, the frame time would be 10ms when VADFRAMET is 10.

56.3.6.4 Initialization Time

An initialization time can be configured by the VADINITT bitfield. During this initialization time no voice detection event is issued, all detectors are kept disabled.

$$initialization\ \ time = (\mathrm{VADINITT}+1) \times frame\ \ time$$

Equation 10. Initialization Time

56.3.6.5 Energy Calculation

In case VADFRENDIS = 0, the sum of the absolute values of all the samples of each frame are used to detect voice. Otherwise, if VADFRENDIS=1, the absolute value of the samples are used to detect voice i.e. the data incoming from CIC is not divided in frames.

56.3.6.6 Pre-Filter

The Pre-FIlter block is a low-pass filter which can be enabled when VADPREFEN=1 .

56.3.6.7 Energy/Envelope-based Detector

To perform voice detection a Noise Filter and Signal Filter are used as shown Figure 56-6. In addition, a minimum block in the output of the Noise Filter and a maximum block in the ouput of the Signal Filter can be used. The result of both blocks can be scaled by gain blocks. Finally, the signal and noise estimated are compared, voice is detected when signal is greater than noise.

56.3.6.7.1 Noise Filter

The Noise Filter is a low-pass filter . This filter could be adjusted by the VADNFILADJ bitfield . In case VADNFILAUTO=1 the noise filter is enabled only when voice is not detected, when voice is detected the filter output does not change. In case VADNFILAUTO=0 the filter is always enabled.

A decimation stage in the input of the Noise Filter can be enabled by the VADNDECEN bitfield.

56.3.6.7.2 Minimum Noise

In order to estimate the noise, a block which calculates the minimum value between the input and output of the noise filter is used. This block can be enabled by VADNMINEN, otherwise the output of the noise filter is passed directly.

The estimated noise of the output of this block is stored in the VADNDATA register for post-processing via software.

56.3.6.7.3 Signal Filter

The Signal Filter is a low-pass filter . This filter will be enabled when VADSFILEN=1, otherwise the filter will be bypassed.

56.3.6.7.4 Maximum Signal

In order to estimate the signal, a block which calculates the maximum value between the input and output of the signal filter can be used. This block can be enabled by VADSMAXEN.

56.3.6.7.5 Filter Result Gain Setting

There are two gain adjustment controls, one for the estimated noise (VADNGAIN) and another for signal estimated (VADSGAIN). Both gain adjustments outputs are compared, the comparison result determines whether or not there is voice in the channel.

56.3.6.8 Zero-Crossing Detector

Optionally, the HWVAD performance can be increased by the use of a Zero-Crossing Detection (ZCD) circuit. It is enabled by a VADZCDEN bit.

The threshold of the ZCD could be static or calculated dynamically depending on the VADZCDAUTO bit. When it is dynamically determined (VADZCDAUTO = 1) the threshold is calculated automatically taking the VADZCDTH bit-field as initial value, otherwise (VADZCDAUTO=0) the threshold is static in the VADZCDTH user configurable value.

The ZCD result can be AND'ed or OR'ed with the energy-based or envelope-based detection, it is selected by the VADZCDAND bit.The filter coefficient is equal to (VADZCDADJ+1)*2^(-4).

56.3.6.9 Interrupt

The HWVAD issues an interrupt when voice activity is detected and the VADIE bit in the VAD_CTRL_1 register is enabled. The voice activity event also will set the VADIF flag in the VAD_STAT register, this bit will be cleared when it is written 1.

56.3.6.10 Extended Operation

The VADIF bit could be used for a HWVAD extended operation i.e. using the VADNDATA bitfield value to determine a more accurate voice detection event by software. The procedure to follow will be:

1. An interrupt is issued by the HWVAD, the VADIF is set.
2. Leave the VADIF asserted while sofware is processing the VADNDATA bitfield content.
3. When software finishes to process the VADNDATA and detects voice activity:
   - If Envelope-based Detection is used, pulse VADST10 by more than 2-cycles and clear VADIF flag.
   - If Energy-based Detection is used, clear VADIF flag.

56.3.6.11 VAD Soft-reset

The VAD soft-reset is requested by writing 1 to the VADRST bit. It resets the following blocks and/or registers:

- VADIF, VADINSATF bitfields.
- All internal VAD buffers.

56.3.7 Bus Interface

The Bus Interface manages the Direct Memory Access (DMA) transactions, the interrupt requests and the user register interface with the SoC.

56.3.7.1 FIFO

The FIFO is a First-In, First-Out buffer that saves the overall filtering results. Each FIFO is 8 entries length. There is one FIFO for each channel. A push writes data into the FIFO, and a read pops data from FIFO. The push and pop operations from FIFO are in different clock domains, the push operation is made using the PDM clock while the pop operation uses the CPU clock . The FIFO has a configurable watermark FIFOWMK in the FIFO_CTRL register. When the amount of data in all the FIFOs of the enabled channels is greater than the watermark value (FIFO_CTRL[FIFOWMK]) a DMA/IRQ is requested depending on the DISEL field in the CTRL_1 register. After the filters are enabled by PDMIEN, the initial FIR results are discarded and not written into the FIFOs. About 68 initial FIR results are not stored on FIFOs (FIR_RDY=0). After the STAT[FIR_RDY] register is set the data generated by the filter is valid and starts to push the results in FIFO.

A new filtered result is discarded (not stored) when the FIFO is full and overflow flag FIFOOVFn rises. Similarly, when trying a pop and FIFO is empty no valid data is read and underflow flag rises. In both cases, when overflow or underflow occurs they are flagged in the FIFO_STAT register to the respective channel, and an error interrupt is generated if the ERREN in the CTRL_1 register is asserted.

When the FIFO is reset by asserting the SRES soft-reset bit, zero values fills all FIFO positions, as well as push and pop pointers are set to initial position.

56.3.7.2 DMA

If DISEL=01 the FIFO stored samples will be read through DMA transactions. Then if there is at least one enabled channel and all FIFOs of all enabled channels reach their watermark the output interface makes a request for DMA transaction. When the PDMIEN is set and the filters start to operate, there is a period to wait the filter results to stabilize and no filter results are stored on the FIFOs. Therefore the first DMA request takes longer to occur than the following ones.

The CHnF flags in the STAT register are cleared when a DMA transaction is finished.

When the PDM is in Low Power mode and the watermark level is surpassed an asynchronous DMA request is delivered to the system, then the system wakes up the CPU clock, returning to Normal mode, to read FIFOs data.

56.3.7.3 Interrupt Requests

If DISEL=10 then an interrupt request is used to indicate that filtering results are stored in the FIFOs to be read by CPU. Also in this case the data can be read in the DATACHn registers and the flag CHnF of the STAT register are asserted for the enabled channels when the CHn FIFO surpasses the watermark level.

When the module is in Low Power mode the CPU clock is disabled, but the PDM clock remains enabled. In this case, an asynchronous interrupt is delivered to the system, it wakes up the CPU clock, returning to Normal mode. The system could read the FIFOs data and after should clear the CHnF flags to get a new interrupt request.

An error interrupt request can be generated also when an exceptional condition happens, such as a overflow or underflow in any channel output, an overflow or underflow of any FIFO, or the PDM clock rate is not the minimum value required to the PDM working (see Minimum Required CLKDIV). This one is enabled by the ERREN bit and the type of error is signalized by its respective status flag: OUTOVFn and OUTUNFn for channel outputs errors, FIFOOVF and FIFOUND flags for FIFO errors, and LOWFREQF for PDM clock rate.

56.4 External Signals

Note

The PDM Microphone Interface module does not provide metastability protection or filtering for input data. The data must be generated using the provided PDM_CLK.

Table 56-8. PDM Microphone Interface External Signals

Signal	Description	Direction
PDM_DATAn	The data bitstreams received from *n*th PDM microphone pair throughout the input interface	I
PDM_CLK	The clock delivered to the PDM microphones from the clock generator	O

56.5 Initialization

Following are some simple initialization steps to be done before using the PDM block.

56.5.1 Initialization Procedure without HWVAD

The sequence of steps for the block initialization without enabling voice activity detector, i.e. using decimation filters only, is as follows:

1. Program the bit-fields as desired for your application (CLKDIV, CHnEN, FIFOWMK, DISEL, ERREN etc.). For more details see PDM_CLK_ROOT rate and CLKDIV calculation examples.
2. Start the overall module asserting the PDMIEN bit.
3. The module is ready to receive data from the input ports of the enabled channels.

56.5.2 Initialization Procedure with HWVAD

In this section is described the initialization procedures to initialize PDM with the voice activity detector.

The voice activity detector can work in two modes: Energy-based mode or Envelope-based mode. Optionally, a Zero-Crossing Detector can be enabled to improve the voice detection.

The Energy-based method separates the audio signal in frames and estimates the energy of these frames to detect voice activity. In the other hand, the Envelope-based method calculates the audio signal envelope to detect voice.

Both methods have the same detection performance, but the Energy-based is recommended for low power applications where is expected that the chip is asleep for long periods. Envelope-based detection is recommended for applications where the device require to wake faster and it is not asleep for long periods.

The Zero-Crossing Detector is recommended to improve detection with fricatives phonemes (/e.g. /f/ or /s/) in noisy environments.

56.5.2.1 HWVAD in Energy-based mode

The sequence of steps to initialize the voice activity detector in Energy-based mode is as follows:

1. Program the control bitfields as desired for your application (CLKDIV, CHnEN, FIFOWMK, DISEL, ERREN etc.). For more details see PDM_CLK_ROOT rate and CLKDIV calculation examples.
2. Configure general HWVAD parameters:
   a. CIC oversampling rate (VADCICOSR bitfield).
   b. Configure the voice source channel (VADCHSEL bitfield).
   c. Configure the internal initialization timer (VADINITT bitfield) if required. More details in Initialization Time.
   d. Assert VADEN bitfield.
3. Configure input, noise and signal gains according to the environmental noise conditions:
   a. Configure the input gain (VADINPGAIN bitfield).
   b. Configure the signal gain (VADSGAIN bitfield).
   c. Configure the noise gain (VADNGAIN bitfield).
4. Enable the high-pass filter if required (VADHPF bitfield).
5. Configure the VADNFILADJ bitfield according to environmental noise conditions (VADNFILADJ = 16 is recommended).
6. Put HWVAD in energy-based mode (default values):
   a. Keep the VADFRENDIS bitfield cleared.
   b. Keep the VADPREFEN bitfield cleared.
   c. Keep the VADSFILEN bitfield cleared.
   d. Keep the VADSMAXEN bitfield cleared.
   e. Keep the VADNFILAUTO bitfield asserted.
   f. Keep the VADNMINEN bitfield cleared.
   g. Keep the VADNDECEN bitfield cleared.
   h. Keep the VADNOREN bitfield cleared.
7. Initialize the Zero-Crossing Detector (Zero-Crossing Detector Initialization) if required.
8. Enable interrupts if required (VADIE and VADERIE bitfields).
9. Start the overall module asserting the PDMIEN bit.
10. The module is ready to receive data from the input ports of the enabled channels and to trigger interrupts when voice is detected.

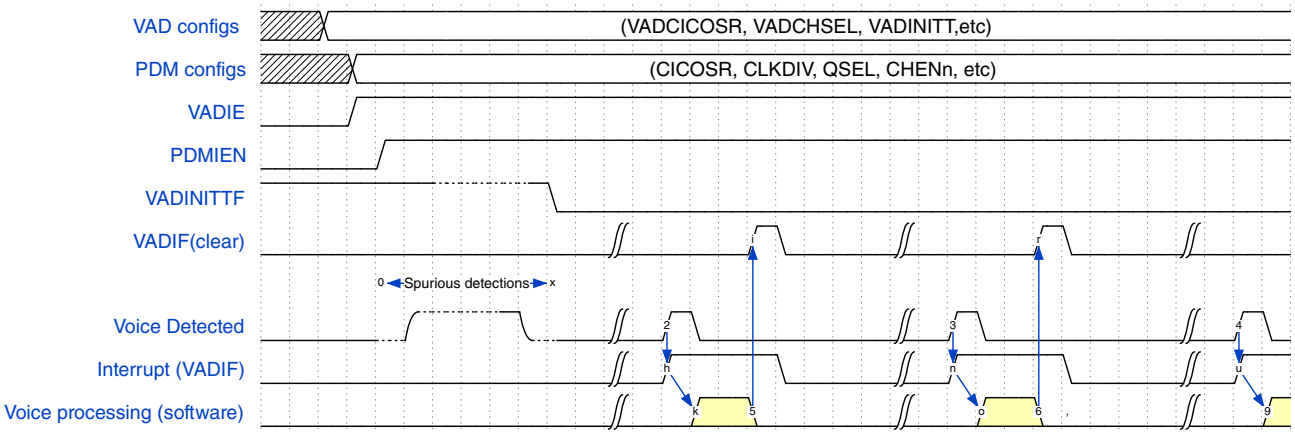

Figure 56-7. Energy-based initialization sequence

56.5.2.2 HWVAD in Envelope-based mode

The sequence of steps to initialize MICIL with the voice activity detector in Envelope-based mode is as follows:

1. Program the control bitfields as desired for your application (CLKDIV, CHnEN, FIFOWMK, DISEL, ERREN etc.). For more details see PDM_CLK_ROOT rate and CLKDIV calculation examples.
2. Configure general HWVAD parameters:
   a. CIC oversampling rate (VADCICOSR bitfield).
   b. Configure the voice source channel (VADCHSEL bitfield).
   c. Configure the internal initialization timer (VADINITT bitfield) if required. More details in Initialization Time.
   d. Assert VADEN bitfield.
3. Configure input, noise and signal gains according the environment noise conditions:
   a. Configure the input gain (VADINPGAIN bitfield).
   b. Configure the signal gain (VADSGAIN bitfield).
   c. Configure the noise gain (VADNGAIN bitfield).
4. Enable the high-pass filter if required (VADHPF bitfield).
5. Put HWVAD in envelope-based mode:
   a. Keep VADNFILADJ bitfield cleared.
   b. Assert the VADFRENDIS bitfield.
   c. Assert the VADPREFEN bitfield.
   d. Assert the VADSFILEN bitfield.
   e. Assert the VADSMAXEN bitfield.
   f. Clear the VADNFILAUTO bitfield.
   g. Assert the VADNMINEN bitfield.
   h. Assert the VADNDECEN bitfield.

i. Assert the VADNOREN bitfield.

6. Initialize the Zero-Crossing Detector (Zero-Crossing Detector Initialization) if required.
7. Start the overall module asserting the PDMIEN bit.
8. Wait for VADINITF to be cleared.
9. Write VADST10 bitfield three times.
10. Enable interrupts if required (VADIE and VADERIE bitfields).
11. The module is ready to receive data from the input ports of the enabled channels and to trigger interrupts when voice is detected.

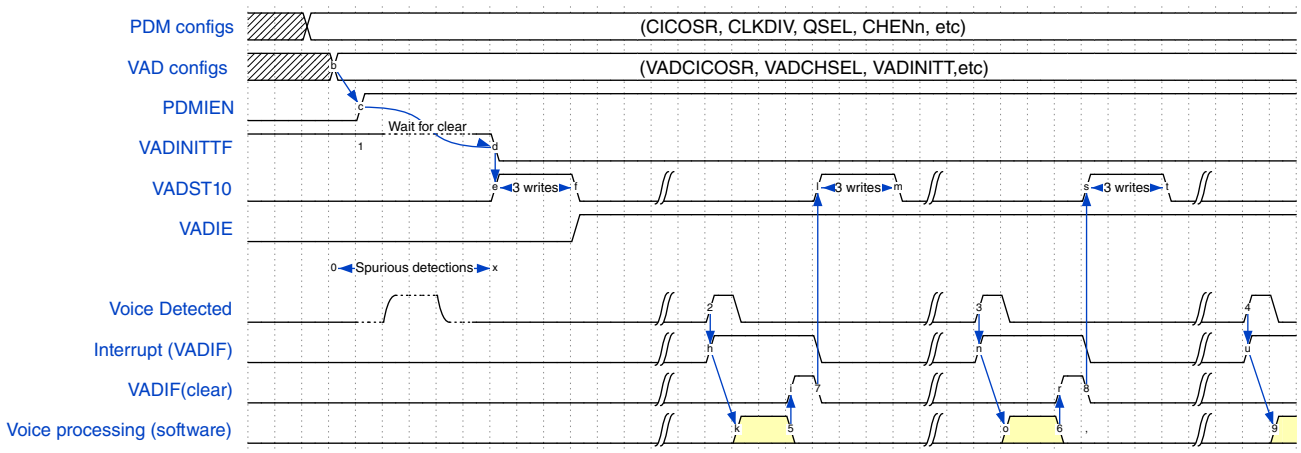

Figure 56-8. Envelope-based initialization sequence

56.5.2.3 Zero-Crossing Detector Initialization

The sequence of steps to initialize the Zero-Crossing Detector in Automatic mode is as follows:

1. Configure VADZCDADJ bitfield.
2. Configure an initial threshold in VADZCDTH according to the environmental noise conditions if required.
3. Configure VADZCDAND bitfield.
4. Keep VADZCDAUTO bitfield asserted.
5. Assert VADZCDEN.

The sequence of steps to initialize the Zero-Crossing Detector in Manual mode is as follows:

1. Configure a threshold in VADZCDTH according to the environmental noise conditions if required.
2. Configure VADZCDAND bitfield.
3. Clear VADZCDAUTO bitfield.

4. Assert VADZCDEN.

56.6 Application Information

56.6.1 Reconfiguration Procedure

The sequence of steps for the block reconfiguration is as follows:

1. Deassert PDMIEN bit.
2. Wait to BSY_FIL to be cleared.
3. Run a soft-reset cycle.
4. Run a initilialization procedure as described in Initialization Procedure without HWVAD or Initialization Procedure with HWVAD.

56.7 PDM register descriptions

This section provides the memory map and detailed description of all PDM registers. Any access to reserved areas can issue a slave bus error indication.

The registers allocated in this memory map are implemented for up to 4 pairs of microphones, that means 8 channels are available.

56.7.1 PDM memory map

PDM base address: 40C2_0000h

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)
0	PDM Control register 1 (CTRL_1)	32	RW	0000_0000
4	PDM Control register 2 (CTRL_2)	32	RW	0000_0000
8	PDM Status register (STAT)	32	W1C	0000_0000
10	PDM FIFO Control register (FIFO_CTRL)	32	RW	0000_0007
14	PDM FIFO Status register (FIFO_STAT)	32	W1C	0000_0000
24 - 40	PDM Output Result Register (DATACH0 - DATACH7)	32	RO	0000_0000
64	PDM DC Remover Control register (DC_CTRL)	32	RW	0000_0000
74	PDM Range Control register (RANGE_CTRL)	32	RW	0000_0000

Table continues on the next page...

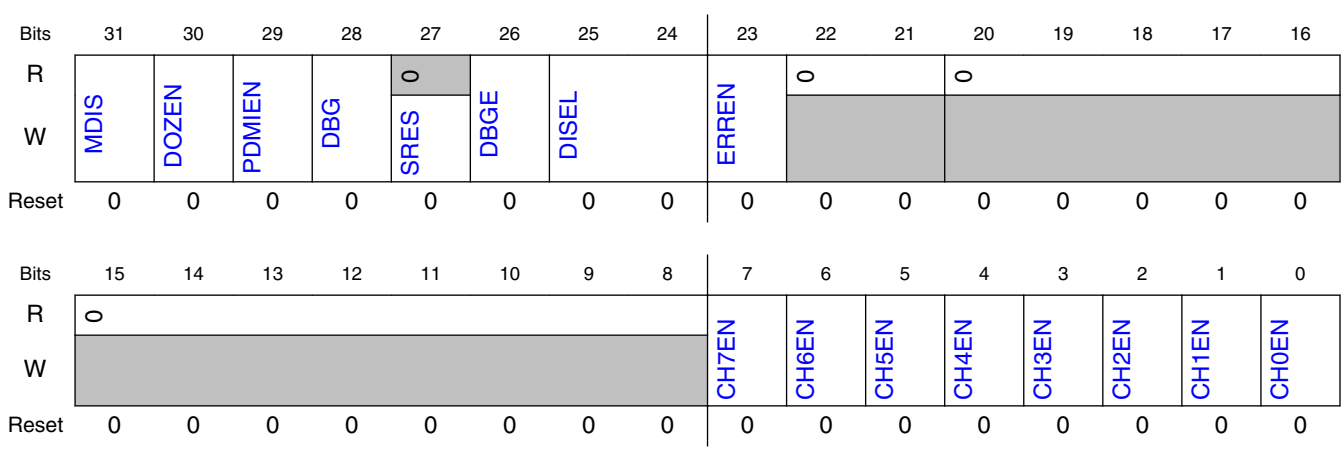
Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)
7C	PDM Range Status register (RANGE_STAT)	32	W1C	0000_0000
90	Voice Activity Detector 0 Control register (VAD0_CTRL_1)	32	RW	0000_0000
94	Voice Activity Detector 0 Control register (VAD0_CTRL_2)	32	RW	000A_0000
98	Voice Activity Detector 0 Status register (VAD0_STAT)	32	W1C	8000_0000
9C	Voice Activity Detector 0 Signal Configuration (VAD0_SCONFIG)	32	RW	0000_0000
A0	Voice Activity Detector 0 Noise Configuration (VAD0_NCONFIG)	32	RW	8000_0000
A4	Voice Activity Detector 0 Noise Data (VAD0_NDATA)	32	RO	0000_0000
A8	Voice Activity Detector 0 Zero-Crossing Detector (VAD0_ZCD)	32	RW	0000_0004

56.7.2 PDM Control register 1 (CTRL_1)

56.7.2.1 Offset

Register	Offset
CTRL_1	0h

56.7.2.2 Diagram



56.7.2.3 Fields

Field	Description
31 MDIS	Module Disable Puts the whole PDM in Disable/Low Leakage mode. The generated PDM_CLK is stopped and consequently no data is generated by the microphones. **NOTE:** When MDIS=1, writes to CTRL_1 and CTRL_2 only are allowed with the exception of writes to the DBG and SRES bits. A slave bus error indication will be issued when any register except CTRL_1 and CTRL_2 is written when MDIS=1. 0 - Normal Mode 1 - Disable/Low Leakage Mode
30 DOZEN	DOZE enable When SoC is in Doze mode and DOZEN is active the module enters to Disable/Low Leakage mode.
29 PDMIEN	PDM Enable Starts the module operation. Only the channels enabled by CHnEN or VAD enabled by VADEN will start to operate. When it is cleared, the whole module is stopped after to finish the pending filtering. **NOTE:** This field must be the latest to be enabled, for more information refer to Initialization . 0 - PDM stopped 1 - PDM operation started
28 DBG	Debug Mode Enables the Debug mode. The module can run on this mode depending on the DBGE bit value. **NOTE:** This bit is writable only when MDIS is cleared. 0 - Normal Mode 1 - Debug Mode
27 SRES	Software-reset bit Provides the CPU with the capability to initialize the PDM module through the slave-bus interface. This bit always reads as zero, and this bit is only effective when MDIS is cleared. This bit is self-cleared. **NOTE:** This bit must be asserted only when BSY_FIL=0 This bit can be used to clear all data in the filters. It resets the following blocks and/or registers: • All internal buffers in decimation filters and Voice Activity Detectors. • All FIFOs. • All CHnF flags and LOWFREQF flag on the STAT register, and the FIFO_STAT register. • Time Generator. 0 - No action 1 - Software reset
26 DBGE	Module Enable in Debug Enables operation in Debug mode. 0 - Disabled after completing the current frame 1 - Enabled
25-24 DISEL	DMA Interrupt Selection

Table continues on the next page...

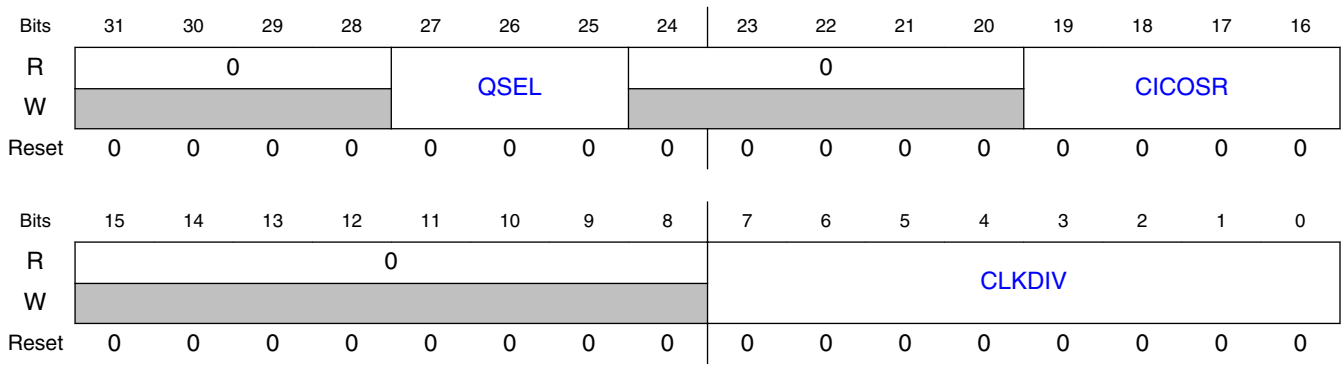
Field	Description
	Selects if the module performs DMA requests or filter interrupt requests when the number of FIFO elements surpasses the configured watermark. Note that requests are only generated from the channels whose CHnEN bits are asserted. **NOTE:** This bit mustn't change when BSY_FIL bit is asserted 00 - DMA and interrupt requests disabled 01 - DMA requests enabled 10 - Interrupt requests enabled 11 - Reserved
23 ERREN	Error Interruption Enable Enables error interrupts (exceptions). This error could be caused by: • an overflow or underflow in the FIFOs (FIFOOVF or FIFOUND bits), • an overflow or underflow in the decimations filters (the RANGEOVF or RANGEUNF bits), or • not enough PDM internal clock frequency (LOWFREQF bit). **NOTE:** This bit mustn't change when BSY_FIL bit is asserted 0 - Error Interrupts disabled 1 - Error Interrupts enabled
22-21 —	Reserved
20-16 —	Reserved
15-8 —	Reserved
7-0 CHnEN	Channel n Enable Enables the decimation filter channel n. Refer to Initialization for more information. **NOTE:** This bit mustn't change when BSY_FIL bit is asserted.

56.7.3 PDM Control register 2 (CTRL_2)

56.7.3.1 Offset

Register	Offset
CTRL_2	4h

56.7.3.2 Diagram



56.7.3.3 Fields

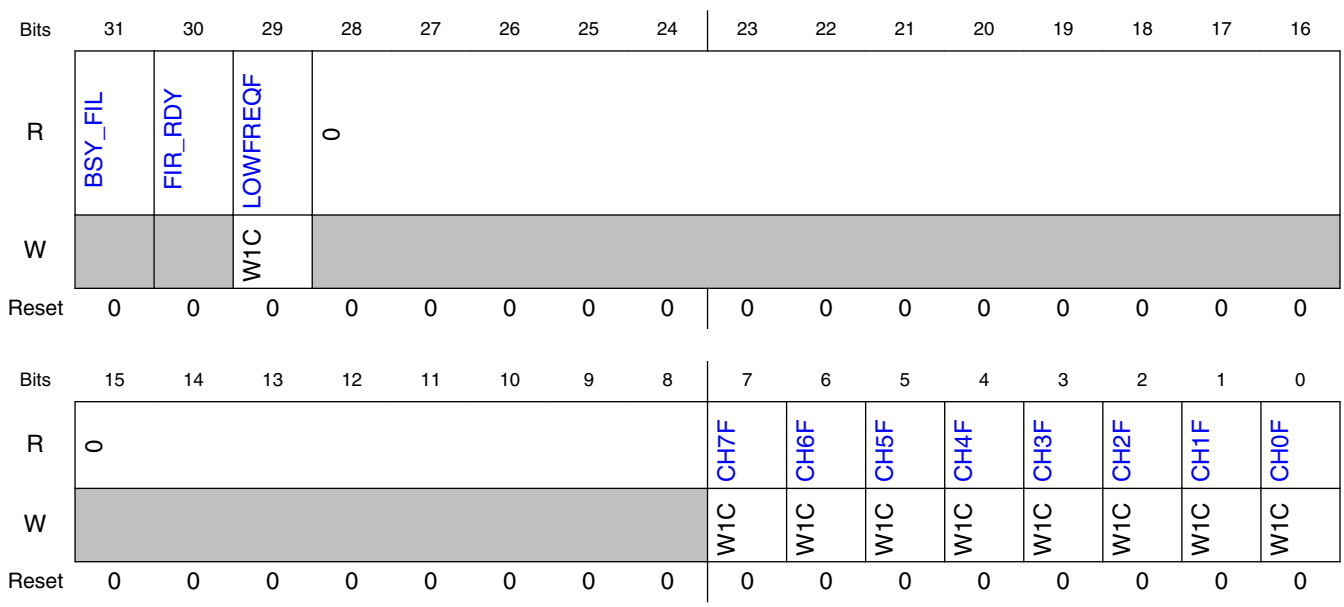
Field	Description
31-28 —	Reserved
27-25 QSEL	Quality Mode Defines the actual quality mode of the decimation filter. **NOTE:** This bitfield mustn't change when BSY_FIL bit is asserted. 000 - Medium quality mode 001 - High quality mode 100 - Very low quality 2 mode 101 - Very low quality 1 mode 110 - Very low quality 0 mode 111 - Low quality mode
24-20 —	Reserved
19-16 CICOSR	CIC Decimation Rate Helps to configure the Equation 8 on page 3425. **NOTE:** This bitfield mustn't change when BSY_FIL bit is asserted.
15-8 —	Reserved
7-0 CLKDIV	Clock Divider Configures the internal clock divider value. **NOTE:** This bitfield mustn't change when BSY_FIL bit is asserted. **NOTE:** CLKDIV=0 has the same effect than CLKDIV=1. CLKDIV=0 or 1 has the same effect than CLKDIV=2 during Medium Quality mode. CLKDIV=0 or 1 is not allowed during High Quality mode.

56.7.4 PDM Status register (STAT)

56.7.4.1 Offset

Register	Offset
STAT	8h

56.7.4.2 Diagram



56.7.4.3 Fields

Field	Description
31 BSY_FIL	Busy Flag Signalizes when at least a decimation filter channel or at least a HWVAD is running and the PDM_CLK is being generated. This bit could be used as a confirmation that all decimation filters are stopped in a transition to Debug (when DBGE=0) or Disable/Low Leakage mode. 0 - PDM is stopped

Table continues on the next page...

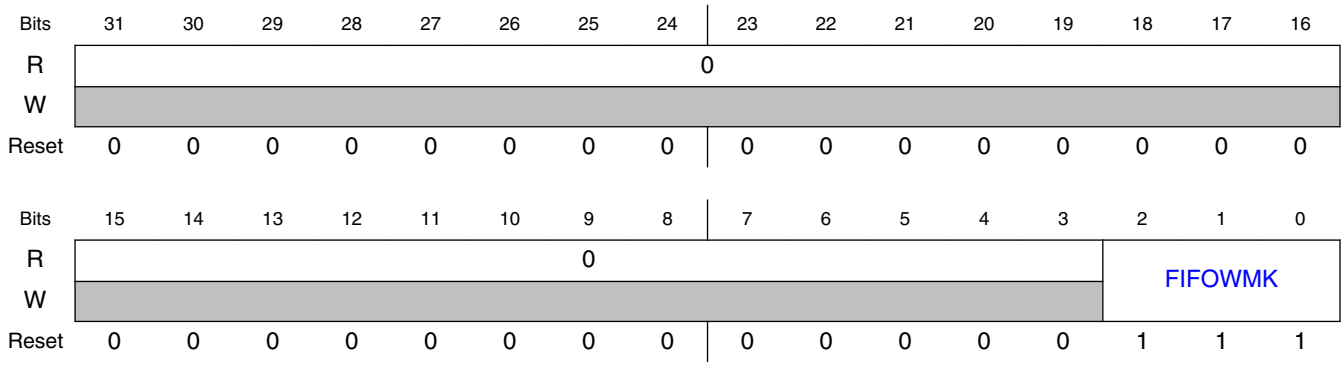
Field	Description
	1 - PDM is running
30 FIR_RDY	Filter Data Ready Indicates that all the decimation filter buffers have been updated, and all data provided from now on will be reliable. 0 - Filter data is not reliable 1 - Filter data is reliable
29 LOWFREQF	Low Frequency Flag Indicates that the CLKDIV bitfield value is not high enough to filter all enabled channels , and the half band filters didn't finish their operations before the next sample arrived. See Minimum Required CLKDIV . Write a logic 1 to this field to clear this flag. **NOTE:** The filtering results in this condition are unpredictable. 0 - CLKDIV value is OK 1 - CLKDIV value is too low
28-16 —	Reserved
15-8 —	Reserved
7-0 CHnF	Channel n Output Data Flag Indicates that the FIFO from this channel has surpassed its watermark value and the data is available at the DATACHn register. This flag contributes to generate an Interrupt or DMA request if enabled by DISEL in the CTRL_1. Write a logic 1 to this field to clear this flag. If DMA request is set (DISEL = 01) the CHnF flag will be set according to watermark level and will be cleared , in the other cases (IRQ included) the CHnF flag will be set according to the watermark level and will be cleared with the w1c functionality of the bit. **NOTE:** If DMA is enabled, this flag is self-cleared when the DMA transaction is finished . 0 - Channel's FIFO did not reach the number of elements configured in watermark bit-field 1 - Channel's FIFO reached the number of elements configured in watermark bit-field

56.7.5 PDM FIFO Control register (FIFO_CTRL)

56.7.5.1 Offset

Register	Offset
FIFO_CTRL	10h

56.7.5.2 Diagram



56.7.5.3 Fields

Field	Description
31-3 —	Reserved
2-0 FIFOWMK	FIFO Watermark Control Controls the watermark of the FIFO used to set CHnF. When the number of results in the FIFO is greater than FIFOWMK value then the CHnF flag is set. A DMA request or interrupt can be also generated according to DISEL bit-field. **NOTE:** This mustn't change when BSY_FIL is asserted. Before changing the watermark value service all filtered data and clear channel flags.

56.7.6 PDM FIFO Status register (FIFO_STAT)

56.7.6.1 Offset

Register	Offset
FIFO_STAT	14h

56.7.6.2 Diagram

56.7.6.3 Fields

Field	Description
31-16 —	Reserved
15-8 FIFOUNDn	FIFO Underflow Exception flag for Channel n Indicates an exceptional underflow condition in the FIFO. If the FIFO is empty and a read operation is requested then this flag is set. Write a logic 1 to this field to clear this flag. 0 - No exception by FIFO Underflow 1 - Exception by FIFO underflow
7-0 FIFOOVFn	FIFO Overflow Exception flag for Channel n Indicates an exceptional overflow condition in the FIFO. If the FIFO is full and an additional result is received to be written then this flag is set. Write a logic 1 to this field to clear this flag. 0 - No exception by FIFO overflow 1 - Exception by FIFO overflow

56.7.7 PDM Output Result Register (DATACH0 - DATACH7)

56.7.7.1 Offset

For a = 0 to 7:

Register	Offset
DATACHa	24h + (a × 4h)

56.7.10.3 Fields

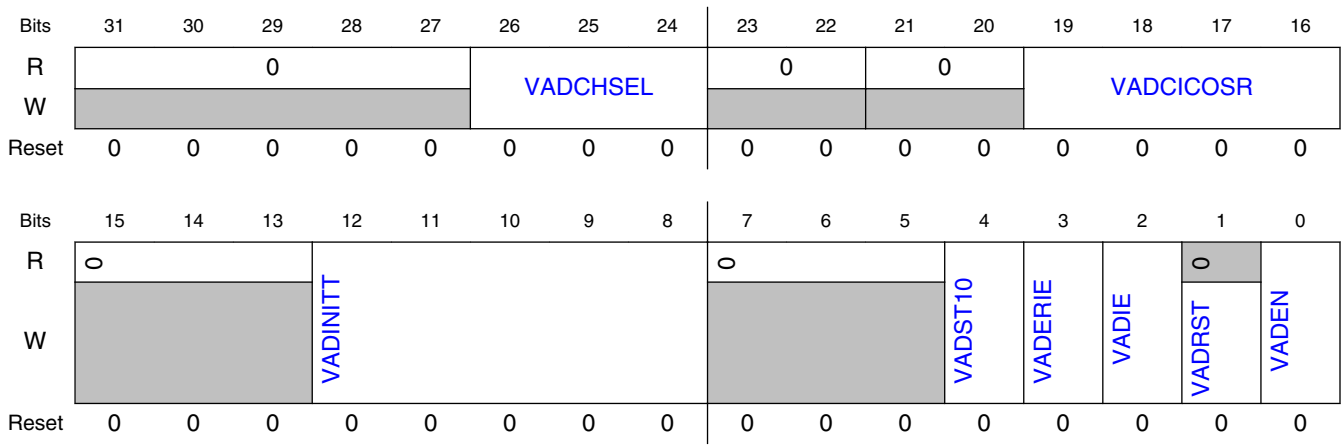
Field	Description
31-24 —	Reserved
23-16 RANGEUNFn	Channel n Range Underflow Error Flag Indicates an exceptional underflow condition in PDM range. **NOTE:** If this error flag is asserted, channel n data is not reliable. Require to adjust the RANGEADJn value until this flag is not asserted anymore. 0 - No exception by range underflow 1 - Exception by range underflow
15-8 —	Reserved
7-0 RANGEOVFn	Channel n Range Overflow Error Flag Indicates an exceptional overflow condition in PDM range. **NOTE:** If this error flag is asserted, channel n data is not reliable. Require to adjust the RANGEADJn value until this flag is not asserted anymore. 0 - No exception by range overflow 1 - Exception by range overflow

56.7.11 Voice Activity Detector 0 Control register (VAD0_CTRL_1)

56.7.11.1 Offset

Register	Offset
VAD0_CTRL_1	90h

56.7.11.2 Diagram



56.7.11.3 Fields

Field	Description
31-27 —	Reserved
26-24 VADCHSEL	Voice Activity Detector Channel Selector Selects the number of channel which the hardware voice activity detector will work. **NOTE:** This bitfield mustn't change when BSY_FIL is asserted.
23-22 —	Reserved
21-20 —	Reserved
19-16 VADCICOSR	Voice Activity Detector CIC Oversampling Rate Defines the oversampling rate of the CIC filter. The oversampling rate is (16-CICOSR). **NOTE:** This bitfield mustn't change when BSY_FIL is asserted.
15-13 —	Reserved
12-8 VADINITT	Voice Activity Detector Initialization Time Selects the number of frames to be used to initialize the voice detection. During this period the output of the voice activity detector is forced to inactive. For more information, refer to Initialization Time . **NOTE:** The initialization time will be the time taken by [VADINITT+1] frames. **NOTE:** This bitfield mustn't change when BSY_FIL is asserted.
7-5 —	Reserved
4	Voice Activity Detector Internal Filters Initialization

Table continues on the next page...

Field	Description
VADST10	Initializes the signal and noise filter with pre-filter value. **NOTE:** If the use of this bit is required, it should be stay pulsed by more than 2 cycles of system clock . **NOTE:** There is not voice activity detection when VADST10 is asserted. 0 - Normal operation. 1 - Filters are initialized.
3 VADERIE	Voice Activity Detector Error Interruption Enable Enables Error Interrupts in the PDM. This error could be caused by an overflow in the input of the HWVAD and it is signalized by the VADINSATF flag. 0 - HWVAD Error Interrupts disabled 1 - HWVAD Error Interrupts enabled
2 VADIE	Voice Activity Detector Interruption Enable Enables interrupts in the PDM when voice activity event has been detected by the Hardware Voice Activity Detector (HWVAD). See the VADIF for more information. 0 - HWVAD Interrupts disabled 1 - HWVAD Interrupts enabled
1 VADRST	Voice Activity Detector Reset Provides the CPU with the capability to initialize the VAD through the slave-bus interface. This bit always reads as zero. This bit is self-cleared. See VAD Soft-reset.
0 VADEN	Voice Activity Detector Enable Enables the use of the Hardware Voice Activity Detector. **NOTE:** This bitfield mustn't change when BSY_FIL is asserted. 0 - The HWVAD is disabled 1 - The HWVAD is enabled

56.7.12 Voice Activity Detector 0 Control register (VAD0_CTRL_2)

NOTE

This register mustn't change when BSY_FIL is asserted.

56.7.17.3 Fields

Field	Description
31-26 —	Reserved
25-16 VADZCDTH	Zero-Crossing Detector Threshold Configures the initial value taken to estimate the ZCD threshold when it is estimated automatically (VASDZCDAUTO = 1), otherwise (VADZCDAUTO = 0) this bit-field is the static value of the ZCD threshold.
15-12 —	Reserved
11-8 VADZCDADJ	Zero-Crossing Detector Adjustment Selects the adjustment value of the threshold estimator. For more information, refer to Zero-Crossing Detector .
7-5 —	Reserved
4 VADZCDAND	Zero-Crossing Detector AND Behavior Selects whether the Zero-Crossing detector results will be AND'ed or OR'ed with the energy-based detection to form the voice activity detection event. 0 - The ZCD result is OR'ed with the energy-based detection. 1 - The ZCD result is AND'ed with the energy-based detection.
3 —	Reserved
2 VADZCDAUTO	Zero-Crossing Detector Automatic Threshold Enables the automatic estimation of the ZCD threshold. 0 - The ZCD threshold is not estimated automatically 1 - The ZCD threshold is estimated automatically
1 —	Reserved
0 VADZCDEN	Zero-Crossing Detector Enable Enables the Zero-Crossing Detector (ZCD) in the Hardware Voice Activity Detector (HWVAD). 0 - The ZCD is disabled 1 - The ZCD is enabled

57.2 Overview

Medium quality sound (MQS) is used to generate medium quality audio via a standard GPIO in the pinmux, allowing the user to connect stereo speakers or headphones to a power amplifier without an additional DAC chip.

57.2.1 Block Diagram

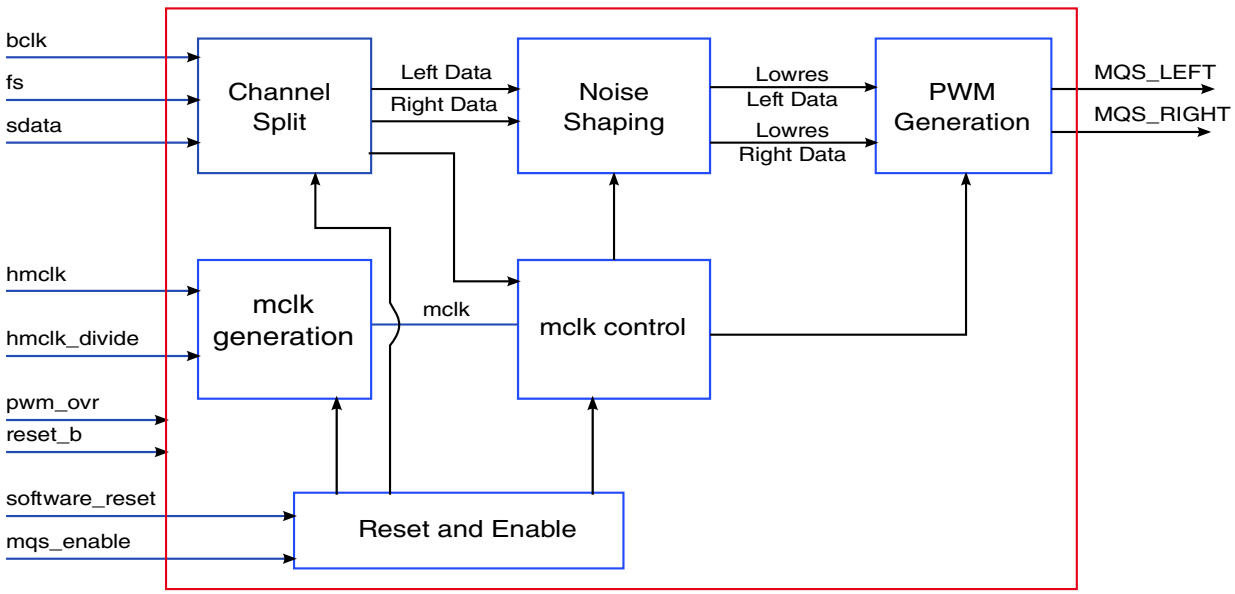

Figure 57-1. Block Diagram

57.2.2 Features

MQS has the following sub-modules:

- Channel Split: Splits the I2S signals into separate left channel and right channel audio data.
- Noise Shaping: Uses the sigma-delta algorithm to generate low-resolution, very high sampling audio, while the audio sampling rate is increased.
- PWM Generation: Generates the bit stream to the GPIO, which is then used to drive the amplifier and then to drive the external speakers or headphones.
- Mclk Generation: Used to generate the master clock (mclk). The frequency of mclk is determined by the final bit duration of PWM generation module.
- Mclk Control:Used as a metronome to co-ordinate the different functional blocks working synchronously.
- Reset and Enable: Used to generate the reset and enable logic to different clock domains.

57.3 Functional Description

MQS accepts the following inputs:

- 2-channel, LSB-valid 16-bit, MSB shift-out first serial data (sdata)

- Frame sync asserting with the first bit of the frame (fs)
- Bit clock used to shift data out on the positive clock edge (bclk)

The signals from the SAI3 are in left_justified format. MQS provides the SNR target as no more than 20dB for the signals below 10 kHz. The signals above 10 kHz will have worse THD+N values.

MQS provides only simple audio reproduction. No internal pop, click or distortion artifact reduction methods are provided.

57.4 External Signals

The following table describes the external signals of MQS:

Table 57-2. MQS External Signals

Signal	Description	Direction
MQS_LEFT	Left signal output	O
MQS_RIGHT	Right signal output	O

57.4.1 Interface Signals

MQS module has the following interface signals.

Signal Name	In/Out	BitWidth	Description	Comments
reset_b	In	1	asynchronous reset	
software_reset	In	1	Software reset	From IOMUXC_GPR3
mqs_enable	In	1	module enable	From IOMUXC_GPR3
pwm_ovr	In	1	PWM oversampling ratio 1=64, 0=32	From IOMUXC_GPR3
hmclk	In	1	Maximum bit clock, used to generate the mclk, divider ratio is controlled by mqs_hmclk_divide	Max 66.5MHzTypical 24.576MHz
hmclk_divide	In	8	Divider ration control for mclk from hmclk	From IOMUXC_GPR3
bclk	In	1	bit clock from I2S signal	
fs	In	1	frame sync clock from I2S signal	
sdata	In	1	serial audio data from I2S signal	

57.5 Application Information

MQS has no internal programmable registers. But it does have some programmability from IOMUXC_GPR3.

Register Bitfields	Description
IOMUXC_GPR3[MQS_OVERSAMPLE]	Used to control the PWM oversampling rate compared with mclk. 1—64, 0—32.
IOMUXC_GPR3[MQS_EN]	MQS enable. 1—Enable MQS, 0—Disable MQS
IOMUXC_GPR3[MQS_SW_RST]	MQS software reset. 1—Enable software reset for MQS 0—Exit software reset for MQS
IOMUXC_GPR3[MQS_CLK_DIV]]	Divider ration control for mclk from hmclk. 0—mclk frequency = hmclk frequency; 1—mclk frequency = ½*hmclk frequency; 2—mclk frequency = 1/3*hmclk frequency; …; n—mclk frequency = 1/(n+1)*hmclk frequency

57.5.1 Usage Model

The user needs to program the SAI3 to output 2-channel LSB-16 bit active left-justified signal, and then program the related IOMUXC_GPR3 bits.

Due to the different devices connected to MQS, and different high frequency behaviors of the connected analog circuits, the user needs choose the appropriate MQS_CLK_DIV and MQS_OVERSAMPLE values for the best audible effects.

NOTE

Number of TX and RX data lines for SAI1 and SAI2/SAI3 are 4, and 1 respectively.

NOTE

In this device, it does NOT support synchronous mode between different SAI peripherals.

MCLK sources are determined outside of the SAI block, as defined in the below table. For additional IOMUXC GPR information, please see the IOMUX chapter. For more details about the features and clocking of the different SAI instances, see theAudio Subsystem Overview chapter.

Table 58-2. SAI MCLK Information

58.2 Overview

The Synchronous Audio Interface (SAI) provides an interface that supports full-duplex serial interfaces with frame synchronization such as I^2S, AC97, TDM, and codec/DSP interfaces.

58.2.1 Block diagram

The following block diagram also shows the module clocks.

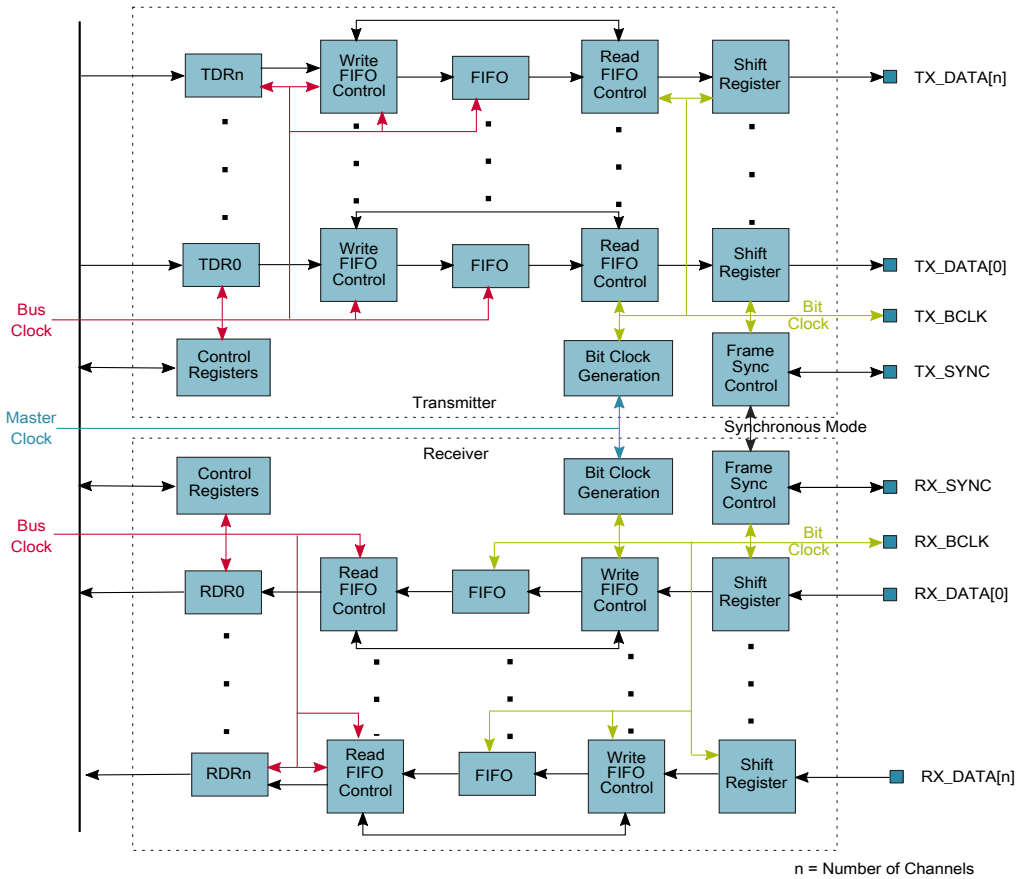

Figure 58-1. SAI block diagram

58.2.2 Features

Some of the features are not supported across all SAI instances; see the chip-specific SAI information in the first section of this chapter.

- Transmitter with independent bit clock and frame sync supporting 4 data lines
- Receiver with independent bit clock and frame sync supporting 4 data lines
- Each data line can support a maximum frame size of 32 words
- 8- to 32-bit word size
- Word size configured separately for the first word and remaining words in a frame
- Asynchronous 32 x 32-bit FIFO for each transmit and receive data line supporting:
  - Graceful restart after FIFO error
  - Automatic restart after FIFO error without software intervention
  - 8-bit and 16-bit data packing into each 32-bit FIFO word
  - Multiple data line FIFOs combining into single data line FIFO

58.3 Functional description

This section provides a complete functional description of the block.

58.3.1 Modes of operation

Module power modes include Run mode, Stop modes, and Debug mode.

58.3.1.1 Run mode

In Run mode, the SAI transmitter and receiver operate normally.

58.3.1.2 Stop modes

In Stop mode, the SAI transmitter and/or receiver can continue operating provided the appropriate Stop Enable bit = 1 (TCSR[STOPE] and/or RCSR[STOPE], respectively), and provided the transmitter and/or receiver is/are using an externally generated bit clock or an Audio Master Clock that remains operating in Stop mode. The SAI transmitter and/or receiver can generate an asynchronous interrupt to wake the CPU from Stop mode.

In Stop mode, if the Transmitter Stop Enable (TCSR[STOPE]) bit is clear, the transmitter is disabled after completing the current transmit frame, and, if the Receiver Stop Enable (RCSR[STOPE]) bit is clear, the receiver is disabled after completing the current receive frame. Entry into Stop mode is prevented (not acknowledged) while waiting for the transmitter and receiver to be disabled at the end of the current frame.

58.3.1.3 Debug mode

In Debug mode, the SAI transmitter and/or receiver continues operating if the Debug Enable bit is set. When TCSR[DBGE] or RCSR[DBGE] bit is clear and Debug mode is entered, the SAI is disabled after completing the current transmit or receive frame. Debug mode does not affect the transmitter and receiver bit clocks.

58.3.2 Synchronous modes

The SAI transmitter and receiver can operate synchronously to each other.

58.3.2.1 Synchronous mode

The SAI transmitter and receiver can be configured to operate with synchronous bit clock and frame sync.

If both the transmitter and receiver use the transmitter bit clock and frame sync:

- Configure the transmitter for asynchronous operation and the receiver for synchronous operation.
- Enable the receiver in synchronous mode only after both the transmitter and receiver are enabled.
- Enable the transmitter last and disable the tranmitter first.

If both the transmitter and receiver use the receiver bit clock and frame sync:

- Configure the receiver for asynchronous operation and the transmitter for synchronous operation.
- Enable the transmitter in synchronous mode only after both the receiver and transmitter are enabled.
- Enable the receiver last and disable the receiver first.

When operating in synchronous mode, the transmitter and receiver share only the bit clock, frame sync, and transmitter/receiver enable. Otherwise, the transmitter and receiver operate independently, although the configuration registers must be configured consistently across both the transmitter and receiver.

58.3.3 Frame sync configuration

When enabled, the SAI continuously transmits and/or receives frames of data. Each frame consists of a fixed number of words and each word consists of a fixed number of bits. Within each frame, any given word can be masked causing the receiver to ignore that word and the transmitter to tri-state for the duration of that word.

The frame sync signal indicates the start of each frame. A valid frame sync requires a rising edge (if active high) or falling edge (if active low) to be detected and the transmitter or receiver cannot be busy with a previous frame. A valid frame sync is also ignored (slave mode) or not generated (master mode) for the first four bit clock cycles after enabling the transmitter or receiver.

The transmitter and receiver frame sync can be configured independently with any of the following options:

- Generate externally or internally
- Require active high or active low
- Assert with the first bit in frame or assert one bit early
- Assert for a duration of between 1 bit clock and the first word length
- Set frame length from 1 to 32 words per frame
- Support word length of 8 to 32 bits per word
    - First word length and remaining word lengths can be configured separately
- Transmit/Receive words MSB first or LSB first

These configuration options cannot be changed after enabling the SAI transmitter or receiver.

58.3.4 Data FIFO

Each transmit and receive channel includes a 32 x 32-bit size FIFO. To access the FIFO data use the SAI Transmit/Receive Data Registers.

58.3.4.1 Data alignment

Data in the FIFO can be aligned anywhere within the 32-bit wide register through the use of the First Bit Shifted configuration field, which selects the bit index (between 31 and 0) of the first bit shifted.

Examples of supported data alignment and the required First Bit Shifted configuration are illustrated in Figure 58-2 for LSB First configurations and Figure 58-3 for MSB First configurations.

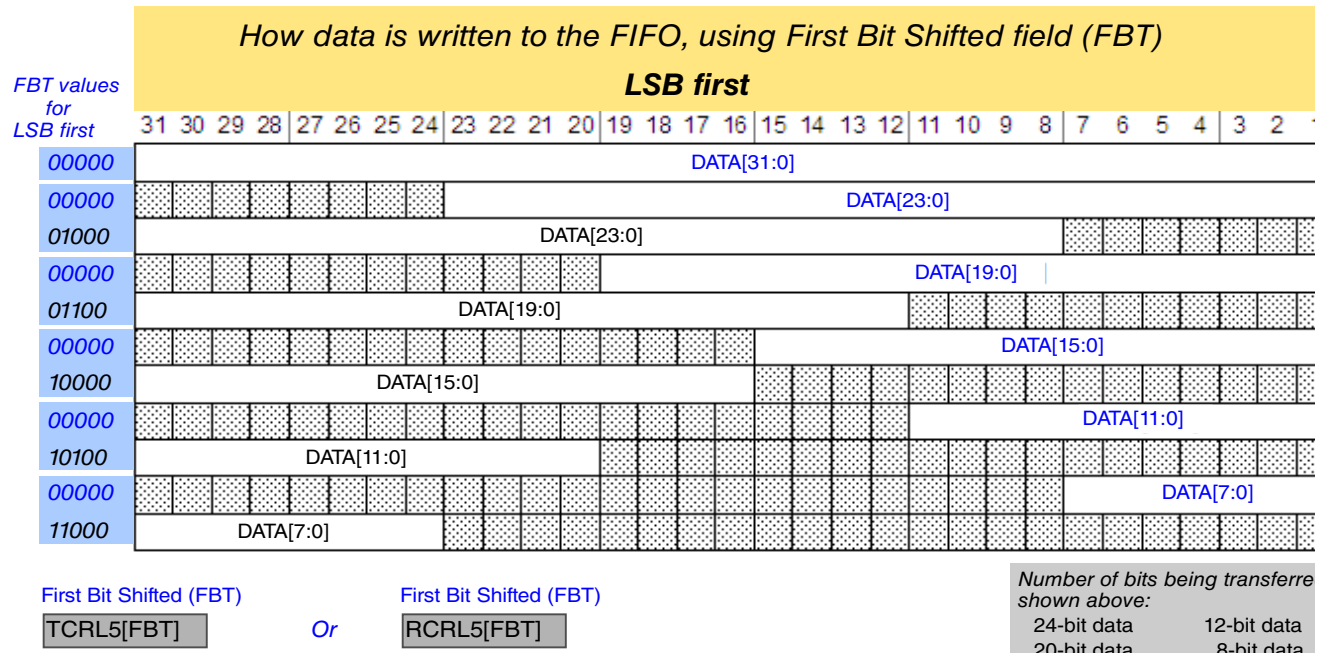

Figure 58-2. SAI first bit shifted, LSB first

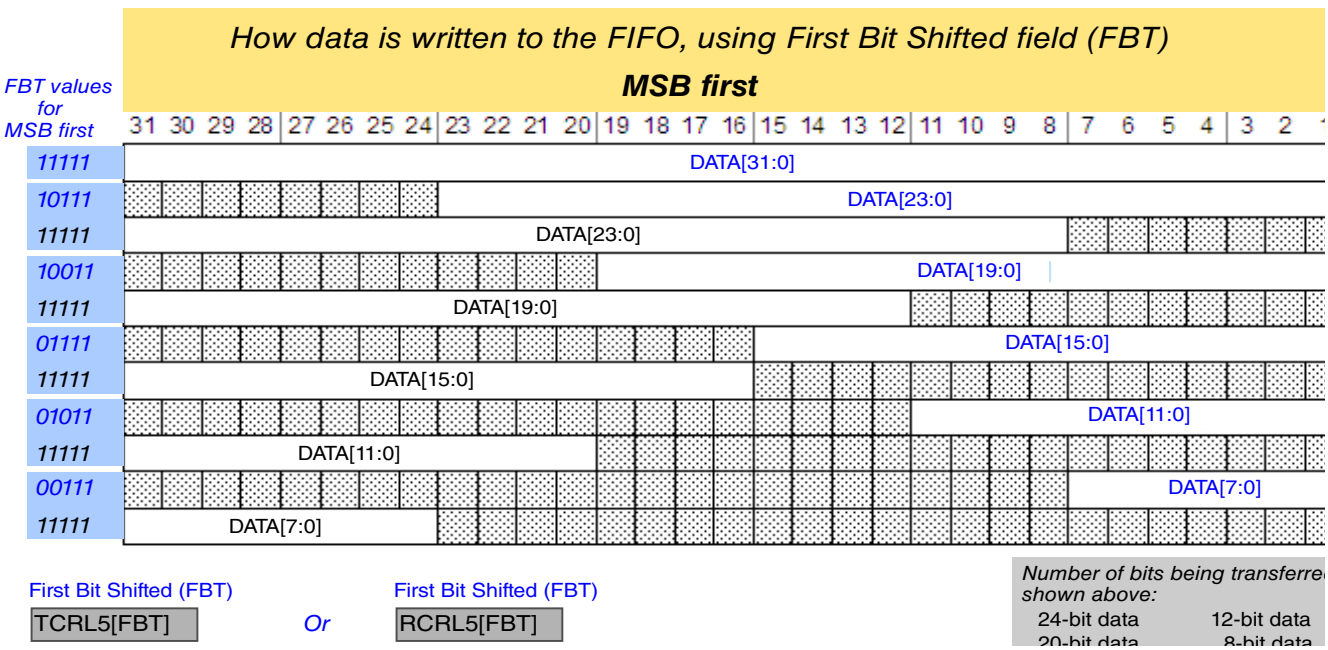

Figure 58-3. SAI first bit shifted, MSB first

58.3.4.2 FIFO pointers

When writing to a Transmit Data Register (TDR*n*), the Write FIFO Pointer (WFP) of the corresponding Transmit FIFO Register (TFR*n*) increments after each valid write. The SAI supports 8-bit, 16-bit, and 32-bit writes to the Transmit Data Register and the FIFO

pointer increments after each individual write. Note that 8-bit writes should only be used when transmitting up to 8-bit data; 16-bit writes should only be used when transmitting up to 16-bit data.

- If the Transmit FIFO is full, writes to a Transmit Data Register are ignored.
- If the Transmit FIFO is empty, to avoid a FIFO underrun, write to the Transmit Data Register at least 3 bit clocks before the start of the next unmasked word. Before enabling the transmitter, initialize the Transmit FIFO with data (because after enabling the transmitter, the transmitter starts a new frame, and if no data is in the FIFO, then the transmitter immediately give an error).

When reading a Receive Data Register (RDR*n*), the Read FIFO Pointer (RFP) of the corresponding Receive FIFO Register (RFR*n*) increments after each valid read. The SAI supports 8-bit, 16-bit and 32-bit reads from the RDR and the FIFO pointer will increment after each individual read. Note that 8-bit reads should only be used when receiving up to 8-bit data; 16-bit reads should only be used when receiving up to 16-bit data.

- If the Receive FIFO is empty, reads from a Receive Data Register are ignored.
- If the Receive FIFO is full, to avoid a FIFO overrun, read the Receive Data Register at least 3 bit clocks before the end of an unmasked word.

58.3.4.3 FIFO packing

FIFO packing supports storing multiple 8-bit or 16-bit data words in one 32-bit FIFO word for the transmitter and/or receiver. While this can be emulated by adjusting the number of bits per word and number of words per frame (for example, one 32-bit word per frame versus two 16-bit words per frame), FIFO packing does not require even multiples of words per frame and fully supports word masking. When FIFO packing is enabled, the FIFO pointers only increment when the full 32-bit FIFO word has been written (transmit) or read (receive) by software, supporting scenarios where different words within each frame are loaded/stored in different areas of memory.

Using 16-bit FIFO packing for transmit, the transmit shift register loads at the start of each frame and after every second unmasked transmit word. The first word transmitted is taken from 16-bit word at byte offset 0x0 (the first bit is selected by TCR5[FBT] and must be configured within this 16-bit word) and the second word transmitted is taken from the 16-bit word at byte offset 0x2 (the first bit is selected by TCR5[FBT][3:0]). The transmitter transmits logic zero until the start of the next word once the 16-bit word has been transmitted.

Using 16-bit FIFO packing for receive, the receive shift register is stored after every second unmasked received word, and at the end of each frame if there is an odd number of unmasked received words in each frame. The first word received is stored in the 16-bit word at byte offset 0x0 (rhe first bit is selected by RCR5[FBT] and must be configured

within this 16-bit word) and the second word received is stored in the 16-bit word at byte offset 0x2 (the first bit is selected by RCR5[FBT][3:0]). The receiver ignores received data until the start of the next word once the 16-bit word has been received.

The 8-bit FIFO packing is similar to 16-bit packing except four words are loaded or stored into each 32-bit FIFO word. The first word is loaded/stored in byte offset 0x0, second word in byte offset 0x1, third word in byte offset 0x2 and fourth word in byte offset 0x3. The TCR5[FBT] and/or RCR5[FBT] must be configured within byte offset 0x0.

58.3.4.4 FIFO Combine

FIFO Combining mode allows the separate FIFOs for multiple data channels to be used as a single FIFO for either software accesses or a single data channel or both. Note that the enabled data channels must be contiguous and data channel 0 must be enabled when using FIFO Combine mode.

Combining FIFOs for software access (writing transmit FIFO registers, reading receive FIFO registers) allows a DMA controller or software to read or write multiple FIFOs without incrementing the address that is accessed. Once enabled, the first software access to a FIFO register accesses the first enabled channel FIFO, while the second access to a FIFO register accesses the second enabled channel FIFO. This continues until software accesses the last enabled channel FIFO and the pointer resets back to the first enabled channel FIFO. To reset the pointer manually, software can reset the FIFOs or disable FIFO combining on software accesses.

Combining FIFOs for transmit data channels allows one data channel to use the FIFOs of all enabled channel FIFOs, with identical data output on each enabled data channel. The transmit shift registers for all enabled data channels load at the start of each frame and every N unmasked words (where N is the number of enabled data channels). The first word transmitted loads from the first enabled channel FIFO, while the second word transmitted loads from the second enabled channel FIFO, and so on until the end of the frame. Because the first word in each frame always loads from the first enabled data channel, it is recommended that the number of unmasked words in each frame is evenly divisible by the number of enabled data channels.

Combining FIFOs for receive data channels allows one data channel to use the FIFOs of all enabled channel FIFOs, with received data from channel 0 stored into each enabled data channel. The receive shift register for all enabled data channels are stored after every N unmasked words (where N is the number of enabled data channels). The first word received stores to the first enabled channel FIFO, while the second word received stores to the second enabled channel FIFO, and so on until the end of the frame. Because the

first word in each frame always stores to the first enabled data channel, it is recommended that the number of unmasked words in each frame is evenly divisible by the number of enabled data channels.

Note that combining FIFOs for data channels loads or stores each channel FIFO at the same time. This means that FIFO error conditions are only checked every N words (where N is the number of enabled data channels) and that the FIFO warning and request flags assert if any of the enabled data channel meets the warning flag or request flag conditions.

58.3.5 Word mask register

The SAI transmitter and receiver each contain a word mask register (TMR and RMR) that can be used to mask any word in the frame. Because the word mask register is double buffered, software can update it before the end of each frame to mask a particular word in the next frame.

The TMR causes the Transmit Data pin to be tri-stated for the length of each selected word and the transmit FIFO is not read for masked words.

The RMR causes the received data for each selected word to be discarded and not written to the receive FIFO.

58.3.6 Interrupts and DMA requests

The SAI transmitter and receiver generate separate interrupts and separate DMA requests, but support the same status flags. Asynchronous versions of the transmitter and receiver interrupts generate to wake up the CPU from Stop mode. Asynchronous interrupts are only generated when the system clock is gated provided the corresponding BCLK continues.

58.3.6.1 FIFO request flag

The FIFO request flag sets based on the number of entries in the FIFO and the FIFO watermark configuration.

The transmit FIFO request flag sets when the number of entries in any of the enabled transmit FIFOs is less than or equal to the transmit FIFO watermark configuration and clears when the number of entries in each enabled transmit FIFO is greater than the transmit FIFO watermark configuration.

The receive FIFO request flag sets when the number of entries in any of the enabled receive FIFOs is greater than the receive FIFO watermark configuration and clears when the number of entries in each enabled receive FIFO is less than or equal to the receive FIFO watermark configuration.

The FIFO request flag can generate an interrupt or a DMA request.

58.3.6.2 FIFO warning flag

The FIFO warning flag sets based on the number of entries in the FIFO.

The transmit warning flag sets when the number of entries in any of the enabled transmit FIFOs is empty and clears when the number of entries in each enabled transmit FIFO is not empty.

The receive warning flag sets when the number of entries in any of the enabled receive FIFOs is full and clears when the number of entries in each enabled receive FIFO is not full.

The FIFO warning flag can generate an Interrupt or a DMA request.

58.3.6.3 FIFO error flag

The Transmit FIFO Error Flag (TCSR[FEF] = 1]) sets when any of the enabled transmit FIFOs underrun. After the error flag sets, all enabled transmit channels transmit zero data before TCSR[FEF] clears.

When FIFO Continue on Error sets (TCR4[FCONT] = 1), the FIFO continues transmitting data following an underrun without software intervention. To ensure that data transmits in the correct order, the transmitter continues from the same word number in the frame that caused the FIFO to underrun, but only after new data writes to the transmit FIFO. Software should still clear the TCSR[FEF] flag, but without reinitializing the transmit FIFOs.

The Receive FIFO Error Flag sets (RCSR[FEF] = 1) when any of the enabled receive FIFOs overflow. After the flag is set, all enabled receive channels discard received data until RCSR[FEF] clears and the next next receive frame starts. Empty all enabled receive FIFOs before RCSR[FEF] clears.

When Receive FIFO Continue on Error sets (RCR4[FCONT] = 1) the FIFO continues receiving data following an overflow without software intervention. To ensure that data is received in the correct order, the receiver continues from the same word number in the

frame that caused the FIFO to overflow, but only after data has been read from the receive FIFO. Software should still clear the RCSR[FEF] flag, but without emptying the receive FIFOs.

The FIFO Error Flag can generate only an interrupt.

58.3.6.4 Sync error flag

The Sync Error Flag, TCSR[SEF] or RCSR[SEF], sets when configured for an externally generated frame sync and the external frame sync asserts when the transmitter or receiver is busy with the previous frame. The external frame sync assertion is ignored and the sync error flag sets. When the Sync Error Flag sets, the transmitter or receiver continues checking for frame sync assertion when idle or at the end of each frame.

The Sync Error Flag can only generate an interrupt.

58.3.6.5 Word start flag

The Word Start Flag sets (TCSR[WSF] = 1) at the start of the second bit clock for the selected word, as configured by the Word Flag Configuration field (TCR3[WDFL]).

The Word Start Flag can generate an interrupt only.

58.3.7 SAI clocking

The SAI clocks include:

- Audio master clock
- Bit clock
- Bus clock

58.3.7.1 Audio master clock

The audio master clock generates the bit clock when the receiver or transmitter is configured for an internally generated bit clock. The transmitter and receiver can independently select between the bus clock and up to three audio master clocks to generate the bit clock.

The audio master clock generation and selection is chip-specific. Refer to chip-specific clocking information about how the audio master clocks are generated.

58.3.7.2 Bit clock

The SAI transmitter and receiver support asynchronous free-running bit clocks that can be generated internally from an audio master clock or supplied externally. There is also the option for synchronous bit clock and frame sync operation between the receiver and transmitter or between multiple SAI peripherals.

- If both transmitter and receiver are configured for asynchronous operation, then the transmitter and receiver will each use *their own* bit clock and frame sync.
- If the *transmitter* is configured for asynchronous mode and the receiver is configured for synchronous mode, then both transmitter and receiver will use the *transmitter* bit clock and frame sync.
- If the *receiver* is configured for asynchronous mode and the transmitter is configured for synchronous mode, then both transmitter and receiver will use the *receiver* bit clock and frame sync.

Note that the software configures synchronous or asynchronous mode, and that choice selects the bit clock/frame sync used.

Externally generated bit clocks must be:

- Enabled before the SAI transmitter or receiver is enabled
- Disabled after the SAI transmitter or receiver is disabled and completes its current frames

If the SAI transmitter or receiver uses an externally generated bit clock in asynchronous mode and that bit clock is generated by an SAI that is disabled in stop mode, then the transmitter or receiver should be disabled by software before entering stop mode. This issue does not apply when the transmitter or receiver is in a synchronous mode because all synchronous SAIs are enabled and disabled simultaneously.

58.3.7.3 Bus clock

The bus clock is used by the control and configuration registers and to generate synchronous interrupts and DMA requests.

NOTE

Although there is no minimum bus clock frequency specified, the bus clock frequency must be fast enough (relative to the bit clock frequency) to ensure that the FIFOs can be serviced,

without generating either a transmitter FIFO underrun or receiver FIFO overflow condition.

58.3.8 SAI resets

The SAI is asynchronously reset on system reset. The SAI has a software reset and a FIFO reset.

58.3.8.1 Software reset

The SAI transmitter includes a software reset that resets all transmitter internal logic, including the bit clock generation, status flags, and FIFO pointers. This software reset does not reset the configuration registers. The software reset remains asserted until cleared by software.

The SAI receiver includes a software reset that resets all receiver internal logic, including the bit clock generation, status flags and FIFO pointers. This software reset does not reset the configuration registers. The software reset remains asserted until cleared by software.

58.3.8.2 FIFO reset

The SAI transmitter includes a FIFO reset that synchronizes the FIFO write pointer to the same value as the FIFO read pointer. This FIFO reset empties the FIFO contents and is used after TCSR[FEF] is set, and before the FIFO is re-initialized and TCSR[FEF] is cleared. The FIFO reset is asserted for one cycle only.

The SAI transmitter can also reset the FIFO of individual data channels by setting the appropriate TCR3[CFR] bit. This should only be done when the corresponding TCR3[TCE] bit is clear.

The SAI receiver includes a FIFO reset that synchronizes the FIFO read pointer to the same value as the FIFO write pointer. This empties the FIFO contents and is to be used after the RCSR[FEF] is set and any remaining data has been read from the FIFO, and before the RCSR[FEF] is cleared. The FIFO reset is asserted for one cycle only.

The SAI receiver can also reset the FIFO of individual data channels by setting the appropriate RCR3[CFR] bit. This should only be done when the corresponding RCR3[RCE] bit is clear.

58.4 External signals

Name	Function	I/O
TX_BCLK	Transmit Bit Clock. The bit clock is an input when externally generated and an output when internally generated.	I/O
TX_SYNC	Transmit Frame Sync. The frame sync is an input sampled synchronously by the bit clock when externally generated and an output generated synchronously by the bit clock when internally generated.	I/O
TX_DATA[3:0]	Transmit Data. The transmit data is generated synchronously by the bit clock and is tristated whenever not transmitting a word.	O
RX_BCLK	Receive Bit Clock. The bit clock is an input when externally generated and an output when internally generated.	I/O
RX_SYNC	Receive Frame Sync. The frame sync is an input sampled synchronously by the bit clock when externally generated and an output generated synchronously by the bit clock when internally generated.	I/O
RX_DATA[3:0]	Receive Data. The receive data is sampled synchronously by the bit clock.	I

58.5 Memory map and register definition

A read or write access to an address from offset 0x100 and above will result in a bus error.

58.5.1.3.4 Fields

Field	Description
31-20 —	Reserved
19-16 FRAME	Frame Size The maximum number of slots per frame is 2^FRAME.
15-12 —	Reserved
11-8 FIFO	FIFO Size The number of words in each FIFO is 2^FIFO.
7-4 —	Reserved
3-0 DATALINE	Number of Datalines The number of datalines implemented.

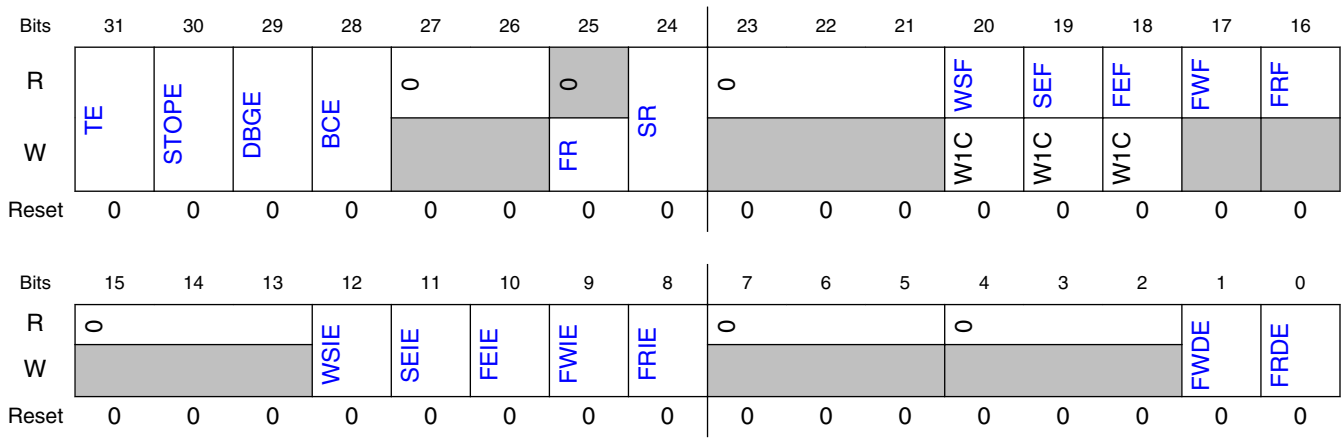
58.5.1.4 Transmit Control (TCSR)

Contains transmitter enable fields including resets, error and interrupt enable fields, and error flag fields.

58.5.1.4.1 Offset

Register	Offset
TCSR	8h

58.5.1.4.2 Diagram



58.5.1.4.3 Fields

Field	Description
31 TE	Transmitter Enable Enables/disables the transmitter. When software clears this field, the transmitter remains enabled, and this bit remains set, until the end of the current frame. 0 - Transmitter is disabled. 1 - Transmitter is enabled, or transmitter has been disabled and has not yet reached end of frame.
30 STOPE	Stop Enable Configures transmitter operation in Stop mode. 0 - Transmitter disabled in Stop mode. 1 - Transmitter enabled in Stop mode.
29 DBGE	Debug Enable Enables/disables transmitter operation in Debug mode. The transmit bit clock is not affected by debug mode. 0 - Transmitter is disabled in Debug mode, after completing the current frame. 1 - Transmitter is enabled in Debug mode.

Table continues on the next page...

Field	Description
28 BCE	Bit Clock Enable Enables the transmit bit clock, separately from the TE. This field is automatically set whenever TE is set. When software clears this field, the transmit bit clock remains enabled, and this bit remains set, until the end of the current frame. 0 - Transmit bit clock is disabled. 1 - Transmit bit clock is enabled.
27-26 —	Reserved
25 FR	FIFO Reset Empties the FIFO, and sets the FIFO read and write pointers to the same value, which may or may not be zero. Reading this field will always return zero. FIFO pointers should only be reset when the transmitter is disabled or the FIFO error flag is set. 0 - No effect. 1 - FIFO reset.
24 SR	Software Reset When set, resets the internal transmitter logic including the FIFO read and write pointers. Software-visible registers are not affected, except for the status registers. 0 - No effect. 1 - Software reset.
23-21 —	Reserved
20 WSF	Word Start Flag Indicates that the start of the configured word has been detected. Write a logic 1 to this field to clear this flag. 0 - Start of word not detected. 1 - Start of word detected.
19 SEF	Sync Error Flag Indicates that an error in the externally-generated frame sync has been detected. Write a logic 1 to this field to clear this flag. 0 - Sync error not detected. 1 - Frame sync error detected.
18 FEF	FIFO Error Flag Indicates that an enabled transmit FIFO has underrun. Write a logic 1 to this field to clear this flag. 0 - Transmit underrun not detected. 1 - Transmit underrun detected.
17 FWF	FIFO Warning Flag Indicates that an enabled transmit FIFO is empty. 0 - No enabled transmit FIFO is empty. 1 - Enabled transmit FIFO is empty.
16 FRF	FIFO Request Flag Indicates that the number of words in an enabled transmit channel FIFO is less than or equal to the transmit FIFO watermark.

Table continues on the next page...

Field	Description
	0 - Transmit FIFO watermark has not been reached. 1 - Transmit FIFO watermark has been reached.
15-13 —	Reserved
12 WSIE	Word Start Interrupt Enable Enables/disables word start interrupts. 0 - Disables interrupt. 1 - Enables interrupt.
11 SEIE	Sync Error Interrupt Enable Enables/disables sync error interrupts. 0 - Disables interrupt. 1 - Enables interrupt.
10 FEIE	FIFO Error Interrupt Enable Enables/disables FIFO error interrupts. 0 - Disables the interrupt. 1 - Enables the interrupt.
9 FWIE	FIFO Warning Interrupt Enable Enables/disables FIFO warning interrupts. 0 - Disables the interrupt. 1 - Enables the interrupt.
8 FRIE	FIFO Request Interrupt Enable Enables/disables FIFO request interrupts. 0 - Disables the interrupt. 1 - Enables the interrupt.
7-5 —	Reserved
4-2 —	Reserved
1 FWDE	FIFO Warning DMA Enable Enables/disables DMA requests. 0 - Disables the DMA request. 1 - Enables the DMA request.
0 FRDE	FIFO Request DMA Enable Enables/disables DMA requests. 0 - Disables the DMA request. 1 - Enables the DMA request.

58.5.1.5 Transmit Configuration 1 (TCR1)

Configures the watermark level for all enabled transmit channels.

58.5.1.5.1 Offset

Register	Offset
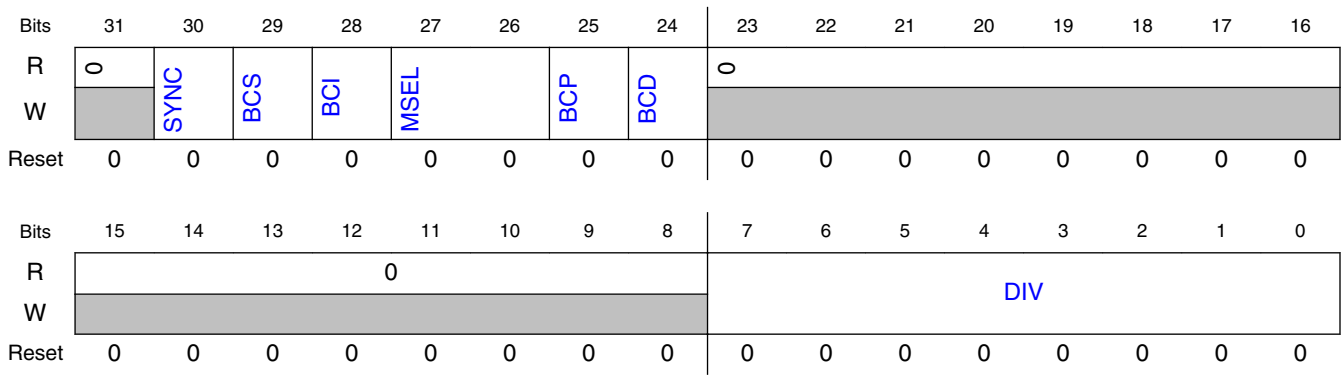
TCR2	10h

58.5.1.6.2 Diagram



58.5.1.6.3 Fields

Field	Description
31 —	Reserved
30 SYNC	Synchronous Mode Configures between asynchronous and synchronous modes of operation. When configured for a synchronous mode of operation, the receiver must be configured for asynchronous operation. 0 - Asynchronous mode. 1 - Synchronous with receiver.
29 BCS	Bit Clock Swap This field swaps the bit clock used by the transmitter. When the transmitter is configured in asynchronous mode and this bit is set, the transmitter is clocked by the receiver bit clock (RX_BCLK). This allows the transmitter and receiver to share the same bit clock, but the transmitter continues to use the transmit frame sync (TX_SYNC). When the transmitter is configured in synchronous mode, the transmitter BCS field and receiver BCS field must be set to the same value. When both are set, the transmitter and receiver are both clocked by the transmitter bit clock (TX_BCLK) but use the receiver frame sync (RX_SYNC). 0 - Use the normal bit clock source. 1 - Swap the bit clock source.
28 BCI	Bit Clock Input

Table continues on the next page...

Field	Description
	When this field is set and using an internally generated bit clock in either synchronous or asynchronous mode, the bit clock actually used by the transmitter is delayed by the pad output delay (the transmitter is clocked by the pad input as if the clock was externally generated). This has the effect of decreasing the data input setup time, but increasing the data output valid time. The slave mode timing from the datasheet should be used for the transmitter when this bit is set. In synchronous mode, this bit allows the transmitter to use the slave mode timing from the datasheet, while the receiver uses the master mode timing. This field has no effect when configured for an externally generated bit clock . 0 - No effect. 1 - Internal logic is clocked as if bit clock was externally generated.
27-26 MSEL	MCLK Select Selects the audio Master Clock option used to generate an internally generated bit clock. This field has no effect when configured for an externally generated bit clock. **NOTE:** Depending on the device, some Master Clock options might not be available. See the chip-specific information for the meaning of each option. 00 - Bus Clock selected. 01 - Master Clock (MCLK) 1 option selected. 10 - Master Clock (MCLK) 2 option selected. 11 - Master Clock (MCLK) 3 option selected.
25 BCP	Bit Clock Polarity Configures the polarity of the bit clock. 0 - Bit clock is active high with drive outputs on rising edge and sample inputs on falling edge. 1 - Bit clock is active low with drive outputs on falling edge and sample inputs on rising edge.
24 BCD	Bit Clock Direction Configures the direction of the bit clock. 0 - Bit clock is generated externally in Slave mode. 1 - Bit clock is generated internally in Master mode.
23-8 —	Reserved
7-0 DIV	Bit Clock Divide Divides down the audio master clock to generate the bit clock when configured for an internal bit clock. The division value is (DIV + 1) * 2.

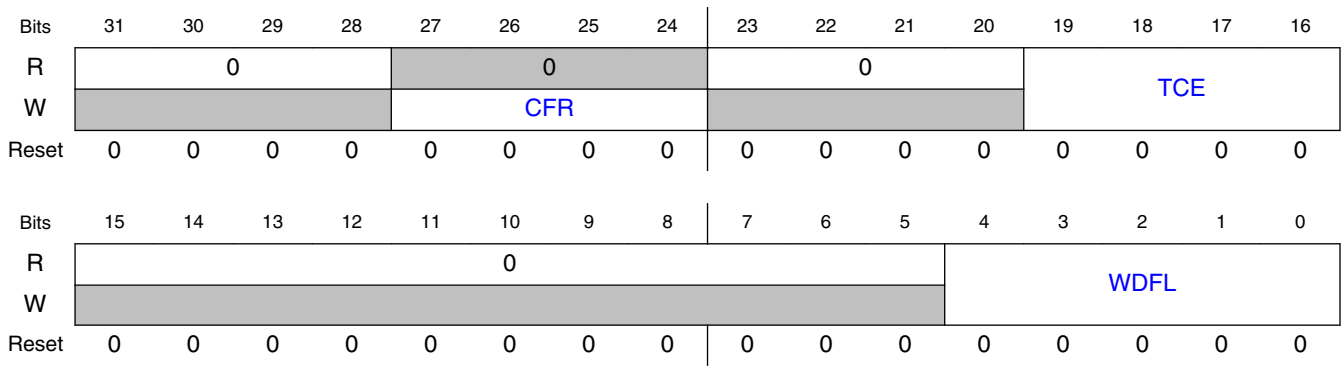
58.5.1.7 Transmit Configuration 3 (TCR3)

Contains the transmit channel settings.

58.5.1.7.1 Offset

Register	Offset
TCR3	14h

58.5.1.7.2 Diagram



58.5.1.7.3 Fields

Field	Description
31-28 —	Reserved
27-24 CFR	Channel FIFO Reset Resets the FIFO pointers for a specific channel. Reading this field always returns zero. FIFO pointers should only be reset when a channel is disabled or the FIFO error flag is set. The width of CFR field = the number of transmit channels (call it N). For example, if CFR is 2 bits wide, then bit position 24 refers to transmit channel 1 FIFO pointer and bit position 25 refers to transmit channel 2 FIFO pointer. Setting bit 24 resets transmit channel 1 FIFO pointer, and setting bit 25 enables transmit channel 2 FIFO pointer. Setting bit N will reset transmit channel N FIFO pointer. **NOTE:** When there is only a single channel, there is no need for individual channel FIFO reset (TCR3[CFR]). In the case of a single channel, use the global FIFO reset (TCSR[FR]). 0b - No effect. 1b - Transmit data channel N FIFO is reset. **NOTE:** This field is not supported in every instance. The following table includes only supported registers.

Field supported in	Field not supported in
SAI1_TCR3	—
—	SAI2_TCR3
—	SAI3_TCR3
—	SAI4_TCR3

Table continues on the next page...

<table>
<tr><th>Field</th><th>Description</th></tr>
<tr><td>23-20
—</td><td>Reserved</td></tr>
<tr><td>19-16
TCE</td><td>Transmit Channel Enable
Enables the corresponding data channel for transmit operation. Changing TCE field will take effect immediately for generating the FIFO request and warning flags, but at the end of each frame for transmit operation.
The width of TCE field = the number of transmit channels (call it N). For example, if TCE field is 2 bits wide, then bit position 16 refers to transmit channel 1 and bit position 17 refers to transmit channel 2. Setting bit 16 enables transmit channel 1, and setting bit 17 enables transmit channel 2. Setting bit N will enable transmit channel N.
0b - Transmit data channel N is disabled.
1b - Transmit data channel N is enabled.
NOTE: This field is not supported in every instance. The following table includes only supported registers.
<table>
<tr><th>Field supported in</th><th>Field not supported in</th></tr>
<tr><td>SAI1_TCR3</td><td>—</td></tr>
<tr><td>SAI2_TCR3[16]</td><td>SAI2_TCR3[19–17]</td></tr>
<tr><td>SAI3_TCR3[16]</td><td>SAI3_TCR3[19–17]</td></tr>
<tr><td>SAI4_TCR3[16]</td><td>SAI4_TCR3[19–17]</td></tr>
</table>
</td></tr>
<tr><td>15-5
—</td><td>Reserved</td></tr>
<tr><td>4-0
WDFL</td><td>Word Flag Configuration
Configures which word sets the start of word flag. The value written must be one less than the word number. For example, writing 0 configures the first word in the frame. When configured to a value greater than TCR4[FRSZ], then the start of word flag is never set.</td></tr>
</table>

58.5.1.8 Transmit Configuration 4 (TCR4)

Contains the transmit fields for FIFO Combine Mode, FIFO Packing Mode, and frame sync settings.

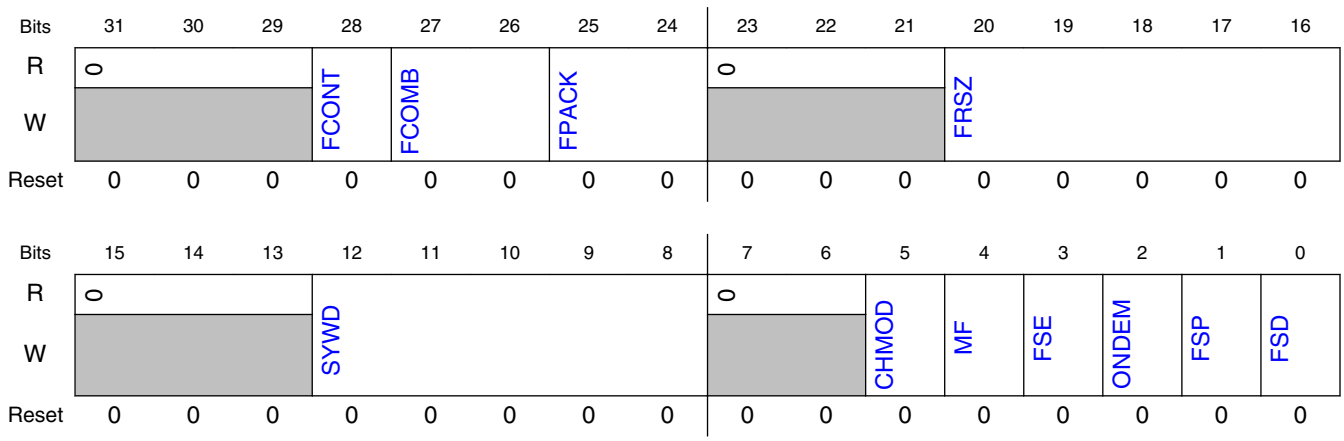
NOTE

This register must not be altered when TCSR[TE] is set.

58.5.1.8.1 Offset

Register	Offset
TCR4	18h

58.5.1.8.2 Diagram



58.5.1.8.3 Fields

Field	Description
31-29 —	Reserved
28 FCONT	FIFO Continue on Error Configures when the SAI will continue transmitting after a FIFO error has been detected. 0 - On FIFO error, the SAI will continue from the start of the next frame after the FIFO error flag has been cleared. 1 - On FIFO error, the SAI will continue from the same word that caused the FIFO error to set after the FIFO warning flag has been cleared.
27-26 FCOMB	FIFO Combine Mode When FIFO combine mode is enabled for FIFO writes, software writing to any FIFO data register will alternate the write among the enabled data channel FIFOs. For example, if two data channels are enabled then the first write will be performed to the first enabled data channel FIFO and the second write will be performed to the second enabled data channel FIFO. Reseting the FIFO or disabling FIFO combine mode for FIFO writes will reset the pointer back to the first enabled data channel. When FIFO combine mode is enabled for FIFO reads from the transmit shift registers, the transmit data channel output will alternate between the enabled data channel FIFOs. For example, if two data channels are enabled then the first unmasked word will be transmitted from the first enabled data channel FIFO and the second unmasked word will be transmitted from the second enabled data channel FIFO. Since the first word of the frame is always transmitted from the first enabled data channel FIFO, it is recommended that the number of unmasked words per frame is evenly divisible by the number of enabled data channels.

Table continues on the next page...

Field	Description
	NOTE: This field is not supported in every instance. The following table includes only supported registers. **Field supported in** / **Field not supported in** SAI1_TCR4 / — — / SAI2_TCR4 — / SAI3_TCR4 — / SAI4_TCR4 00 - FIFO combine mode disabled. 01 - FIFO combine mode enabled on FIFO reads (from transmit shift registers). 10 - FIFO combine mode enabled on FIFO writes (by software). 11 - FIFO combine mode enabled on FIFO reads (from transmit shift registers) and writes (by software).
25-24 FPACK	FIFO Packing Mode Enables packing of 8-bit data or 16-bit data into each 32-bit FIFO word. If the word size is greater than 8-bit or 16-bit then only the first 8-bit or 16-bits are loaded from the FIFO. The first word in each frame always starts with a new 32-bit FIFO word and the first bit shifted must be configured within the first packed word. When FIFO packing is enabled, the FIFO write pointer will only increment when the full 32-bit FIFO word has been written by software. 00 - FIFO packing is disabled. 01 - Reserved 10 - 8-bit FIFO packing is enabled. 11 - 16-bit FIFO packing is enabled.
23-21 —	Reserved
20-16 FRSZ	Frame size Configures the number of words in each frame. The value written must be one less than the number of words in the frame. For example, write 0 for one word per frame. The maximum supported frame size is 32 words.
15-13 —	Reserved
12-8 SYWD	Sync Width Configures the length of the frame sync in number of bit clocks. The value written must be one less than the number of bit clocks. For example, write 0 for the frame sync to assert for one bit clock only. The sync width cannot be configured longer than the first word of the frame.
7-6 —	Reserved
5 CHMOD	Channel Mode Configures if transmit data pins are configured for TDM mode or Output mode. 0 - TDM mode, transmit data pins are tri-stated when slots are masked or channels are disabled. 1 - Output mode, transmit data pins are never tri-stated and will output zero when slots are masked or channels are disabled.

Table continues on the next page...

Field	Description
4 MF	MSB First Configures whether the LSB or the MSB is transmitted first. 0 - LSB is transmitted first. 1 - MSB is transmitted first.
3 FSE	Frame Sync Early 0 - Frame sync asserts with the first bit of the frame. 1 - Frame sync asserts one bit before the first bit of the frame.
2 ONDEM	On Demand Mode When set, and the frame sync is generated internally, a frame sync is only generated when the FIFO warning flag is clear. 0 - Internal frame sync is generated continuously. 1 - Internal frame sync is generated when the FIFO warning flag is clear.
1 FSP	Frame Sync Polarity Configures the polarity of the frame sync. 0 - Frame sync is active high. 1 - Frame sync is active low.
0 FSD	Frame Sync Direction Configures the direction of the frame sync. 0 - Frame sync is generated externally in Slave mode. 1 - Frame sync is generated internally in Master mode.

58.5.1.9 Transmit Configuration 5 (TCR5)

Contains transmit word width and bit index settings.

NOTE

This register must not be altered when TCSR[TE] is set.

58.5.1.15 Receive Configuration 2 (RCR2)

Contains the SYNC mode and clock setting fields.

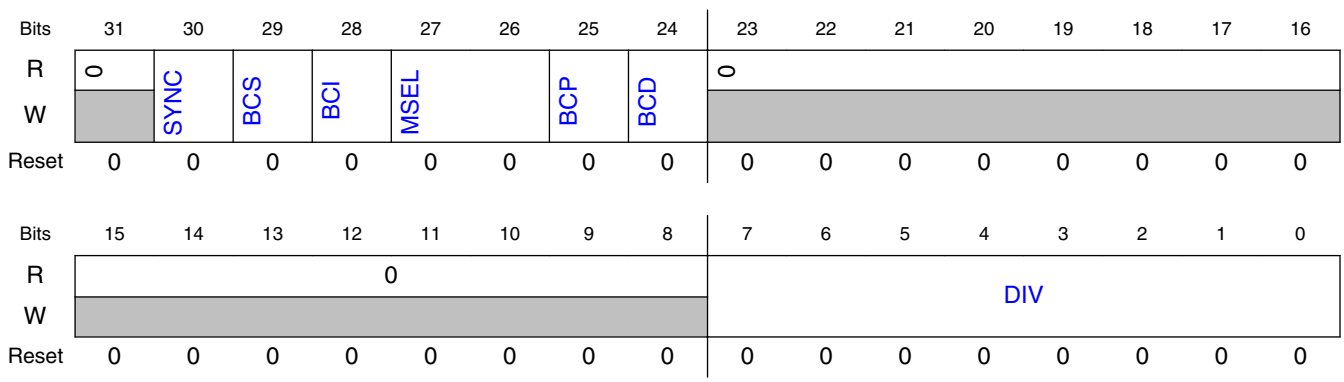
NOTE

This register must not be altered when RCSR[RE] is set.

58.5.1.15.1 Offset

Register	Offset
RCR2	90h

58.5.1.15.2 Diagram



58.5.1.15.3 Fields

Field	Description
31 —	Reserved
30	Synchronous Mode

Table continues on the next page...

Field	Description
SYNC	Configures between asynchronous and synchronous modes of operation. When configured for a synchronous mode of operation, the transmitter must be configured for asynchronous operation. 0 - Asynchronous mode. 1 - Synchronous with transmitter.
29 BCS	Bit Clock Swap This field swaps the bit clock used by the receiver. When the receiver is configured in asynchronous mode and this bit is set, the receiver is clocked by the transmitter bit clock (TX_BCLK). This allows the transmitter and receiver to share the same bit clock, but the receiver continues to use the receiver frame sync (RX_SYNC). When the receiver is configured in synchronous mode, the transmitter BCS field and receiver BCS field must be set to the same value. When both are set, the transmitter and receiver are both clocked by the receiver bit clock (RX_BCLK) but use the transmitter frame sync (TX_SYNC). 0 - Use the normal bit clock source. 1 - Swap the bit clock source.
28 BCI	Bit Clock Input When this field is set and using an internally generated bit clock in either synchronous or asynchronous mode, the bit clock actually used by the receiver is delayed by the pad output delay (the receiver is clocked by the pad input as if the clock was externally generated). This has the effect of decreasing the data input setup time, but increasing the data output valid time. The slave mode timing from the datasheet should be used for the receiver when this bit is set. In synchronous mode, this bit allows the receiver to use the slave mode timing from the datasheet, while the transmitter uses the master mode timing. This field has no effect when configured for an externally generated bit clock . 0 - No effect. 1 - Internal logic is clocked as if bit clock was externally generated.
27-26 MSEL	MCLK Select Selects the audio Master Clock option used to generate an internally generated bit clock. This field has no effect when configured for an externally generated bit clock. **NOTE:** Depending on the device, some Master Clock options might not be available. See the chip-specific information for the availability and chip-specific meaning of each option. 00 - Bus Clock selected. 01 - Master Clock (MCLK) 1 option selected. 10 - Master Clock (MCLK) 2 option selected. 11 - Master Clock (MCLK) 3 option selected.
25 BCP	Bit Clock Polarity Configures the polarity of the bit clock. 0 - Bit Clock is active high with drive outputs on rising edge and sample inputs on falling edge. 1 - Bit Clock is active low with drive outputs on falling edge and sample inputs on rising edge.
24 BCD	Bit Clock Direction Configures the direction of the bit clock. 0 - Bit clock is generated externally in Slave mode. 1 - Bit clock is generated internally in Master mode.
23-8	Reserved

Table continues on the next page...

Field	Description
—	
7-0 DIV	Bit Clock Divide Divides down the audio master clock to generate the bit clock when configured for an internal bit clock. The division value is (DIV + 1) * 2.

58.5.1.16 Receive Configuration 3 (RCR3)

Contains the receive channel settings.

58.5.1.16.3 Fields

Field	Description
31-28 —	Reserved
27-24 CFR	Channel FIFO Reset Resets the FIFO pointers for a specific channel. Reading this field will always return zero. FIFO pointers should only be reset when a channel is disabled or the FIFO error flag is set.

Table continues on the next page...

<table>
<tr><th>Field</th><th>Description</th></tr>
<tr><td></td><td>The width of CFR field = the number of receive channels (call it N). For example, if CFR is 2 bits wide, then bit position 24 refers to receive channel 1 FIFO pointer and bit position 25 refers to receive channel 2 FIFO pointer. Setting bit 24 resets receive channel 1 FIFO pointer, and setting bit 25 enables receive channel 2 FIFO pointer. Setting bit N will reset receive channel N FIFO pointer.
0b - No effect.
1b - Receive data channel N FIFO is reset.
NOTE: This field is not supported in every instance. The following table includes only supported registers.
<table><tr><th>Field supported in</th><th>Field not supported in</th></tr><tr><td>SAI1_RCR3</td><td>—</td></tr><tr><td>—</td><td>SAI2_RCR3</td></tr><tr><td>—</td><td>SAI3_RCR3</td></tr><tr><td>—</td><td>SAI4_RCR3</td></tr></table></td></tr>
<tr><td>23-20
—</td><td>Reserved</td></tr>
<tr><td>19-16
RCE</td><td>Receive Channel Enable
Enables the corresponding data channel for receive operation. Changing this field will take effect immediately for generating the FIFO request and warning flags, but at the end of each frame for receive operation.
The width of RCE field = the number of receive channels (call it N). For example, if RCE field is 2 bits wide, then bit position 16 refers to receive channel 1 and bit position 17 refers to receive channel 2. Setting bit 16 enables receive channel 1, and setting bit 17 enables receive channel 2. Setting bit N will enable receive channel N.
NOTE: When there is only a single channel, there is no need for individual channel FIFO reset (RCR3[CFR]). In the case of a single channel, use the global FIFO reset (RCSR[FR]).
0b - Receive data channel N is disabled.
1b - Receive data channel N is enabled.
NOTE: This field is not supported in every instance. The following table includes only supported registers.
<table><tr><th>Field supported in</th><th>Field not supported in</th></tr><tr><td>SAI1_RCR3</td><td>—</td></tr><tr><td>SAI2_RCR3[16]</td><td>SAI2_RCR3[19–17]</td></tr><tr><td>SAI3_RCR3[16]</td><td>SAI3_RCR3[19–17]</td></tr><tr><td>SAI4_RCR3[16]</td><td>SAI4_RCR3[19–17]</td></tr></table></td></tr>

28 FCONT	FIFO Continue on Error Configures when the SAI will continue receiving after a FIFO error has been detected. 0 - On FIFO error, the SAI will continue from the start of the next frame after the FIFO error flag has been cleared.

Table continues on the next page...

<table>
<tr><th>Field</th><th>Description</th></tr>
<tr><td></td><td>1 - On FIFO error, the SAI will continue from the same word that caused the FIFO error to set after the FIFO warning flag has been cleared.</td></tr>
<tr><td>27-26
FCOMB</td><td>FIFO Combine Mode

When FIFO combine mode is enabled for FIFO reads, software reading any FIFO data register will alternate the read among the enabled data channel FIFOs. For example, if two data channels are enabled then the first read will be performed to the first enabled data channel FIFO and the second read will be performed to the second enabled data channel FIFO. Reseting the FIFO or disabling FIFO combine mode for FIFO reads will reset the pointer back to the first enabled data channel.

When FIFO combine mode is enabled for FIFO writes from the receive shift registers, the first enabled data channel input will alternate between the enabled data channel FIFOs. For example, if two data channels are enabled then the first unmasked received word will be stored in the first enabled data channel FIFO and the second unmasked received word will be stored in the second enabled data channel FIFO. Since the first word of the frame is always stored in the first enabled data channel FIFO, it is recommended that the number of unmasked words per frame is evenly divisible by the number of enabled data channels.

NOTE: This field is not supported in every instance. The following table includes only supported registers.

<table>
<tr><th>Field supported in</th><th>Field not supported in</th></tr>
<tr><td>SAI1_RCR4</td><td>—</td></tr>
<tr><td>—</td><td>SAI2_RCR4</td></tr>
<tr><td>—</td><td>SAI3_RCR4</td></tr>
<tr><td>—</td><td>SAI4_RCR4</td></tr>
</table>

00 - FIFO combine mode disabled.

01 - FIFO combine mode enabled on FIFO writes (from receive shift registers).

10 - FIFO combine mode enabled on FIFO reads (by software).

11 - FIFO combine mode enabled on FIFO writes (from receive shift registers) and reads (by software).</td></tr>
<tr><td>25-24
FPACK</td><td>FIFO Packing Mode

Enables packing of 8-bit data or 16-bit data into each 32-bit FIFO word. If the word size is greater than 8-bit or 16-bit then only the first 8-bit or 16-bits are stored to the FIFO. The first word in each frame always starts with a new 32-bit FIFO word and the first bit shifted must be configured within the first packed word. When FIFO packing is enabled, the FIFO read pointer will only increment when the full 32-bit FIFO word has been read by software.

00 - FIFO packing is disabled

01 - Reserved.

10 - 8-bit FIFO packing is enabled

11 - 16-bit FIFO packing is enabled</td></tr>

59.2 Overview

The Sony/Philips Digital Interface (SPDIF) audio block is a stereo transceiver that allows the processor to receive and transmit digital audio.

59.2.1 Block Diagram

The figure below shows a block diagram of the SPDIF transceiver data paths (receiver and transmitter) and its interface.

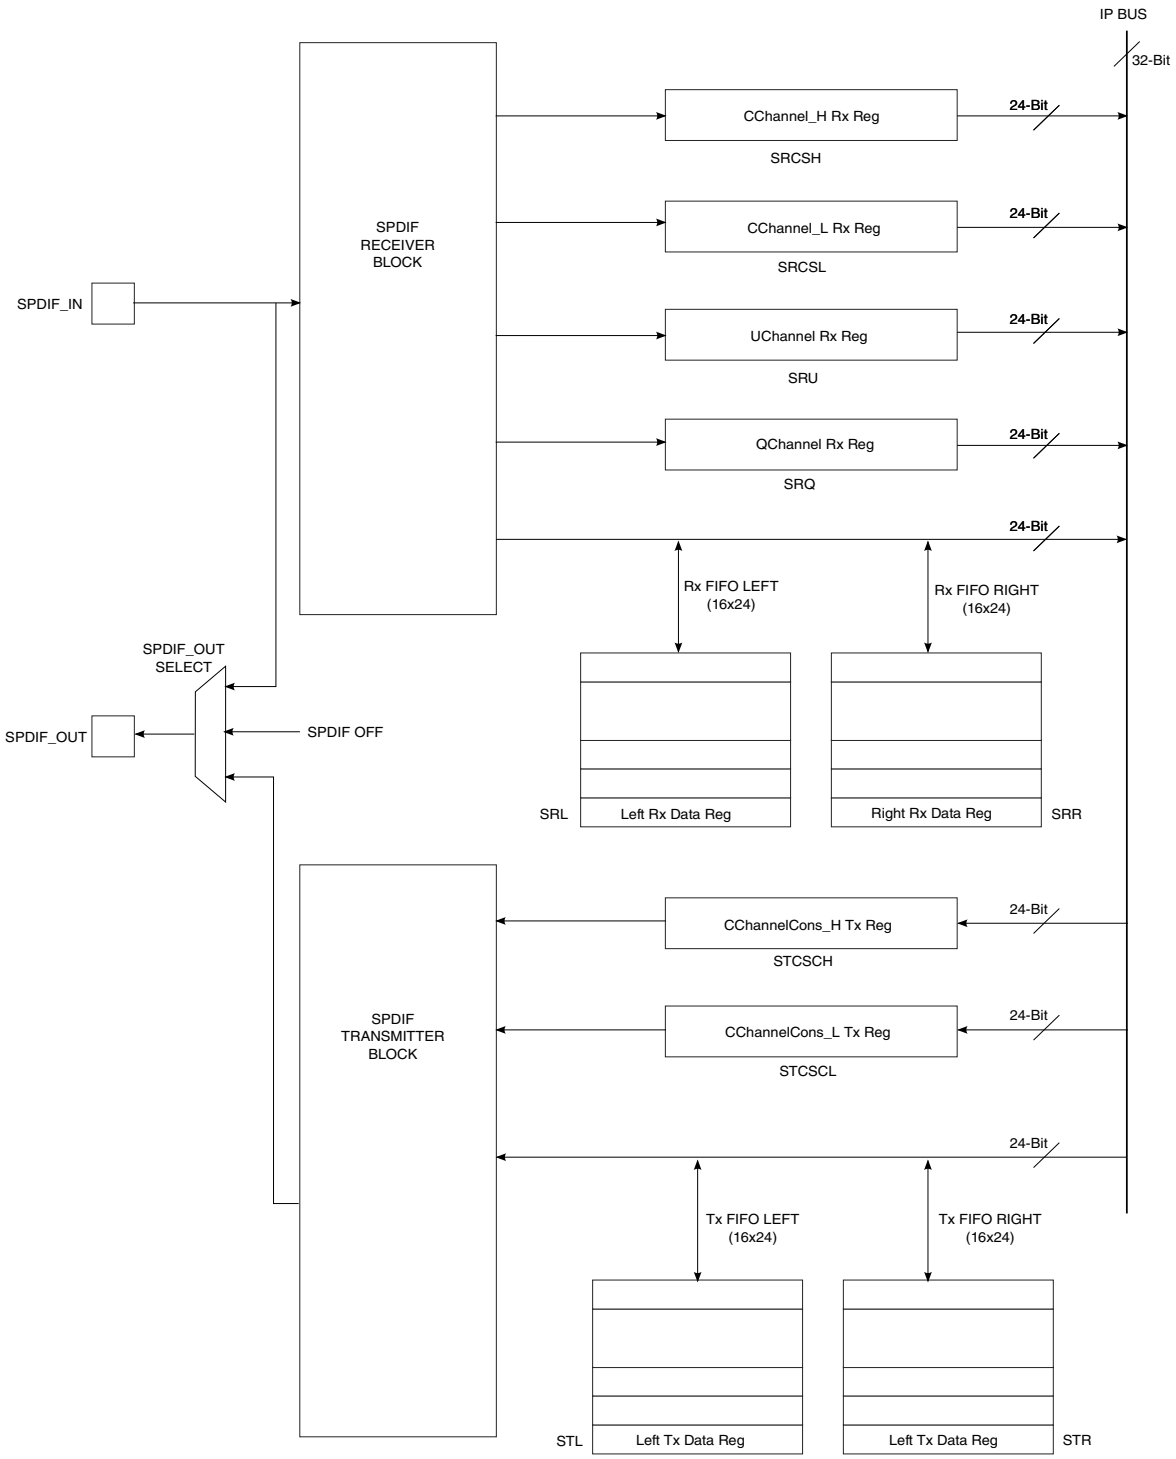

Figure 59-1. SPDIF Transceiver Data Interface Block Diagram

59.2.2 Features

- Allows the handling of both SPDIF channel status (CS) and User (U) data
- Includes a frequency measurement block that allows the precise measurement of an incoming sampling frequency
- Provides a recovered clock to drive both internal components in the system, such as SAI ports, and external components, such as A/Ds or D/As, with clocking control provided via related registers

59.3 Functional Description

The SPDIF is composed of two parts: SPDIF Receiver and SPDIF Transmitter.

The SPDIF receiver extracts the audio data from each SPDIF frame and places the data in the SPDIF Rx left and right FIFOs. The Channel Status and User Bits are also extracted from each frame and placed in the corresponding registers. The SPDIF receiver also provides a bypass option for direct transfer of the SPDIF input signal to the SPDIF transmitter.

For the SPDIF transmitter, the audio data is provided by the processor via the SPDIFTxLeft and SPDIFTxRight registers. The Channel Status bits are also provided via the corresponding registers. The SPDIF transmitter generates a SPDIF output bitstream in the biphase mark format (IEC60958), which consists of audio data, channel status and user bits.

In the SPDIF transmitter, the IEC60958 biphase bit stream is generated on both edges of the SPDIF Transmit clock. The SPDIF Transmit clock is generated by the SPDIF internal clock generate block and the sources are from outside of the SPDIF block. For the SPDIF receiver, it can recover the SPDIF Rx clock.

Figure 59-2 shows the clock structure of the SPDIF transceiver.

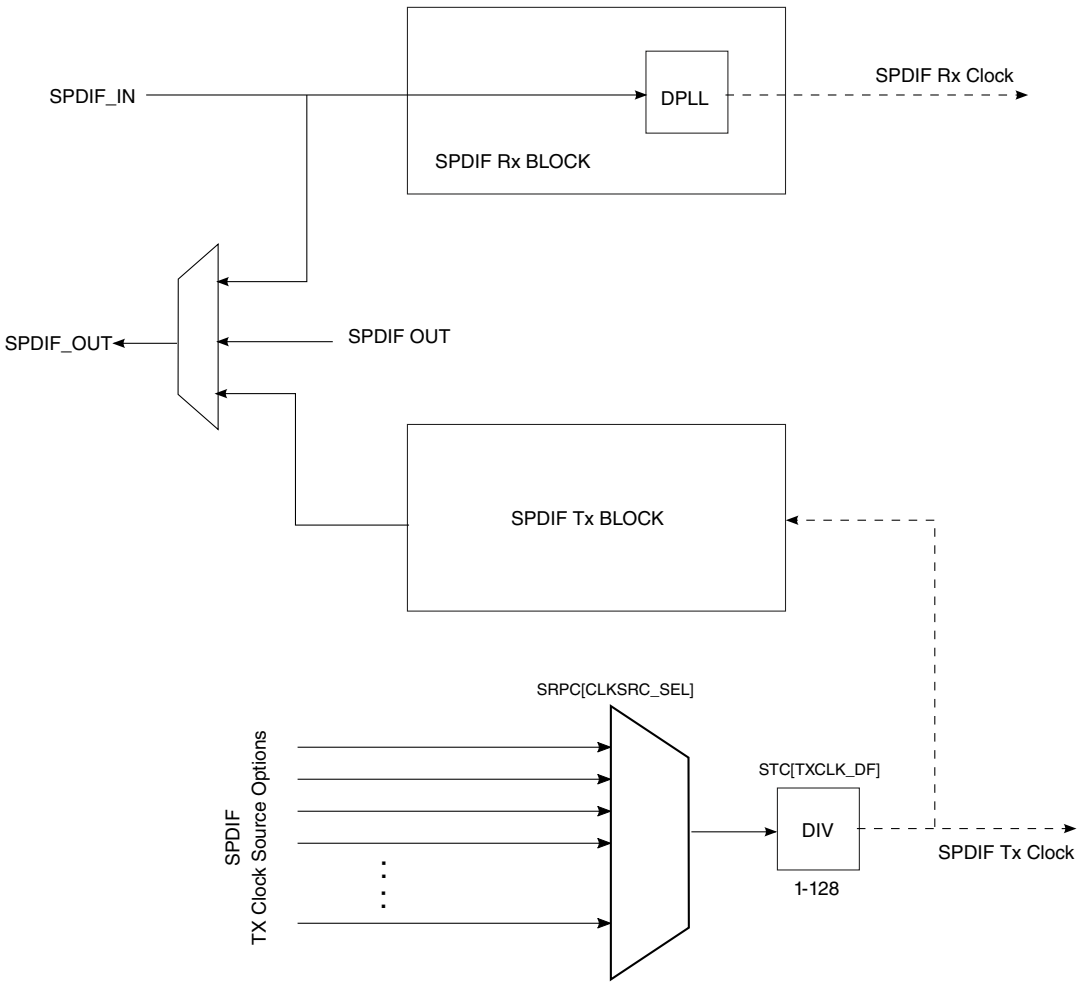

Figure 59-2. SPDIF Transceiver Clock Diagram

59.3.1 SPDIF Receiver

The SPDIF receiver extracts the audio data from each SPDIF frame and places the data in Rx left and right FIFOs.

The Tx left and right FIFOs are 16-deep and 24-bit-wide (equal to the audio data width). The Channel Status and User Bits are also extracted from each frame and placed in corresponding registers. The SPDIF receiver also provides a bypass option for direct transfer of the SPDIF input signal to the SPDIF transmitter.

The SPDIF receiver handles the main data audio stream and recovers the bit clock from the SPDIF input signal. The sample rate can be determined from the frequency measuring block. Additionally, the receiver supports the SPDIF C and U channels. The SPDIF C and U channel data is interfaced directly to memory-mapped registers.

All the data registers are controlled by the Interrupt Control Block and transferred to the memory-mapped IP bus.

59.3.1.1 Audio Data Reception

The SPDIF Receiver block extracts the audio data from the IEC60958 stream, and outputs this via Rx left and right FIFOs to the memory-mapped registers SPDIFRxLeft and SPDIFRxRight.

Data from the SPDIF receiver is buffered in receive FIFO, and can be read by the processor from the memory-mapped registers.

59.3.1.1.1 SPDIF receiver data registers - Behavior on overrun, underrun

The SPDIF Data Receive registers (SPDIFRxLeft and SPDIFRxRight) have individual FIFOs for left and right channel. As a result, there is always the possibility that left and right FIFOs may go out of sync due to FIFO underruns and FIFO overruns that affect only one part (left or right) of any FIFOs. To prevent this from happening, hardware has been added to the device. Two mechanisms to prevent mismatch between the FIFOs are available.

If a SPDIF Data Rx FIFO overrun occurs on e.g. the right half of the FIFO, the sample that caused the overrun is not written to the right half (due to overrun). Special hardware will make sure the next sample is not written to the left half of the FIFO. If the overrun occurs on the left half of the FIFO, the next sample is not written to the right half of the FIFO.

59.3.1.1.2 SPDIF receiver data registers - Automatic resynchronization of FIFOs

An automatic FIFO resynchronization feature is available. It can be enabled and disabled separately for every FIFO. If it is enabled, the hardware will check to see if the left and right FIFOs are in sync. If that is not the case, it will set the filling pointer of the right FIFO to be equal to the filling pointer of the left FIFO.

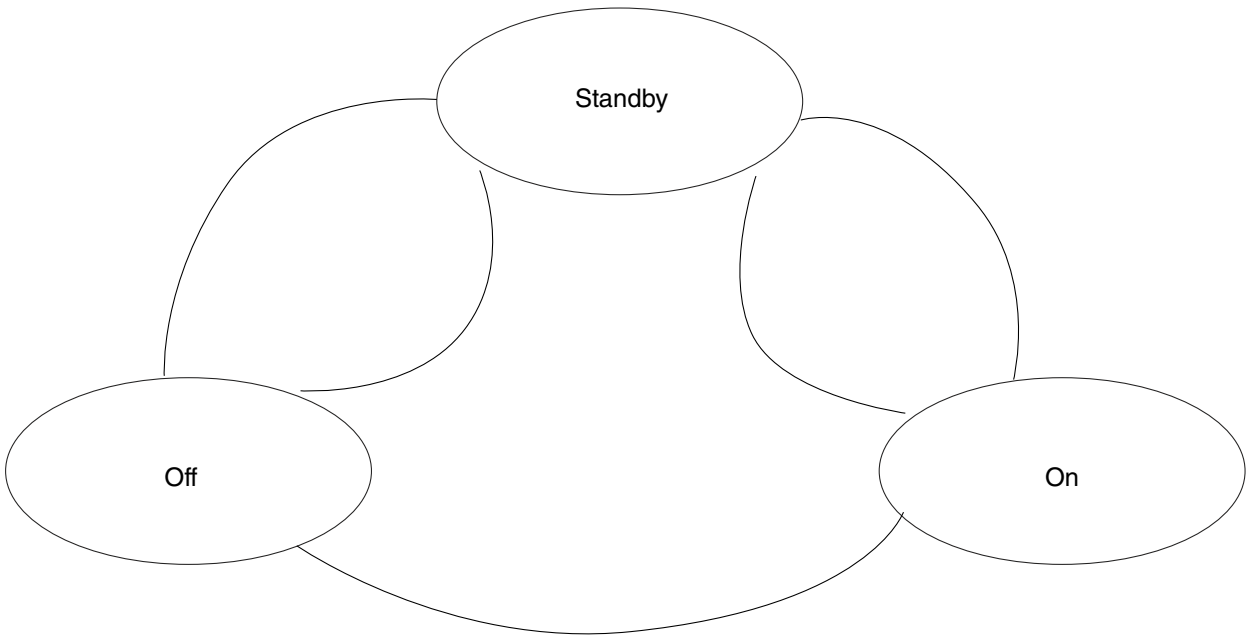

Figure 59-3. FIFO Auto-resync Controller State Machine

The operation is explained from the state diagram shown above. Every FIFO auto-resync controller has a state machine with 3 states: Off, StandBy and On. In the On state, the filling of the left FIFO is compared with the filling of right, and if they are not equal, right is made equal to left, and an interrupt is generated.

The controller will stay in Off state when the feature is disabled. When not disabled, the state machine will go to Off state on any processor read or write to the FIFO. It will go from On or Off to Standby on any left sample read from SPDIF Tx FIFOs, or on any left sample write to SPDIF Rx FIFOs. The controller will go from Standby to On on any right sample read from SPDIF Tx FIFO, or on any right sample write to SPDIF Rx FIFO. There is a control bit in the SPDIF Configuration Register (SCR) to enable/disable the feature for the SPDIF Rx FIFO and SPDIF Tx FIFO.

See for additional details.

59.3.1.2 Channel Status Reception

59.3.1.2.1 48bits Mode

A total of 48 channel status bits are received in two registers. No interpretation is performed by the SPDIF receiver block.

Channel Status Bits are ordered first bit left. CS-channel MSB bit "0" is located in bit position 23 in the memory-mapped register SPDIFRxCChannel_h. CS-channel bit "23" is considered the LSB bit 0 in the register. C-channel bit 24 to 47 is seen as [23:0] bits of register SPDIFRxCChannel_l.

59.3.1.2.2 Channel Status Interrupt

When the value of a new SPDIF "CS" channel status frame is loaded in the register, an interrupt is generated. The interrupt is cleared when the processor writes the corresponding bit in the InterruptStat register.

59.3.1.3 User Bit Reception

There are two modes for U Channel reception, CD and non-CD. As is decided by USyncMode (bit 1 of CDText_Control register).

59.3.1.3.1 Behavior of U Channel receive interface on incoming CD U Channel Sub-code in SPDIF receiver

This mode is selected if UsyncMode, bit 1 in register CD Text control is set "1".

The CD sub-code stream embedded into the SPDIF U channel consists of a sequence of packets. Every packet is made up 98 "symbols". The first two symbols of every packet are "sync symbols", the other 96 symbols are "data symbols".

Any sequence found in the SPDIF U channel stream starting with a leading one, followed by 7 information bits, is recognized as a "data symbol". Subsequent data symbols are separated by "pauses". During the "pause", "zero bits" are seen on the SPDIF U channel.

Data symbols are coming in MSB first. The MSB is the leading one.

When a "long pause" is seen between 2 subsequent "data symbols", the SPDIF receiver will assume the reception of one or more "sync symbols". Table below gives details.

Table 59-2. Sync Control Bits

Number of U Channel zero bits	Corresponding number of sync symbols
0-1	Unpredictable, not allowed
2-10	0
11-22	1
23-34	2
35-46	3
>45	Unpredictable, not allowed

The recognition of the number of sync symbols derives from the fact that the U channel transmitter in the CD channel decoder will transmit one symbol on average every 12 SPDIF channel bits. On this average rate, there is a maximum tolerance of 5%.

The SPDIF receiver is tolerant of symbol errors. Due to the physical nature of the transmission of the data over the CD disc, not more than 1 out of any 5 consecutive user channel symbols may be in error. The error may cause a change in data value, which is not detected by this interface, or it may cause a data symbol to be seen as a sync symbol, or a sync symbol to be seen as a data symbol. However, not more than 1 out of any 5 consecutive user channel symbols should be affected in this way.

The SPDIF U channel circuitry recognizes the 98-symbol packet structure, and sends the 96 symbol payload to the processor application. The 96 symbol payload is transmitted to the processor via 2 registers:

- The SPDIFRxUChannel register. In this register, data is presented 3 symbols at the time to the processor. Every time 3 new valid symbols, received on the SPDIF U Channel are present, the UChannelRxFull interrupt is asserted. For one 98-symbol packet, 96 symbols are carried across SPDIFRxUChannel. To transfer all this data, 32 UChannelRxFull interrupts are generated.
- The QChannelReceive register. In this register, only the Q bit of the packet is accumulated.Operation is similar to UChannelReceive. Because only Q-bit is transferred, only 96 Q-bits are transferred for any 98-symbol packet. To transfer this data, 4 QChannelRxFull interrupts are generated. When QChannelRxFull occurs, it is coincident with UChannelRxFull. There is only one QChannelRxFull for every 8 UChannelRxFull. The convention is that most significant data is transmitted first, and is left-aligned in the registers.
- Timing regarding packet boundary is extracted by hardware. The last UChannelRxFull corresponding to a given packet should be coincident with the last QChannelRxFull. In this last U, Q channel interrupt, symbols 95-98 are received, Q channel bits 67-98. The interrupts are coincident with UQSyncFound, flagging last symbols of the current frame.
- When the start of the new packet is found before the current packet is complete (less than 98 symbols in the packet), the UQFrameError interrupt is set. The application software should read out UChannelReceive and QchannelReceive registers, discard the value, and assume the start of a new packet.
- As already said, packet sync extraction is tolerant for single-symbol errors. Packet sync detection is based on the recognition of the sequence data-sync-sync-data in the symbol stream, because this is the only syncing sequence that is not affected by single errors. If the sync symbols are not found 98 symbols after the previous

occurrence, it is assumed to be destroyed by channel error, and a new sync symbols is interpolated.
- Normally, only data bytes are passed to the application software. Every databyte will have its most significant bit set. If sync symbols are passed to the application software, they are seen as all-zero symbols. Sync symbols can only end up in the data stream due to channel error.

59.3.1.3.2 Behavior of U Channel receive interface on incoming non-CD data

This mode is selected if UsyncMode, bit 1 in register CD Text control is set'0'.

In non-CD mode, the SPDIF U channel stream is recognized as a sequence of "data symbols". No packet recognition is done.

Any sequence found in the SPDIF U channel stream starting with a leading one, followed by 7 information bits, is recognized as a "data symbol". Subsequent data symbols are separated by "pauses". During the "pause", "zero bits" are seen on the SPDIF U channel.

3 consecutive data symbols seen in the SPDIF U Channel stream are grouped together into the SPDIFRxUChannel register. First symbol is left, last symbol is right aligned. When SPDIFRxUChannel contains 3 new data symbols, UChannelRxFull is asserted.

In this mode, the operation of QchannelRx and associated interrupt QchannelRxFull is reserved, undefined. And the operation of UQFrameError and UQSyncFound is also reserved, undefined.

The U channel is extracted, and output by the SPDIF Rx on SPDIFRxUChannel-Stream.

When incoming SPDIF data parity error or bit error is detected, and if the next SPDIF word for that channel is error-free, the SPDIF word in error is replaced with the average of the previous word and next word. When incoming SPDIF data parity error or bit error is detected, and the next SPDIF word is in error, the previous SPDIF word is repeated.

59.3.1.4 Validity Flag Reception

An interrupt is associated with the Validity flag. (interrupt 16 - SPDIFValNoGood). This interrupt is set every time a frame is seen on the SPDIF interface with the validity bit set to "invalid".

59.3.1.5 SPDIF Receiver Interrupt Exception Definition

Several SPDIF exceptions can trigger an interrupt. They are:

- Control Status channel change. Set when SPDIFRxCChannel_1 register is updated. The register is updated for every new C-Channel received. The exception is reset on write to InterruptClear register.
- SPDIF Illegal Symbol. Set on reception of illegal symbol during SPDIF receive. Reset by writing register InterruptClear.[1]
- SPDIF bit error. Set on reception of bit error. (Parity bit does not match). Reset on write to InterruptClear register.
- Receive data FIFO full. Set when SPDIF receive data FIFO is full.
- Receive data FIFO underrun/overrun. Set when there is a underrun/overrun on the SPDIF receive data FIFO.
- Receive data FIFO resynchronization. Set when a resynchronization event occurs on the SPDIF receive data FIFO.
- Receive U Channel buffer full. Set when next 24 bits of U channel code are available.
- Receive Q Channel buffer overrun. Set when Q channel buffer overrun.
- Receive U Channel buffer overrun. Set on U channel buffer overrun.
- Receive Q Channel buffer full. Set when next 24 bits of Q channel code are available.
- Receive UQ sync found. Set when UQ channel sync found.
- Receive UQ frame error. Set when UQ frame error found.

59.3.1.6 Standards Compliance

The SPDIF interface is compatible with the Tech 3250-E standard of the European Broadcasting Union, except clause 6.3.3 and the IEC60958-3 Ed2 for relevant topics.

Supported input frequency range is 12 Khz up to 96 Khz. (fully compliant) and 96 Khz up to 176 Khz (Can interface with compliant SPDIF transmitter within same cabinet, making reasonable assumptions on jitter added due to interconnecting wire.)

Tolerated jitter on SPDIF input signals are 0.25 bit peak-peak for high frequencies. There is no jitter limit for low frequencies. The user channel extraction in CD mode is capable of coping with single-symbol errors, and still retrieve U channel frames on correct boundaries. This capability is required for reliable reception of CD-Text from some Philips CD channel decoders. This capability was deemed more important than compliance with the IEC60958 annex A.3 standard, and for this reason user channel

1. The SPDIF input is a biphase/mark modulated signal. The time between any two successive transitions of the SPDIF signal is always 1, 2 or 3 SPDIF symbol periods long. The SPDIF receiver will parse the stream, and split it in so-called symbols. It recognizes s1, s2 and s3 symbols, depending on the length of the symbols. Not all sequences of these symbols are allowed. To give an example, a sequence s2-s1-s1-s1-s2 cannot occur in a no-error SPDIF signal. If the receiver finds such an illegal sequence, the illegal symbol interrupt is set. No corrective action is undertaken. When the interrupt occurs, this means that(a) The SPDIF signal is destroyed by noise (b) The SPDIF frequency changed.

reception is not compliant with IEC60958 annex A.3. However, the interface is capable to receive U channel inserted by a typical CD channel decoder. Also, in this case, it is more robust and tolerant for channel error than what is required by IEC60958 annex A.3.

59.3.1.7 SPDIF PLOCK Detection and Rxclk Output

Using the high speed system clock, the internal DPLL can extract the bit clock (advanced pulse) from the input bitstream. When this internal DPLL is locked, the LOCK bit of PhaseConfig Register will be set, and the SPDIF Lock output pin SPDIF_LOCK will be asserted.

After DPLL has locked, the pulses are generated, and the average pulse rate is 128 x the sampling frequency.(For a 44.1 Khz input sampling frequency, the average pulse rate = 128 x 44.1 Khz.) The pulse signal is used in the FreqMeas circuit to generate the frequency measurement result.

59.3.1.8 Measuring Frequency of SPDIF_RxClk

The internal DPLL can extract the bit clock (advanced plus) from the input bitstream. To do that, it is necessary to measure the frequency of the incoming signal in relationship with the system clock (BUS_CLK).

Associated with it are two registers, PhaseConfig and FreqMeas. The circuit will measure the frequency of the incoming clock as a function of the BUS_CLK. The circuit is a second-order filter. The output is a value represented by an unsigned number stored in the 24-bit FreqMeas register, giving the frequency of the source as a function of the BUS_CLK.

FreqMeas[23:0] = FreqMeas_CLK / BUS_CLK * 2^{10} * GAIN.

For example, if the GAIN is selected as 8*(2**10) (PhaseConfig[5:3] = 3'b011), the actual result

FreqMeas_CLK / BUS_CLK is equal to FreqMeas[23:0] / 2^{23}.

59.3.2 SPDIF Transmitter

Audio data for the SPDIF transmitter is provided by processor via the SPDIFTxLeft and SPDIFTxRight registers.

Clocking for SPDIF transmitter is selected through a multiplexer from several clock sources (see register bitfield description STC[TxClk_Source] for transmit clock source inputs). The SPDIF transmitter clock source can be divided down as needed using Txclk_DF. The SPDIF transmitter output can be chosen from either the SPDIF transmitter block, directly from the SPDIF receiver (via the output multiplexer), or disabled.

The SPDIF transmitter generates a SPDIF output bitstream in IEC60958 biphase mark format, consisting of audio data, channel status.

59.3.2.1 Audio Data Transmission

Audio data for the SPDIF transmitter is provided by the processor via SPDIFTxLeft and SPDIFTxRight registers. They send audio data to Tx left and right FIFOs. The Tx left and right FIFOs are also 16-deep and 24-width (equal to the audio data width).

59.3.2.1.1 SPDIF transmitter data registers - Behavior on overrun, underrun

The SPDIF Data Transmit registers (SPDIFTxLeft and SPDIFTxRight) have individual FIFOs for left and right channel. As a result, there is always the possibility that left and right FIFOs may go out of sync due to FIFO underruns and FIFO overruns that affect only one part (left or right) of any FIFO. To prevent this from happening, hardware has been added on the device. Two mechanisms to prevent mismatch between the FIFOs are available.

If SPDIF Tx FIFO underruns on the right half of the FIFO, no sample leaves that FIFO (because it was already empty). Special hardware will make sure that the next sample read from the left FIFO will not leave the FIFO (no read strobe is generated). If the underrun occurs on the left half of the FIFO, next read strobe to the right FIFO is blocked.

59.3.2.1.2 SPDIF transmitter data registers - Automatic resynchronization of FIFOs

See Audio Data Reception and .

59.3.2.2 Channel Status Transmission

59.3.2.2.1 48bits Mode

A total of 48 Consumer channel status bits are transmitted from two registers. Channel Status Bits are ordered first bit left.

CS-channel MSB bit "0" is located in bit position 23 in the memory-mapped register SPDIFTxCChannelCons_h. CS-channel bit "23" is considered bit 0 in the register. C-channel bits 24-47 are seen as MSB-LSB bits of register SPDIFTxCChannelCons_l.

59.3.2.3 Validity Flag Transmission

The validity bit setting is performed via the ValCtrl bit of the SPDIF_SCR register.

59.3.3 Clocks

The table found here describes the clock sources for SPDIF.

Please see clock control block for clock setting, configuration and gating information.

Table 59-3. SPDIF Clocks

Clock name	Description
gclkw_t0	Global clock
ipg_clk_s	Peripheral access clock
tx_clk	Module Tx clock

59.4 External Signals

The following table describes the external signals of SPDIF:

Table 59-4. SPDIF External Signals

Signal	Description	Direction
SPDIF_EXT_CLK	External clock signal	I
SPDIF_IN	Input line	I
SPDIF_LOCK	Lock signal	O
SPDIF_OUT	Output line signal	O
SPDIF_SR_CLK	RX Clock	O
SPDIF_OUT_CLK	TX Clock	O

59.5 Application Information

The automatic FIFO resynchronization can be switched on, and will avoid all mismatches between left and right FIFOs, if the software obeys the following rules:

1. When the left data is read or written to the left FIFO, in the same place of the program, data must be read or written to the right FIFO. Maximum time difference between left and right is 1/2 sample clock. (E.g. if sample frequency is 44 Khz, approximately 10 micro-seconds. For 88 Khz, approximately 5 micro-seconds.)
2. Write/read data to FIFOs at least 2 samples at the time. If there is a mismatch Left-Right, the resync logic may go on only 1 sample clock after last data is read/written to the FIFO. Also acceptable is polling the FIFO, if at least part of the time 2 samples will be read/written to it.
3. The first 192 frames (after DPLL lock) must be discarded.

59.5.1 SPDIF receiver details

There are three exceptions associated with the SPDIF Receiver FIFOs

- full
- under/overrun
- resync

When the "full" condition is set for processor data input registers, the processor should read data from the FIFO, before overrun occurs. When "full" is set, and the FIFO contains e.g. 6 samples, it is acceptable for the software to read first 6 samples from the LEFT address, followed by 6 samples from the RIGHT address, or 6 samples from the RIGHT address, followed by 6 samples from the LEFT address, or 1 sample LEFT, followed by 1 sample RIGHT repeated 6 times. There is no order specified.

The implementation for SPDIF Rx is a double FIFO, one for left and one for right. "full" is set when both FIFOs are full. "underrun, overrun" are set when one of the FIFOs do underrun or do overrun. The resync interrupt means hardware took special action to resynchronize left and right FIFOs.

The FIFO level at which the "full" interrupt is generated, is programmable via the Full Select field in the SPDIFConfigReg register.

59.5.2 Rx FIFO on and Rx FIFO reset

Two additional control fields of the SPDIF Rx FIFO are the on/off select and FIFO reset fields.

If on/off select is set to off, all-zero will be read from the FIFO, irrespective of the data received over the SPDIF interface.

If FIFO reset is set, the FIFO is blocked at "1 sample in FIFO". In this, the full interrupt will be on if FullSelect is set to "00". If FullSelect is set to any other value, interrupt will be off. The other interrupts are always off.

59.5.3 SPDIFTxLeft, SPDIFTxRight details

With SPDIF Tx FIFOs three exceptions are associated:

- empty
- under/overrun
- resync

When the empty condition is set for processor data output registers, the processor should write data to the FIFO, before underrun occurs. When empty is set and, for instance, 6 samples need to be written, it is acceptable for the software to write first 6 samples from the LEFT address, followed by 6 samples from the RIGHT address, or 1 sample LEFT, followed by 1 sample RIGHT repeated 6 times. Left should be written before right. The implementation of all data out FIFOs is a double FIFO, one for left and one for right. Empty is set when both FIFOs are empty. Underrun, overrun are set when one of the FIFOs do underrun or do overrun. Resync is set when the hardware resynchronizes left and right FIFOs.

On receiving underrun, overrun interrupt, synchronization between Left and Right words in the FIFOs may be lost. Synchronization will not be lost when the underrun or overrun comes from the IEC60958 side of the FIFO. If the processor reads or writes more data from, for example, left than from right, synchronization will be lost. If automatic resynchronization is enabled, and if the software obeys the rules to let this work, resynchronization will be automatic.

59.6 SPDIF Memory Map/Register Definition

59.6.1 SPDIF register descriptions

59.6.1.1 SPDIF memory map

ipv_spdif base address: 4040_0000h

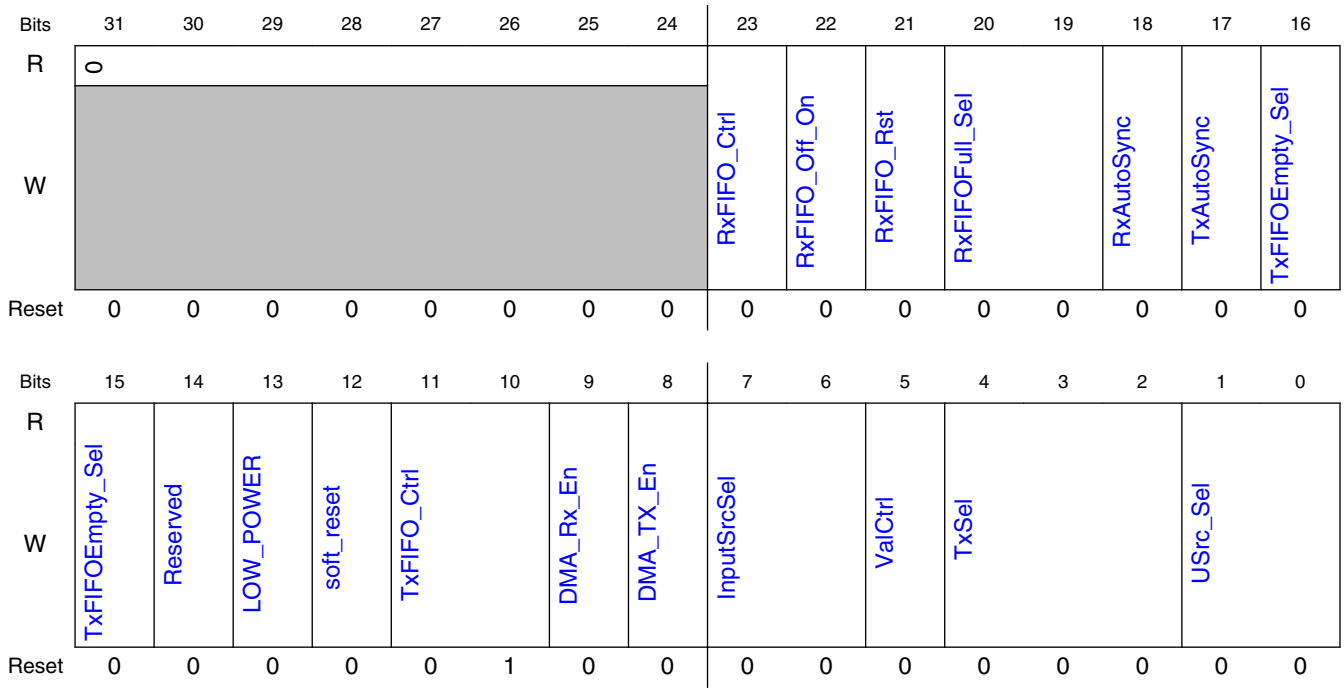
59.6.1.2 SPDIF Configuration Register (SCR)

Contains SPDIF configuration selections.

59.6.1.2.1 Offset

Register	Offset
SCR	0h

59.6.1.2.2 Diagram



59.6.1.2.3 Fields

Field	Description
31-24 —	Reserved
23 RxFIFO_Ctrl	RxFIFO_Ctrl 0 - Normal operation 1 - Always read zero from Rx data register
22 RxFIFO_Off_On	RxFIFO_Off_On 0 - SPDIF Rx FIFO is on 1 - SPDIF Rx FIFO is off. Does not accept data from interface
21 RxFIFO_Rst	RxFIFO_Rst 0 - Normal operation 1 - Reset register to 1 sample remaining
20-19 RxFIFOFull_Sel	RxFIFOFull_Sel 00 - Full interrupt if at least 1 sample in Rx left and right FIFOs 01 - Full interrupt if at least 4 sample in Rx left and right FIFOs 10 - Full interrupt if at least 8 sample in Rx left and right FIFOs 11 - Full interrupt if at least 16 sample in Rx left and right FIFO
18	RxAutoSync

Table continues on the next page...

Field	Description
RxAutoSync	0 - Rx FIFO auto sync off 1 - RxFIFO auto sync on
17 TxAutoSync	TxAutoSync 0 - Tx FIFO auto sync off 1 - Tx FIFO auto sync on
16-15 TxFIFOEmpty_Sel	TxFIFOEmpty_Sel 00 - Empty interrupt if 0 sample in Tx left and right FIFOs 01 - Empty interrupt if at most 4 sample in Tx left and right FIFOs 10 - Empty interrupt if at most 8 sample in Tx left and right FIFOs 11 - Empty interrupt if at most 12 sample in Tx left and right FIFOs
14 —	- Reserved
13 LOW_POWER	LOW_POWER When write 1 to this bit, it will cause SPDIF enter low-power mode. return 1 when SPDIF in Low-Power mode.
12 soft_reset	soft_reset When write 1 to this bit, it will cause SPDIF software reset. The software reset will last 8 cycles. When in the reset process, return 1 when read. else return 0 when read.
11-10 TxFIFO_Ctrl	TxFIFO_Ctrl 00 - Send out digital zero on SPDIF Tx 01 - Tx Normal operation 10 - Reset to 1 sample remaining 11 - Reserved
9 DMA_Rx_En	DMA_Rx_En DMA Receive Request Enable (RX FIFO full)
8 DMA_TX_En	DMA_TX_En DMA Transmit Request Enable (Tx FIFO empty)
7-6 InputSrcSel	InputSrcSel Input Source Selector 00 - SPDIF_IN 01-11 - None
5 ValCtrl	ValCtrl 0 - Outgoing Validity always set 1 - Outgoing Validity always clear
4-2	TxSel

Table continues on the next page...

Field	Description
TxSel	000 - Off and output 0 001 - Feed-through SPDIFIN 101 - Tx Normal operation
1-0 USrc_Sel	USrc_Sel U channel source select 00 - No embedded U channel 01 - U channel from SPDIF receive block (CD mode) 10 - Reserved 11 - U channel from on chip transmitter

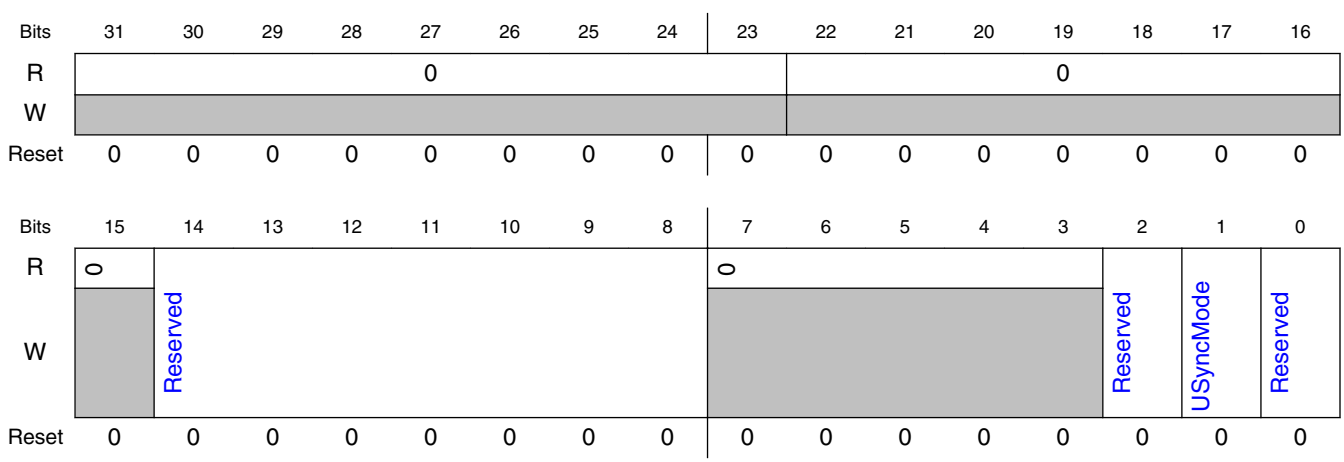
59.6.1.3 CDText Control Register (SRCD)

Contains CD text controls

59.6.1.3.1 Offset

Register	Offset
SRCD	4h

59.6.1.3.2 Diagram



59.6.1.3.3 Fields

7 tx_all_clk_en	tx_all_clk_en Spdif transfer clock enable.When data is going to be transfered, this bit should be set to1. 0 - disable transfer clock. 1 - enable transfer clock.
6-0 TxClk_DF	TxClk_DF Divider factor (1-128) 0000000 - divider factor is 1 0000001 - divider factor is 2 1111111 - divider factor is 128

Chapter 60
10/100 /1000 -Mbps Ethernet MAC (ENET/ENET1G)

60.1 Chip-specific ENET information

Table 60-1. Reference links to related information

Topic	Related module(s)	Reference
System memory map	-	System Memory Map
Clocking	CCM	Clock Management Clock Control Module (CCM)
Power management	PMU	Power Management Power Management Unit
Signal multiplexing	IOMUX	External Signals and Pin Multiplexing IOMUX
Interrupts, DMA Events and XBAR Assignments	-	Interrupts, DMA Events and XBAR Assignments

This chip supports two instances of ENET IP:

ENET supports 10M/100M Ethernet, and has the following key features:

- 3.3V RMII and MII operation
- IEEE1588

ENET_1G supports 1G Ethernet, and has the following features:

- RGMII/RMII/MII operation
- IEEE1588
- AVB

60.2 Overview

The core implements a triple-speed 10/100/1000-Mbit/s ENET compliant with the IEEE802.3-2002 standard. The MAC layer provides compatibility with half- or full-duplex 10/100-Mbit/s and full-duplex gigabit Ethernet LANs.

The MAC operation is fully programmable and can be used in Network Interface Card (NIC), bridging, or switching applications. The core implements the remote network monitoring (RMON) counters according to IETF RFC 2819.

The core also implements a hardware acceleration block to optimize the performance of network controllers providing TCP/IP, UDP, and ICMP protocol services. The acceleration block performs critical functions in hardware, which are typically implemented with large software overhead.

The core implements programmable embedded FIFOs that can provide buffering on the receive path for lossless flow control.

Advanced power management features are available with magic packet detection and programmable power-down modes.

A unified DMA (uDMA), internal to the ENET module, optimizes data transfer between the ENET core and the SoC, and supports an enhanced buffer descriptor programming model to support IEEE 1588 functionality.

The programmable ENET with IEEE 1588 integrates a standard IEEE 802.3 Ethernet MAC with a time-stamping module. The IEEE 1588 standard provides accurate clock synchronization for distributed control nodes for industrial automation applications.

NOTE

The terminology in this chapter has been updated to align with Annex K (informative) Optional alternative terminology, IEEE 802.3, as shown in the table below.

Table 60-2. Updated terms

Updated term	Deprecated term
Leader	Master
Follower	Slave

60.2.1 Block diagram

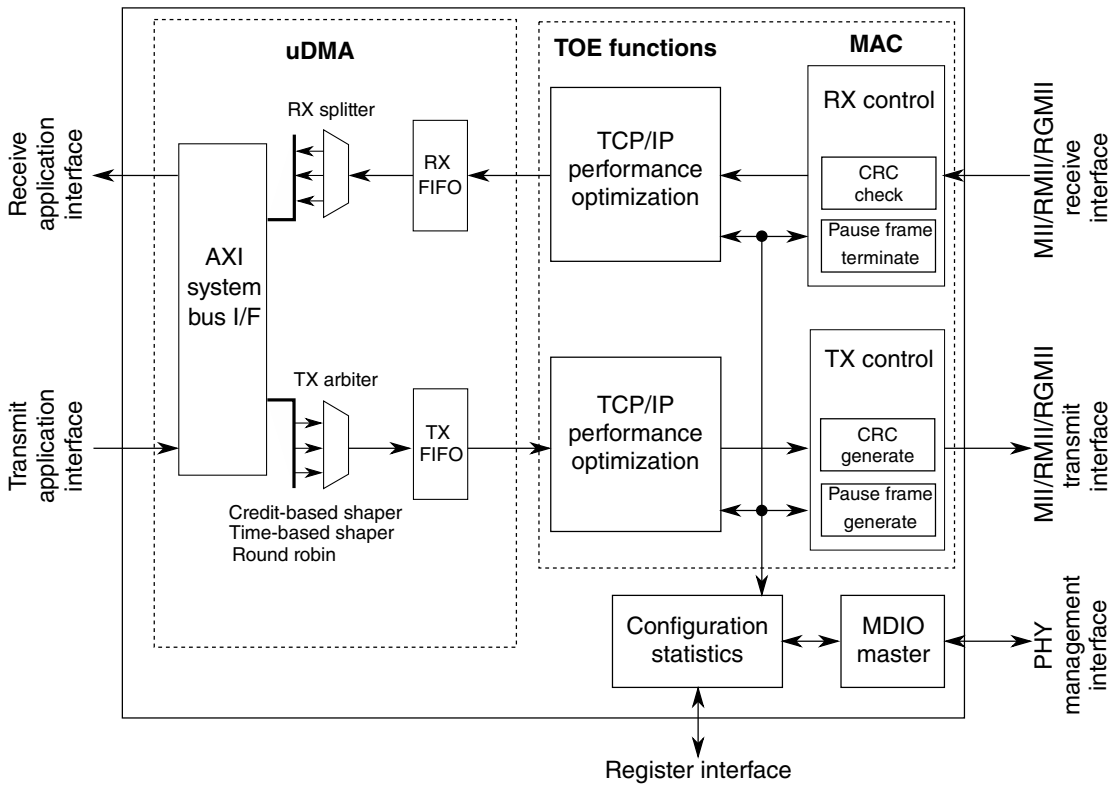

Figure 60-1. Ethernet MAC-NET core block diagram

60.2.2 Features

The MAC-NET core includes the following features.

60.2.2.1 Ethernet MAC features

- Implements the full 802.3 specification with preamble/SFD generation, frame padding generation, CRC generation and checking
- Supports zero-length preamble
- Dynamically configurable to support 10/100-Mbit/s and gigabit operation
- Supports 10/100 Mbit/s full-duplex and configurable half-duplex operation
- Supports gigabit full-duplex operation
- Compliant with the AMD magic packet detection with interrupt for node remote power management
- Seamless interface to commercial Ethernet PHY devices via one of the following:
  - a 4-bit Media Independent Interface (MII) operating at 2.5/25 MHz.

    - a 4-bit non-standard MII-Lite (MII without the CRS and COL signals) operating at 2.5/25 MHz.
    - a 2-bit Reduced MII (RMII) operating at 50 MHz.
    - a (double data rate) 4-bit Reduced GMII (RGMII) operating at 125 MHz.
- CRC-32 checking at full speed with optional forwarding of the frame check sequence (FCS) field to the client
- CRC-32 generation and append on transmit or forwarding of user application provided FCS selectable on a per-frame basis
- In full-duplex mode:
    - Supports Ethernet pause frame (802.3 Annex 31A) providing fully automated flow control without any user application overhead
    - Pause quanta used to form pause frames, dynamically programmable
    - Pause frame generation additionally controllable by user application offering flexible traffic flow control
    - Optional forwarding of received pause frames to the user application
    - Implements standard flow-control mechanism
- In half-duplex mode: provides full collision support, including jamming, backoff, and automatic retransmission
- Supports VLAN-tagged frames according to IEEE 802.1Q
- Programmable MAC address: Insertion on transmit; discards frames with mismatching destination address on receive (except broadcast and pause frames)
- Programmable promiscuous mode support to omit MAC destination address checking on receive
- Multicast and unicast address filtering on receive based on 64-entry hash table, reducing higher layer processing load
- Programmable frame maximum length providing support for any standard or proprietary frame length
- Statistics indicators for frame traffic and errors (alignment, CRC, length) and pause frames providing for IEEE 802.3 basic and mandatory management information database (MIB) package and remote network monitoring (RFC 2819)
- Simple handshake user application FIFO interface with fully programmable depth and threshold levels
- Provides separate status word for each received frame on the user interface providing information such as frame length, frame type, VLAN tag, and error information
- Supports internal loopback option
- Programmable Clause 22 and Clause 45 MDIO Leader interface for PHY device configuration and management
- Supports legacy FEC buffer descriptors
- Supports interrupt coalescing

- Supports credit-based shaping and round robin QoS scheme for traffic shaping bandwidth distribution. Either policy can be combined with time-based shaping.
- AVB (Audio Video Bridging, IEEE 802.1Qav) features:
  - Credit-based bandwidth distribution policy can be combined with time-based shaping
  - AVB endpoint talker and listener support
  - Support for arbitration between different priority traffic (for example, AVB class A, AVB class B, and non-AVB)

60.2.2.2 IP protocol performance optimization features

- Operates on TCP/IP and UDP/IP and ICMP/IP protocol data or IP header only
- Enables wire-speed processing
- Supports IPv4 and IPv6
- Transparent passing of frames of other types and protocols
- Supports VLAN tagged frames according to IEEE 802.1q with transparent forwarding of VLAN tag and control field
- Automatic IP-header and payload (protocol specific) checksum calculation and verification on receive
- Automatic IP-header and payload (protocol specific) checksum generation and insertion on transmit. Configurable on a per-frame basis
- Supports IP and TCP, UDP, ICMP data for checksum generation and checking
- Supports full header options for IPv4 and TCP protocol headers
- Provides IPv6 support to datagrams with base header only — datagrams with extension headers are passed transparently unmodifed/unchecked
- Provides statistics information for received IP and protocol errors
- Configurable automatic discard of erroneous frames
- Configurable automatic host-to-network (RX) and network-to-host (TX) byte order conversion for IP and TCP/UDP/ICMP headers within the frame
- Configurable padding remove for short IP datagrams on receive

- Configurable Ethernet payload alignment to allow for 32-bit word-aligned header and payload processing
- Programmable store-and-forward operation with clock and rate decoupling FIFOs

60.2.2.3 IEEE 1588 features

- Supports all IEEE 1588 frames.
- Allows reference clock to be chosen independently of network speed.
- Software-programmable precise time-stamping of ingress and egress frames
- Timer monitoring capabilities for system calibration and timing accuracy management
- Precise time-stamping of external events with programmable interrupt generation
- Programmable event and interrupt generation for external system control
- Supports hardware- and software-controllable timer synchronization.
- Provides a 4-channel IEEE 1588 timer. Each channel supports input capture and output compare using the 1588 counter.

60.3 Functional description

This section provides a complete functional description of the MAC-NET core.

60.3.1 Ethernet MAC frame formats

- Minimum length of 64 bytes
- Maximum length of 1518 bytes excluding the preamble and the start frame delimiter (SFD) bytes

An Ethernet frame consists of the following fields:

- Seven bytes preamble
- Start frame delimiter (SFD)
- Two address fields

- Length or type field
- Data field
- Frame check sequence (CRC value)

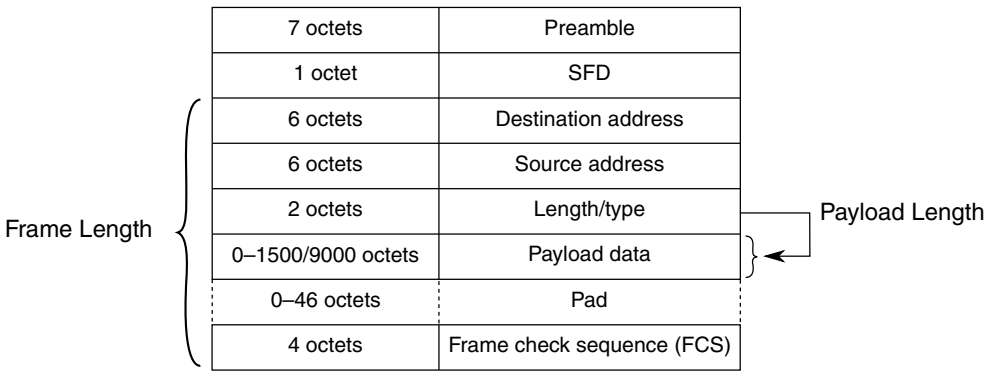

Figure 60-2. MAC frame format overview

Optionally, MAC frames can be VLAN-tagged with an additional four-byte field inserted between the MAC source address and the type/length field. VLAN tagging is defined by the IEEE P802.1q specification. VLAN-tagged frames have a maximum length of 1522 bytes, excluding the preamble and the SFD bytes.

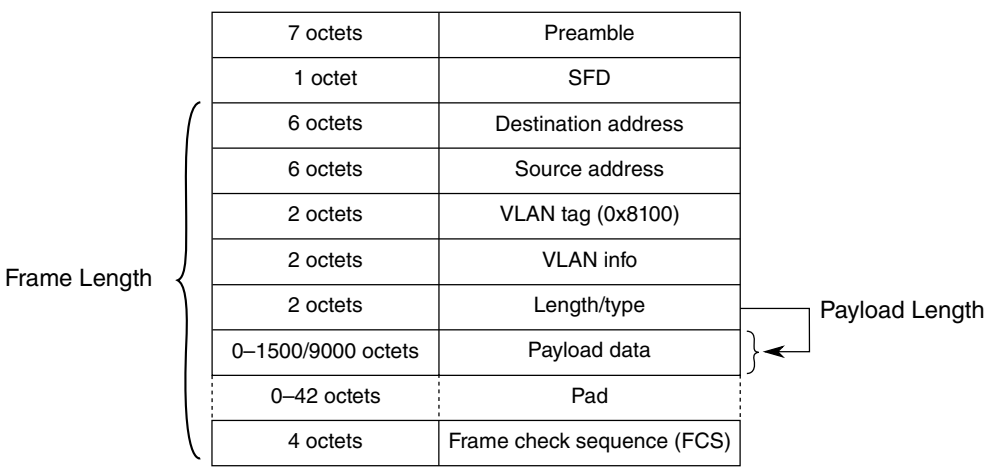

Figure 60-3. VLAN-tagged MAC frame format overview

Table 60-3. MAC frame definition

Term	Description
Frame length	Defines the length, in octets, of the complete frame without preamble and SFD. A frame has a valid length if it contains at least 64 octets and does not exceed the programmed maximum length.
Payload length	The length/type field indicates the length of the frame's payload section. The most significant byte is sent/received first.

Table continues on the next page...

Table 60-3. MAC frame definition (continued)

Term	Description
	• If the length/type field is set to a value less than 46, the payload is padded so that the minimum frame length requirement (64 bytes) is met. For VLAN-tagged frames, a value less than 42 indicates a padded frame. • If the length/type field is set to a value larger than the programmed frame maximum length (e.g. 1518) it is interpreted as a type field.
Destination and source address	48-bit MAC addresses. The least significant byte is sent/received first and the first two least significant bits of the MAC address distinguish MAC frames, as detailed in MAC address check.

Note

Although the IEEE specification defines a maximum frame length, the MAC core provides the flexibility to program any value for the frame maximum length.

60.3.1.1 Pause frames

The receiving device generates a pause frame to indicate a congestion to the emitting device, which should stop sending data.

Pause frames are indicated by the length/type set to 0x8808. The two first bytes of a pause frame following the type, defines a 16-bit opcode field set to 0x0001 always. A 16-bit pause quanta is defined in the frame payload bytes 2 (P1) and 3 (P2) as defined in the following table. The P1 pause quanta byte is the most significant.

Table 60-4. Pause Frame Format (Values in Hex)

1	2	3	4	5	6	7	8	9	10	11	12	13	14
55	55	55	55	55	55	55	D5	01	80	C2	00	00	01
Preamble							SFD	Multicast Destination Address					
15	16	17	18	19	20	21	22	23	24	25	26	27 –68	
00	00	00	00	00	00	88	08	00	01	hi	lo	00	
Source Address						Type		Opcode		P1	P2	pad (42)	
69	70	71	72										
26	6B	AE	0A										
CRC-32													

There is no payload length field found within a pause frame and a pause frame is always padded with 42 bytes (0x00).

If a pause frame with a pause value greater than zero (XOFF condition) is received, the MAC stops transmitting data as soon the current frame transfer is completed. The MAC stops transmitting data for the value defined in pause quanta. One pause quanta fraction refers to 512 bit times.

If a pause frame with a pause value of zero (XON condition) is received, the transmitter is allowed to send data immediately (see Full-duplex flow control operation for details).

60.3.1.2 Magic packets

A magic packet is a unicast, multicast, or broadcast packet, which carries a defined sequence in the payload section.

Magic packets are received and inspected only under specific conditions as described in Magic packet detection.

The defined sequence to decode a magic packet is formed with a synchronization stream which consists of six consecutive 0xFF bytes, and is followed by sequence of sixteen consecutive unicast MAC addresses of the node to be awakened.

This sequence can be located anywhere in the magic packet payload. The magic packet is formed with a standard Ethernet header, optional padding, and CRC.

60.3.2 IP and higher layers frame format

The following sections use the term datagram to describe the protocol specific data unit that is found within the payload section of its container entity.

For example, an IP datagram specifies the payload section of an Ethernet frame. A TCP datagram specifies the payload section within an IP datagram.

60.3.2.1 Ethernet types

IP datagrams are carried in the payload section of an Ethernet frame. The Ethernet frame type/length field discriminates several datagram types.

The following table lists the types of interest:

Table 60-5. Ethernet type value examples

Type	Description
0x8100	VLAN-tagged frame. The actual type is found 4 octets later in the frame.

Table continues on the next page...

Table 60-5. Ethernet type value examples (continued)

Type	Description
0x0800	IPv4
0x0806	ARP
0x86DD	IPv6

60.3.2.2 IPv4 datagram format

The following figure shows the IP Version 4 (IPv4) header, which is located at the beginning of an IP datagram. It is organized in 32-bit words. The first byte sent/received is the leftmost byte of the first word (in other words, version/IHL field).

The IP header can contain further options, which are always padded if necessary to guarantee the payload following the header is aligned to a 32-bit boundary.

The IP header is immediately followed by the payload, which can contain further protocol headers (for example, TCP or UDP, as indicated by the protocol field value). The complete IP datagram is transported in the payload section of an Ethernet frame.

Table 60-6. IPv4 header format

31 30 29 28	27 26 25 24	23 22 21 20	19 18 17 16	15 14 13 12	11 10 9 8	7 6 5 4	3 2 1 0
Version	IHL	TOS		Length			
Fragment ID				Flags	Fragment offset		
TTL		Protocol		Header checksum			
Source address							
Destination address							
Options							

Table 60-7. IPv4 header fields

Field name	Description
Version	4-bit IP version information. 0x4 for IPv4 frames.
IHL	4-bit Internet header length information. Determines number of 32-bit words found within the IP header. If no options are present, the default value is 0x5.
TOS	Type of service/DiffServ field.
Length	Total length of the datagram in bytes, including all octets of header and payload.
Fragment ID, flags, fragment offset	Fields used for IP fragmentation.
TTL	Time-to-live. In effect, is decremented at each router arrival. If zero, datagram must be discarded.
Protocol	Identifier of protocol that follows in the datagram.

Table continues on the next page...

Table 60-7. IPv4 header fields (continued)

Field name	Description
Header checksum	Checksum of IP header. For computational purposes, this field's value is zero.
Source address	Source IP address.
Destination address	Destination IP address.

60.3.2.3 IPv6 datagram format

The following figure shows the IP version 6 (IPv6) header, which is located at the beginning of an IP datagram. It is organized in 32-bit words and has a fixed length of ten words (40 bytes). The next header field identifies the type of the header that follows the IPv6 header. It is defined similar to the protocol identifier within IPv4, with new definitions for identifying extension headers. These headers can be inserted between the IPv6 header and the protocol header, which will shift the protocol header accordingly. The accelerator currently only supports IPv6 without extension headers (in other words, the next header specifies TCP, UDP, or IMCP).

The first byte sent/received is the leftmost byte of the first word (in other words, version/ traffic class fields).

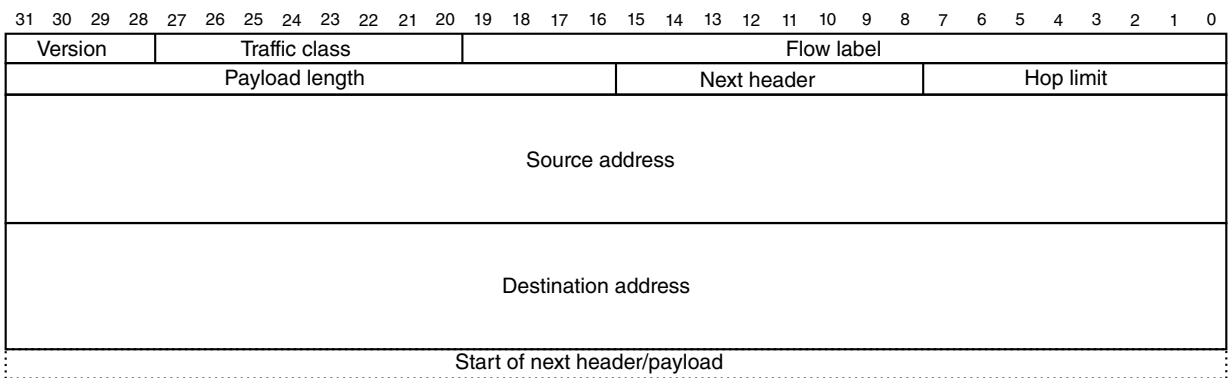

Figure 60-4. IPv6 header format

Table 60-8. IPv6 header fields

Field name	Description
Version	4-bit IP version information. 0x6 for all IPv6 frames.
Traffic class	8-bit field defining the traffic class.
Flow label	20-bit flow label identifying frames of the same flow.
Payload length	16-bit length of the datagram payload in bytes. It includes all octets following the IPv6 header.
Next header	Identifies the header that follows the IPv6 header. This can be the protocol header or any IPv6 defined extension header.

Table continues on the next page...

Table 60-8. IPv6 header fields (continued)

Field name	Description
Hop limit	Hop counter, decremented by one by each station that forwards the frame. If hop limit is 0 the frame must be discarded.
Source address	128-bit IPv6 source address.
Destination address	128-bit IPv6 destination address.

60.3.2.4 Internet Control Message Protocol (ICMP) datagram format

An internet control message protocol (ICMP) is found following the IP header, if the protocol identifier is 1. The ICMP datagram has a four-octet header followed by additional message data.

Table 60-9. ICMP header format

31 30 29 28	27 26 25 24	23 22 21 20	19 18 17 16	15 14 13 12	11 10 9 8	7 6 5 4	3 2 1 0
Type		Code		Checksum			
ICMP message data							

Table 60-10. IP header fields

Field name	Description
Type	8-bit type information
Code	8-bit code that is related to the message type
Checksum	16-bit one's complement checksum over the complete ICMP datagram

60.3.2.5 User Datagram Protocol (UDP) datagram format

A user datagram protocol header is found after the IP header, when the protocol identifier is 17.

The payload of the datagram is after the UDP header. The header byte order follows the conventions given for the IP header above.

Table 60-11. UDP header format

31 30 29 28	27 26 25 24	23 22 21 20	19 18 17 16	15 14 13 12	11 10 9 8	7 6 5 4	3 2 1 0
Source port				Destination port			
Length				Checksum			

Table 60-12. UDP header fields

Field name	Description
Source port	Source application port
Destination port	Destination application port
Length	Length of user data which immediately follows the header, including the UDP header (that is, minimum value is 8)
Checksum	Checksum over the complete datagram and some IP header information

60.3.2.6 TCP datagram format

A TCP header is found following the IP header, when the protocol identifier has a value of 6. The TCP payload immediately follows the TCP header.

Table 60-13. TCP header format

31 30 29 28	27 26 25 24	23 22 21 20	19 18 17 16	15 14 13 12	11 10 9 8	7 6 5 4	3 2 1 0
Source port				Destination port			
Sequence number							
Acknowledgement number							
Offset	Reserved		Flags	Window			
Checksum				Urgent pointer			
Options							

Table 60-14. TCP header fields

Field name	Description
Source port	Source application port
Destination port	Destination application port
Sequence number	Transmit sequence number
Ack. number	Receive sequence number
Offset	Data offset, which is number of 32-bit words within TCP header — if no options selected, defaults to value of 5
Flags	URG, ACK, PSH, RST, SYN, FIN flags
Window	TCP receive window size information
Checksum	Checksum over the complete datagram (TCP header and data) and IP header information
Options	Additional 32-bit words for protocol options

60.3.3 IEEE 1588 message formats

The following sections describe the IEEE 1588 message formats.

60.3.3.1 Transport encapsulation

The precision time protocol (PTP) datagrams are encapsulated in Ethernet frames using the UDP/IP transport mechanism, or optionally, with the newer 1588v2 directly in Ethernet frames (layer 2).

Typically, multicast addresses are used to allow efficient distribution of the synchronization messages.

60.3.3.1.1 UDP/IP

The 1588 messages (v1 and v2) can be transported using UDP/IP multicast messages.

The table below shows IP multicast groups defined for PTP. The table also shows their respective MAC layer multicast address mapping according to RFC 1112 (last three octets of IP follow the fixed value of 01-00-5E).

Table 60-15. UDP/IP multicast domains

Name	IP Address	MAC Address mapping
DefaultPTPdomain	224.0.1.129	01-00-5E-00-01-81
AlternatePTPdomain1	224.0.1.130	01-00-5E-00-01-82
AlternatePTPdomain2	224.0.1.131	01-00-5E-00-01-83
AlternatePTPdomain3	224.0.1.132	01-00-5E-00-01-84

Table 60-16. UDP port numbers

Message type	UDP port	Note
Event	319	Used for SYNC and DELAY_REQUEST messages
General	320	All other messages (for example, follow-up, delay-response)

60.3.3.1.2 Native Ethernet (PTPv2)

In addition to using UDP/IP frames, IEEE 1588v2 defines a native Ethernet frame format that uses ethertype = 0x88F7. The payload of the Ethernet frame immediately contains the PTP datagram, starting with the PTPv2 header.

Besides others, version 2 adds a peer delay mechanism to allow delay measurements between individual point-to-point links along a path over multiple nodes. The following multicast domains are also defined in PTPv2.

Table 60-17. PTPv2 multicast domains

Name	MAC address
Normal messages	01-1B-19-00-00-00
Peer delay messages	01-80-C2-00-00-0E

60.3.3.2 PTP header

All PTP frames contain a common header that determines the protocol version and the type of message, which defines the remaining content of the message.

All multi-octet fields are transmitted in big-endian order (the most significant byte is transmitted/received first).

The last four bits of versionPTP are at the same position (second byte) for PTPv1 and PTPv2 headers. This allows accurate identification by inspecting the first two bytes of the message.

60.3.3.2.1 PTPv1 header

Table 60-18. Common PTPv1 message header

Offset	Octets	Bits							
		7	6	5	4	3	2	1	0
0	2	versionPTP = 0x0001							
2	2	versionNetwork							
4	16	subdomain							
20	1	messageType

16	4	reserved							
20	10	sourcePortIdentity							
30	2	sequenceId							
32	1	control							
33	1	logMeanMessageInterval							

The type of message is encoded in the field messageId as follows:

Table 60-21. PTPv2 message type identification

messageId	Message name	Message
0x0	SYNC	Event message
0x1	DELAY_REQ	Event message
0x2	PATH_DELAY_REQ	Event message
0x3	PATH_DELAY_RESP	Event message
0x4–0x7	—	Reserved
0x8	FOLLOW_UP	General message
0x9	DELAY_RESP	General message

Table continues on the next page...

Table 60-21. PTPv2 message type identification (continued)

messageId	Message name	Message
0xa	PATH_DELAY_FOLLOW_UP	General message
0xb	ANNOUNCE	General message
0xc	SIGNALING	General message
0xd	MANAGEMENT	General message

The PTPv2 flags field contains further details on the type of message, especially if one-step or two-step implementations are used. The one- or two-step implementation is controlled by the TWO_STEP bit in the first octet of the flags field as shown below. Reserved bits are cleared.

Table 60-22. PTPv2 message flags field definitions

Bit	Name	Description
0	ALTERNATE_MASTER	See IEEE 1588 Clause 17.4
1	TWO_STEP	1 Two-step clock 0 One-step clock
2	UNICAST	1 Transport layer address uses a unicast destination address 0 Multicast is used
3	—	Reserved
4	—	Reserved
5	Profile specific	
6	Profile specific	
7	—	Reserved

60.3.4 MAC receive

The MAC receive engine performs the following tasks:

- Check frame framing
- Remove frame preamble and frame SFD field
- Discard frame based on frame destination address field
- Terminate pause frames
- Check frame length
- Remove payload padding if it exists

- Calculate and verify CRC-32
- Write received frames in the core receive FIFO

If the MAC is programmed to operate in half-duplex mode, it will also check if the frame is received with a collision.

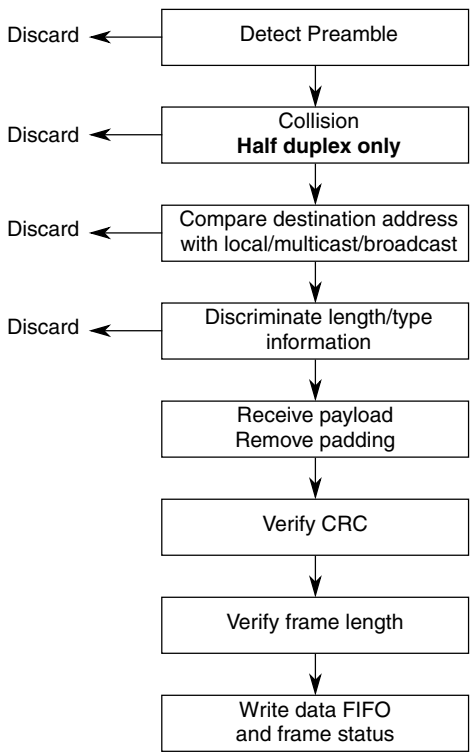

Figure 60-5. MAC receive flow

60.3.4.1 Collision detection in half-duplex mode

If the packet is received with a collision detected during reception of the first 64 bytes, the packet is discarded (if frame size was less than ~14 octets) or transmitted to the user application with an error and RxBD[CE] set.

60.3.4.2 Preamble processing

The IEEE 802.3 standard allows a maximum size of 56 bits (seven bytes) for the preamble, while the MAC core allows any preamble length, including zero length preamble.

The MAC core checks for the start frame delimiter (SFD) byte. If the next byte of the preamble, which is different from 0x55, is not 0xD5, the frame is discarded.

Although the IEEE specification dictates that the inner-packet gap should be at least 96 bits, the MAC core is designed to accept frames separated by only 64 10/100-Mbit/s operation (MII) bits.

The MAC core removes the preamble and SFD bytes.

60.3.4.3 MAC address check

The destination address bit 0 differentiates between multicast and unicast addresses.

- If bit 0 is 0, the MAC address is an individual (unicast) address.
- If bit 0 is 1, the MAC address defines a group (multicast) address.
- If all 48 bits of the MAC address are set, it indicates a broadcast address.

60.3.4.3.1 Unicast address check

If a unicast address is received, the destination MAC address is compared to the node MAC address programmed by the host in the PADDR1/2 registers.

If the destination address matches any of the programmed MAC addresses, the frame is accepted.

If Promiscuous mode is enabled (RCR[PROM] = 1) no address checking is performed and all unicast frames are accepted.

60.3.4.3.2 Multicast and unicast address resolution

The hash table algorithm used in the group and individual hash filtering operates as follows.

- The 48-bit destination address is mapped into one of 64 bits, represented by 64 bits in ENET*n*_GAUR/GALR (group address hash match) or ENET*n*_IAUR/IALR (individual address hash match).
- This mapping is performed by passing the 48-bit address through the on-chip 32-bit CRC generator and selecting the six most significant bits of the CRC-encoded result to generate a number between 0 and 63.
- The msb of the CRC result selects ENET*n*_GAUR (msb = 1) or ENET*n*_GALR (msb = 0).
- The five least significant bits of the hash result select the bit within the selected register.
- If the CRC generator selects a bit set in the hash table, the frame is accepted; else, it is rejected.

For example, if eight group addresses are stored in the hash table and random group addresses are received, the hash table prevents roughly 56/64 (or 87.5%) of the group address frames from reaching memory. Those that do reach memory must be further filtered by the processor to determine if they truly contain one of the eight desired addresses.

The effectiveness of the hash table declines as the number of addresses increases.

The user must initialize the hash table registers. Use this CRC32 polynomial to compute the hash:

- $FCS(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^{8} + x^{7} + x^{5} + x^{4} + x^{2} + x^{1} + 1$

If Promiscuous mode is enabled (ENET*n*_RCR[PROM] = 1) all unicast and multicast frames are accepted regardless of ENET*n*_GAUR/GALR and ENET*n*_IAUR/IALR settings.

60.3.4.3.3 Broadcast address reject

All broadcast frames are accepted if BC_REJ is cleared or ENET*n*_RCR[PROM] is set. If PROM is cleared when ENET*n*_RCR[BC_REJ] is set, all broadcast frames are rejected.

Table 60-23. Broadcast address reject programming

PROM	BC_REJ	Broadcast frames
0	0	Accepted
0	1	Rejected
1	0	Accepted
1	1	Accepted

60.3.4.3.4 Miss-bit implementation

For higher layer filtering purposes, RxBD[M] indicates an address miss when the MAC operates in promiscuous mode and accepts a frame that would otherwise be rejected.

If a group/individual hash or exact match does not occur and Promiscuous mode is enabled (RCR[PROM] = 1), the frame is accepted and the M bit is set in the buffer descriptor; otherwise, the frame is rejected.

This means the status bit is set in any of the following conditions during Promiscuous mode:

- A broadcast frame is received when BC_REJ is set

- A unicast is received that does not match either:
  - Node address (PALR[PADDR1] and PAUR[PADDR2])
  - Hash table for unicast (IAUR[IADDR1] and IALR[IADDR2])
- A multicast is received that does not match the GAUR[GADDR1] and GALR[GADDR2] hash table entries

60.3.4.4 Frame length/type verification: payload length check

If the length/type is less than 0x600 and NLC is set, the MAC checks the payload length and reports any error in the frame status word RCR[NLC] and interrupt bit EIR[PLR].

If the length/type is greater than or equal to 0x600, the MAC interprets the field as a type and no payload length check is performed.

The length check is performed on VLAN and stacked VLAN frames. If a padded frame is received, no length check can be performed due to the extended frame payload because padded frames can never have a payload length error.

60.3.4.5 Frame length/type verification: frame length check

When the receive frame length exceeds MAX_FL bytes, the BABR interrupt is generated and the RxBD[LG] bit is set.

The frame is not truncated unless the frame length exceeds the value programmed in ENET*n*_FTRL[TRUNC_FL]. If the frame is truncated, RxBD[TR] is set. In addition, a truncated frame always has the CRC error indication set (RxBD[CR]).

60.3.4.6 VLAN frames processing

VLAN frames have a length/type field set to 0x8100 immediately followed by a 16-Bit VLAN control information field.

VLAN-tagged frames are received as normal frames because the VLAN tag is not interpreted by the MAC function, and are pushed complete with the VLAN tag to the user application. If the length/type field of the VLAN-tagged frame, which is found four octets later in the frame, is less than 42, the padding is removed. In addition, the frame status word (RxBD[VLAN]) indicates that the current frame is VLAN tagged.

60.3.4.7 Pause frame termination

The receive engine terminates pause frames and does not transfer them to the receive FIFO. The quanta is extracted and sent to the MAC transmit path via a small internal clock rate decoupling asynchronous FIFO.

The quanta is written only if a correct CRC and frame length are detected by the control state machine. If not, the quanta is discarded and the MAC transmit path is not paused.

Valid pause frames are ignored if ENET*n*_RCR[FCE] is cleared and are forwarded to the client interface when ENET*n*_RCR[PAUFWD] is set.

60.3.4.8 CRC check

The CRC-32 field is checked and forwarded to the core FIFO interface if ENET*n*_RCR[CRCFWD] is cleared and ENET*n*_RCR[PADEN] is cleared. When CRCFWD is set (regardless of PADEN), the CRC-32 field is checked and terminated (not transmitted to the FIFO).

The CRC polynomial, as specified in the 802.3 standard, is:

- $FCS(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^{8} + x^{7} + x^{5} + x^{4} + x^{2} + x^{1} + 1$

The 32 bits of the CRC value are placed in the frame check sequence (FCS) field with the x^{31} term as right-most bit of the first octet. The CRC bits are thus received in the following order: x^{31}, x^{30},..., x^{1}, x^{0}.

If a CRC error is detected, the frame is marked invalid and RxBD[CR] is set.

60.3.4.9 Frame padding removal

When a frame is received with a payload length field set to less than 46 (42 for VLAN-tagged frames and 38 for frames with stacked VLANs), the zero padding can be removed before the frame is written into the data FIFO depending on the setting of ENET*n*_RCR[PADEN].

Note

If a frame is received with excess padding (in other words, the length field is set as mentioned above, but the frame has more than 64 octets) and padding removal is enabled, then the

padding is removed as normal and no error is reported if the frame is otherwise correct (for example: good CRC, less than maximum length, and no other error).

60.3.4.10 Frame classification (AVB)

To support protocols such as Audio Video Bridging (AVB, IEEE 802.1Qav), normal traffic is separated from time-sensitive traffic immediately at the application interface to allow storing them in different queues for further processing. For every frame received, a classification based on VLAN priority can be performed. When a frame is received, and it contains a VLAN tag, the priority is compared against the values set in the classification match registers (see RCMR register and the following figure.

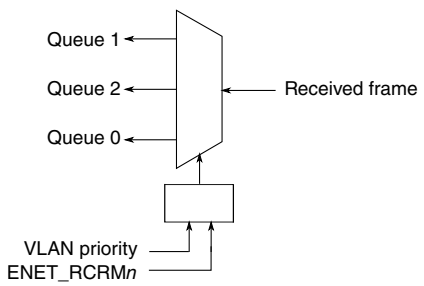

Figure 60-6. AVB frame classification

60.3.4.11 Receive flushing

RX flushing prevents frames in the RX FIFO from being blocked. Blocking can occur if the frame at the head of the RX FIFO cannot be forwarded because the ring it is associated with cannot accept it. This situation occurs when either the ring's RxBD[EMPTY] is not set or ENET_RDAR*n* is not set. When RX flushing is enabled, via QOS[RX_FLUSHn], the blocking frame will be flushed (discarded).

60.3.5 MAC transmit

Frame transmission starts when the transmit FIFO holds enough data.

After a transfer starts, the MAC transmit function performs the following tasks:

- Generates preamble and SFD field before frame transmission

- Generates XOFF pause frames if the receive FIFO reports a congestion or if ENET*n*_TCR[TFC_PAUSE] is set with ENET*n*_OPD[PAUSE_DUR] set to a non-zero value
- Generates XON pause frames if the receive FIFO congestion condition is cleared or if TFC_PAUSE is set with PAUSE_DUR cleared
- Suspends Ethernet frame transfer (XOFF) if a non-zero pause quanta is received from the MAC receive path
- Adds padding to the frame if required
- Calculates and appends CRC-32 to the transmitted frame
- Sends the frame with correct inter-packet gap (IPG) (deferring)

When the MAC is configured to operate in half-duplex mode, the following additional tasks are performed:

- Collision detection
- Frame retransmit after back-off timer expires

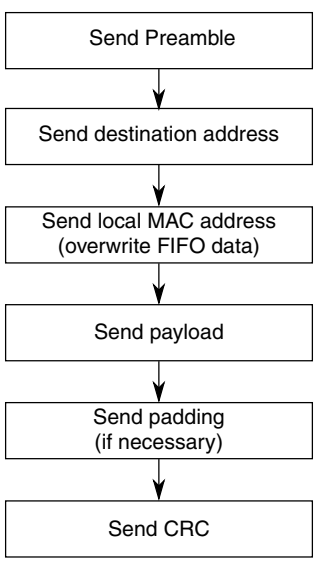

Figure 60-7. Frame transmit overview

60.3.5.1 Frame payload padding

The IEEE specification defines a minimum frame length of 64 bytes.

If the frame sent to the MAC from the user application has a size smaller than 60 bytes, the MAC automatically adds padding bytes (0x00) to comply with the Ethernet minimum frame length specification. Transmit padding is always performed and cannot be disabled.

If the MAC is not allowed to append a CRC (TxBD[TC] = 1), the user application is responsible for providing frames with a minimum length of 64 octets.

60.3.5.2 MAC address insertion

On each frame received from the core transmit FIFO interface, the source MAC address is either:

- Replaced by the address programmed in the PADDR1/2 fields (ENET*n*_TCR[ADDINS] = 1)
- Transparently forwarded to the Ethernet line (ENET*n*_TCR[ADDINS] = 0)

60.3.5.3 CRC-32 generation

The CRC-32 field is optionally generated and appended at the end of a frame.

The CRC polynomial, as specified in the 802.3 standard, is:

- $FCS(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^{8} + x^{7} + x^{5} + x^{4} + x^{2} + x^{1} + 1$

The 32 bits of the CRC value are placed in the FCS field so that the x^{31} term is the right-most bit of the first octet. The CRC bits are thus transmitted in the following order: x^{31}, x^{30},..., x^{1}, x^{0}.

60.3.5.4 Inter-packet gap (IPG)

In full-duplex mode, after frame transmission and before transmission of a new frame, an IPG (programmed in ENET*n*_TIPG) is maintained. The minimum IPG can be programmed between 8 and 26 byte-times (64 and 208 bit-times).

In half-duplex mode, the core constantly monitors the line. Actual transmission of the data onto the network occurs only if it has been idle for a 96-bit time period, and any back-off time requirements have been satisfied. In accordance with the standard, the core begins to measure the IPG from CRS/GMII_CRS de-assertion.

60.3.5.5 Collision detection and handling — half-duplex operation only

A collision occurs on a half-duplex network when concurrent transmissions from two or more nodes take place. During transmission, the core monitors the line condition and detects a collision when the PHY device asserts COL.

When the core detects a collision while transmitting, it stops transmission of the data and transmits a 32-bit jam pattern. If the collision is detected during the preamble or the SFD transmission, the jam pattern is transmitted after completing the SFD, which results in a minimum 96-bit fragment. The jam pattern is a fixed pattern that is not compared to the actual frame CRC, and has a very low probability (0.532) of having a jam pattern identical to the CRC.

If a collision occurs before transmission of 64 bytes (including preamble and SFD), the MAC core waits for the backoff period and retransmits the packet data (stored in a 64-byte re-transmit buffer) that has already been sent on the line. The backoff period is generated from a pseudo-random process (truncated binary exponential backoff).

If a collision occurs after transmission of 64 bytes (including preamble and SFD), the MAC discards the remainder of the frame, optionally sets the LC interrupt bit, and sets TxBD[LCE].

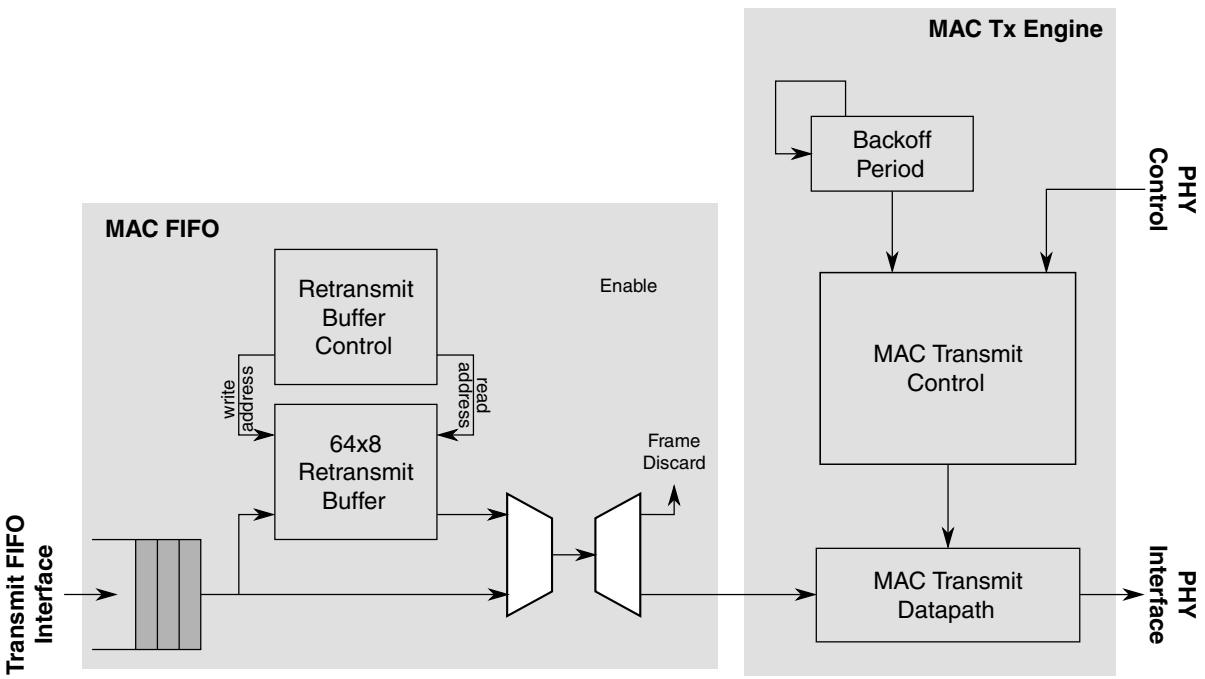

Figure 60-8. Packet re-transmit overview

The backoff time is represented by an integer multiple of slot times. One slot is equal to a 512-bit time period. The number of the delay slot times, before the n^{th} re-transmission attempt, is chosen as a uniformly-distributed random integer in the range:

- $0 < r < 2^k$
- $k = \min(n, N)$; where n is the number of retransmissions and $N = 10$

For example, after the first collision, the backoff period is 0 or 1 slot time. If a collision occurs on the first retransmission, the backoff period is 0, 1, 2, or 3, and so on.

The maximum backoff time (in 512-bit time slots) is limited by N = 10 as specified in the IEEE 802.3 standard.

If a collision occurs after 16 consecutive retransmissions, the core reports an excessive collision condition (ENET*n*_EIR[RL] interrupt field and TxBD[EE]) and discards the current packet from the FIFO.

In networks violating the standard requirements, a collision may occur after transmission of the first 64 bytes. In this case, the core stops the current packet transmission and discards the rest of the packet from the transmit FIFO. The core resumes transmission with the next packet available in the core transmit FIFO.

warning

Ethernet PHYs that support the SQE Test, or "heartbeat," feature must disable this feature. When this feature is enabled, the PHY asserts the collision signal after a frame is transmitted to indicate to the ENET that the PHY's collision logic is working. This may cause data corruption in the next frame from the ENET. This corrupted frame contains up to 21 zero bytes which start somewhere within the MAC destination address field. The ENET, however, will still generate a good FCS (CRC-32) but with corrupted data.

60.3.5.6 Rate limiting / traffic shaping support

The MAC-NET supports two methods to optimize frame traffic for either time-sensitive AVB frames (Class A and Class B) or best-effort non-AVB frames:

- Round-robin scheme
- Credit-based traffic shaping

To ensure that sufficient bandwidth is allocated for the AVB frames, the credit-based shaper must be used. Either method can be combined with a time-based shaper to ensure that a frame is always transmitted in its correct time slot.

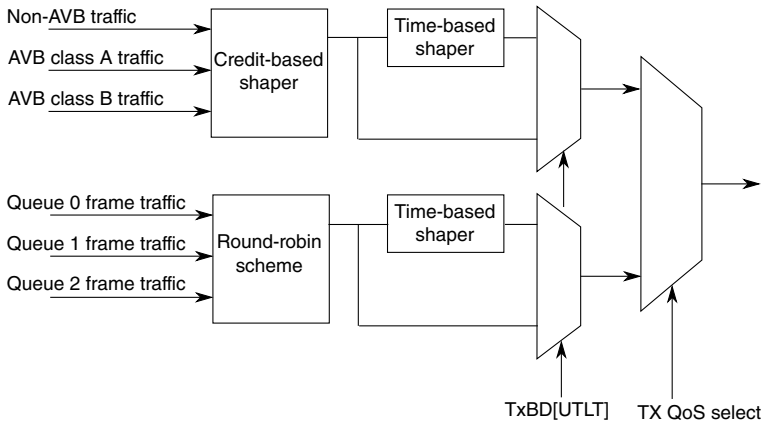

Figure 60-9. Transmit arbitration schemes

60.3.5.6.1 Round-robin policy

In the round-robin QoS scheme, each queue is given an equal opportunity to transmit one frame. For example, if queue *n* has a frame to transmit, the queue transmits its frame. After queue *n* has transmitted its frame, or if queue *n* does not have a frame to transmit, queue *n*+1 is then allowed to transmit its frame, and so on.

60.3.5.6.2 Credit-based shaper

The AVB credit based shaper acts independently, per class, to control the bandwidth distribution between normal traffic and time-sensitive traffic with respect to the total link bandwidth available. As per the IEEE 802.1Q, the maximum bandwidth distribution that can be allocated for the time-sensitive frames is 75%. The following example uses 70% for AVB frames and 30% for non-AVB frames:

Table 60-24. Bandwidth allocation example

AVB Class A	50%
AVB Class B	20%
non-AVB frames	30%
Total	100%

See DMACFG register for information on how to allocate bandwidth. The following figure shows how frame traffic is controlled within the MAC-NET core.

60.3.5.6.3 Time-based shaper

The time-based shaper enables the user to specify when a frame can be transmitted. It is always used in combination with either the round-robin scheme or the credit-based shaper. Use of the time-based shaper can ensure that frames are always transmitted in the correct time slot.

60.3.5.6.3.1 Time-based shaper example

Time-based shaping involves the following procedure:

1. Read the current value of the timer. See ATVR register and ATCR register.
2. Calculate the frame launch time and write this value to the TLT field of the frame's TxBD. See Enhanced transmit buffer descriptor.
3. Instruct the ENET to use the TLT by setting TxBD[UTLT].

The frame will be fetched and transmitted only if TxBD[TLT] is less than the current value of the timer. In other words, the timer must be past, that is, be greater than, the transmit launch time before the frame will be fetched and transmitted.

The transmit launch time must not be greater than the current value of ENET_ATVR + (0.5 × ENET_ATPER). This means the application cannot prepare frames with launch times beyond ENET_ATVR + (0.5 × ENET_ATPER). Because ENET_ATVR wraps, calculate TLT using the equation:

(ENET_ATVR + (0.5 × ENET_ATPER)) mod ENET_ATPER

For example, if ENET_ATPER is set to the recommended value of 1,000,000,000 ns (one second), then the user must not prepare future frames with launch times greater than (500,000,000 + ENET_ATVR).

As a specific example, if the current value of ENET_ATVR is 100,000, then you can prepare the following frames:

1. Frame 1 TxBD[TLT] = 100,000ns + 125,000ns
2. Frame 2 TxBD[TLT] = 100,000ns + 250,000ns
3. And so on.

60.3.6 Full-duplex flow control operation

Three conditions are handled by the core's flow control engine:

- Remote device congestion — The remote device connected to the same Ethernet segment as the core reports congestion and requests that the core stop sending data.

- Core FIFO congestion — When the core's receive FIFO reaches a user-programmable threshold (RX section empty), the core sends a pause frame back to the remote device requesting the data transfer to stop.
- Local device congestion — Any device connected to the core can request (typically, via the host processor) the remote device to stop transmitting data.

60.3.6.1 Remote device congestion

When the MAC transmit control gets a valid pause quanta from the receive path and if ENET*n*_RCR[FCE] is set, the MAC transmit logic:

- Completes the transfer of the current frame.
- Stops sending data for the amount of time specified by the pause quanta in 512 bit time increments.
- Sets ENET*n*_TCR[RFC_PAUSE].

Frame transfer resumes when the time specified by the quanta expires and if no new quanta value is received, or if a new pause frame with a quanta value set to 0x0000 is received. The MAC also resets RFC_PAUSE to zero.

If ENET*n*_RCR[FCE] cleared, the MAC ignores received pause frames.

Optionally and independent of ENET*n*_RCR[FCE], pause frames are forwarded to the client interface if PAUFWD is set.

60.3.6.2 Local device/FIFO congestion

The MAC transmit engine generates pause frames when the local receive FIFO is not able to receive more than a pre-defined number of words (FIFO programmable threshold) or when pause frame generation is requested by the local host processor.

- To generate a pause frame, the host processor sets ENET*n*_TCR[TFC_PAUSE]. A single pause frame is generated when the current frame transfer is completed and TFC_PAUSE is automatically cleared. Optionally, an interrupt is generated.

- An XOFF pause frame is generated when the receive FIFO asserts its section empty flag (internal). An XOFF pause frame is generated automatically, when the current frame transfer completes.
- An XON pause frame is generated when the receive FIFO deasserts its section empty flag (internal). An XON pause frame is generated automatically, when the current frame transfer completes.

When an XOFF pause frame is generated, the pause quanta (payload byte P1 and P2) is filled with the value programmed in ENET*n*_OPD[PAUSE_DUR].

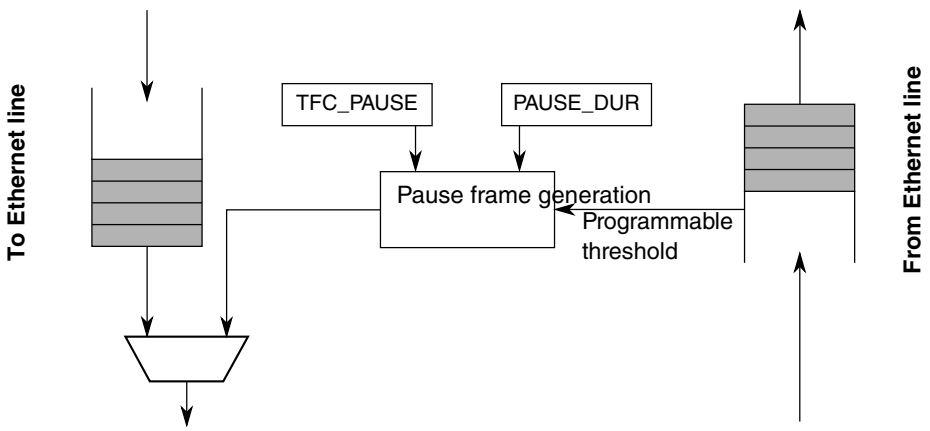

Figure 60-10. Pause frame generation overview

Note

Although the flow control mechanism should prevent any FIFO overflow on the MAC core receive path, the core receive FIFO is protected. When an overflow is detected on the receive FIFO, the current frame is truncated with an error indication set in the frame status word. The frame should subsequently be discarded by the user application.

60.3.7 IP accelerator functions

The following sections describe the IP accelerator functions.

60.3.7.1 Checksum calculation

The IP and ICMP, TCP, UDP checksums are calculated with one's complement arithmetic summing up 16-bit values.

- For ICMP, the checksum is calculated over the complete ICMP datagram, in other words without IP header.
- For TCP and UDP, the checksums contain the header and data sections and values from the IP header, which can be seen as a pseudo-header that is not actually present in the data stream.

Table 60-25. IPv4 pseudo-header for checksum calculation

31 30 29 28	27 26 25 24	23 22 21 20	19 18 17 16	15 14 13 12	11 10 9 8	7 6 5 4	3 2 1 0
Source address							
Destination address							
Zero		Protocol		TCP/UDP length			

Table 60-26. IPv6 pseudo-header for checksum calculation

31 30 29 28	27 26 25 24	23 22 21 20	19 18 17 16	15 14 13 12	11 10 9 8	7 6 5 4	3 2 1 0
Source address							
Destination address							
TCP/UDP length							
Zero						Next header	

The TCP/UDP length value is the length of the TCP or UDP datagram, which is equal to the payload of an IP datagram. It is derived by subtracting the IP header length from the complete IP datagram length that is given in the IP header (IPv4), or directly taken from the IP header (IPv6). The protocol field is the corresponding value from the IP header. The Zero fields are all zeroes.

For IPv6, the complete 128-bit addresses are considered. The next header value identifies the upper layer protocol as either TCP or UDP. It may differ from the next header value of the IPv6 header if extension headers are inserted before the protocol header.

The checksum calculation uses 16-bit words in network byte order: The first byte sent/received is the MSB, and the second byte sent/received is the LSB of the 16-bit value to add to the checksum. If the frame ends on an odd number of bytes, a zero byte is appended for checksum calculation only, and is not actually transmitted.

60.3.7.2 Additional padding processing

According to IEEE 802.3, any Ethernet frame must have a minimum length of 64 octets.

The MAC usually removes padding on receive when a frame with length information is received. Because IP frames have a type value instead of length, the MAC does not remove padding for short IP frames, as it is not aware of the frame contents.

The IP accelerator function can be configured to remove the Ethernet padding bytes that might follow the IP datagram.

On transmit, the MAC automatically adds padding as necessary to fill any frame to a 64-byte length.

60.3.7.3 32-bit Ethernet payload alignment

The data FIFOs allow inserting two additional arbitrary bytes in front of a frame. This extends the 14-byte Ethernet header to a 16-byte header, which leads to alignment of the Ethernet payload, following the Ethernet header, on a 32-bit boundary.

This function can be enabled for transmit and receive independently with the corresponding SHIFT16 bits in the ENET*n*_TACC and ENET*n*_RACC registers.

When enabled, the valid frame data is arranged as shown in Table 60-27.

Table 60-27. 64-bit interface data structure with SHIFT16 enabled

63 56	55 48	47 40	39 32	31 24	23 16	15 8	7 0
Byte 5	Byte 4	Byte 3	Byte 2	Byte 1	Byte 0	Any value	Any value
Byte 13	Byte 12	Byte 11	Byte 10	Byte 9	Byte 8	Byte 7	Byte 6
...							

60.3.7.3.1 Receive processing

When ENET*n*_RACC[SHIFT16] is set, each frame is received with two additional bytes in front of the frame.

The user application must ignore these first two bytes and find the first byte of the frame in bits 23–16 of the first word from the RX FIFO.

Note

SHIFT16 must be set during initialization and kept set during the complete operation, because it influences the FIFO write behavior.

60.3.7.3.2 Transmit processing

When ENET*n*_TACC[SHIFT16] is set, the first two bytes of the first word written (bits 15–0) are discarded immediately by the FIFO write logic.

The SHIFT16 bit can be enabled/disabled for each frame individually if required, but can be changed only between frames.

60.3.7.4 Received frame discard

Because the receive FIFO must be operated in store and forward mode (ENET*n*_RSFL cleared), received frames can be discarded based on the following errors:

- The MAC function receives the frame with an error:
  - The frame has an invalid payload length
  - Frame length is greater than MAX_FL
  - Frame received with a CRC-32 error
  - Frame truncated due to receive FIFO overflow
  - Frame is corrupted as PHY signaled an error (RX_ERR asserted during reception)
- An IP frame is detected and the IP header checksum is wrong
- An IP frame with a valid IP header and a valid IP header checksum is detected, the protocol is known but the protocol-specific checksum is wrong

If one of the errors occurs and the IP accelerator function is configured to discard frames (ENET*n*_RACC), the frame is automatically discarded. Statistics are maintained normally and are not affected by this discard function.

60.3.7.5 IPv4 fragments

When an IPv4 IP fragment frame is received, only the IP header is inspected and its checksum verified. 32-bit alignment operates the same way on fragments as it does on normal IP frames, as specified above.

The IP fragment frame payload is not inspected for any protocol headers. As such, a protocol header would only exist in the very first fragment. To assist in protocol-specific checksum verification, the one's-complement sum is calculated on the IP payload (all bytes following the IP header) and provided with the frame status word.

The frame fragment status field (RxBD[FRAG]) is set to indicate a fragment reception, and the one's-complement sum of the IP payload is available in RxBD[Payload checksum].

Note

After all fragments have been received and reassembled, the application software can take advantage of the payload checksum delivered with the frame's status word to calculate the protocol-specific checksum of the datagram.

For example, if a TCP payload is delivered by multiple IP fragments, the application software can calculate the pseudo-header checksum value from the first fragment, and add the payload checksums delivered with the status for all fragments to verify the TCP datagram checksum.

60.3.7.6 IPv6 support

The following sections describe the IPv6 support.

60.3.7.6.1 Receive processing

An Ethernet frame of type 0x86DD identifies an IP Version 6 frame (IPv6) frame. If an IPv6 frame is received, the first IP header is inspected (first ten words), which is available in every IPv6 frame.

If the receive SHIFT16 function is enabled, the IP header is aligned on a 32-bit boundary allowing more efficient processing (see 32-bit Ethernet payload alignment).

For TCP and UDP datagrams, the pseudo-header checksum calculation is performed and verified.

To assist in protocol-specific checksum verification, the one's-complement sum is always calculated on the IP payload (all bytes following the IP header) and provided with the frame status word. For example, if extension headers were present, their sums can be subtracted in software from the checksum to isolate the TCP/UDP datagram checksum, if required.

60.3.7.6.2 Transmit processing

For IPv6 transmission, the SHIFT16 function is supported to process 32-bit aligned datagrams.

IPv6 has no IP header checksum; therefore, the IP checksum insertion configuration is ignored.

The protocol checksum is inserted only if the next header of the IP header is a known protocol (TCP, UDP, or ICMP). If a known protocol is detected, the checksum over all bytes following the IP header is calculated and inserted in the correct position.

The pseudo-header checksum calculation is performed for TCP and UDP datagrams accordingly.

60.3.8 IEEE 1588 functions

To allow for IEEE 1588 or similar time synchronization protocol implementations, the MAC is combined with a time-stamping module to support precise time-stamping of incoming and outgoing frames. Set ENET*n*_ECR[EN1588] to enable 1588 support.

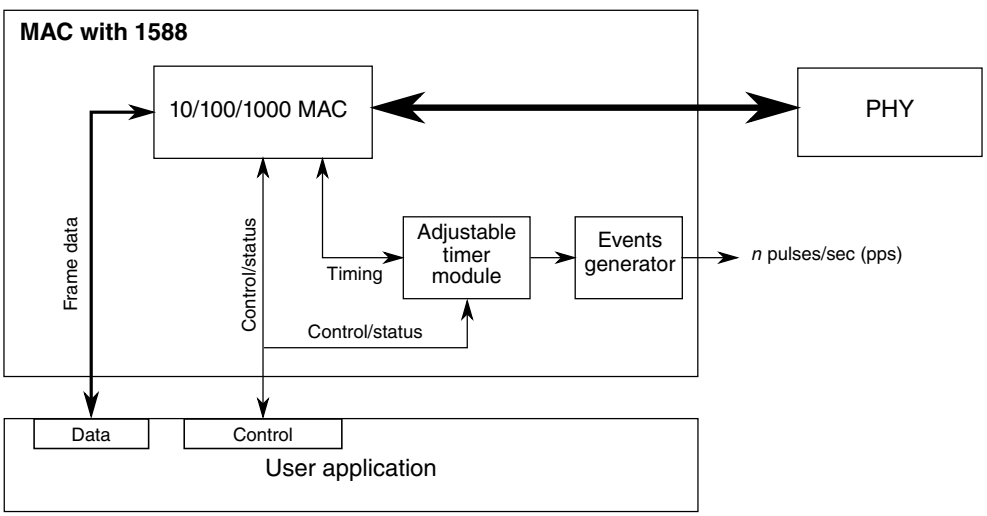

Figure 60-11. IEEE 1588 functions overview

60.3.8.1 Adjustable timer module

The adjustable timer module (TSM) implements the free-running counter (FRC), which generates the timestamps. The FRC operates with the time-stamping clock, which can be set to any value depending on your system requirements.

Through dedicated correction logic, the timer can be adjusted to allow synchronization to a remote leader and provide a synchronized timing reference to the local system. The timer can be configured to cause an interrupt after a fixed time period, to allow synchronization of software timers or perform other synchronized system functions.

The timer is typically used to implement a period of one second; hence, its value ranges from 0 to (1×10^9)-1. The period event can trigger an interrupt, and software can maintain the seconds and hours time values as necessary.

60.3.8.1.1 Adjustable timer implementation

The adjustable timer consists of a programmable counter/accumulator and a correction counter. The periods of both counters and their increment rates are freely configurable, allowing very fine tuning of the timer. See Timer synchronization for multi-port implementations, for external clock input options.

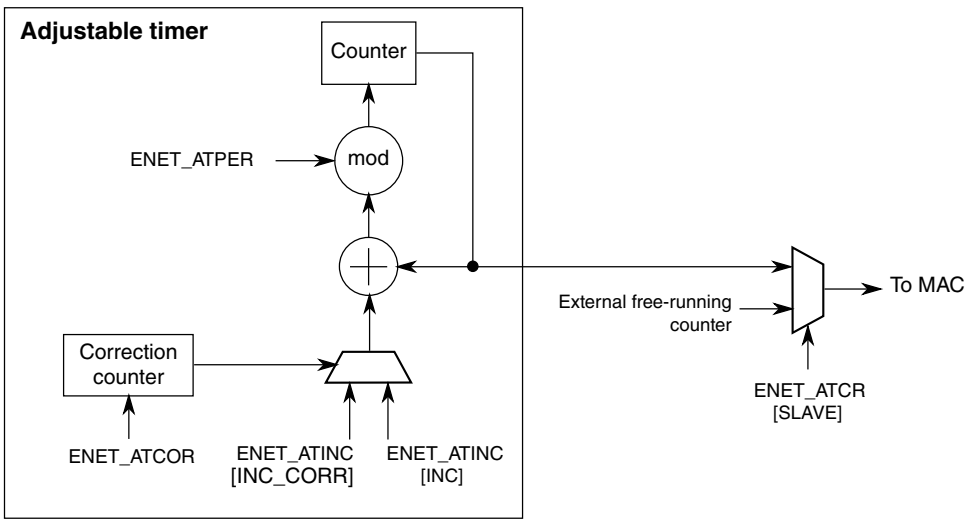

Figure 60-12. Adjustable timer implementation detail

The counter produces the current time. During each time-stamping clock cycle, a constant value is added to the current time as programmed in ENET*n*_ATINC. The value depends on the chosen time-stamping clock frequency. For example, if it operates at 125 MHz, setting the increment to eight represents 8 ns.

The period, configured in ENET*n*_ATPER, defines the modulo when the counter wraps. In a typical implementation, the period is set to 1×10^9 so that the counter wraps every second, and hence all timestamps represent the absolute nanoseconds within the one second period. When the period is reached, the counter wraps to start again respecting the period modulo. This means it does not necessarily start from zero, but instead the counter is loaded with the value (Current + Inc $-(1 \times 10^9)$), assuming the period is set to 1×10^9.

The correction counter operates fully independently, and increments by one with each time-stamping clock cycle. When it reaches the value configured in ENET*n*_ATCOR, it restarts and instructs the timer once to increment by the correction value, instead of the normal value.

The normal and correction increments are configured in ENET*n*_ATINC. To speed up the timer, set the correction increment more than the normal increment value. To slow down the timer, set the correction increment less than the normal increment value.

The correction counter only defines the distance of the corrective actions, not the amount. This allows very fine corrections and low jitter (in the range of 1 ns) independent of the chosen clock frequency.

By enabling follower mode (ENET*n*_ATCR[SLAVE] = 1), the timer is ignored and the current time is externally provided from one of the external modules. See the Chip Configuration details for which clock source is used. This is useful if multiple modules within the system must operate from a single timer (see Timer synchronization for multi-port implementations). When follower mode is enabled, you still must set ENET*n*_ATINC[INC] to the value of the leader, since it is used for internal comparisons.

60.3.8.2 Timer synchronization for multi-port implementations

Additional inputs are available to provide a timer value for all time-stamping functions. This is necessary to synchronize the two MACs to a single reference timer. See the Chip Configuration details for available clock inputs to the time-stampimg functions. To operate the MAC in follower mode, ENET*n*_ATCR[SLAVE] disables the internal adjustable timer and uses the externally provided timer.

60.3.8.3 Transmit timestamping

Only 1588 event frames need to be time-stamped on transmit. The client application (for example, the MAC driver) should detect 1588 event frames and set TxBD[TS] together with the frame.

If TxBD[TS] is set, the MAC records the timestamp for the frame in ENET*n*_ATSTMP. ENET*n*_EIR[TS_AVAIL] is set to indicate that a new timestamp is available.

Software implements a handshaking procedure by setting TxBD[TS] when it transmits the frame for which a timestamp is needed, and then waits for ENET*n*_EIR[TS_AVAIL] to determine when the timestamp is available. The timestamp is then read from ENET*n*_ATSTMP. This is done for all event frames. Other frames do not use TxBD[TS] and, therefore, do not interfere with the timestamp capture.

60.3.8.4 Receive timestamping

When a frame is received, the MAC latches the value of the timer when the frame's start of frame delimiter (SFD) field is detected, and provides the captured timestamp on RxBD[1588 timestamp]. This is done for all received frames.

60.3.8.5 Time synchronization

The adjustable timer module is available to synchronize the local clock of a node to a remote leader. It implements a free running 32-bit counter, and also contains an additional correction counter.

The correction counter increases or decreases the rate of the free running counter, enabling very fine granular changes of the timer for synchronization, yet adding only very low jitter when performing corrections.

The application software implements, in a follower scenario, the required control algorithm, setting the correction to compensate for local oscillator drifts and locking the timer to the remote leader clock on the network.

The timer and all timestamp-related information should be configured to show the true nanoseconds value of a second (in other words, the timer is configured to have a period of one second). Hence, the values range from 0 to (1×10^9)–1. In this application, the seconds counter is implemented in software using an interrupt function that is executed when the nanoseconds counter wraps at 1×10^9.

60.3.8.6 Input capture and output compare

The input capture and output compare block can be used to provide precise hardware timing for input and output events.

60.3.8.6.1 Input capture

The TCCR*n* capture registers latch the time value when the corresponding external event occurs. An event can be a rising-, falling-, or either-edge of one of the 1588_TMR*n* signals. An event will cause the corresponding TCSR*n*[TF] timer flag to be set, indicating that an input capture has occurred. If the corresponding interrupt is enabled with the TCSR*n*[TIE] field, an interrupt can be generated.

60.3.8.6.2 Output compare

The TCCR*n* compare registers are loaded with the time at which the corresponding event should occur. When the ENET free-running counter value matches the output compare reference value in the TCCR*n* register, the corresponding flag, TCSR*n*[TF], is set, indicating that an output compare has occurred. The corresponding interrupt, if enabled by TCSR*n*[TIE], will be generated.The corresponding 1588_TMR*n* output signal will be asserted according to TCSR*n*[TMODE].

NOTE

If TCSR*n*[TMODE] is set to 10X1b or 1010b then the timer output pin toggle-on-overflow will occur only when PINPER, PEREN, and EN bits of the ATCR register are one.

60.3.8.6.3 DMA requests

A DMA request can be enabled by setting TCSR*n*[TDRE]. The corresponding DMA request is generated when the TCSR*n*[TF] timer flag is set. When the DMA has completed, the corresponding TCSRn[TF] flag is cleared.

60.3.9 FIFO thresholds

The core FIFO thresholds are fully programmable to dynamically change the FIFO operation.

For example, store and forward transfer can be enabled by a simple change in the FIFO threshold registers.

The thresholds are defined in 64-bit words.

The receive and transmit FIFOs both have a depth of 1024 words.

60.3.9.1 Receive FIFO

Four programmable thresholds are available, which can be set to any value to control the core operation as follows.

Table 60-28. Receive FIFO thresholds definition

Register	Description
ENET*n*_RSFL [RX_SECTION_FULL]	When the FIFO level reaches the ENET*n*_RSFL value, the MAC status signal is asserted to indicate that data is available in the receive FIFO (cut-through operation). Once asserted, if the FIFO empties below the threshold set with ENET*n*_RAEM and if the end-of-frame is not yet stored in the FIFO, the status signal is deasserted again.

Table continues on the next page...

Table 60-28. Receive FIFO thresholds definition (continued)

Register	Description
	If a frame has a size smaller than the threshold (in other words, an end-of-frame is available for the frame), the status is also asserted. To enable store and forward on the receive path, clear ENET*n*_RSFL. The MAC status signal is asserted only when a complete frame is stored in the receive FIFO. When programming a non-zero value to ENET*n*_RSFL (cut-through operation) it should be greater than ENET*n*_RAEM.
ENET*n*_RAEM [RX_ALMOST_EMPTY]	When the FIFO level reaches the ENET*n*_RAEM value and the end-of-frame has not been received, the core receive read control stops the FIFO read (and subsequently stops transferring data to the MAC client application). It continues to deliver the frame, if again more data than the threshold or the end-of-frame is available in the FIFO. Set ENET*n*_RAEM to a minimum of four.
ENET*n*_RAFL [RX_ALMOST_FULL]	When the FIFO level approaches the maximum and there is no more space remaining for at least ENETn_RAFL number of words, the MAC control logic stops writing data in the FIFO and truncates the receive frame to avoid FIFO overflow. The corresponding error status is set when the frame is delivered to the application. Set ENET*n*_RAFL to a minimum of 4.
ENET*n*_RSEM [RX_SECTION_EMPTY]	When the FIFO level reaches the ENET*n*_RSEM value, an indication is sent to the MAC transmit logic, which generates an XOFF pause frame. This indicates FIFO congestion to the remote Ethernet client. When the FIFO level goes below the value programmed in ENET*n*_RSEM, an indication is sent to the MAC transmit logic, which generates an XON pause frame. This indicates the FIFO congestion is cleared to the remote Ethernet client. Clearing ENET*n*_RSEM disables any pause frame generation.

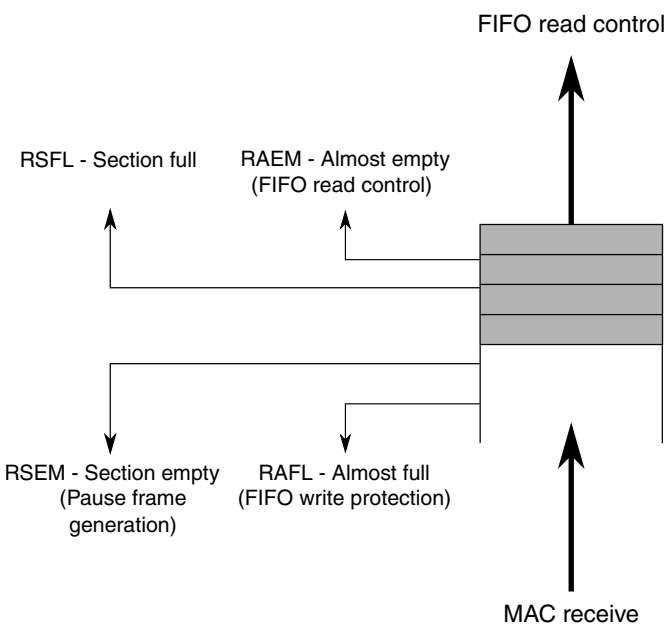

Figure 60-13. Receive FIFO overview

60.3.9.2 Transmit FIFO

Four programmable thresholds are available which control the core operation as described below.

Table 60-29. Transmit FIFO thresholds definition

Register	Description
ENET*n*_TAEM [TX_ALMOST _EMPTY]	When the FIFO level reaches the ENET*n*_TAEM value and no end-of-frame is available for the frame, the MAC transmit logic avoids a FIFO underflow by stopping FIFO reads and transmitting the Ethernet frame with an MII error indication. Set ENET*n*_TAEM to a minimum of 4.
ENET*n*_TAFL [TX_ALMOST _FULL]	When the FIFO level approaches the maximum, so that there is no more space for at least ENET*n*_TAFL number of words, the MAC deasserts its control signal to the application. If the application does not react on this signal, the FIFO write control logic avoids FIFO overflow by truncating the current frame and setting the error status. As a result, the frame is transmitted with an GMII/MII error indication. Set ENET*n*_TAFL to a minimum of 4. Larger values allow more latency for the application to react on the MAC control signal deassertion, before the frame is truncated. A typical setting is 8, which offers 3–4 clock cycles of latency to the application to react on the MAC control signal deassertion.
ENET*n*_TSEM [TX_SECTION _EMPTY]	When the FIFO level reaches the ENET*n*_TSEM value, a MAC status signal is deasserted to indicate that the transmit FIFO is getting full. This gives the ENET module an indication to slow or stop its write transaction to avoid a buffer overflow. This is a pure indication function to the application. It has no effect within the MAC. When ENET*n*_TSEM is 0, the signal is never deasserted.
ENET*n*_TFWR	When the FIFO level reaches the ENET*n*_TFWR value and when STRFWD is cleared, the MAC transmit control logic starts frame transmission before the end-of-frame is available in the FIFO (cut-through operation). If a complete frame has a size smaller than the ENET*n*_TFWR threshold, the MAC also transmits the frame to the line. To enable store and forward on the transmit path, set STRFWD. In this case, the MAC starts to transmit data only when a complete frame is stored in the transmit FIFO.

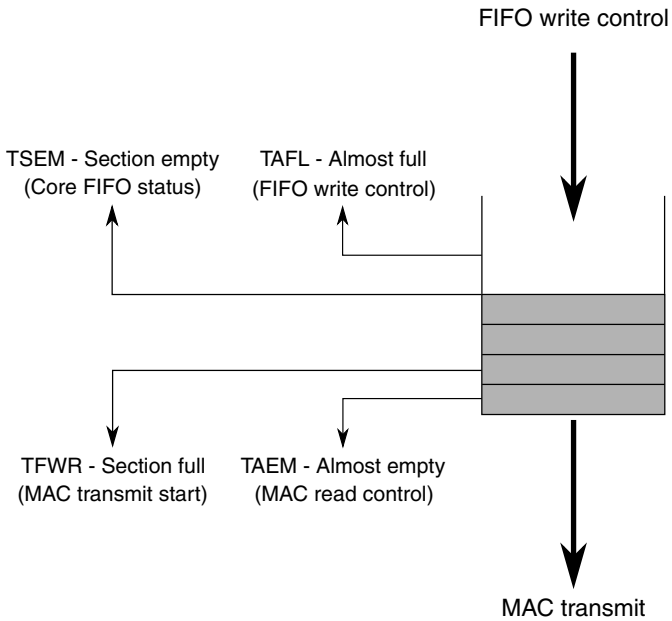

Figure 60-14. Transmit FIFO overview

60.3.10 Internal loopback option

The core implements internal loopback option. To use internal loopback mode, the RX clock must be provided externally at the RGMII_RCK pin of the PHY interface. The loopback mode is controlled by the following ENET*n*_RCR register field:

Table 60-30. Loopback option

Register field	Description
LOOP	Internal MII loopback. The MAC transmit is returned to the MAC receive. No data is transmitted to the external interfaces. In MII internal loopback, MII_TXCLK and MII_RXCLK must be provided with a clock signal (2.5 MHz for 10 Mbit/s, and 25 MHz for 100 Mbit/s))

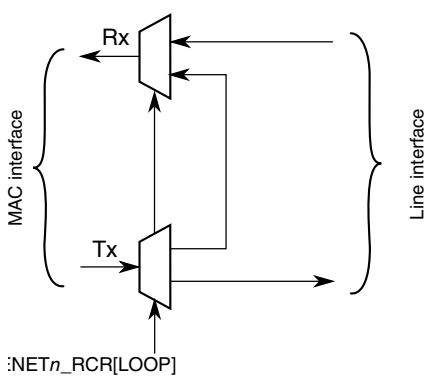

Figure 60-15. Loopback option

60.3.11 Legacy buffer descriptors

To support the Ethernet controller on previous chips, legacy FEC buffer descriptors are available. To enable legacy support, write 0 to ENET*n*_ECR[1588EN].

NOTE

- Legacy buffer descriptors are used in single-ring mode, that is, when DMA*n*CFG[DMA_CLASS_EN] are zero. In multi-ring mode, legacy TxBDs are used only with the round-robin scheme.
- The legacy buffer descriptor tables show the byte order for little-endian chips. ECR[DBSWP] must be set to 1 after reset to enable little-endian mode.

60.3.11.1 Legacy receive buffer descriptor

The following table shows the legacy FEC receive buffer descriptor. Table 60-34 contains the descriptions for each field.

Table 60-31. Legacy FEC receive buffer descriptor (RxBD)

	Byte 1								Byte 0							
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Offset + 0	Data length															
Offset + 2	E	RO1	W	RO2	L	—	—	M	BC	MC	LG	NO	—	CR	OV	TR
Offset + 4	Rx data buffer pointer — low halfword															
Offset + 6	Rx data buffer pointer — high halfword															

60.3.11.2 Legacy transmit buffer descriptor

The following table shows the legacy FEC transmit buffer descriptor. Table 60-36 contains the descriptions for each field.

Table 60-32. Legacy FEC transmit buffer descriptor (TxBD)

	Byte 1								Byte 0

Offset + 6	Tx Data Buffer Pointer — high halfword

1. This field is not supported by the uDMA.

60.3.12 Enhanced buffer descriptors

This section provides a description of the enhanced operation of the driver/uDMA via the buffer descriptors.

It is followed by a detailed description of the receive and transmit descriptor fields. To enable the enhanced features, set ENET*n*_ECR[1588EN].

NOTE

The enhanced buffer descriptor tables show the byte order for little-endian chips. ECR[DBSWP] must be set to 1 after reset to enable little-endian mode.

60.3.12.1 Enhanced receive buffer descriptor

The following table shows the enhanced uDMA receive buffer descriptor. Table 60-34 contains the descriptions for each field.

Table 60-33. Enhanced uDMA receive buffer descriptor (RxBD)

	Byte 1								Byte 0

Table 60-34. Receive buffer descriptor field definitions

Word	Field	Description
Offset + 0	15–0 Data Length	Data length. Written by the MAC. Data length is the number of octets written by the MAC into this BD's data buffer if L is cleared (the value is equal to EMRBR), or the length of the frame including CRC if L is set. It is written by the MAC once as the BD is closed.
Offset + 2	15 E	Empty. Written by the MAC (= 0) and user (= 1). 0 The data buffer associated with this BD is filled with received data, or data reception has aborted due to an error condition. The status and length fields have been updated as required. 1 The data buffer associated with this BD is empty, or reception is currently in progress.
Offset + 2	14 RO1	Receive software ownership. This field is reserved for use by software. This read/write field is not modified by hardware, nor does its value affect hardware.
Offset + 2	13 W	Wrap. Written by user. 0 The next buffer descriptor is found in the consecutive location. 1 The next buffer descriptor is found at the location defined in ENET*n*_RDSR.
Offset + 2	12 RO2	Receive software ownership. This field is reserved for use by software. This read/write field is not modified by hardware, nor does its value affect hardware.
Offset + 2	11 L	Last in frame. Written by the uDMA. 0 The buffer is not the last in a frame. 1 The buffer is the last in a frame.
Offset + 2	10–9	Reserved, must be cleared.
Offset + 2	8 M	Miss. Written by the MAC. This field is set by the MAC for frames accepted in promiscuous mode, but flagged as a miss by the internal address recognition. Therefore, while in promiscuous mode, you can use the this field to quickly determine whether the frame was destined to this station. This field is valid only if the L and PROM bits are set. 0 The frame was received because of an address recognition hit. 1 The frame was received because of promiscuous mode. The information needed for this field comes from the promiscuous_miss(ff_rx_err_stat[26]) sideband signal.
Offset + 2	7 BC	Set if the DA is broadcast (FFFF_FFFF_FFFF).
Offset + 2	6 MC	Set if the DA is multicast and not BC.
Offset + 2	5 LG	Receive frame length violation. Written by the MAC. A frame length greater than RCR[MAX_FL] was recognized. This field is valid only if the L field is set. The receive data is not altered in any way unless the length exceeds TRUNC_FL bytes.

Table continues on the next page...

Table 60-34. Receive buffer descriptor field definitions (continued)

Word	Field	Description
Offset + 2	4 NO	Receive non-octet aligned frame. Written by the MAC. A frame that contained a number of bits not divisible by 8 was received, and the CRC check that occurred at the preceding byte boundary generated an error or a PHY error occurred. This field is valid only if the L field is set. If this field is set, the CR field is not set.
Offset + 2	3	Reserved, must be cleared.
Offset + 2	2 CR	Receive CRC or frame error. Written by the MAC. This frame contains a PHY or CRC error and is an integral number of octets in length. This field is valid only if the L field is set.
Offset + 2	1 OV	Overrun. Written by the MAC. A receive FIFO overrun occurred during frame reception. If this field is set, the other status fields, M, LG, NO, and CR, lose their normal meaning and are zero. This field is valid only if the L field is set.
Offset + 2	0 TR	Set if the receive frame is truncated (frame length >TRUNC_FL). If the TR field is set, the frame must be discarded and the other error fields must be ignored because they may be incorrect.
Offset + 4	15–0 Data buffer pointer low	Receive data buffer pointer, low halfword
0ffset + 6	15–0 Data buffer pointer high	Receive data buffer pointer, high halfword[1]
Offset + 8	15–13 VPCP	VLAN priority code point. This field is written by the uDMA to indicate the frame priority level. Valid values are from 0 (best effort) to 7 (highest). This value can be used to prioritize different classes of traffic (e.g., voice, video, data). This field is only valid if the L field is set.
Offset + 8	12–6	Reserved, must be cleared.
Offset + 8	5 ICE	IP header checksum error. This is an accelerator option. This field is written by the uDMA. Set when either a non-IP frame is received or the IP header checksum was invalid. An IP frame with less than 3 bytes of payload is considered to be an invalid IP frame. This field is only valid if the L field is set.
Offset + 8	4 PCR	Protocol checksum error. This is an accelerator option. This field is written by the uDMA. Set when the checksum of the protocol is invalid or an unknown protocol is found and checksumming could not be performed. This field is only valid if the L field is set.
Offset + 8	3	Reserved, must be cleared.
Offset + 8	2 VLAN	VLAN. This is an accelerator option. This field is written by the uDMA. It means that the frame has a VLAN tag. This field is valid only if the L field is set.
Offset + 8	1 IPV6	IPV6 Frame. This field is written by the uDMA. This field indicates that the frame has an IPv6 frame type. If this field is not set it means that an IPv4 or other protocol frame was received. This field is valid only if the L field is set.
Offset + 8	0 FRAG	IPv4 Fragment. This is an accelerator option. This field is written by the uDMA. It indicates that the frame is an IPv4 fragment frame. This field is only valid when the L field is set.
Offset + A	15 ME	MAC error. This field is written by the uDMA. This field means that the frame stored in the system memory was received with an error (typically, a receive FIFO overflow). This field is only valid when the L field is set.
Offset + A	14–11	Reserved, must be cleared.
Offset + A	10 PE	PHY Error. This field is written by the uDMA. Set to "1" when the frame was received with an Error character on the PHY interface. The frame is invalid. This field is valid only when the L field is set.

Table continues on the next page...

Table 60-34. Receive buffer descriptor field definitions (continued)

Word	Field	Description
Offset + A	9 CE	Collision. This field is written by the uDMA. Set when the frame was received with a collision detected during reception. The frame is invalid and sent to the user application. This field is valid only when the L field is set.
Offset + A	8 UC	Unicast. This field is written by the uDMA, and means that the frame is unicast. This field is valid regardless of whether the L field is set.
Offset + A	7 INT	Generate RXB/RXF interrupt. This field is set by the user to indicate that the uDMA is to generate an interrupt on the *dma_int_rxb* / *dma_int_rxfevent*.
Offset + A	6–0	Reserved, must be cleared.
Offset + C	15–0 Payload checksum	Internet payload checksum. This is an accelerator option. It is the one's complement sum of the payload section of the IP frame. The sum is calculated over all data following the IP header until the end of the IP payload. This field is valid only when the L field is set.
Offset + E	15–11 Header length	Header length. This is an accelerator option. This field is written by the uDMA. This field is the sum of 32-bit words found within the IP and its following protocol headers. If an IP datagram with an unknown protocol is found, then the value is the length of the IP header. If no IP frame or an erroneous IP header is found, the value is 0. The following values are minimum values if no header options exist in the respective headers: • ICMP/IP: 6 (5 IP header, 1 ICMP header) • UDP/IP: 7 (5 IP header, 2 UDP header) • TCP/IP: 10 (5 IP header, 5 TCP header) This field is only valid if the L field is set.
Offset + E	10–8	Reserved, must be cleared.
Offset + E	7–0 Protocol type	Protocol type. This is an accelerator option. The 8-bit protocol field found within the IP header of the frame. It is valid only when ICE is cleared. This field is valid only when the L field is set.
Offset + 10	15–0	Reserved, must be cleared.
Offset + 12	15 BDU	Last buffer descriptor update done. Indicates that the last BD data has been updated by uDMA. This field is written by the user (=0) and uDMA (=1).
Offset + 12	14–0	Reserved, must be cleared.
Offset + 14	15–0 1588 timestamp	This value is written by the uDMA. It is only valid if the L field is set.
Offset + 16		
Offset + 18 – Offset + 1E	15–0	Reserved, must be cleared.

1. The receive buffer pointer, containing the address of the associated data buffer, must always be evenly divisible by 64. The buffer must reside in memory external to the MAC. The Ethernet controller never modifies this value.

60.3.12.2 Enhanced transmit buffer descriptor

Table 60-35. Enhanced transmit buffer descriptor (TxBD)

	Byte 1								Byte 0							
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 60-36. Enhanced transmit buffer descriptor field definitions

Word	Field	Description
Offset + 0	15–0 Data Length	Data length, written by user. Data length is the number of octets the MAC should transmit from this BD's data buffer. It is never modified by the MAC.
Offset + 2	15 R	Ready. Written by the MAC and you. 0 The data buffer associated with this BD is not ready for transmission. You are free to manipulate this BD or its associated data buffer. The MAC clears this field after the buffer has been transmitted or after an error condition is encountered. 1 The data buffer, prepared for transmission by you, has not been transmitted or currently transmits. You may write no fields of this BD after this field is set.
Offset + 2	14 TO1	Transmit software ownership. This field is reserved for software use. This read/write field is not modified by hardware and its value does not affect hardware.
Offset + 2	13 W	Wrap. Written by user. 0 The next buffer descriptor is found in the consecutive location 1 The next buffer descriptor is found at the location defined in ETDSR.
Offset + 2	12 TO2	Transmit software ownership. This field is reserved for use by software. This read/write field is not modified by hardware and its value does not affect hardware.
Offset + 2	11	Last in frame. Written by user.

Table continues on the next page...

Table 60-36. Enhanced transmit buffer descriptor field definitions (continued)

Word	Field	Description
	L	0 The buffer is not the last in the transmit frame 1 The buffer is the last in the transmit frame
Offset + 2	10 TC	Transmit CRC. Written by user, and valid only when L is set. 0 End transmission immediately after the last data byte 1 Transmit the CRC sequence after the last data byte This field is valid only when the L field is set.
Offset + 2	9 ABC	Append bad CRC. **Note:** This field is not supported by the uDMA and is ignored.
Offset + 2	8–0	Reserved, must be cleared.
Offset + 4	15–0 Data buffer pointer low	Tx data buffer pointer, low halfword
Offset + 6	15–0 Data buffer pointer high	Tx data buffer pointer, high halfword. The buffer must reside in memory external to the MAC. This value is never modified by the Ethernet controller. **NOTE:** For optimal performance, make the transmit buffer pointer evenly divisible by 64.
Offset + 8	15 TXE	Transmit error occurred. This field is written by the uDMA. This field indicates that there was a transmit error of some sort reported with the frame. Effectively this field is an OR of the other error fields including UE, EE, FE, LCE, OE, and TSE. This field is valid only when the L field is set.
Offset + 8	14	Reserved, must be cleared.
Offset + 8	13 UE	Underflow error. This field is written by the uDMA. This field indicates that the MAC reported an underflow error on transmit. This field is valid only when the L field is set.
Offset + 8	12 EE	Excess Collision error. This field is written by the uDMA. This field indicates that the MAC reported an excess collision error on transmit. This field is valid only when the L field is set.
Offset + 8	11 FE	Frame with error. This field is written by the uDMA. This field indicates that the MAC reported that the uDMA reported an error when providing the packet. This field is valid only when the L field is set.
Offset + 8	10 LCE	Late collision error. This field is written by the uDMA. This field indicates that the MAC reported that there was a Late Collision on transmit. This field is valid only when the L field is set.
Offset + 8	9 OE	Overflow error. This field is written by the uDMA. This field indicates that the MAC reported that there was a FIFO overflow condition on transmit. This field is only valid when the L field is set.
Offset + 8	8 TSE	Timestamp error. This field is written by the uDMA. This field indicates that the MAC reported a different frame type then a timestamp frame. This field is valid only when the L field is set.
Offset + 8	7–0	Reserved, must be cleared.
Offset + A	15	Reserved, must be cleared.
Offset + A	14 INT	Generate interrupt flags. This field is written by the user. This field is valid regardless of the L field and must be the same for all EBD for a given frame. The uDMA does not update this value.

Table continues on the next page...

Table 60-36. Enhanced transmit buffer descriptor field definitions (continued)

Word	Field	Description
Offset + A	13 TS	Timestamp. This field is written by the user. This indicates that the uDMA is to generate a timestamp frame to the MAC. This field is valid regardless of the L field and must be the same for all EBD for the given frame. The uDMA does not update this value.
Offset + A	12 PINS	Insert protocol specific checksum. This field is written by the user. If set, the MAC's IP accelerator calculates the protocol checksum and overwrites the corresponding checksum field with the calculated value. The checksum field must be cleared by the application generating the frame. The uDMA does not update this value. This field is valid regardless of the L field and must be the same for all EBD for a given frame.
Offset + A	11 IINS	Insert IP header checksum. This field is written by the user. If set, the MAC's IP accelerator calculates the IP header checksum and overwrites the corresponding header field with the calculated value. The checksum field must be cleared by the application generating the frame. The uDMA does not update this value. This field is valid regardless of the L field and must be the same for all EBD for a given frame.
Offset + A	10–9	Reserved, must be cleared.
Offset + A	8 UTLT	Use transmit launch time. If set to 1, TLT high and low values are used to determine if frame can be transmitted. This field must only be set in the *first* BD of a frame. TLT is always used in combination with either the round-robin scheme or the credit-based shaper. TLT can be used with a single BD queue. However, at least one DMA class, DMA*n*CFG[DMA_CLASS_ EN] must be enabled. For example, to use TLT with only queue 0, enable one of the DMA*n*CFG[DMA_CLASS_EN] fields and clear both TDAR1 and TDAR2. Although this enables multi-queue, only the single queue 0 is used.
Offset + A	7–4 FTYPE	Type of frame to be transmitted. If a credit-based scheme is used, this field must match the BD ring queue. 0x0 – Non-AVB. Corresponds to ENET_TDSR. 0x1 – AVB Class A. Corresponds to ENET_TDSR1. 0x2 – AVB Class B. Corresponds to ENET_TDSR2. All other values are reserved.
Offset + A	3–0	Reserved, must be cleared.
Offset + C	15–0 TLT low	Transmit launch time low. Low two bytes of time value that specifies when frame can be transmitted.
Offset + E	15–0 TLT high	Transmit launch time high. High two bytes of time value that specifies when frame can be transmitted.
Offset + 10	15–0	Reserved, must be cleared.
Offset + 12	15 BDU	Last buffer descriptor update done. Indicates that the last BD data has been updated by uDMA. This field is written by the user (=0) and uDMA (=1).
Offset + 12	14–0	Reserved, must be cleared.
Offset + 14	15–0 1588 timestamp	This value is written by the uDMA . It is valid only when the L field is set.
Offset + 16		
Offset + 18–Offset + 1E	15–0	Reserved, must be cleared.

60.3.13 Client FIFO application interface

The FIFO interface is completely asynchronous from the Ethernet line, and the transmit and receive interface can operate at a different clock rate.

All transfers to/from the user application are handled independently of the core operation, and the core provides a simple interface to user applications based on a two-signal handshake.

60.3.13.1 Data structure description

The data structure defined in the following tables for the FIFO interface must be respected to ensure proper data transmission on the Ethernet line. Byte 0 is sent to and received from the line first.

Table 60-37. FIFO interface data structure

	63 56	55 48	47 40	39 32	31 24	23 16	15 8	7 0
Word 0	Byte 7	Byte 6	Byte 5	Byte 4	Byte 3	Byte 2	Byte 1	Byte 0
Word 1	Byte 15	Byte 14	Byte 13	Byte 12	Byte 11	Byte 10	Byte 9	Byte 8
...	...							

The size of a frame on the FIFO interface may not be a modulo of 64-bit.

The user application may not care about the Ethernet frame formats in full detail. It needs to provide and receive an Ethernet frame with the following structure:

- Ethernet MAC destination address
- Ethernet MAC source address
- Optional 802.1q VLAN tag (VLAN type and info field)
- Ethernet length/type field
- Payload

Frames on the FIFO interface do not contain preamble and SFD fields, which are inserted and discarded by the MAC on transmit and receive, respectively.

- On receive, CRC and frame padding can be stripped or passed through transparently.
- On transmit, padding and CRC can be provided by the user application, or appended automatically by the MAC independently for each frame. No size restrictions apply.

Note

On transmit, if ENET*n*_TCR[ADDINS] is set, bytes 6–11 of each frame can be set to any value, since the MAC overwrites the bytes with the MAC address programmed in the ENET*n*_PAUR and ENET*n*_PALR registers.

Table 60-38. FIFO interface frame format

Byte number	Field
0–5	Destination MAC address
6–11	Source MAC address
12–13	Length/type field
14–N	Payload data

VLAN-tagged frames are supported on both transmit and receive, and implement additional information (VLAN type and info).

Table 60-39. FIFO interface VLAN frame format

Byte number	Field
0–5	Destination MAC address
6–11	Source MAC address
12–15	VLAN tag and info
16–17	Length/type field
18–N	Payload data

Note

The standard defines that the LSB of the MAC address is sent/received first, while for all the other header fields — in other words, length/type, VLAN tag, VLAN info, and pause quanta — the MSB is sent/received first.

60.3.13.2 Data structure examples

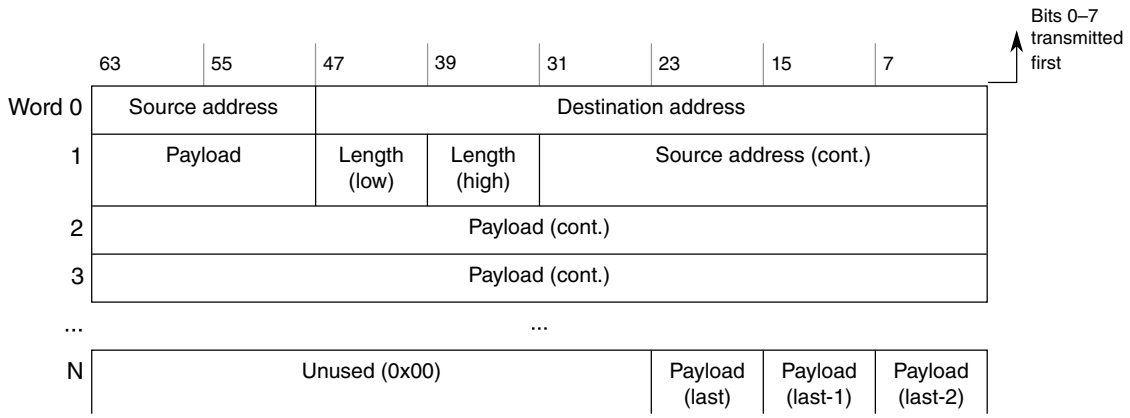

Figure 60-16. Normal Ethernet frame 64-bit mapping example

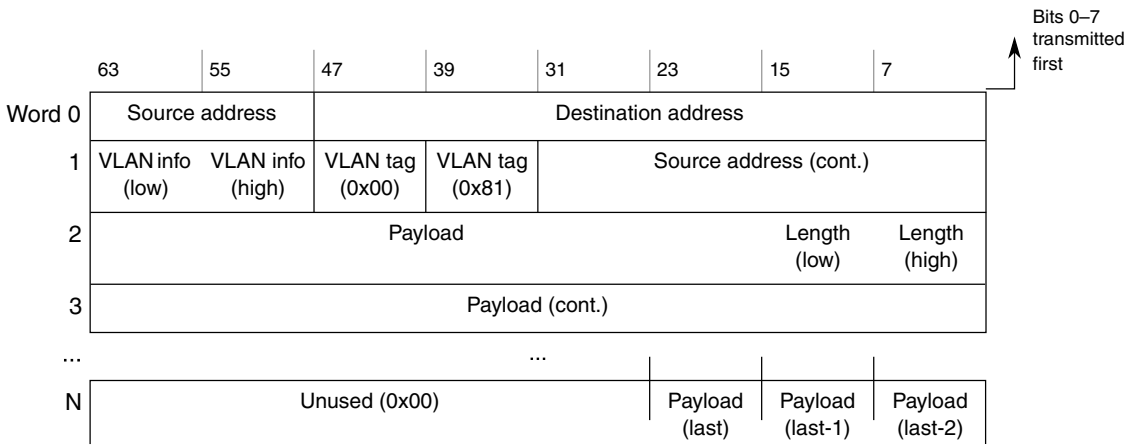

Figure 60-17. VLAN-tagged frame 64-bit mapping example

If CRC forwarding is enabled (CRCFWD = 0), the last four valid octets of the frame contain the FCS field. The non-significant bytes of the last word can have any value.

60.3.13.3 Frame status

A MAC layer status word and an accelerator status word is available in the receive buffer descriptor.

See Enhanced buffer descriptors for details.

The status is available with each frame with the last data of the frame.

If the frame status contains a MAC layer error (for example, CRC or length error), RxBD[ME] is also set with the last data of the frame.

60.3.14 FIFO protection

The following sections describe the FIFO protection mechanisms.

60.3.14.1 Transmit FIFO underflow

During a frame transfer, when the transmit FIFO reaches the almost empty threshold with no end-of-frame indication stored in the FIFO, the MAC logic:

- Stops reading data from the FIFO
- Asserts the MII error signal (MII_TXER) (1 in Figure 60-18) to indicate that the fragment already transferred is not valid
- Deasserts the MII transmit enable signal (MII_TXEN) to terminate the frame transfer (2)

After an underflow, when the application completes the frame transfer (3), the MAC transmit logic discards any new data available in the FIFO until the end of packet is reached (4) and sets the enhanced TxBD[UE] field.

The MAC starts to transfer data on the MII interface when the application sends a new frame with a start of frame indication (5).

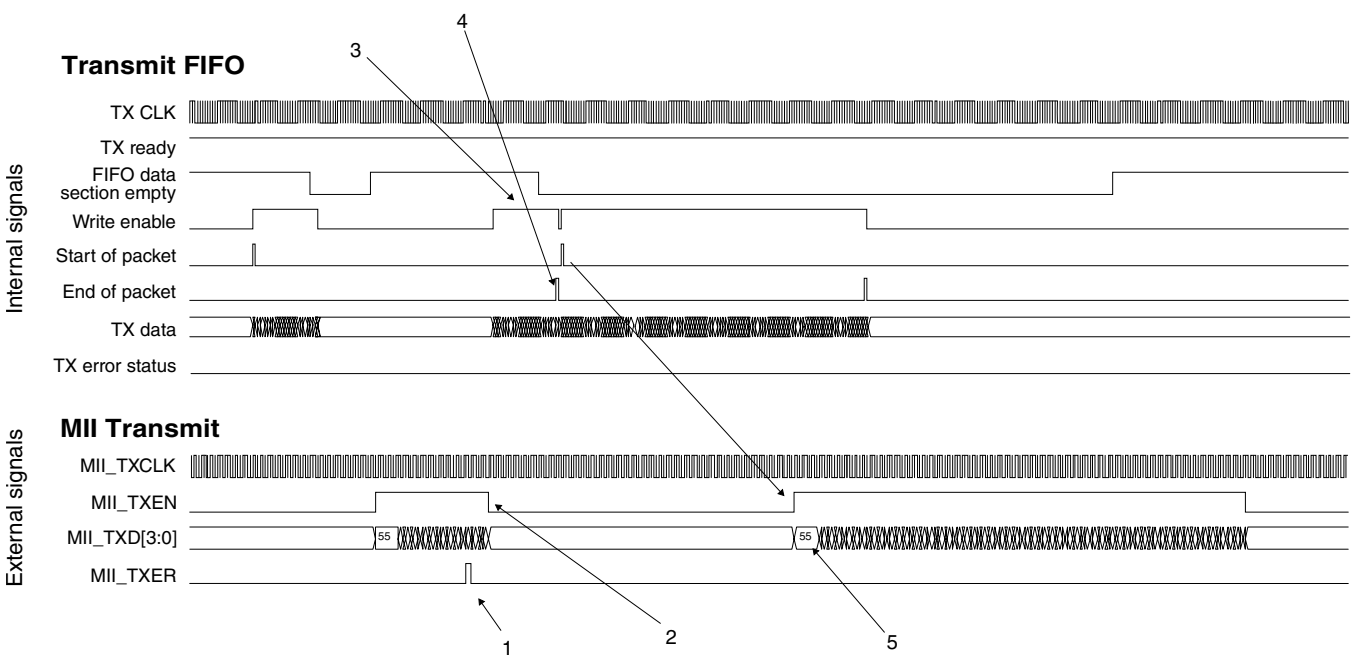

Figure 60-18. Transmit FIFO underflow protection

60.3.14.2 Transmit FIFO overflow

On the transmit path, when the FIFO reaches the programmable almost full threshold, the internal MAC ready signal is deasserted. The application should stop sending new data.

However, if the application keeps sending data, the transmit FIFO overflows, corrupting contents that were previously stored. The core logic sets the enhanced TxBD[OE] field for the next frame transmitted to indicate this overflow occurence.

Note

Overflow is a fatal error and must be addressed by resetting the core or clearing ENET*n*_ECR[ETHER_EN], to clear the FIFOs and prepare for normal operation again.

60.3.14.3 Receive FIFO overflow

During a frame reception, if the client application is not able to receive data (1), the MAC receive control truncates the incoming frame when the FIFO reaches the programmable almost-full threshold to avoid an overflow.

The frame is subsequently received on the FIFO interface with an error indication (enhanced RxBD[ME] field set together with receive end-of-packet) (2) with the truncation error status field set (3).

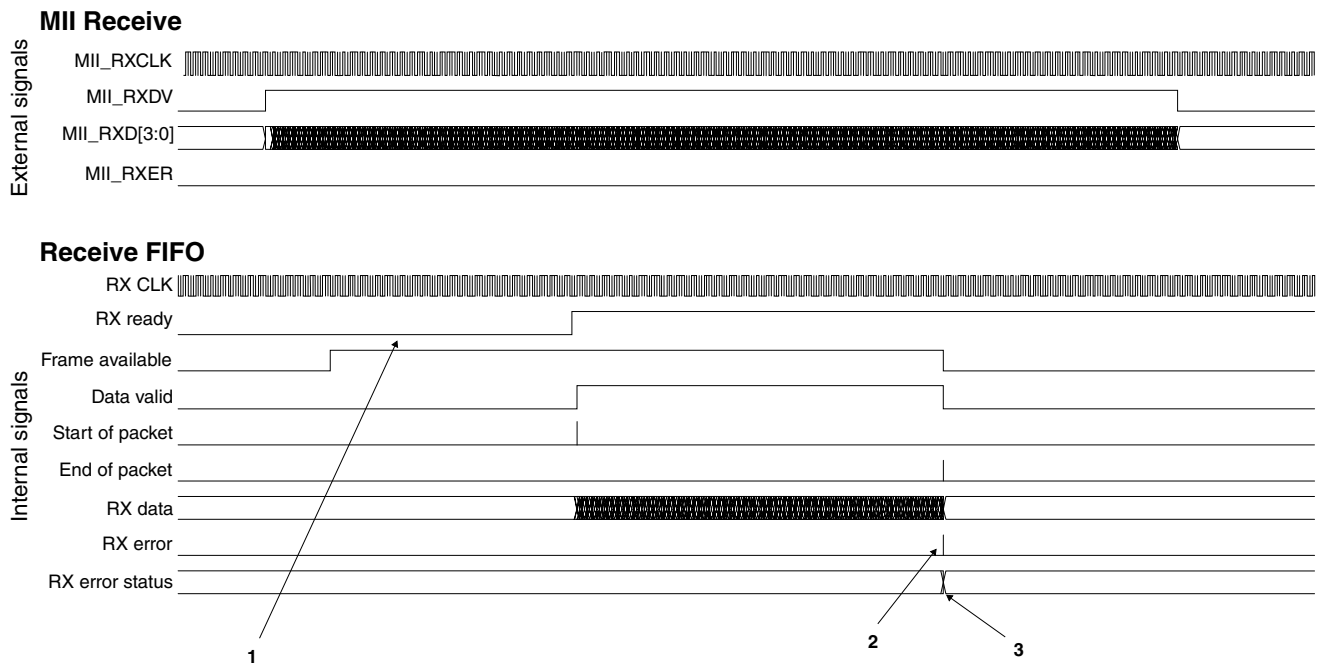

Figure 60-19. Receive FIFO overflow protection

60.3.15 PHY management interface

The MDIO interface is a two-wire management interface. The MDIO management interface implements a standardized method to access the PHY device management registers.

The core implements a leader MDIO interface, which can be connected to up to 32 PHY devices.

60.3.15.1 MDIO clause 22 frame format

The core MDIO leader controller communicates with the follower (PHY device) using frames that are defined in the following table.

A complete frame has a length of 64 bits made up of an optional 32-bit preamble, 14-bit command, 2-bit bus direction change, and 16-bit data. Each bit is transferred on the rising edge of the MDIO clock (MDC signal). The MDIO data signal is tri-stated between frames.

The core PHY management interface supports the standard MDIO specification (IEEE 802.3 Clause 22).

Table 60-40. MDIO clause 22 frame structure

ST	OP	PHYADR	REGADR	TA	DATA

Table 60-41. MDIO frame field descriptions

Field	Description
ST (2 bits)	Start indication field, programmed with ENET*n*_MMFR[ST] and equal to 01 for Standard MDIO (Clause 22).
OP (2 bits)	Opcode defines type of operation. Programmed with ENET*n*_MMFR[OP]. 01 Write operation 10 Read operation
PHYADR (5 bits)	Five-bit PHY device address, programmed with ENET*n*_MMFR[PA]. Up to 32 devices can be addressed.
REGADR (5 bits)	Five-bit register address, programmed with ENET*n*_MMFR[RA]. Each PHY can implement up to 32 registers.
TA (2 bits)	Turnaround time, programmed with ENET*n*_MMFR[TA]. Two bit-times are reserved for read operations to switch the data bus from write to read. The PHY device presents its register contents in the data phase and drives the bus from the second bit of the turnaround phase.
Data	Data, set by ENET*n*_MMFR[DATA]. Written to or read from the PHY

Table 60-41. MDIO frame field descriptions

Field	Description
(16 bits)	

60.3.15.2 MDIO clause 45 frame format

The extended MDIO frame structure defined in IEEE 802.3 Clause 45 introduces indirect addressing. First, a write transaction to an address register is done, followed by a write or read transaction which will put the 16-bit data in the register or retrieve the register contents respectively. A preamble of 32 bits of logical ones is sent prior to every transaction. The MDIO data signal is tri-stated between frames.

The extended MDIO defines four transactions, which are determined by the two-bit opcode field.

Table 60-42. MDIO clause 45 frame structure

ST	OP	PRTAD	DEVAD	TA	ADDR/DATA

All bits are transmitted from left to right (Preamble bits first) and all fields have their Most-Significant bit sent first (leftmost in above table). The complete frame has a length of 64 bits (32-bit preamble, 14-bit command, 2-bit bus direction change, 16-bit data). Each bit is transferred with the rising edge of the MDIO clock (MDC).

The fields and transactions are summarized in the following tables.

Table 60-43. MDIO clause 45 frame field descriptions

Field	Description
ST	Start indication. Indicates the end of the preamble and start of the frame. This value is 00 for extended MDIO (Clause 45) frames.
OP	Opcode defines if a read or write operation is performed and is programmed with ENET*n*_MMFR[OP]. See Table 60-44 for more information. 00 Address write 01 Write operation 10 Read inc. operation 11 Read operation
PRTAD	The port address specifies a MDIO port. Each Port can have up to 32 devices which each can have a separate set of registers.
DEVAD	Device address. Up to 32 devices can be addressed (within a port).
TA	Turnaround time, programmed with ENET*n*_MMFR[TA]. Two bit-times are reserved for read operations to switch the data bus from write to read. The PHY device presents its register contents in the data phase and drives the bus from the second bit of the turnaround phase.

Table continues on the next page...

Table 60-43. MDIO clause 45 frame field descriptions (continued)

Field	Description
ADDR/DATA	16-bit address (for address write) or data, set by ENET*n*_MMFR[DATA], written to or read from the PHY.

Table 60-44. MDIO Clause 45 Transactions

Transaction Type	Description
Address	A write transaction to the internal address register of the device/port. The data section of the frame contains the value to be stored in the device's internal address "pointer" register for further transactions.
Write	Data write to a register. The 16 bit data will be written to the register identified by the device-internal address.
Read	Data is read from the register identified by the device-internal address.
Read inc.	Read with address postincrement. The register identified by the device-internal address is read. After this, the device-internal address is incremented. If the address register is all '1' (0xFFFF) no increment is done (i.e. increment does not wrap around).

60.3.15.3 MDIO clock generation

The MDC clock is generated from the internal bus clock (i.e., IPS bus clock) divided by the value programmed in ENET*n*_MSCR[MII_SPEED].

60.3.15.4 MDIO operation

To perform an MDIO access, set the MDIO command register (ENET*n*_MMFR) according to the description provided in MII Management Frame Register (ENETn_MMFR).

To check when the programmed access completes, read the ENET*n*_EIR[MII] field.

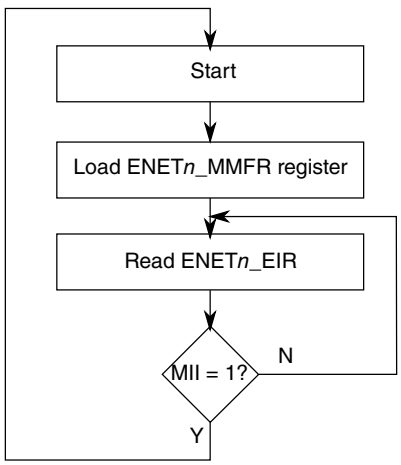

Figure 60-20. MDIO access overview

60.3.16 Ethernet interfaces

The following Ethernet interfaces are implemented:

- Fast Ethernet MII 10/100 (Media Independent Interface)
- RMII 10/100 using interface converters/gaskets
- RGMII 10/100/1000 by way of interface converters/gaskets

The following table shows how to configure ENET registers to select each interface.

Mode	ECR[SPEED]	RCR[RMII_10T]	RCR[RMII_MODE]	RCR[RGMII_EN]
MII - 10 Mbit/s	0	—	0	0
MII - 100 Mbit/s	0	—	0	0
RMII - 10 Mbit/s	0	1	1	0
RMII - 100 Mbit/s	0	0	1	0
RGMII - 10 Mbit/s	0	1	0	1
RGMII - 100 Mbit/s	0	0	0	1
RGMII - 1000 Mbit/s	1	—	0	1

60.3.16.1 RMII interface

In RMII receive mode, for normal reception following assertion of CRS_DV, RXD[1:0] is 00 until the receiver determines that the receive event has a proper start-of-stream delimiter (SSD).

The preamble appears (RXD[1:0]=01) and the MACs begin capturing data following detection of SFD.

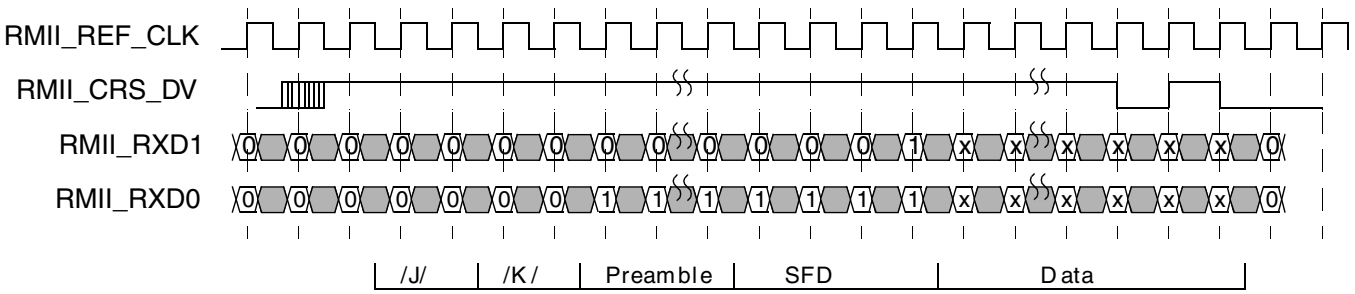

Figure 60-21. RMII receive operation

If a false carrier is detected (bad SSD), then RXD[1:0] is 10 until the end of the receive event. This is a unique pattern since a false carrier can only occur at the beginning of a packet where the preamble is decoded (RXD[1:0] = 01).

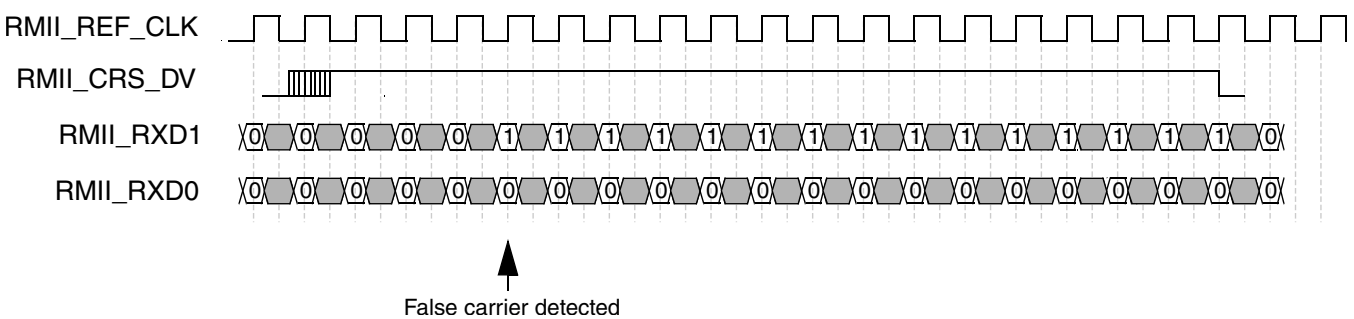

Figure 60-22. RMII receive operation with false carrier

In RMII transmit mode, TXD[1:0] provides valid data for each REF_CLK period while TXEN is asserted.

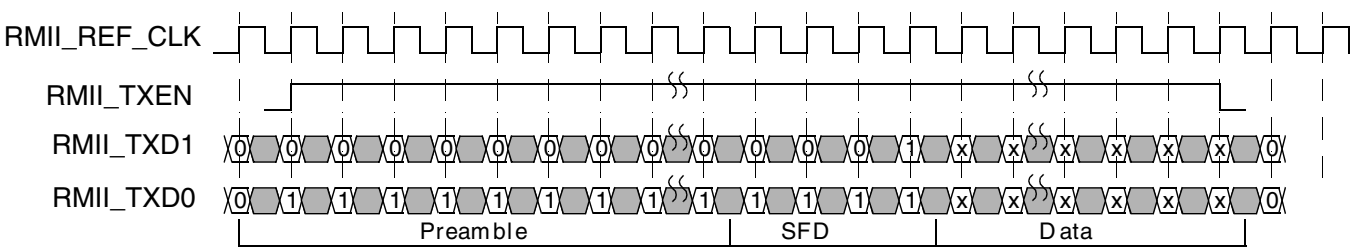

Figure 60-23. RMII transmit operation

60.3.16.2 RGMII interface

In RGMII modes, the data and control information is multiplexed by taking advantage of both edges of the reference clocks.

The data signals contain the lower four data bits on the rising edge and the upper four bits on the falling edge. The control signals are multiplexed into a single clock cycle using the same technique.

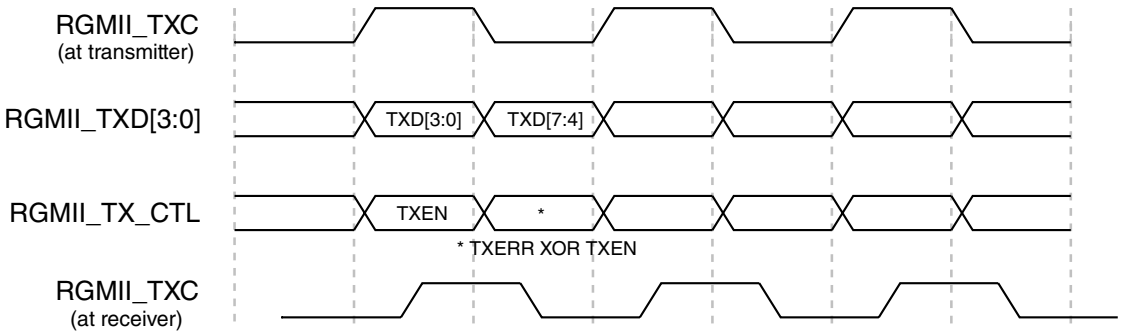

Figure 60-24. RGMII transmit operation

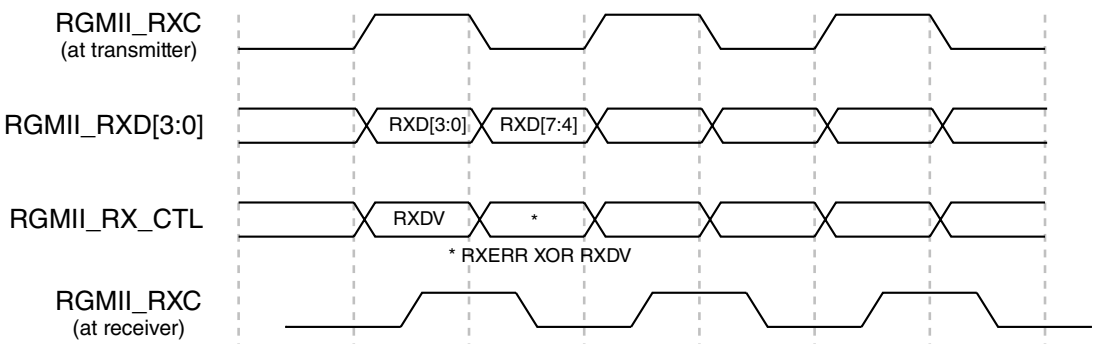

Figure 60-25. RGMII receive operation

60.3.16.3 MII interface — transmit

On transmit, all data transfers are synchronous to MII_TXCLK rising edge. The MII data enable signal MII_TXEN is asserted to indicate the start of a new frame, and remains asserted until the last byte of the frame is present on the MII_TXD[3:0] bus.

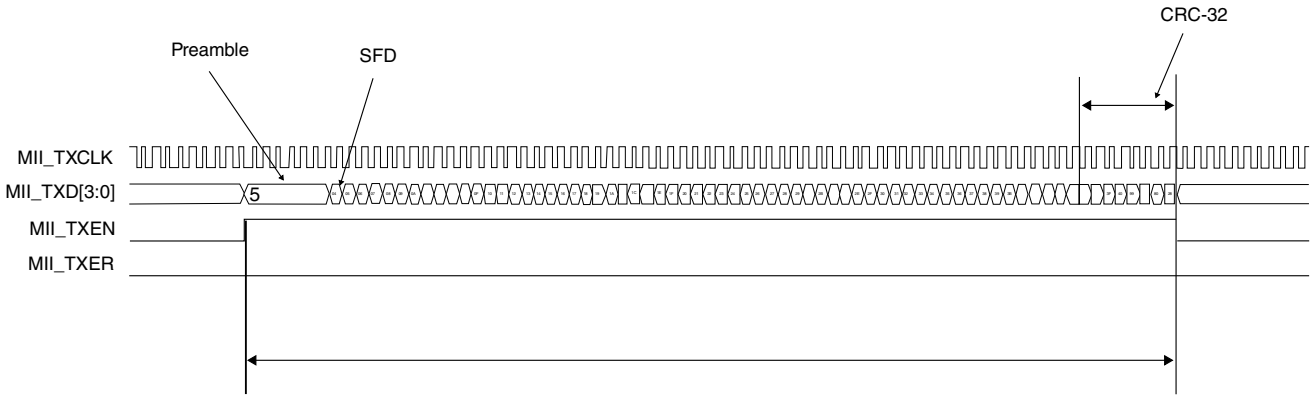

Figure 60-26. MII transmit operation

If a frame is received on the FIFO interface with an error (for example, RxBD[ME] set) the frame is subsequently transmitted with the MII_TXER error signal for one clock cycle at any time during the packet transfer.

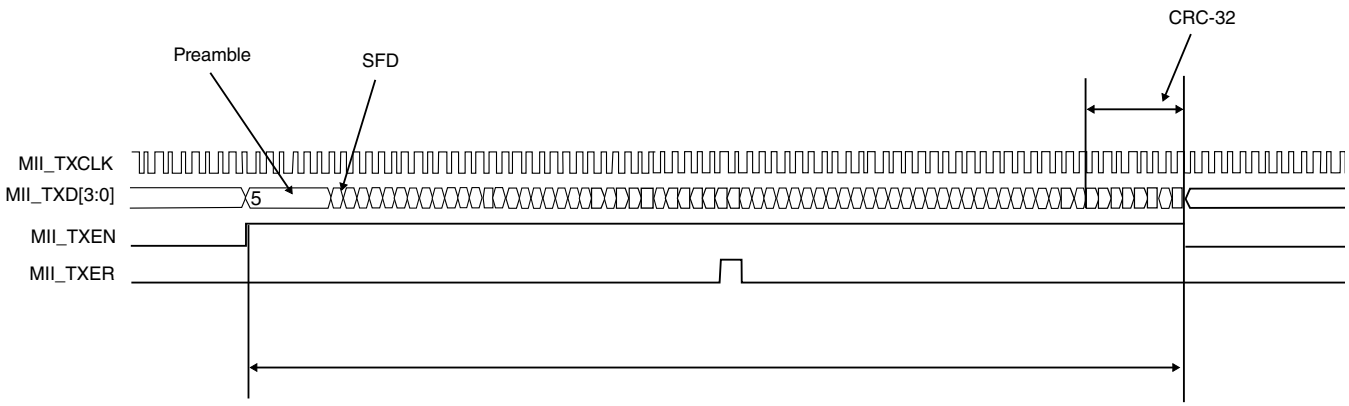

Figure 60-27. MII transmit operation — errored frame

60.3.16.3.1 Transmit with collision — half-duplex

When a collision is detected during a frame transmission (MII_COL asserted), the MAC stops the current transmission, sends a 32-bit jam pattern, and re-transmits the current frame.

(See Collision detection in half-duplex mode for details)

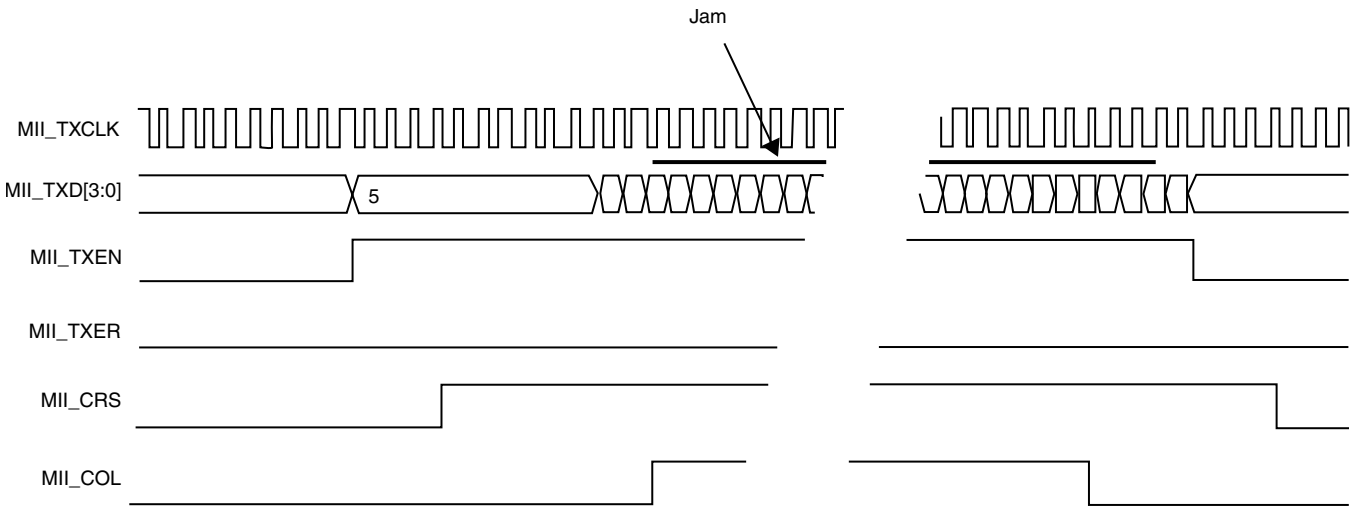

Figure 60-28. MII transmit operation — transmission with collision

60.3.16.4 MII interface — receive

On receive, all signals are sampled on the MII_RXCLK rising edge. The MII data enable signal, MII_RXDV, is asserted by the PHY to indicate the start of a new frame and remains asserted until the last byte of the frame is present on MII_RXD[3:0] bus.

Between frames, MII_RXDV remains deasserted.

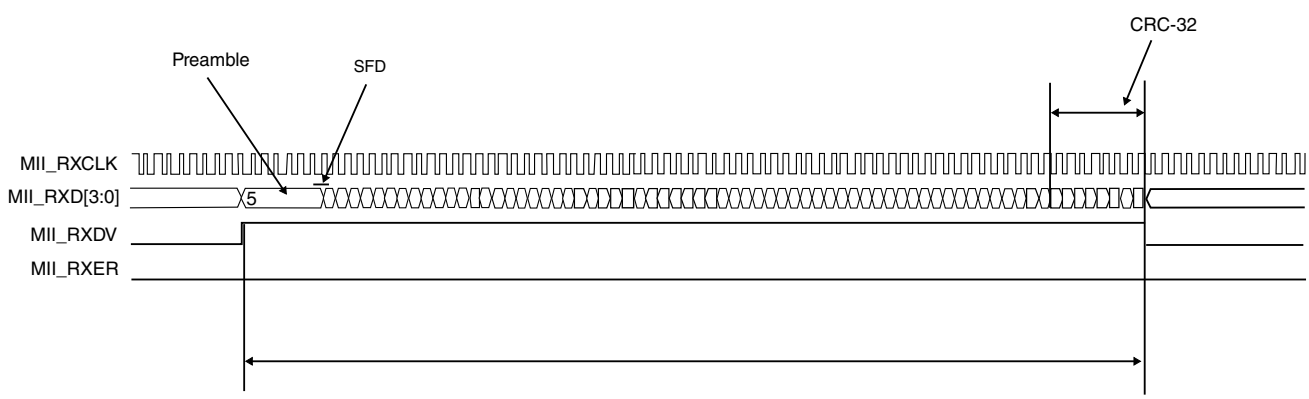

Figure 60-29. MII receive operation

If the PHY detects an error on the frame received from the line, the PHY asserts the MII error signal, MII_RXER, for at least one clock cycle at any time during the packet transfer.

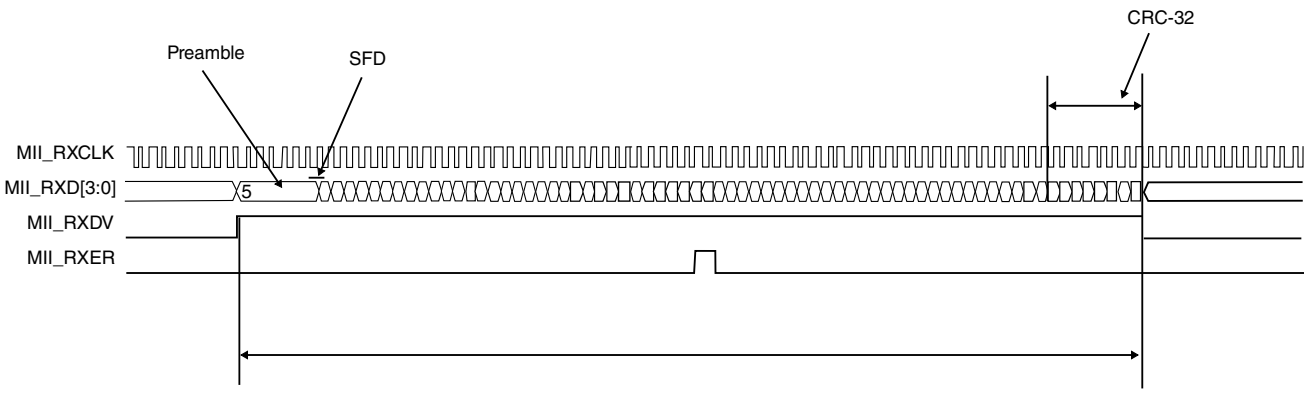

Figure 60-30. MII receive operation — errored frame

A frame received on the MII interface with a PHY error indication is subsequently transferred on the FIFO interface with RxBD[ME] set.

60.3.17 AVB configuration

The following steps give an example of how to initialize the ENET module for AVB.

1. Set up QOS register:
   - Set TX_SCHEME to 000b, credit-based scheme.
   - Set RX_FLUSH0 to 1, enable RX flush for ring 0.
2. Set up TX BD ring and RX BD ring for each queue, 0-2.
   - Program ENET_MRBR, ENET_TDSR, and ENET_RDSR.
   - Program ENET_MRBR1, ENET_TDSR1, and ENET_RDSR1.
   - Program ENET_MRBR2, ENET_TDSR2, and ENET_RDSR2.
   - Program each TX and RX BD ring queue for all classes used in memory.

NOTE

If using credit-based scheme, ensure that enhanced transmit buffer descriptor FTYPE field matches BD ring queue, for example:
- FTYPE = 0h corresponds to ENET_TDSR
- FTYPE = 1h corresponds to ENET_TDSR1
- FTYPE = 2h corresponds to ENET_TDSR2

3. Program ENET_DMA1CFG and ENET_DMA2CFG for class 1 and class 2 corresponding to BD ring queue 1 and 2. DMA_CLASS_EN must be set to one for

that class to be enabled. See DMACFG register for information on how to program IDLE_SLOPE.

4. Program ENET_RCMR1 and ENET_RCMR2 for class 1 and class 2 matching for receive.

NOTE

Even if a match occurs, if ENET_DMA*n*CFG[DMA_CLASS_EN] is zero for the corresponding class, the RX frame will be automatically forwarded to BD ring queue 0.

5. Program the other ENET registers according to application requirements.
6. Program ENET_RDAR, ENET_RDAR1, ENET_RDAR2, ENET_TDAR, ENET_TDAR1, and ENET_TDAR2 to 0100_0000h according to the classes used.
7. Set ENET_ECR[ETHEREN] to one.

60.3.18 Magic packet detection

Magic packet detection wakes a node that is put in power-down mode by the node management agent. Magic packet detection is supported only if the MAC is configured in sleep mode.

60.3.18.1 Sleep mode

To put the MAC in Sleep mode, set ENET*n*_ECR[SLEEP]. At the same time ENET*n*_ECR[MAGICEN] should also be set to enable magic packet detection.

In addition, if ENET is enabled, write 1 to ENET*n*_ECR[SLEEP] before entering into low power mode.

When the MAC is in Sleep mode:

- The transmit logic is disabled.
- The FIFO receive/transmit functions are disabled.
- The receive logic is kept in Normal mode, but it ignores all traffic from the line except magic packets. They are detected so that a remote agent can wake the node.

60.3.18.2 Magic packet detection

The core is designed to detect magic packets (See "Magic Packets" topics) with the destination address set to:

- Any multicast address
- The broadcast address
- The unicast address programmed in PADDR1/2

When a magic packet is detected, EIR[WAKEUP] is set and none of the statistic registers are incremented.

60.3.18.3 Wakeup

When a magic packet is detected, indicated by ENET*n*_EIR[WAKEUP], ENET*n*_ECR[SLEEP] should be cleared to resume normal operation of the MAC. Clearing the SLEEP bit automatically masks ENET*n*_ECR[MAGICEN], disabling magic packet detection.

60.3.19 Clocking

The table found here describes the clock sources for ENET. See chip-specific clocking section for clock setting, configuration and gating information.

Table 60-45. ENET clocks

Clock name	Description
ipg_clk	Module clock
ipg_clk_rmii	Module clock for RMII
ipg_clk_s	Peripheral access clock
ipg_clk_time (ts_clk)	Peripheral clock
txc_sampling_clk	Transmit sampling clock

60.3.20 Reset

The following sections describe the resets and stop controls.

60.3.20.1 Hardware reset

To reset the Ethernet module, set ENET*n*_ECR[RESET].

60.3.20.2 Soft reset

When ENET*n*_ECR[ETHER_EN] is cleared during operation, the following occurs:

- uDMA, buffer descriptor, and FIFO control logic are reset, including the buffer descriptor and FIFO pointers.
- A currently ongoing transmit is terminated by asserting GMII/TXER to the PHY.
- A currently ongoing transmit FIFO write from the application is terminated by stopping the write to the FIFO, and all further data from the application is ignored. All subsequent writes are ignored until re-enabled.
- A currently ongoing receive FIFO read is terminated. The RxBD has arbitrary values in this case.

60.3.20.3 Debug mode

When the processor enters debug mode and ECR[DBGEN] is set, the MAC enters a freeze state where it stops all transmit and receive activities gracefully.

The following happens when the MAC enters hardware freeze:

- A currently ongoing receive transaction on the receive application interface is completed as normal. No further frames are read from the FIFO.
- A currently ongoing transmit transaction on the transmit application interface is completed as normal (in other words, until writing end-of-packet (EOP)).
- A currently ongoing frame receive is completed normally, after which no further frames are accepted from the MII/GMII.
- A currently ongoing frame transmit is completed normally, after which no further frames are transmitted.

60.3.20.4 Graceful stop

During a graceful stop, any currently ongoing transactions are completed normally and no further frames are accepted. The MAC can resume from a graceful stop without the need for a reset (for example, clearing ETHER_EN is not required).

The following conditions lead to a graceful stop of the MAC transmit or receive datapaths.

60.3.20.4.1 Graceful transmit stop (GTS)

When gracefully stopped, the MAC is no longer reading frame data from the transmit FIFO and has completed any ongoing transmission.

In any of the following conditions, the transmit datapath stops after an ongoing frame transmission has been completed normally.

- ENET*n*_TCR[GTS] is set by software.
- ENET*n*_TCR[TFC_PAUSE] is set by software requesting a pause frame transmission. The status (and register bit) is cleared after the pause frame has been sent.
- A pause frame was received stopping the transmitter. The stopped situation is terminated when the pause timer expires or a pause frame with zero quanta is received.
- MAC is placed in Sleep mode by software or the processor entering Stop mode (see Sleep mode).
- The MAC is in Hardware Freeze mode.

When the transmitter has reached its stopped state, the following events occur:

- The GRA interrupt is asserted, when transitioned into stopped state.
- In Hardware Freeze mode, the GRA interrupt does not wait for the application write completion and asserts when the transmit state machine (in other words, line side of TX FIFO) reaches its stopped state.

60.3.20.4.2 Graceful receive stop (GRS)

When gracefully stopped, the MAC is no longer writing frames into the receive FIFO.

The receive datapath stops after any ongoing frame reception has been completed normally, if any of the following conditions occur:

- MAC is placed in Sleep mode either by the software or the processor is in Stop mode). The MAC continues to receive frames and search for magic packets if enabled (see Magic packet detection). However, no frames are written into the receive FIFO, and therefore are not forwarded to the application.
- The MAC is in Hardware Freeze mode. The MAC does not accept any frames from the MII/GMII.

When the receive datapath is stopped, the following events occur:

- If the RX is in the stopped state, RCR[GRS] is set
- The GRA interrupt is asserted when the transmitter and receiver are stopped
- Any ongoing receive transaction to the application (RX FIFO read) continues normally until the frame end of package (EOP) is reached. After this, the following occurs:
  - When Sleep mode is active, all further frames are discarded, flushing the RX FIFO
  - In Hardware Freeze mode, no further frames are delivered to the application and they stay in the receive FIFO.

Note

The assertion of GRS does not wait for an ongoing FIFO read transaction on the application side of the FIFO (FIFO read).

60.3.20.4.3 Graceful stop interrupt (GRA)

The graceful stop interrupt (GRA) is asserted for the following conditions:

- In Sleep mode, the interrupt asserts only after both TX and RX datapaths are stopped.
- In Hardware Freeze mode, the interrupt asserts only after both TX and RX datapaths are stopped.
- The MAC transmit datapath is stopped for any other condition (GTS, TFC_PAUSE, pause received).

The GRA interrupt is triggered only once when the stopped state is entered. If the interrupt is cleared while the stop condition persists, no further interrupt is triggered.

60.3.21 Interrupts

The purpose of the interrupt coalescing is to reduce the number of interrupts generated by the MAC so as to reduce the CPU loading.

To facilitate this interrupt coalescing for each queue, these registers are available with the same control and configuration fields.

- Transmit Interrupt Coalescing Register (TXICn) where n=0,1,2 for queue/class 0,1,2.
- Receive Interrupt Coalescing Register (RXICn) where n=0,1,2 for queue/class 0,1,2.

When coalescing is enabled by asserting the corresponding ICEN field and such interrupt is also enabled by the corresponding interrupt mask of the EIMR register, the MAC generates an interrupt when the threshold number of frames is reached (defined by ICFT) or when the threshold timer expires (defined by ICTT).

When coalescing is disabled by de-asserting ICEN, but interrupt is enabled by the corresponding interrupt mask of the EIMR register, the MAC generates an interrupt as they are received without using coalescing. Interrupt coalescing is done for each transmit and receive queue/class independently.

60.3.21.1 Interrupt coalescence setup

Interrupt coalescence supports both legacy and enhanced BDs. The following guidelines are recommended when setting up interrupt coalescence.

- When the MAC is configured for enhanced (IEEE 1588) mode, that is, enhanced BDs:
  - Set the INT bit in the enhanced received buffer descriptor to one.
  - Set the INT bit in the enhanced transmit buffer descriptor(s) to one.
- Clear the RXB, RXB1, and RXB2 fields in the EIMR register.
- Clear the TXB, TXB1, and TXB2 fields in the EIMR register.

60.3.21.2 Updating the frame count threshold on-the-fly

To update the ICFT field in the RXIC*n* and TXIC*n* registers:

1. Disable interrupt coalescence by clearing the appropriate ICEN field. This will allow the internal interrupt coalescence counter to reset to zero.

NOTE

When disabling interrupt coalescence, if an interrupt event is pending, that is, the interrupt counter is not zero, then an interrupt will occur.

2. Write the new threshold value to the ICFT field.

3. Set ICEN to one.

NOTE

The ICFT field can be updated on-the-fly without disabling the ICEN field. The hardware interrupt will continue and there is a possibility that an interrupt will occur depending on the state of the hardware counter and the previous ICFT value.

60.3.21.3 Updating the timer threshold on-the-fly

To update the ICTT field in the RXIC*n* and TXIC*n* registers:

1. Disable interrupt coalescence by clearing the appropriate ICEN field. This will allow the internal interrupt coalescence counter to reset to zero.

NOTE

When disabling interrupt coalescence, if an interrupt event is pending, that is, the interrupt counter is not zero, then an interrupt will occur.

2. Write the new timer value to the ICTT field.
3. Set ICEN to one.

60.4 External signals

The table found here describes the external signals of ENET.

Table 60-46. ENET external signals

Signal	Description	Mode	Direction
1588_EVENT_IN/ 1588_EVENT_OUT	Capture/compare block input/output event bus signal. • When configured for capture and a rising edge is detected, the current timer value is latched and transferred into the corresponding ENET_TCCRn register for inspection by software. • When configured for compare, the corresponding signal 1588_EVENT is asserted for one cycle when the timer reaches the compare value programmed in the register ENET_TCCRn. An interrupt or DMA request can be triggered if the corresponding bit in ENET_TCSRn[TIE] or ENET_TCSRn[TDRE] is set.	MII/RMII	IO
ENET_1588_CLKIN	Alternate IEEE 1588 Ethernet clock input; Clock period should be an integer number in nanoseconds.	MII/RMII	I
MII_COL	Asserted upon detection of a collision and remains asserted while the collision persists. This signal is not defined for full-duplex mode.	MII	I

Table continues on the next page...

Table 60-46. ENET external signals (continued)

Signal	Description	Mode	Direction
MII_CRS	Carrier sense. Asserted if receive or transmit equals 1 and negated if both transmit and receive equals 0. **NOTE:** In RMII mode, this signal is present on the RMII_CRS_DV pin.	MII	I
MDC	Output clock provides a timing reference to the PHY for data transfers on the MDIO signal.	MII/RGMII/RMII	O
MDIO	Transfers control information between the external PHY and the media access controller. Data is synchronous to MDC. This signal is an input after reset.	MII/RGMII/RMII	IO
MII_RXCLK	In MII mode, provides a timing reference for RXDV, RXD[3:0], and RXER. **NOTE:** In RGMII mode, this pin is present as RGMII_RXC and provides a timing reference for RGMII_RXD[3:0] and RGMII_RX_CTL.	MII	I
RXER	When asserted with RXDV, indicates an error detection from the PHY in the current frame.	MII/RMII	I
RX_EN	Asserting this input indicates the PHY has valid nibbles present on the MII. RX_EN must remain asserted from the first recovered nibble of the frame through to the last nibble. Asserting RX_EN must start no later than the SFD and exclude any EOF. **NOTE:** In RMII mode, this pin also generates the CRS signal.	MII/RMII	I
MII_TXCLK	Input clock, which provides a timing reference for TXEN, TXD[3:0], and TXER.	MII	I
MII_TXER	When asserted for one or more clock cycles while TXEN is also asserted, PHY sends one or more illegal symbols.	MII	O
TXEN	Indicates when valid nibbles are present on the MII. This signal is asserted with the first nibble of a preamble and is de-asserted before the first TXCLK following the final nibble of the frame. **NOTE:** In RGMII mode, it is present as RGMII_TX_CTL, and contains TXEN on the rising edge of RGMII_TXC, and a logical derivative of TXEN and TXER (TXEN XOR TXER) on the falling edge of RGMII_TXC.	MII/RMII	O
RXD[3:0]	Contains the Ethernet input data transferred from the PHY to the media-access controller when RXEN is asserted. **NOTE:** In RMII mode, bits [1:0] provide the Ethernet input data.	MII/RMII/RGMII	I
TXD[3:0]	Serial output Ethernet data. Only valid during TX_EN assertion. **NOTE:** In RMII mode, bits [1:0] provide the Serial output Ethernet data.	MII/RMII/RGMII	O
RGMII_RX_CTL	Asserting this input indicates the PHY has valid nibbles present on the MII. RXDV must remain asserted from the first recovered nibble of the frame through to the last nibble. Asserting RXDV must start no later than the SFD and exclude any EOF. **NOTE:** • In RMII mode, this signal is used as RMII_CRS_DV. • In RGMII mode, contains RXDV on the rising edge of RGMII_RXC, and a logical derivative of RXDV	RGMII	I

Table continues on the next page...

Table 60-46. ENET external signals (continued)

Signal	Description	Mode	Direction
	and RXER (RXDV XOR RXER) on the falling edge of RGMII_RXC. • In MII mode, this signal is used as MII_RXDV.		
RGMII_RXC	Timing reference for RGMII_RXD[3:0] and RGMII_RX_CTL	RGMII	I
RGMII_TX_CTL	Indicates when valid nibbles are present on the MII. This signal is asserted with the first nibble of a preamble and is deasserted before the first TXCLK following the final nibble of the frame. **NOTE:** In RGMII mode, contains TXEN on the rising edge of RGMII_TXC, and a logical derivative of TXEN and TXER (TXEN XOR TXER) on the falling edge of RGMII_TXC.	RGMII	O
RGMII_TXC	Timing reference for RGMII_TXD[3:0] and RGMII_TX_CTL.	RGMII	O
RMII_REF_CLK	In RMII mode, this signal is the reference clock for receive, transmit, and the control interface.	RMII	IO
RGMII_REF_CLK	In RGMII mode, this signal provides 125Mhz external reference clock input.	RGMII	I

60.5 Memory map/register definition

ENET registers must be read or written with 32-bit accesses. Non-32 bit accesses will terminate with an error.

Reserved bits should be written with 0 and ignored on read. Unused registers read zero and a write has no effect.

This table shows Ethernet registers organization.

Table 60-47. Register map summary

Offset Address	Section	Description
0x0000 – 0x01FF	Configuration	Core control and status registers
0x0200 – 0x03FF	Statistics counters	MIB and Remote Network Monitoring (RFC 2819) registers
0x0400 – 0x0430	1588 control	1588 adjustable timer (TSM) and 1588 frame control
0x0600 – 0x07FC	Capture/Compare block	Registers for the Capture/Compare block

60.5.1 ENET register descriptions

60.5.1.1 ENET memory map

ENET base address: 4042_4000h

ENET_1G base address: 4042_0000h

60.5.1.2 Interrupt Event (EIR)

60.5.1.2.1 Offset

Register	Offset
EIR	4h

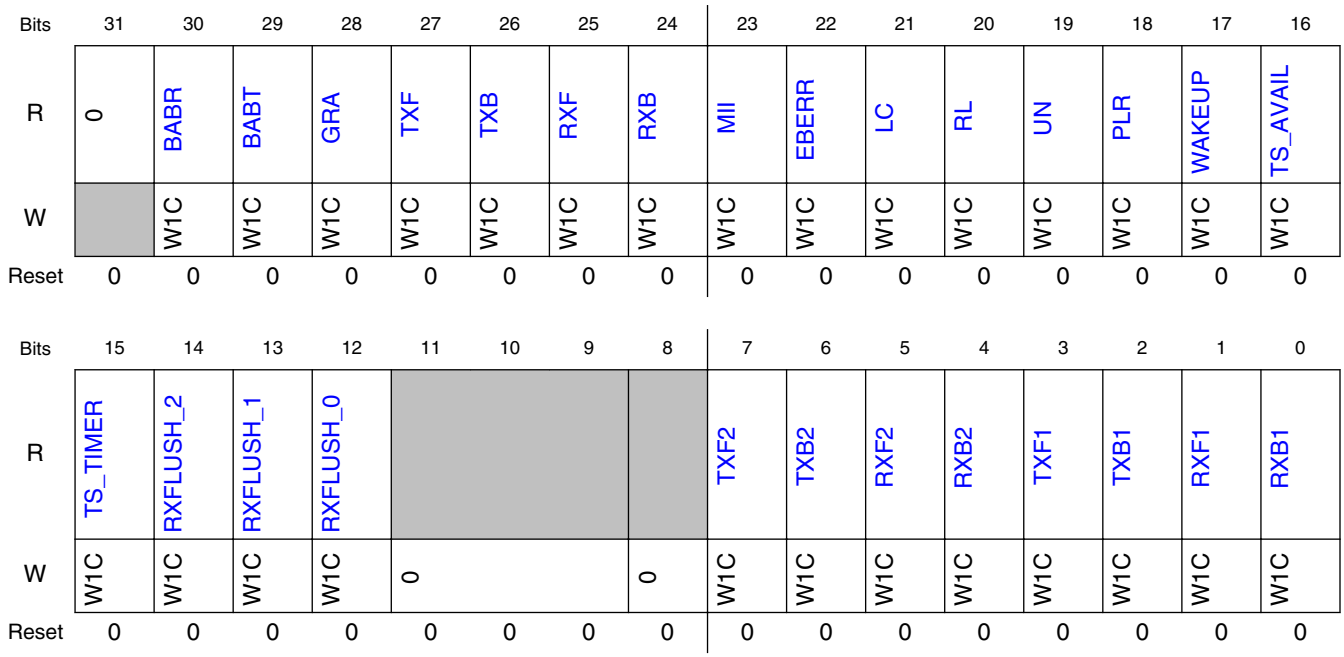
60.5.1.2.2 Function

When an event occurs that sets a bit in EIR, an interrupt occurs if the corresponding bit in the interrupt mask register (EIMR) is also set. Writing a 1 to an EIR bit clears it; writing 0 has no effect. This register is cleared upon hardware reset.

NOTE

TxBD[INT] and RxBD[INT] must be set to 1 to allow setting the corresponding EIR register flags in enhanced mode, ENET_ECR[EN1588] = 1. Legacy mode does not require these flags to be enabled.

60.5.1.2.3 Diagram



60.5.1.2.4 Fields

Field	Function
31 —	Reserved
30 BABR	Babbling Receive Error Indicates a frame was received with length in excess of RCR[MAX_FL] bytes.
29 BABT	Babbling Transmit Error Indicates the transmitted frame length exceeds RCR[MAX_FL] bytes. Usually this condition is caused when a frame that is too long is placed into the transmit data buffer(s). Truncation does not occur.
28 GRA	Graceful Stop Complete This interrupt is asserted after the transmitter is put into a pause state after completion of the frame currently being transmitted. See Graceful Transmit Stop (GTS) for conditions that lead to graceful stop. **NOTE:** The GRA interrupt is asserted only when the TX transitions into the stopped state. If this bit is cleared by writing 1 and the TX is still stopped, the bit is not set again.
27 TXF	Transmit Frame Interrupt Indicates a frame has been transmitted and the last corresponding buffer descriptor has been updated.
26 TXB	Transmit Buffer Interrupt Indicates a transmit buffer descriptor has been updated.
25 RXF	Receive Frame Interrupt Indicates a frame has been received and the last corresponding buffer descriptor has been updated.
24	Receive Buffer Interrupt

Table continues on the next page...

Field	Function
RXB	Indicates a receive buffer descriptor is not the last in the frame has been updated.
23 MII	MII Interrupt. Indicates that the MII has completed the data transfer requested.
22 EBERR	Ethernet Bus Error Indicates a system bus error occurred when a uDMA transaction is underway. When this bit is set, ECR[ETHEREN] is cleared, halting frame processing by the MAC. When this occurs, software must ensure proper actions, possibly resetting the system, to resume normal operation.
21 LC	Late Collision Indicates a collision occurred beyond the collision window (slot time) in half-duplex mode. The frame truncates with a bad CRC and the remainder of the frame is discarded.
20 RL	Collision Retry Limit Indicates a collision occurred on each of 16 successive attempts to transmit the frame. The frame is discarded without being transmitted and transmission of the next frame commences. This error can only occur in half-duplex mode.
19 UN	Transmit FIFO Underrun Indicates the transmit FIFO became empty before the complete frame was transmitted. **NOTE:** In situations where the device has various leaders generating high traffic, a FIFO underrun can occur on the transmit FIFO. To avoid transmit FIFO underrun, store and forward can be enabled in ENET_TFWR[STRFWD]. See Transmit FIFO Watermark (TFWR). Also, a higher priority can be set for ENET traffic using available means on the central bus fabric connecting the ENET module.
18 PLR	Payload Receive Error Indicates a frame was received with a payload length error. See Frame Length/Type Verification: Payload Length Check for more information.
17 WAKEUP	Node Wakeup Request Indication Read-only status bit to indicate that a magic packet has been detected. Will act only if ECR[MAGICEN] is set.
16 TS_AVAIL	Transmit Timestamp Available Indicates that the timestamp of the last transmitted timing frame is available in the ATSTMP register.
15 TS_TIMER	Timestamp Timer The adjustable timer reached the period event. A period event interrupt can be generated if ATCR[PEREN] is set and the timer wraps according to the periodic setting in the ATPER register. Set the timer period value before setting ATCR[PEREN].
14 RXFLUSH_2	RX DMA Ring 2 flush indication. This ring's RX frame has been flushed due to either RDAR2[RDAR] or RxBD[E] being clear and only if QOS[RXFLUSH_2] is enabled. **NOTE:** This field is not supported in every instance. The following table includes only supported registers. **Instance** / **Field supported in** / **Field not supported in** ENET / — / EIR ENET_1G / EIR / —
13 RXFLUSH_1	RX DMA Ring 1 flush indication. This ring's RX frame has been flushed due to either RDAR1[RDAR] or RxBD[E] being clear and only if QOS[RXFLUSH_1] is enabled.

60.5.1.3 Interrupt Mask (EIMR)

60.5.1.3.1 Offset

Register	Offset
EIMR	8h

60.5.1.3.2 Function

EIMR controls which interrupt events are allowed to generate actual interrupts. A hardware reset clears this register. If the corresponding bits in the EIR and EIMR registers are set, an interrupt is generated. The interrupt signal remains asserted until a 1 is written to the EIR field (write 1 to clear) or a 0 is written to the EIMR field.

60.5.1.3.4 Fields

Field	Function
31 —	This write-only field is reserved. It must always be written with the value 0.
30 BABR	BABR Interrupt Mask Corresponds to interrupt source EIR[BABR] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR BABR field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared. 0b - The corresponding interrupt source is masked. 1b - The corresponding interrupt source is not masked.
29 BABT	BABT Interrupt Mask Corresponds to interrupt source EIR[BABT] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR BABT field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared. 0b - The corresponding interrupt source is masked. 1b - The corresponding interrupt source is not masked.
28 GRA	GRA Interrupt Mask Corresponds to interrupt source EIR[GRA] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR GRA field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared. 0b - The corresponding interrupt source is masked. 1b - The corresponding interrupt source is not masked.
27 TXF	TXF Interrupt Mask Corresponds to interrupt source EIR[TXF] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The

Table continues on the next page...

Field	Function
	corresponding EIR TXF field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared. 0b - The corresponding interrupt source is masked. 1b - The corresponding interrupt source is not masked.
26 TXB	TXB Interrupt Mask Corresponds to interrupt source EIR[TXB] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR TXF field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared. 0b - The corresponding interrupt source is masked. 1b - The corresponding interrupt source is not masked.
25 RXF	RXF Interrupt Mask Corresponds to interrupt source EIR[RXF] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR RXF field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared. 0b - The corresponding interrupt source is masked. 1b - The corresponding interrupt source is not masked.
24 RXB	RXB Interrupt Mask Corresponds to interrupt source EIR[RXB] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR RXB field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared. 0b - The corresponding interrupt source is masked. 1b - The corresponding interrupt source is not masked.
23 MII	MII Interrupt Mask Corresponds to interrupt source EIR[MII] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR MII field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared. 0b - The corresponding interrupt source is masked. 1b - The corresponding interrupt source is not masked.
22 EBERR	EBERR Interrupt Mask Corresponds to interrupt source EIR[EBERR] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR EBERR field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared. 0b - The corresponding interrupt source is masked. 1b - The corresponding interrupt source is not masked.
21 LC	LC Interrupt Mask Corresponds to interrupt source EIR[LC] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR LC field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared. 0b - The corresponding interrupt source is masked. 1b - The corresponding interrupt source is not masked.
20 RL	RL Interrupt Mask Corresponds to interrupt source EIR[RL] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR RL field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.

Table continues on the next page...

Field	Function
	0b - The corresponding interrupt source is masked. 1b - The corresponding interrupt source is not masked.
19 UN	UN Interrupt Mask Corresponds to interrupt source EIR[UN] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR UN field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared. 0b - The corresponding interrupt source is masked. 1b - The corresponding interrupt source is not masked.
18 PLR	PLR Interrupt Mask Corresponds to interrupt source EIR[PLR] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR PLR field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared. 0b - The corresponding interrupt source is masked. 1b - The corresponding interrupt source is not masked.
17 WAKEUP	WAKEUP Interrupt Mask Corresponds to interrupt source EIR[WAKEUP] register and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR WAKEUP field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared. 0b - The corresponding interrupt source is masked. 1b - The corresponding interrupt source is not masked.
16 TS_AVAIL	TS_AVAIL Interrupt Mask Corresponds to interrupt source EIR[TS_AVAIL] register and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR TS_AVAIL field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared. 0b - The corresponding interrupt source is masked. 1b - The corresponding interrupt source is not masked.
15 TS_TIMER	TS_TIMER Interrupt Mask Corresponds to interrupt source EIR[TS_TIMER] register and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR TS_TIMER field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared. 0b - The corresponding interrupt source is masked. 1b - The corresponding interrupt source is not masked.
14 RXFLUSH_2	Corresponds to interrupt source EIR[RXFLUSH_2] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. EIR[RXFLUSH_2] reflects the state of the interrupt signal even if the corresponding EIMR field is cleared. **NOTE:** This field is not supported in every instance. The following table includes only supported registers. **Instance** / **Field supported in** / **Field not supported in** ENET / — / EIMR ENET_1G / EIMR / — 0b - The corresponding interrupt source is masked.

60.5.1.4 Receive Descriptor Active Register - Ring 0 (RDAR)

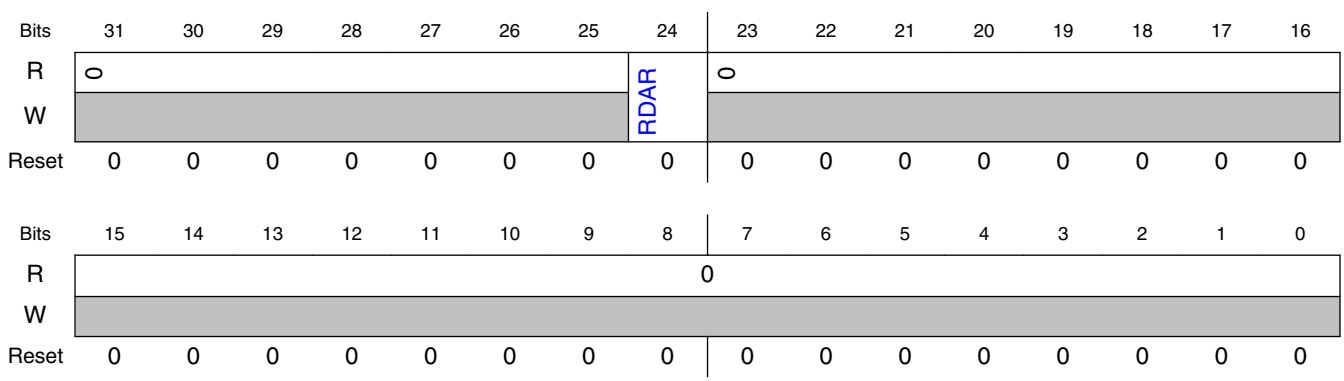
60.5.1.4.1 Offset

Register	Offset
RDAR	10h

60.5.1.4.2 Function

RDAR is a command register, written by the user, to indicate that the receive descriptor ring 0 has been updated, that is, that the driver produced empty receive buffers with the empty bit set.

60.5.1.4.3 Diagram



60.5.1.4.4 Fields

Field	Function
31-25 —	Reserved
24 RDAR	Receive Descriptor Active Always set to 1 when this register is written, regardless of the value written. This field is cleared by the MAC device when no additional empty descriptors remain in the receive ring. It is also cleared when ECR[ETHEREN] transitions from set to cleared or when ECR[RESET] is set.
23-0 —	Reserved

60.5.1.5 Transmit Descriptor Active Register - Ring 0 (TDAR)

60.5.1.5.1 Offset

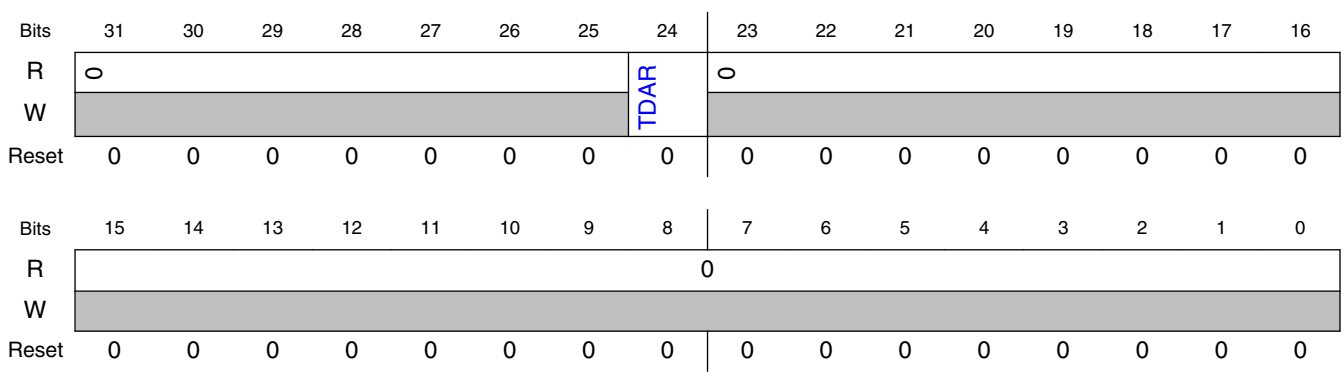
Register	Offset
TDAR	14h

60.5.1.5.2 Function

The TDAR is a command register that the user writes to indicate that the transmit descriptor ring 0 has been updated, that is, that transmit buffers have been produced by the driver with the ready bit set in the buffer descriptor.

The TDAR register is cleared at reset, when ECR[ETHEREN] transitions from set to cleared, or when ECR[RESET] is set.

60.5.1.5.3 Diagram



60.5.1.5.4 Fields

Field	Function
31-25 —	Reserved
24 TDAR	Transmit Descriptor Active Always set to 1 when this register is written, regardless of the value written. This bit is cleared by the MAC device when no additional ready descriptors remain in the transmit ring. Also cleared when ECR[ETHEREN] transitions from set to cleared or when ECR[RESET] is set.
23-0 —	Reserved

60.5.1.6 Ethernet Control (ECR)

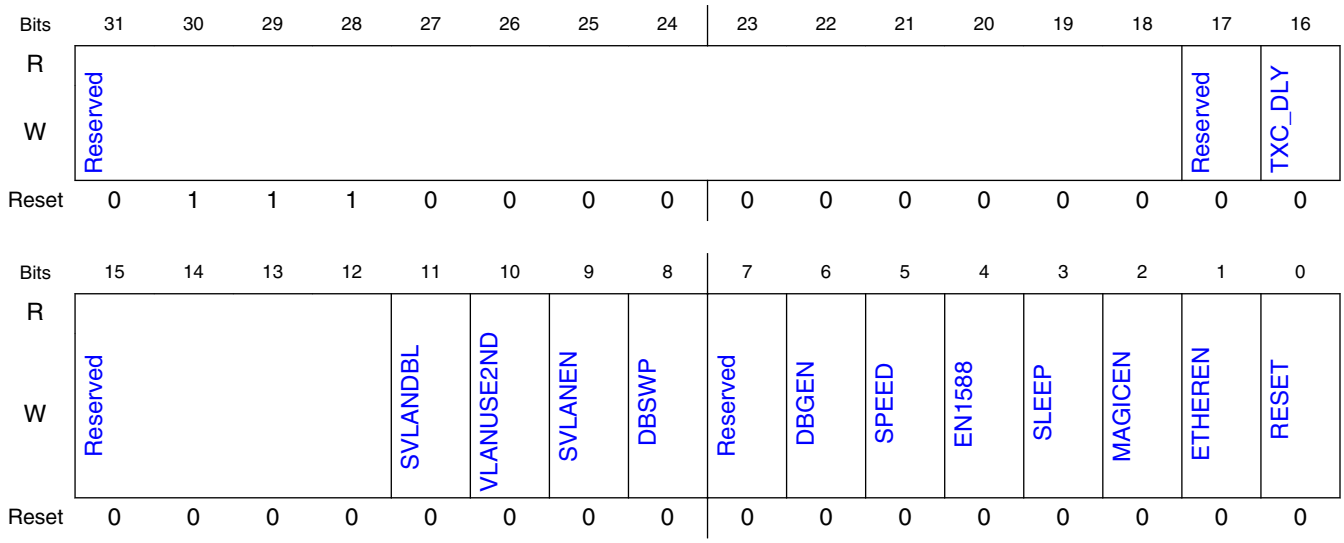
60.5.1.6.1 Offset

Register	Offset
ECR	24h

60.5.1.6.2 Function

ECR is a read/write user register, though hardware may also alter fields in this register. It controls many of the high level features of the Ethernet MAC, including legacy FEC support through the EN1588 field.

60.5.1.6.3 Diagram



60.5.1.6.4 Fields

Field	Function
31-18 —	Always write 01110000000000b to this field.
17 —	Always write 0 to this field.
16 TXC_DLY	Transmit Clock Delay This field allows you to generate a delayed version of the RGMII_TXC clock. **NOTE:** This field is not supported in every instance. The following table includes only supported registers. 0b - RGMII_TXC is not delayed. 1b - Generate delayed version of RGMII_TXC.
15-12 —	Always write 0 to this field.
11 SVLANDBL	S-VLAN Double Tag If enabled, S-VLAN detection requires a double-tagged frame to define a frame as being a VLAN frame. The following rules apply: • If the first tag is the S-VLAN type, it must be followed by a second tag with the C-VLAN type to declare the frame as VLAN frame.

Instance	Field supported in	Field not supported in
ENET	—	ECR
ENET_1G	ECR	—

Table continues on the next page...

<table>
<tr><th>Field</th><th>Function</th></tr>
<tr><td></td><td>
• If the first tag is the S-VLAN type but no 2nd tag follows, it is not considered a VLAN frame but instead treated as an untagged frame.
• If the first tag is the C-VLAN type, it is considered a VLAN frame as normal.

NOTE: VLANUSE2ND can be used to determine from which tag the data should be extracted. This applies only if SVLAN_EN = 1, ignored otherwise.
NOTE: This field is not supported in every instance. The following table includes only supported registers.

<table>
<tr><th>Instance</th><th>Field supported in</th><th>Field not supported in</th></tr>
<tr><td>ENET</td><td>—</td><td>ECR</td></tr>
<tr><td>ENET_1G</td><td>ECR</td><td>—</td></tr>
</table>

0b - Disable S-VLAN double tag
1b - Enable S-VLAN double tag
</td></tr>
<tr><td>10
VLANUSE2ND</td><td>
VLAN Use Second Tag

NOTE: This field is not supported in every instance. The following table includes only supported registers.

<table>
<tr><th>Instance</th><th>Field supported in</th><th>Field not supported in</th></tr>
<tr><td>ENET</td><td>—</td><td>ECR</td></tr>
<tr><td>ENET_1G</td><td>ECR</td><td>—</td></tr>
</table>

0b - Always extract data from the first VLAN tag if it exists.
1b - When a double-tagged frame is detected, the data of the second tag is extracted for further processing. A double-tagged frame is defined as: The first tag can be a C-VLAN or a S-VLAN (if SVLAN_ENA = 1) The second tag must be a C-VLAN
</td></tr>
<tr><td>9
SVLANEN</td><td>
S-VLAN Enable

Enable additional detection of S-VLAN tag according to IEEE802.1Q.

NOTE: This field is not supported in every instance. The following table includes only supported registers.

<table>
<tr><th>Instance</th><th>Field supported in</th><th>Field not supported in</th></tr>
<tr><td>ENET</td><td>—</td><td>ECR</td></tr>
<tr><td>ENET_1G</td><td>ECR</td><td>—</td></tr>
</table>

0b - Only the EtherType 0x8100 will be considered for VLAN detection.
1b - The EtherType 0x88a8 will be considered in addition to 0x8100 (C-VLAN) to identify a VLAN frame in receive. When a VLAN frame is identified, the two bytes following the VLAN type are extracted and used by the classification match comparators, RCMRn.
</td></tr>
<tr><td>8
DBSWP</td><td>
Descriptor Byte Swapping Enable

Swaps the byte locations of the buffer descriptors.

NOTE: This field must be written to 1 after reset.
0b - The buffer descriptor bytes are not swapped to support big-endian devices.
1b - The buffer descriptor bytes are swapped to support little-endian devices.
</td></tr>
</table>

0b - 10/100-Mbit/s mode
1b - 1000-Mbit/s mode</td></tr>
<tr><td>4
EN1588</td><td>EN1588 Enable
Enables enhanced functionality of the MAC.
0b - Legacy FEC buffer descriptors and functions enabled.
1b - Enhanced frame time-stamping functions enabled. Has no effect within the MAC besides controlling the DMA control bit ena_1588.</td></tr>
<tr><td>3
SLEEP</td><td>Sleep Mode Enable
0b - Normal operating mode.
1b - Sleep mode.</td></tr>
<tr><td>2
MAGICEN</td><td>Magic Packet Detection Enable
Enables/disables magic packet detection.
NOTE: MAGICEN is relevant only if the SLEEP field is set. If MAGICEN is set, changing the SLEEP field enables/disables sleep mode and magic packet detection.
NOTE: EIMR[WAKEUP] must be written to one if Magic packet wakeup is programed to wake up the chip from low power mode.
0b - Magic detection logic disabled.
1b - The MAC core detects magic packets and asserts EIR[WAKEUP] when a frame is detected.</td></tr>
<tr><td>1
ETHEREN</td><td>Ethernet Enable
Enables/disables the Ethernet MAC. When the MAC is disabled, the buffer descriptors for an aborted transmit frame are not updated. The uDMA, buffer descriptor, and FIFO control logic are reset, including the buffer descriptor and FIFO pointers.
Hardware clears this field under the following conditions:
• RESET is set by software
• An error condition causes the EBERR field to set.
NOTE:
• ETHEREN must be set at the very last step during ENET configuration/setup/initialization, only after all other ENET-related registers have been configured.
• If ETHEREN is cleared to 0 by software then next time ETHEREN is set, the EIR interrupts must cleared to 0 due to previous pending interrupts.
0b - Reception immediately stops and transmission stops after a bad CRC is appended to any currently transmitted frame.</td></tr>
</table>

Table continues on the next page...

Field	Function
	1b - MAC is enabled, and reception and transmission are possible.
0 RESET	Ethernet MAC Reset When this field is set, it clears the ETHEREN field.

60.5.1.7 MII Management Frame (MMFR)

60.5.1.7.1 Offset

Register	Offset
MMFR	40h

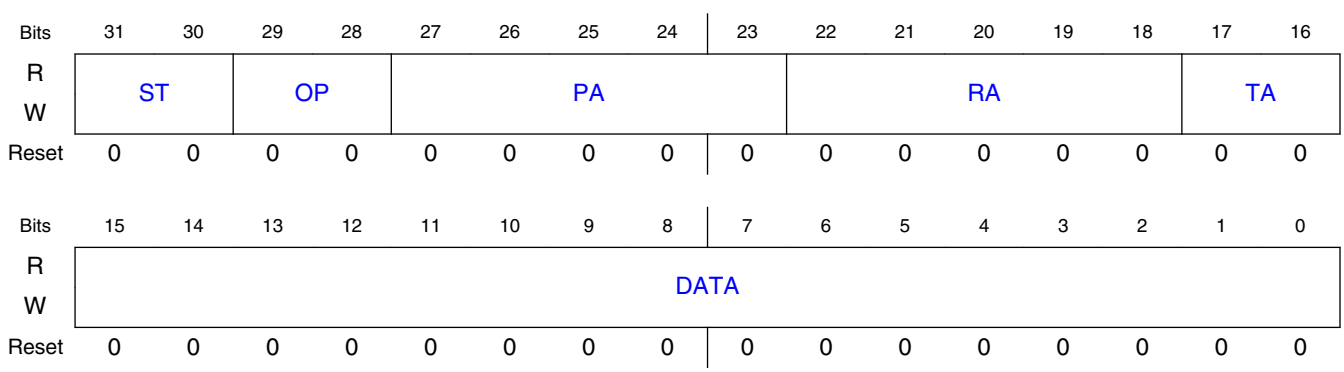
60.5.1.7.2 Function

Writing to MMFR triggers a management frame transaction to the PHY device unless MSCR is programmed to zero.

If MSCR is changed from zero to non-zero during a write to MMFR, an MII frame is generated with the data previously written to the MMFR. This allows MMFR and MSCR to be programmed in either order if MSCR is currently zero.

If the MMFR register is written while frame generation is in progress, the frame contents are altered. Software must use the EIR[MII] interrupt indication to avoid writing to the MMFR register while frame generation is in progress.

60.5.1.7.3 Diagram



60.5.1.7.4 Fields

Field	Function
31-30 ST	Start Of Frame Delimiter See Table 60-40 (Clause 22) or Table 60-42 (Clause 45) for correct value.
29-28 OP	Operation Code See Table 60-40 (Clause 22) or Table 60-42 (Clause 45) for correct value.
27-23 PA	PHY Address See Table 60-40 (Clause 22) or Table 60-42 (Clause 45) for correct value.
22-18 RA	Register Address See Table 60-40 (Clause 22) or Table 60-42 (Clause 45) for correct value.
17-16 TA	Turn Around This field must be programmed to 10 to generate a valid MII management frame.
15-0 DATA	Management Frame Data This is the field for data to be written to or read from the PHY register.

60.5.1.8 MII Speed Control (MSCR)

60.5.1.8.1 Offset

Register	Offset
MSCR	44h

60.5.1.8.2 Function

MSCR provides control of the MII clock (MDC pin) frequency and allows a preamble drop on the MII management frame.

The MII_SPEED field must be programmed with a value to provide an MDC frequency of less than or equal to 2.5 MHz to be compliant with the IEEE 802.3 MII specification. The MII_SPEED must be set to a non-zero value to source a read or write management frame. After the management frame is complete, the MSCR register may optionally be cleared to turn off MDC. The MDC signal generated has a 50% duty cycle except when MII_SPEED changes during operation. This change takes effect following a rising or falling edge of MDC.

For example, if the internal module clock (that is, peripheral bus clock) is 25 MHz, programming MII_SPEED to 0x4 results in an MDC as given in the following equation:

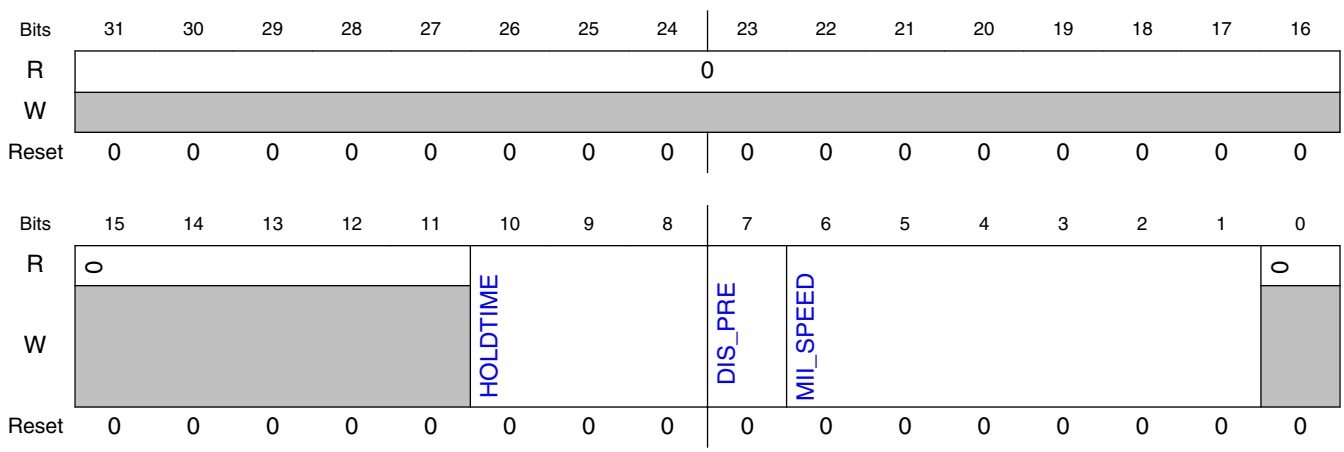
MII clock frequency = 25 MHz / ((4 + 1) x 2) = 2.5 MHz

The following table shows the optimum values for MII_SPEED as a function of IPS bus clock frequency.

Table 60-48. Programming Examples for MSCR

Internal module clock frequency	MSCR [MII_SPEED]	MDC frequency
25 MHz	0x4	2.50 MHz
33 MHz	0x6	2.36 MHz
40 MHz	0x7	2.50 MHz
50 MHz	0x9	2.50 MHz
66 MHz	0xD	2.36 MHz

60.5.1.8.3 Diagram



60.5.1.8.4 Fields

Field	Function
31-11 —	Reserved
10-8 HOLDTIME	Hold time On MDIO Output IEEE802.3 clause 22 defines a minimum of 10 ns for the hold time on the MDIO output. Depending on the host bus frequency, the setting may need to be increased. 000b - 1 internal module clock cycle 001b - 2 internal module clock cycles 010b - 3 internal module clock cycles 111b - 8 internal module clock cycles
7 DIS_PRE	Disable Preamble

Table continues on the next page...

Field	Function
	Enables/disables prepending a preamble to the MII management frame. The MII standard allows the preamble to be dropped if the attached PHY devices do not require it. 0b - Preamble enabled. 1b - Preamble (32 ones) is not prepended to the MII management frame.
6-1 MII_SPEED	MII Speed Controls the frequency of the MII management interface clock (MDC) relative to the internal module clock. A value of 0 in this field turns off MDC and leaves it in low voltage state. Any non-zero value results in the MDC frequency of: 1/((MII_SPEED + 1) x 2) of the internal module clock frequency
0 —	Reserved

60.5.1.9 MIB Control (MIBC)

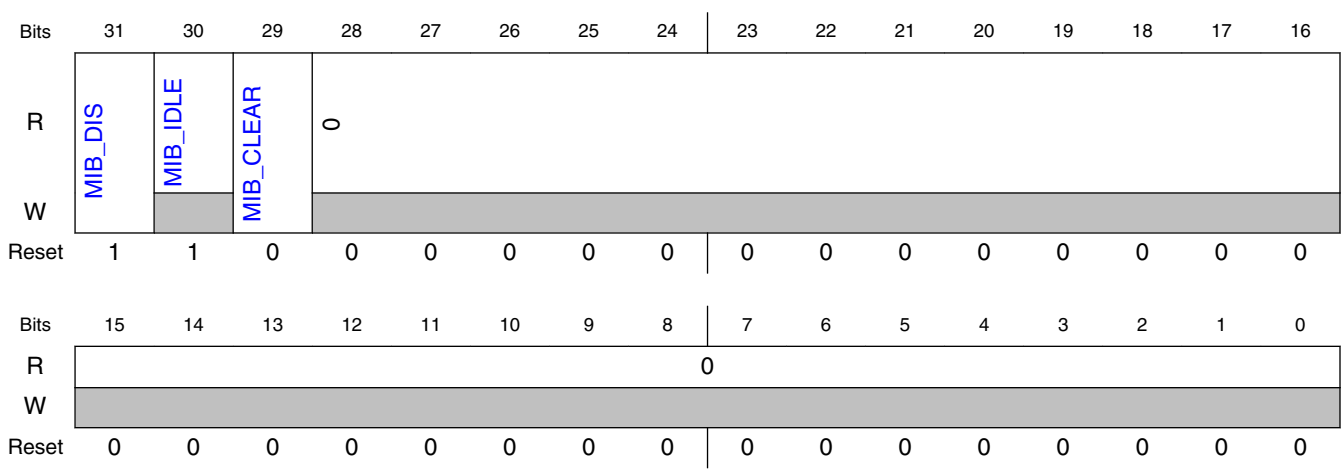
60.5.1.9.1 Offset

Register	Offset
MIBC	64h

60.5.1.9.2 Function

MIBC is a read/write register controlling and observing the state of the MIB block. Access this register to disable the MIB block operation or clear the MIB counters. The MIB_DIS field resets to 1.

60.5.1.9.3 Diagram



60.5.1.9.4 Fields

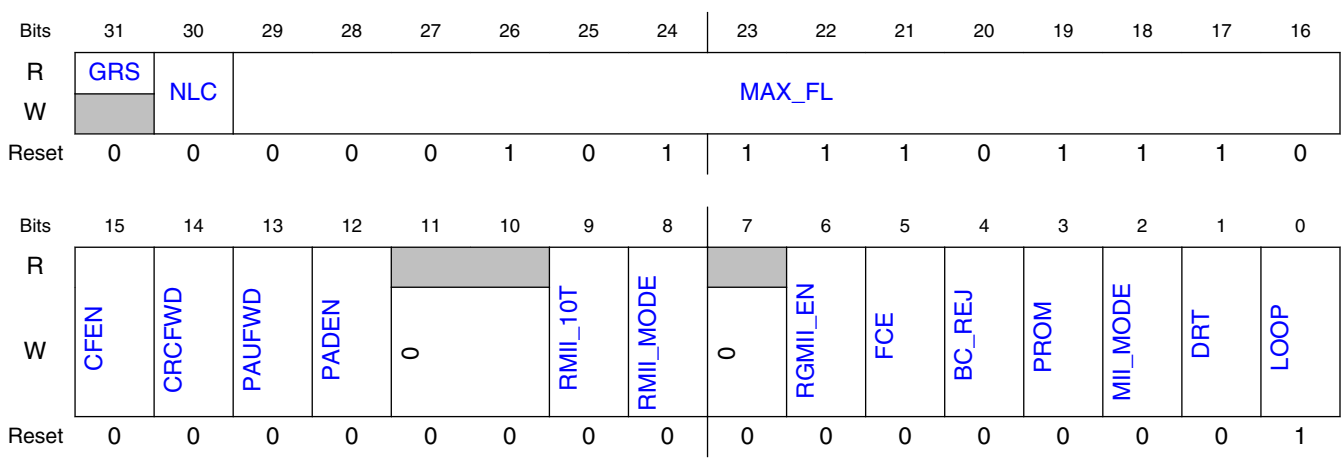
Field	Function
31 MIB_DIS	Disable MIB Logic If this control field is set, 0b - MIB logic is enabled. 1b - MIB logic is disabled. The MIB logic halts and does not update any MIB counters.
30 MIB_IDLE	MIB Idle 0b - The MIB block is updating MIB counters. 1b - The MIB block is not currently updating any MIB counters.
29 MIB_CLEAR	MIB Clear **NOTE:** This field is not self-clearing. To clear the MIB counters set and then clear this field. 0b - See note above. 1b - All statistics counters are reset to 0.
28-0 —	Reserved

60.5.1.10 Receive Control (RCR)

60.5.1.10.1 Offset

Register	Offset
RCR	84h

60.5.1.10.2 Diagram



60.5.1.10.3 Fields

Field	Function
31 GRS	Graceful Receive Stopped Read-only status indicating that the MAC receive datapath is stopped. 0b - Receive not stopped 1b - Receive stopped
30 NLC	Payload Length Check Disable Enables/disables a payload length check. 0b - The payload length check is disabled. 1b - The core checks the frame's payload length with the frame length/type field. Errors are indicated in the EIR[PLR] field.
29-16 MAX_FL	Maximum Frame Length Resets to decimal 1518. Length is measured starting at DA and includes the CRC at the end of the frame. Transmit frames longer than MAX_FL cause the BABT interrupt to occur. Receive frames longer than MAX_FL cause the BABR interrupt to occur and set the LG field in the end of frame receive buffer descriptor. The recommended default value to be programmed is 1518 or 1522 if VLAN tags are supported.
15 CFEN	MAC Control Frame Enable Enables/disables the MAC control frame. 0b - MAC control frames with any opcode other than 0x0001 (pause frame) are accepted and forwarded to the client interface. 1b - MAC control frames with any opcode other than 0x0001 (pause frame) are silently discarded.
14 CRCFWD	Terminate/Forward Received CRC Specifies whether the CRC field of received frames is transmitted or stripped. **NOTE:** If padding function is enabled (PADEN = 1), CRCFWD is ignored and the CRC field is checked and always terminated and removed. 0b - The CRC field of received frames is transmitted to the user application. 1b - The CRC field is stripped from the frame.
13 PAUFWD	Terminate/Forward Pause Frames Specifies whether pause frames are terminated or forwarded. 0b - Pause frames are terminated and discarded in the MAC. 1b - Pause frames are forwarded to the user application.
12 PADEN	Enable Frame Padding Remove On Receive Specifies whether the MAC removes padding from received frames. 0b - No padding is removed on receive by the MAC. 1b - Padding is removed from received frames.
11-10 —	This write-only field is reserved. It must always be written with the value 0.
9 RMII_10T	Enables 10-Mbit/s mode of the RMII or RGMII . **NOTE:** The descriptions of the field settings vary by module instance.

Instance	Field value and description
ENET	0b - 100-Mbit/s operation. 1b - 10-Mbit/s operation.
ENET_1G	0b - 100-Mbit/s or 1-Gbit/s operation. 1b - 10-Mbit/s operation.

Table continues on the next page...

<table>
<tr><th>Field</th><th>Function</th></tr>
<tr><td>8
RMII_MODE</td><td>RMII Mode Enable
Specifies whether the MAC is configured for MII mode or RMII operation , when ECR[SPEED] is cleared .
NOTE: Do not set both RCR[RGMII_EN] and RCR[RMII_MODE].
0b - MAC configured for MII mode.
1b - MAC configured for RMII operation.</td></tr>
<tr><td>7
—</td><td>This write-only field is reserved. It must always be written with the value 0.</td></tr>
<tr><td>6
RGMII_EN</td><td>RGMII Mode Enable
NOTE: Do not set both RCR[RGMII_EN] and RCR[RMII_MODE].
NOTE: This field is not supported in every instance. The following table includes only supported registers.
<table>
<tr><th>Instance</th><th>Field supported in</th><th>Field not supported in</th></tr>
<tr><td>ENET</td><td>—</td><td>RCR</td></tr>
<tr><td>ENET_1G</td><td>RCR</td><td>—</td></tr>
</table>
0b - MAC configured for non-RGMII operation
1b - MAC configured for RGMII operation. ECR[SPEED] should be configured before enable RGMII. If ECR[SPEED] is set, the MAC is in RGMII 1000-Mbit/s mode. If ECR[SPEED] is cleared, the MAC is in RGMII 10/100-Mbit/s mode.</td></tr>
<tr><td>5
FCE</td><td>Flow Control Enable
If set, the receiver detects PAUSE frames. Upon PAUSE frame detection, the transmitter stops transmitting data frames for a given duration.
0b - Disable flow control
1b - Enable flow control</td></tr>
<tr><td>4
BC_REJ</td><td>Broadcast Frame Reject
If set, frames with destination address (DA) equal to 0xFFFF_FFFF_FFFF are rejected unless the PROM field is set. If BC_REJ and PROM are set, frames with broadcast DA are accepted and the MISS (M) is set in the receive buffer descriptor.
0b - Will not reject frames as described above
1b - Will reject frames as described above</td></tr>
<tr><td>3
PROM</td><td>Promiscuous Mode
All frames are accepted regardless of address matching.
0b - Disabled.
1b - Enabled.</td></tr>
<tr><td>2
MII_MODE</td><td>Media Independent Interface Mode
This field must always be set.
0b - Reserved.
1b - MII or RMII mode, as indicated by the RMII_MODE field.</td></tr>
<tr><td>1
DRT</td><td>Disable Receive On Transmit
0b - Receive path operates independently of transmit (i.e., full-duplex mode). Can also be used to monitor transmit activity in half-duplex mode.
1b - Disable reception of frames while transmitting. (Normally used for half-duplex mode.)</td></tr>
<tr><td>0
LOOP</td><td>Internal Loopback
This is an MII internal loopback, therefore MII_MODE must be written to 1 and RMII_MODE must be written to 0.</td></tr>
</table>

Field	Function
	0b - Loopback disabled. 1b - Transmitted frames are looped back internal to the device and transmit MII output signals are not asserted. DRT must be cleared.

60.5.1.11 Transmit Control (TCR)

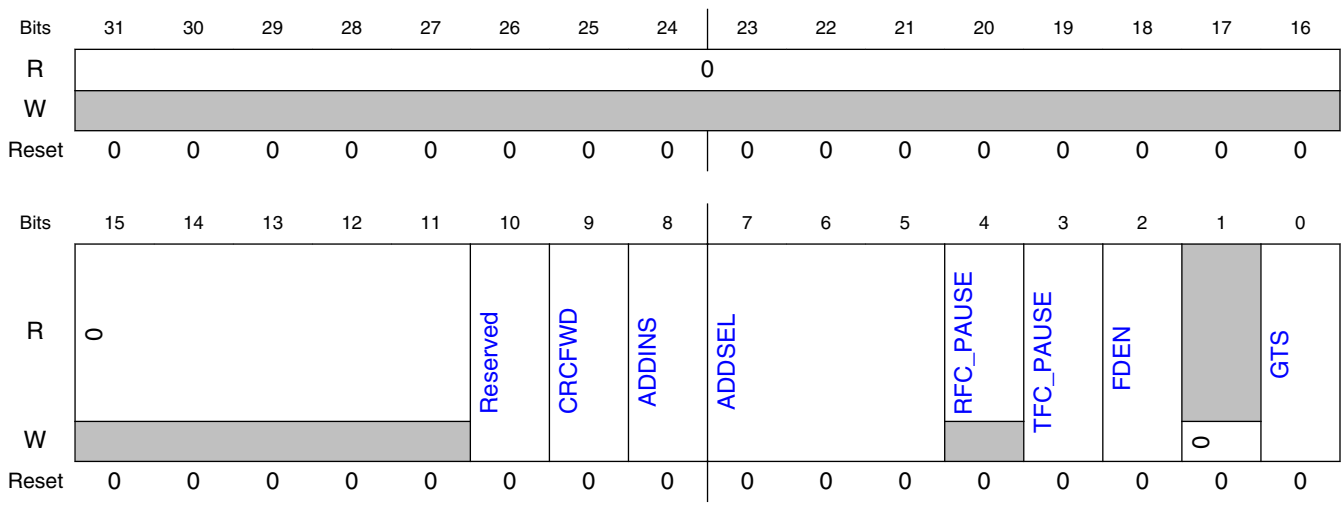
60.5.1.11.1 Offset

Register	Offset
TCR	C4h

60.5.1.11.2 Function

TCR is read/write and configures the transmit block. This register is cleared at system reset. FDEN can only be modified when ECR[ETHEREN] is cleared.

60.5.1.11.3 Diagram



60.5.1.11.4 Fields

Field	Function
31-11 —	Reserved

Table continues on the next page...

Field	Function
10 —	This field is read/write and must be set to 0.
9 CRCFWD	Forward Frame From Application With CRC 0b - TxBD[TC] controls whether the frame has a CRC from the application. 1b - The transmitter does not append any CRC to transmitted frames, as it is expecting a frame with CRC from the application.
8 ADDINS	Set MAC Address On Transmit 0b - The source MAC address is not modified by the MAC. 1b - The MAC overwrites the source MAC address with the programmed MAC address according to ADDSEL.
7-5 ADDSEL	Source MAC Address Select On Transmit If ADDINS is set, indicates the MAC address that overwrites the source MAC address. 000b - Node MAC address programmed on PADDR1/2 registers. 100b - Reserved. 101b - Reserved. 110b - Reserved.
4 RFC_PAUSE	Receive Frame Control Pause This status field is set when a full-duplex flow control pause frame is received and the transmitter pauses for the duration defined in this pause frame. This field automatically clears when the pause duration is complete.
3 TFC_PAUSE	Transmit Frame Control Pause Pauses frame transmission. When this field is set, EIR[GRA] is set. With transmission of data frames stopped, the MAC transmits a MAC control PAUSE frame. Next, the MAC clears TFC_PAUSE and resumes transmitting data frames. If the transmitter pauses due to user assertion of GTS or reception of a PAUSE frame, the MAC may continue transmitting a MAC control PAUSE frame. 0b - No PAUSE frame transmitted. 1b - The MAC stops transmission of data frames after the current transmission is complete.
2 FDEN	Full-Duplex Enable If this field is set, frames transmit independent of carrier sense and collision inputs. Only modify this bit when ECR[ETHEREN] is cleared. 0b - Disable full-duplex 1b - Enable full-duplex
1 —	This write-only field is reserved. It must always be written with the value 0.
0 GTS	Graceful Transmit Stop When this field is set, MAC stops transmission after any frame currently transmitted is complete and EIR[GRA] is set. If frame transmission is not currently underway, the GRA interrupt is asserted immediately. After transmission finishes, clear GTS to restart. The next frame in the transmit FIFO is then transmitted. If an early collision occurs during transmission when GTS is set, transmission stops after the collision. The frame is transmitted again after GTS is cleared. There may be old frames in the transmit FIFO that transmit when GTS is reasserted. To avoid this, clear ECR[ETHEREN] following the GRA interrupt. 0b - Disable graceful transmit stop 1b - Enable graceful transmit stop

60.5.1.12 Physical Address Lower (PALR)

60.5.1.12.1 Offset

Register	Offset
PALR	E4h

60.5.1.12.2 Function

PALR contains the lower 32 bits (bytes 0, 1, 2, 3) of the 48-bit address used in the address recognition process to compare with the destination address (DA) field of receive frames with an individual DA. In addition, this register is used in bytes 0 through 3 of the six-byte source address field when transmitting PAUSE frames.

60.5.1.12.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	PADDR1															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	PADDR1															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

60.5.1.12.4 Fields

Field	Function
31-0 PADDR1	Pause Address Bytes 0 (bits 31:24), 1 (bits 23:16), 2 (bits 15:8), and 3 (bits 7:0) of the 6-byte individual address are used for exact match and the source address field in PAUSE frames.

60.5.1.13 Physical Address Upper (PAUR)

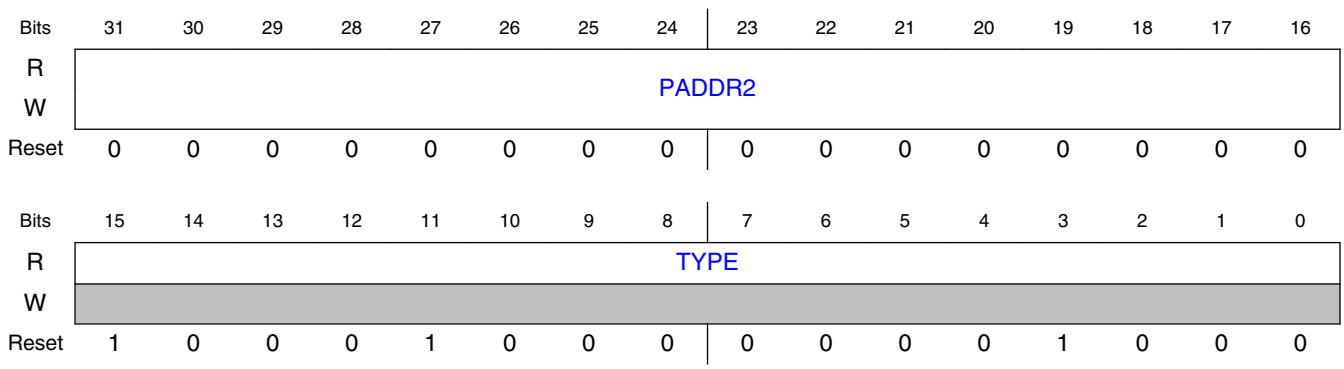
60.5.1.13.1 Offset

Register	Offset
PAUR	E8h

60.5.1.13.2 Function

PAUR contains the upper 16 bits (bytes 4 and 5) of the 48-bit address used in the address recognition process to compare with the destination address (DA) field of receive frames with an individual DA. In addition, this register is used in bytes 4 and 5 of the six-byte source address field when transmitting PAUSE frames. Bits 15:0 of PAUR contain a constant type field (0x8808) for transmission of PAUSE frames.

60.5.1.13.3 Diagram



60.5.1.13.4 Fields

Field	Function
31-16 PADDR2	Bytes 4 (bits 31:24) and 5 (bits 23:16) of the 6-byte individual address used for exact match, and the source address field in PAUSE frames.
15-0 TYPE	Type Field In PAUSE Frames These fields have a constant value of 0x8808.

60.5.1.14 Opcode/Pause Duration (OPD)

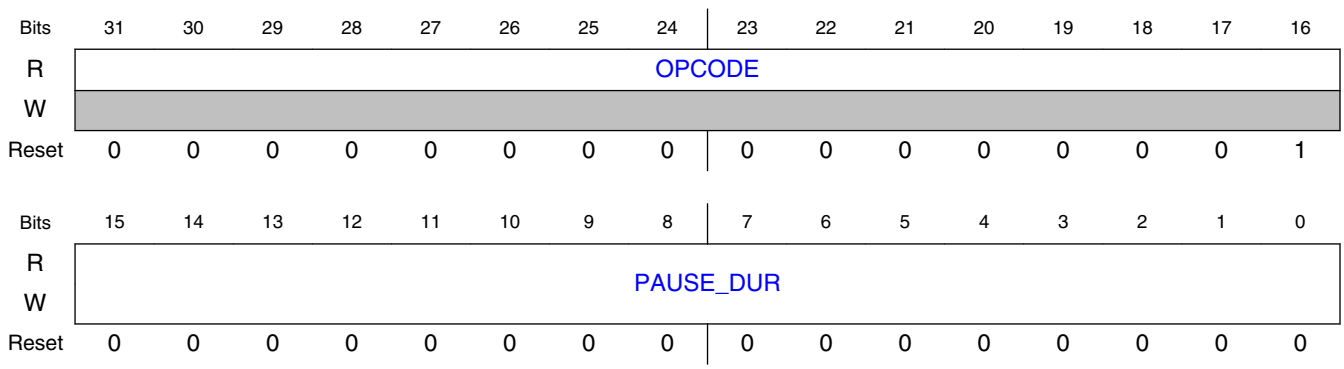
60.5.1.14.1 Offset

Register	Offset
OPD	ECh

60.5.1.14.2 Function

OPD is read/write accessible. This register contains the 16-bit opcode and 16-bit pause duration fields used in transmission of a PAUSE frame. The opcode field is a constant value, 0x0001. When another node detects a PAUSE frame, that node pauses transmission for the duration specified in the pause duration field. The lower 16 bits of this register are not reset and you must initialize it.

60.5.1.14.3 Diagram



60.5.1.14.4 Fields

Field	Function
31-16 OPCODE	Opcode Field In PAUSE Frames These fields have a constant value of 0x0001.
15-0 PAUSE_DUR	Pause Duration Pause duration field used in PAUSE frames.

60.5.1.15 Transmit Interrupt Coalescing (TXIC0 - TXIC2)

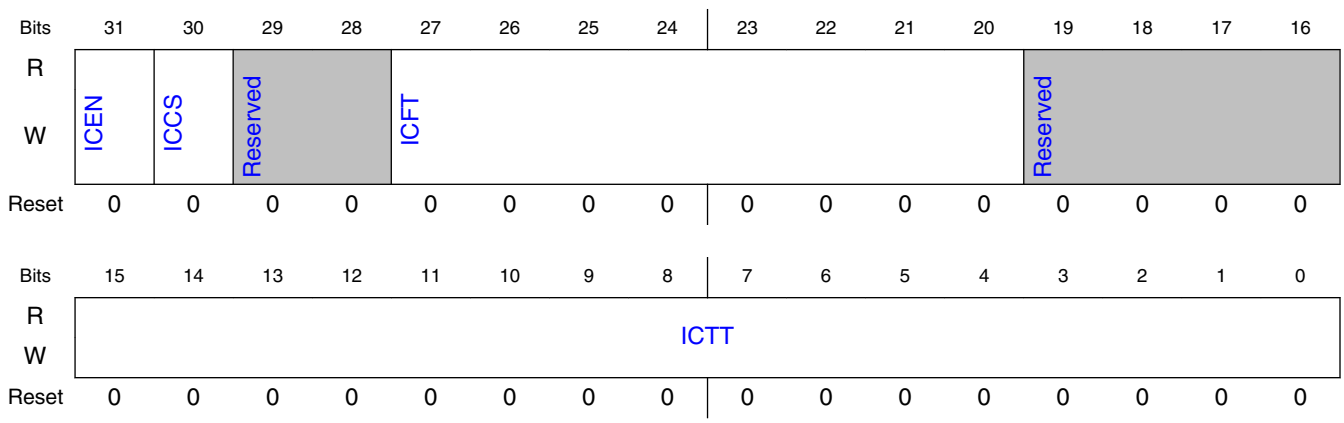
60.5.1.15.1 Offset

Register	Offset
TXIC0	F0h
TXIC1	F4h
TXIC2	F8h

60.5.1.15.2 Function

See Interrupts for more information.

60.5.1.15.3 Diagram



60.5.1.15.4 Fields

Field	Function
31 ICEN	Interrupt Coalescing Enable 0b - Disable Interrupt coalescing. 1b - Enable Interrupt coalescing.
30 ICCS	Interrupt Coalescing Timer Clock Source Select 0b - Use MII/GMII TX clocks. 1b - Use ENET system clock.
29-28 —	This field must be set to 0.
27-20 ICFT	Interrupt coalescing frame count threshold This value determines the number of frames needed to be transmitted for raising an interrupt. Frame counter restarts after reaching this threshold value or after the expiring of the coalescing timer. Must be greater than zero to avoid unpredictable behavior.
19-16 —	This field must be set to 0.

Table continues on the next page...

Field	Function
15-0 ICTT	Interrupt coalescing timer threshold Interrupt coalescing timer threshold in units of 64 TX clock periods. This value determines the maximum amount of time after transmitting a frame before raising an interrupt. The threshold timer is disabled after expiring or number of frame transmission defined by ICFT and starts again upon transmission of the next first frame. Must be greater than zero to avoid unpredictable behavior.

60.5.1.16 Receive Interrupt Coalescing (RXIC0 - RXIC2)

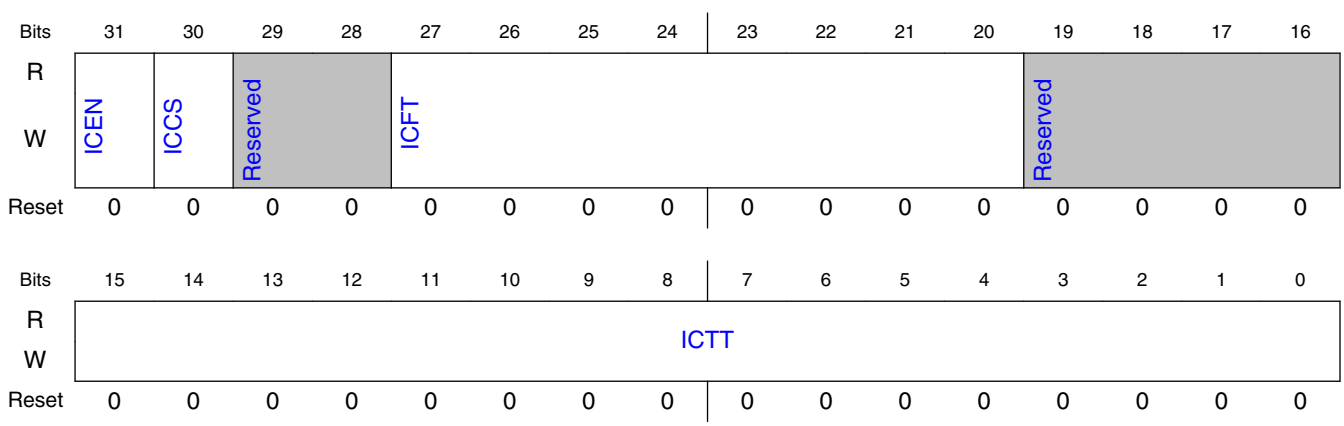
60.5.1.16.1 Offset

Register	Offset
RXIC0	100h
RXIC1	104h
RXIC2	108h

60.5.1.16.2 Function

See Interrupts for more information.

60.5.1.16.3 Diagram



60.5.1.16.4 Fields

Field	Function
31	Interrupt Coalescing Enable 0b - Disable Interrupt coalescing.

Table continues on the next page...

Field	Function
ICEN	1b - Enable Interrupt coalescing.
30 ICCS	Interrupt Coalescing Timer Clock Source Select 0b - Use MII/GMII TX clocks. 1b - Use ENET system clock.
29-28 —	This field must be set to 0.
27-20 ICFT	Interrupt coalescing frame count threshold This value determines the number of frames needed to be received for raising an interrupt. Frame counter restarts after reaching this threshold value or after the expiring of the coalescing timer. Must be greater than zero to avoid unpredictable behavior.
19-16 —	This field must be set to 0.
15-0 ICTT	Interrupt coalescing timer threshold Interrupt coalescing timer threshold in units of 64 RX clock periods. This value determines the maximum amount of time after receiving a frame before raising an interrupt. The threshold timer is disabled after expiring or number of frame reception defined by ICFT and starts again upon reception of the next first frame. Must be greater than zero to avoid unpredictable behavior.

60.5.1.17 Descriptor Individual Upper Address (IAUR)

60.5.1.17.1 Offset

Register	Offset
IAUR	118h

60.5.1.17.2 Function

IAUR contains the upper 32 bits of the 64-bit individual address hash table. The address recognition process uses this table to check for a possible match with the destination address (DA) field of receive frames with an individual DA. This register is not reset and you must initialize it.

60.5.1.17.3 Diagram

60.5.1.20.4 Fields

Field	Function
31-0 GADDR2	Contains the lower 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a multicast address. Bit 31 of GADDR2 contains hash index bit 31. Bit 0 of GADDR2 contains hash index bit 0.

60.5.1.21 Transmit FIFO Watermark (TFWR)

60.5.1.21.1 Offset

Register	Offset
TFWR	144h

60.5.1.21.2 Function

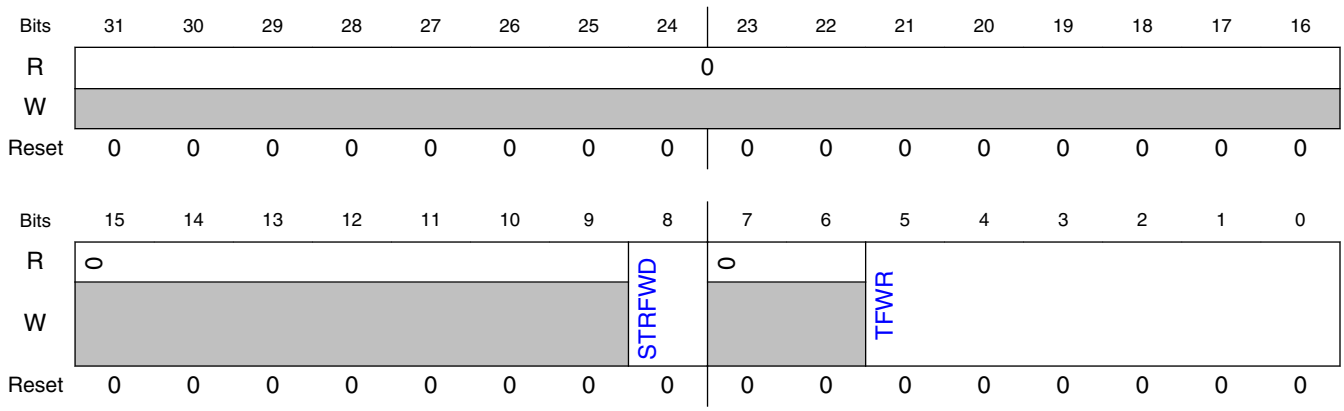
If TFWR[STRFWD] is cleared, TFWR[TFWR] controls the amount of data required in the transmit FIFO before transmission of a frame can begin. This allows you to minimize transmit latency (TFWR = 00 or 01) or allow for larger bus access latency (TFWR = 11) due to contention for the system bus. Setting the watermark to a high value minimizes the risk of transmit FIFO underrun due to contention for the system bus. The byte counts associated with the TFWR field may need to be modified to match a given system requirement, for example, worst-case bus access latency by the transmit data uDMA channel.

When the FIFO level reaches the value the TFWR field and when the STR_FWD is set to ‘0’, the MAC transmit control logic starts frame transmission even before the end-of-frame is available in the FIFO (cut-through operation).

If a complete frame has a size smaller than the threshold programmed with TFWR, the MAC also transmits the Frame to the line.

To enable store and forward on the Transmit path, set STR_FWD to ‘1’. In this case, the MAC starts to transmit data only when a complete frame is stored in the Transmit FIFO.

60.5.1.21.3 Diagram



60.5.1.21.4 Fields

Field	Function
31-9 —	Reserved
8 STRFWD	Store And Forward Enable 0b - Reset. The transmission start threshold is programmed in TFWR[TFWR]. 1b - Enabled.
7-6 —	Reserved
5-0 TFWR	Transmit FIFO Write If TFWR[STRFWD] is cleared, this field indicates the number of bytes, in steps of 64 bytes, written to the transmit FIFO before transmission of a frame begins. **NOTE:** If a frame with less than the threshold is written, it is still sent independently of this threshold setting. The threshold is relevant only if the frame is larger than the threshold given. **NOTE:** The descriptions of the field settings vary by module instance.

Instance	Field value and description
ENET	00_0000b - 64 bytes written.

Field	Function	
	Instance	Field value and description
		00_0001b - 64 bytes written. 00_0010b - 128 bytes written. 00_0011b - 192 bytes written. 01_1111b - 1984 bytes written.
	ENET_1G	00_0000b - 64 bytes written. 00_0001b - 64 bytes written. 00_0010b - 128 bytes written. 00_0011b - 192 bytes written. 11_1111b - 4032 bytes written.

60.5.1.22 Receive Descriptor Ring 1 Start (RDSR1)

60.5.1.22.1 Offset

Register	Offset
RDSR1	160h

60.5.1.22.2 Function

RDSR1 points to the beginning of circular receive buffer descriptor queue 1 in external memory. This pointer must be 64-bit aligned (bits 2–0 must be zero); however, for optimal performance the pointer should be 512-bit aligned, that is, evenly divisible by 64.

NOTE

This register must be initialized prior to operation.

NOTE

Each module instance supports a different number of registers.

60.5.1.24 Maximum Receive Buffer Size Register - Ring 1 (MRBR1)

60.5.1.24.1 Offset

Register	Offset
MRBR1	168h

60.5.1.24.2 Function

MRBR1 is a user-programmable register that dictates the maximum size of all ring-1 receive buffers. This value should take into consideration that the receive CRC is always written into the last receive buffer.

- To allow one maximum size frame per buffer, MRBR1 must be set to RCR[MAX_FL] or larger.
- R_BUF_SIZE is concatenated with the four least-significant bits of this register and are used as the maximum receive buffer size.
- To properly align the buffer, MRBR1 must be evenly divisible by 64. To ensure this, set the lower two bits of R_BUF_ZIZE to zero. The lower four bits are already set to zero by the device.
- To minimize bus usage (descriptor fetches), set MRBR1 greater than or equal to 256 bytes.

NOTE

This register must be initialized before operation.

NOTE

Each module instance supports a different number of registers.

Field	Function
31-10 —	Reserved

Table continues on the next page...

Field	Function
9-0 TX_ALMOST_FULL	Value Of The Transmit FIFO Almost Full Threshold Value, in 64-bit words, of the transmit FIFO almost full threshold. A minimum value of six is required . A recommended value of at least 8 should be set allowing a latency of two clock cycles to the application. If more latency is required the value can be increased as necessary (latency = TAFL - 5). When the FIFO level comes close to the maximum, so that there is no more space for at least TX_ALMOST_FULL number of words, the pin ff_tx_rdy is deasserted. If the application does not react on this signal, the FIFO write control logic, to avoid FIFO overflow, truncates the current frame and sets the error status. As a result, the frame will be transmitted with an GMII/MII error indication. See Transmit FIFO for more information. **NOTE:** A FIFO overflow is a fatal error and requires a global reset on the transmit datapath or at least deassertion of ETHEREN. **NOTE:** This field is not supported in every instance. The following table includes only supported registers.

Instance	Field supported in	Field not supported in

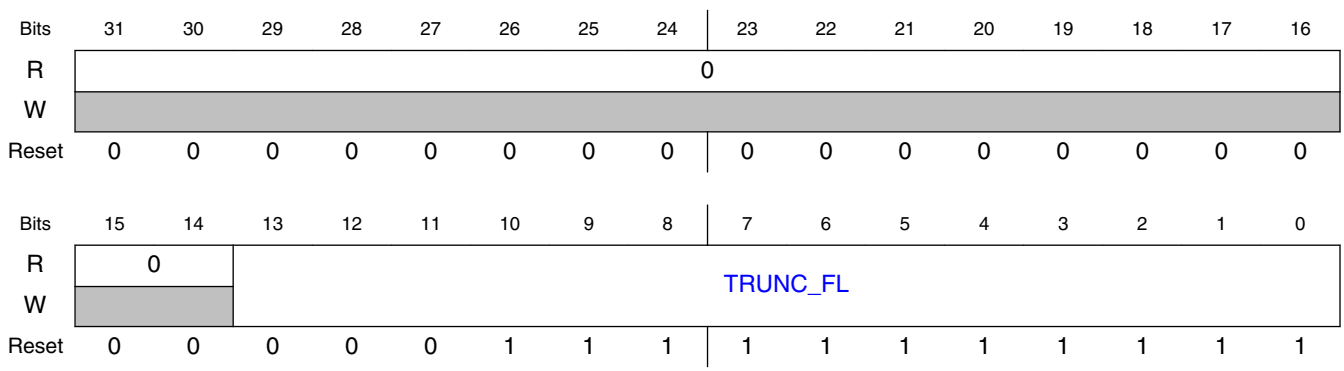
4-0 IPG	Transmit Inter-Packet Gap Indicates the IPG, in bytes, between transmitted frames. Valid values range from 8 to 26. If the written value is less than 8 or greater than 26, the internal (effective) IPG is 12. **NOTE:** The IPG value read will be the value that was written, even if it is out of range.

60.5.1.39 Frame Truncation Length (FTRL)

60.5.1.39.1 Offset

Register	Offset
FTRL	1B0h

60.5.1.39.2 Diagram



60.5.1.39.3 Fields

Field	Function
31-14 —	Reserved
13-0 TRUNC_FL	Frame Truncation Length Indicates the value a receive frame is truncated, if it is greater than this value. Must be greater than or equal to RCR[MAX_FL].

Field	Function
	NOTE: Truncation happens at TRUNC_FL. However, when truncation occurs, the application (FIFO) may receive less data, guaranteeing that it never receives more than the set limit.

60.5.1.40 Transmit Accelerator Function Configuration (TACC)

60.5.1.40.1 Offset

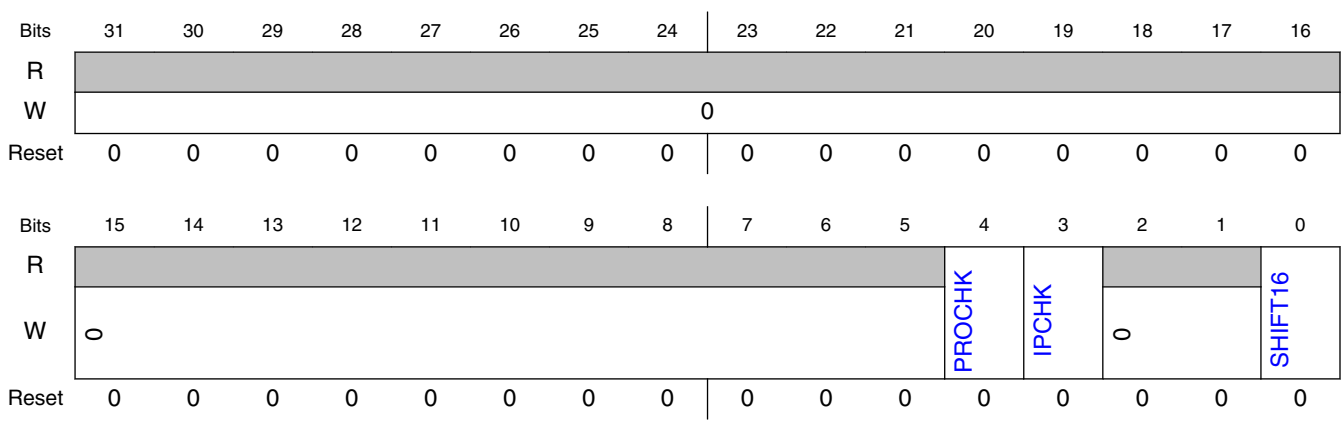
Register	Offset
TACC	1C0h

60.5.1.40.2 Function

TACC controls accelerator actions when sending frames. The register can be changed before or after each frame, but it must remain unmodified during frame writes into the transmit FIFO.

The TFWR[STRFWD] field must be set to use the checksum feature.

60.5.1.40.3 Diagram



60.5.1.40.4 Fields

Field	Function
31-5 —	This write-only field is reserved. It must always be written with the value 0.

Table continues on the next page...

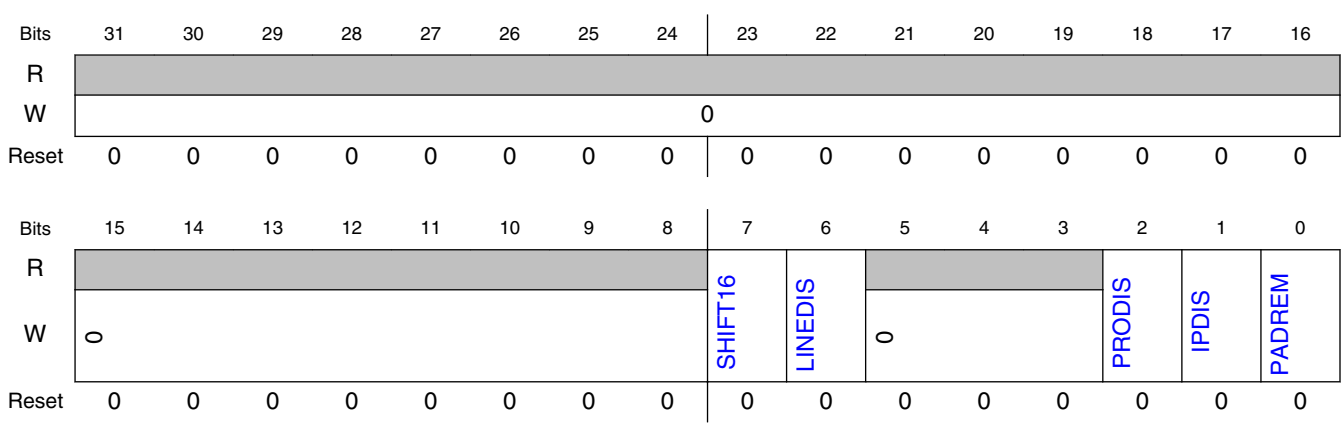
Field	Function
4 PROCHK	Enables insertion of protocol checksum. 0b - Checksum not inserted. 1b - If an IP frame with a known protocol is transmitted, the checksum is inserted automatically into the frame. The checksum field must be cleared. The other frames are not modified.
3 IPCHK	Enables insertion of IP header checksum. 0b - Checksum is not inserted. 1b - If an IP frame is transmitted, the checksum is inserted automatically. The IP header checksum field must be cleared. If a non-IP frame is transmitted the frame is not modified.
2-1 —	This write-only field is reserved. It must always be written with the value 0.
0 SHIFT16	TX FIFO Shift-16 0b - Disabled. 1b - Indicates to the transmit data FIFO that the written frames contain two additional octets before the frame data. This means the actual frame begins at bit 16 of the first word written into the FIFO. This function allows putting the frame payload on a 32-bit boundary in memory, as the 14-byte Ethernet header is extended to a 16-byte header.

60.5.1.41 Receive Accelerator Function Configuration (RACC)

60.5.1.41.1 Offset

Register	Offset
RACC	1C4h

60.5.1.41.2 Diagram



60.5.1.41.3 Fields

Field	Function
31-8 —	This write-only field is reserved. It must always be written with the value 0.
7 SHIFT16	RX FIFO Shift-16 When this field is set, the actual frame data starts at bit 16 of the first word read from the RX FIFO aligning the Ethernet payload on a 32-bit boundary. **NOTE:** This function only affects the FIFO storage and has no influence on the statistics, which use the actual length of the frame received. 0b - Disabled. 1b - Instructs the MAC to write two additional bytes in front of each frame received into the RX FIFO.
6 LINEDIS	Enable Discard Of Frames With MAC Layer Errors 0b - Frames with errors are not discarded. 1b - Any frame received with a CRC, length, or PHY error is automatically discarded and not forwarded to the user application interface.
5-3 —	This write-only field is reserved. It must always be written with the value 0.
2 PRODIS	Enable Discard Of Frames With Wrong Protocol Checksum 0b - Frames with wrong checksum are not discarded. 1b - If a TCP/IP, UDP/IP, or ICMP/IP frame is received that has a wrong TCP, UDP, or ICMP checksum, the frame is discarded. Discarding is only available when the RX FIFO operates in store and forward mode (RSFL cleared).
1 IPDIS	Enable Discard Of Frames With Wrong IPv4 Header Checksum 0b - Frames with wrong IPv4 header checksum are not discarded. 1b - If an IPv4 frame is received with a mismatching header checksum, the frame is discarded. IPv6 has no header checksum and is not affected by this setting. Discarding is only available when the RX FIFO operates in store and forward mode (RSFL cleared).
0 PADREM	Enable Padding Removal For Short IP Frames 0b - Padding not removed. 1b - Any bytes following the IP payload section of the frame are removed from the frame.

60.5.1.42 Receive Classification Match Register for Class n (RCMR1 - RCMR2)

60.5.1.42.1 Offset

Register	Offset
RCMR1	1C8h
RCMR2	1CCh

60.5.1.42.2 Function

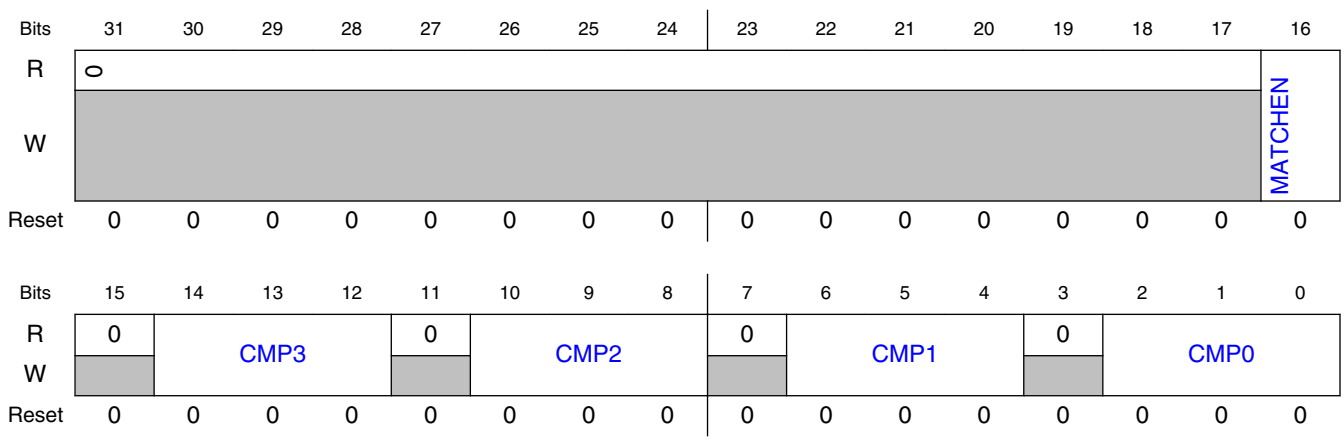
This match register allows specifying up to four priorities, which are tested (OR'ed) simultaneously. The match detection uses the extracted VLAN field according to the rules for VLAN detection configured through the ECR register. If both match registers, RCMR1 and RCMR2, report a match at the same time, only the class 1 match is indicated as the final result.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
ENET	—	RCMR1–RCMR2
ENET_1G	RCMR1–RCMR2	—

60.5.1.42.3 Diagram



60.5.1.42.4 Fields

Field	Function
31-17 —	This write-only field is reserved. It must always be written with the value 0.
16 MATCHEN	Match Enable **NOTE:** A comparison is done only on incoming VLAN frames. If no VLAN frame is received no match will occur. If both match registers have overlapping compare values and hence can match both on the same frame, only class 1 will be indicated and the class 2 match is ignored.

Table continues on the next page...

Field	Function
	0b - Disabled (default): no compares will occur and the classification indicator for this class will never assert. 1b - The register contents are valid and a comparison with all compare values is done when a VLAN frame is received.
15 —	This write-only field is reserved. It must always be written with the value 0.
14-12 CMP3	Compare 3 Fourth value to compare against. If unused it must be set to the same value as CMP0.
11 —	This write-only field is reserved. It must always be written with the value 0.
10-8 CMP2	Compare 2 Third value to compare against. If unused it must be set to the same value as CMP0.
7 —	This write-only field is reserved. It must always be written with the value 0.
6-4 CMP1	Compare 1 Second value to compare against. If unused it must be set to the same value as CMP0.
3 —	This write-only field is reserved. It must always be written with the value 0.
2-0 CMP0	Compare 0 A three-bit value that will be compared with the frame's VLAN priority field (if a VLAN frame is received). All four compare values, CMP0..3, will be used in parallel. If any of the values match, a match for the class is reported (if MATCHEN is 1). **NOTE:** To implement a single priority match, all four compare values must be set to the same value.

60.5.1.43 DMA Class Based Configuration (DMA1CFG - DMA2CFG)

60.5.1.43.1 Offset

Register	Offset
DMA1CFG	1D8h
DMA2CFG	1DCh

60.5.1.43.2 Function

The DMA class based configuration registers are used to configure the DMA controller interface to support the additional class 1 (buffer descriptor ring 1) and class 2 (buffer descriptor ring 2) traffic and define configuration options such as bandwidth allocation as needed.

NOTE

The registers are cleared when ECR[ETHEREN] becomes 0.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported

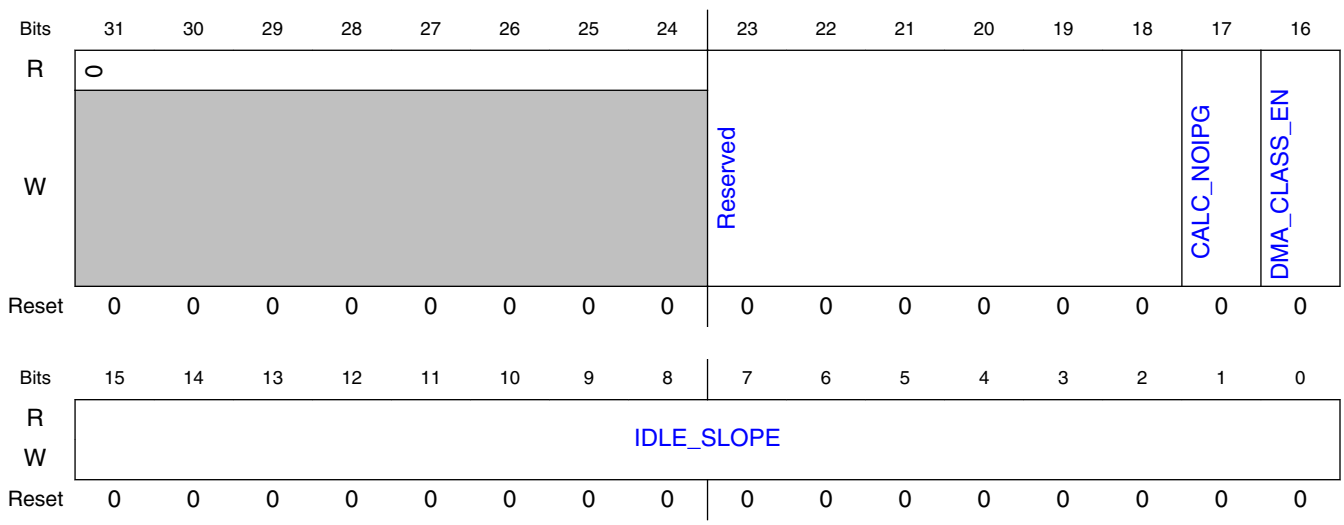
60.5.1.43.3 Diagram



60.5.1.43.4 Fields

Field	Function
31-24 —	Reserved
23-18 —	Write only zeroes to this field **NOTE:** Write only zeroes to this field.
17 CALC_NOIPG	Calculate no IPG Disable inclusion of IPG bytes for bandwidth calculations. 0b - The traffic shaper function should consider 12 octets of IPG in addition to the frame data transferred for a frame when doing bandwidth calculations. This is the default. 1b - Addition of 12 bytes for the IPG should be omitted when calculating the bandwidth (for traffic shaping, when writing a frame into the transmit FIFO, the shaper will usually consider 12 bytes of IPG for every frame as part of the bandwidth allocated by the frame. This addition can be

Table continues on the next page...

Field	Function
	suppressed, meaning short frames will become more bandwidth than large frames due to the relation of data to IPG overhead).
16 DMA_CLASS_EN	DMA class enable 0b - The DMA controller's channel for the class is not used. Disabling the DMA controller of a class also requires disabling the class match comparator for the class (see registers RCMRn). When class 1 and class 2 queues are disabled then their frames will be placed in queue 0. 1b - Enable the DMA controller to support the corresponding descriptor ring for this class of traffic.
15-0 IDLE_SLOPE	Idle slope 16-bit value to define the per class idle slope setting used by the credit based shaper defining allocated bandwidth for the class. This value is used to calculate the BW (bandwidth) fraction, given by the equation, BW fraction = 1/(1+512/IDLE_SLOPE). Idle slope is restricted to certain values. For values less than 128, idle slope = 2^n, where n = 0, 1, 2, ...6. For values equal to or greater than 128, idle slope = 128×m, where m = 1, 2, 3, ...12. Example 1. BW fraction = 0.20 = 1/(1+(512/128)); therefore idleslope = 128. Example 2. BW fraction = 0.33 = 1/(1+(512/256)); therefore idleslope = 256. Example 3. BW fraction = 0.75 = 1/(1+(512/1536)); therefore idleslope = 1536. **NOTE:** For AVB applications, the BW fraction of class 1 and class 2 combined must not exceed .75.

60.5.1.44 Receive Descriptor Active Register - Ring 1 (RDAR1)

60.5.1.44.1 Offset

Register	Offset
RDAR1	1E0h

60.5.1.44.2 Function

RDAR1 is a command register, written by the user, to indicate that the receive descriptor ring 1 has been updated, that is, that the driver produced empty receive buffers with the empty bit set.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
ENET	—	RDAR1
ENET_1G	RDAR1	—

60.5.1.99.3 Fields

Field	Function
31-0 COUNT	Number of octets for frames received without error **NOTE:** Counts total octets (includes header and FCS fields). Does not increment for the broadcast frames when broadcast reject is enabled and promiscuous mode is disabled within the receive control register (RCR).

60.5.1.100 Adjustable Timer Control (ATCR)

60.5.1.100.1 Offset

Register	Offset
ATCR	400h

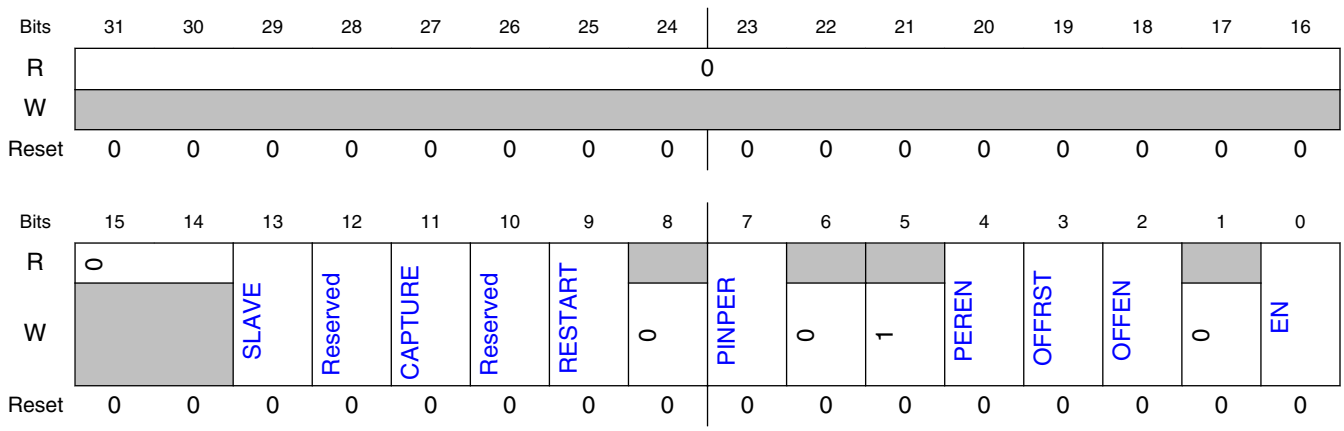
60.5.1.100.2 Function

ATCR command fields can trigger the corresponding events directly. It is not necessary to preserve any of the configuration fields when a command field is set in the register, that is, no read-modify-write is required.

NOTE

The CAPTURE and RESTART fields and bits 12 and 10 must be 0 in order to write to the other fields in this register.

60.5.1.100.3 Diagram



60.5.1.100.4 Fields

Field	Function
31-14 —	Reserved
13 SLAVE	Enable Timer Follower Mode 0b - The timer is active and all configuration fields in this register are relevant. 1b - The internal timer is disabled and the externally provided timer value is used. All other fields, except CAPTURE, in this register have no effect. CAPTURE can still be used to capture the current timer value.
12 —	Always write 0 to this field Always write 0 to this field.
11 CAPTURE	Capture Timer Value When this field is set, all other fields are ignored during a write. This field automatically clears to 0 after the command completes. **NOTE:** **WARNING:** To ensure that the correct time value is read from the ATVR register, a minimum amount of time must elapse from issuing this command to reading the ATVR register. This minimum time is defined by the greater of either six register clock cycles or six 1588/timestamp clock cycles.

Table continues on the next page...

Field	Function
	0b - No effect. 1b - The current time is captured and can be read from the ATVR register.
10 —	Always write 0 to this field Always write 0 to this field.
9 RESTART	Reset Timer Resets the timer to zero. This has no effect on the counter enable. If the counter is enabled when this field is set, the timer is reset to zero and starts counting from there. When set, all other fields are ignored during a write. This field automatically clears to 0 after the command completes. RESTART should be used when the timer is enabled. **NOTE:** **WARNING:** The Reset Timer command requires at least 6 clock cycles of either the register clock or the 1588/timestamp clock, whichever is greater, to complete.
8 —	Reserved
7 PINPER	Enables event signal output external pin frc_evt_period assertion on period event Enables event signal output assertion on period event. **NOTE:** Not all devices contain the event signal output. See the chip configuration details. 0b - Disable. 1b - Enable.
6 —	Reserved
5 —	This field must be written always with one **NOTE:** This field must be written always with one.
4 PEREN	Enable Periodical Event 0b - Disable. 1b - A period event interrupt can be generated (EIR[TS_TIMER]) and the event signal output is asserted when the timer wraps around according to the periodic setting ATPER. The timer period value must be set before setting this bit. Not all devices contain the event signal output. See the chip configuration details.
3 OFFRST	Reset Timer On Offset Event 0b - The timer is not affected and no action occurs, besides clearing OFFEN, when the offset is reached. 1b - If OFFEN is set, the timer resets to zero when the offset setting is reached. The offset event does not cause a timer interrupt.
2 OFFEN	Enable One-Shot Offset Event 0b - Disable. 1b - The timer can be reset to zero when the given offset time is reached (offset event). The field is cleared when the offset event is reached, so no further event occurs until the field is set again. The timer offset value must be set before setting this field.
1 —	Reserved
0 EN	Enable Timer 0b - The timer stops at the current value. 1b - The timer starts incrementing.

60.5.1.101 Timer Value (ATVR)

60.5.1.101.1 Offset

Register	Offset

R W	PERIOD															
Reset	1	1	0	0	1	0	1	0	0	0	0	0	0	0	0	0

60.5.1.103.3 Fields

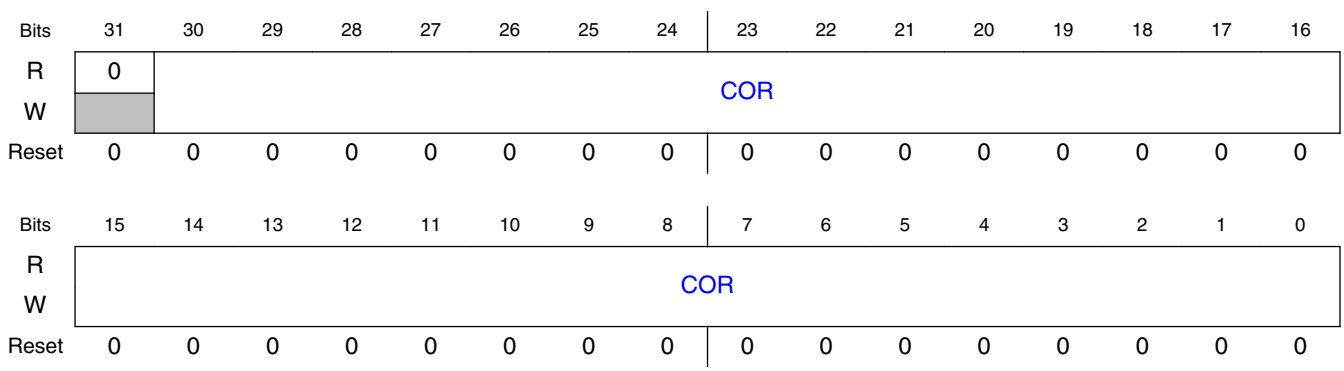
Field	Function
31-0 PERIOD	Value for generating periodic events Value for generating periodic events. Each instance the timer reaches this value, the period event occurs and the timer restarts. If the increment value in ATINC is given in true nanoseconds, this value is also given in true nanoseconds. The value should be initialized to 1,000,000,000 (1×10^9) to represent a timer wrap around of one second. The increment value set in ATINC should be set to the true nanoseconds of the period of clock ts_clk, hence implementing a true 1 second counter. **NOTE:** The value of PERIOD has the following constraint: 2^{32} – ENET_ATINC[INC_COR] – 3×ENET_ATINC[INC] ≥ PERIOD > 0.

60.5.1.104 Timer Correction (ATCOR)

60.5.1.104.1 Offset

Register	Offset
ATCOR	410h

60.5.1.104.2 Diagram



60.5.1.104.3 Fields

Field	Function
31 —	Reserved

Table continues on the next page...

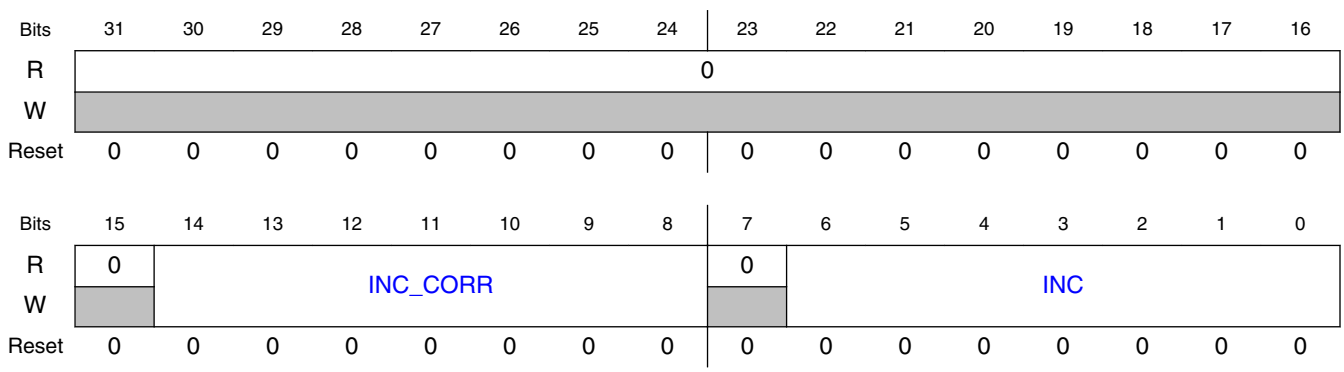
Field	Function
30-0 COR	Correction Counter Wrap-Around Value Defines after how many timer clock cycles (ts_clk) the correction counter should be reset and trigger a correction increment on the timer. The amount of correction is defined in ATINC[INC_CORR]. A value of 0 disables the correction counter and no corrections occur. **NOTE:** This value is given in clock cycles, not in nanoseconds as all other values.

60.5.1.105 Time-Stamping Clock Period (ATINC)

60.5.1.105.1 Offset

Register	Offset
ATINC	414h

60.5.1.105.2 Diagram



60.5.1.105.3 Fields

Field	Function
31-15 —	Reserved
14-8 INC_CORR	Correction Increment Value This value is added every time the correction timer expires (every clock cycle given in ATCOR). A value less than INC slows down the timer. A value greater than INC speeds up the timer.
7 —	Reserved
6-0	Clock Period Of The Timestamping Clock (ts_clk) In Nanoseconds

Field	Function
INC	The timer increments by this amount each clock cycle. For example, set to 10 for 100 MHz, 8 for 125 MHz, 5 for 200 MHz. **NOTE:** For highest precision, use a value that is an integer fraction of the period set in ATPER.

60.5.1.106 Timestamp of Last Transmitted Frame (ATSTMP)

60.5.1.106.1 Offset

Register	Offset
ATSTMP	418h

60.5.1.109.3 Fields

Field	Function
31-0 TCC	Timer Capture Compare This register is double buffered between the module clock and 1588 clock domains. When configured for compare, the 1588 clock domain updates with the value in the module clock domain whenever the Timer Channel is first enabled and on each subsequent compare. Write to this register with the first compare value before enabling the Timer Channel. When the Timer Channel is enabled, write the second compare value either immediately, or at least before the first compare occurs. After each compare, write the next compare value before the previous compare occurs and before clearing the Timer Flag. The compare occurs one 1588 clock cycle after the IEEE 1588 Counter increments past the compare value in the 1588 clock domain. If the compare value is less than the value of the 1588 Counter when the Timer Channel is first enabled, then the compare does not occur until following the next overflow of the 1588 Counter. If the compare value is greater than the IEEE 1588 Counter when the 1588 Counter overflows, or the compare value is less than the value of the IEEE 1588 Counter after the overflow, then the compare occurs one 1588 clock cycle following the overflow. When configured for capture, the value of the IEEE 1588 Counter is captured into the 1588 clock domain and then updated into the module clock domain, provided the Timer Flag is clear. Always read the capture value before clearing the Timer Flag.

61.2 Overview

NOTE

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

The EQoS-TSN module supports the 10/100/1000Mbps applications in compliance with IEEE802.3-2015 specifications. It can support advanced applications such as Time-Sensitive Networking (TSN) and Audio Video Bridge (AVB). Other prominent features of the MAC core include a flexible receive parser, media clock recovery and generation, and safety.

61.2.1 Block diagram

The following figure shows the block diagram of this module. The module has four main blocks to perform all functions. The AHB interface is connected to all DMA channels. The DMA arbiter helps in arbitration of all paths (transmit and receive) in channels. Each channel has a separate set of control and status registers (CSR) for managing the transmit and receive functions, descriptor handling, and interrupt handling.

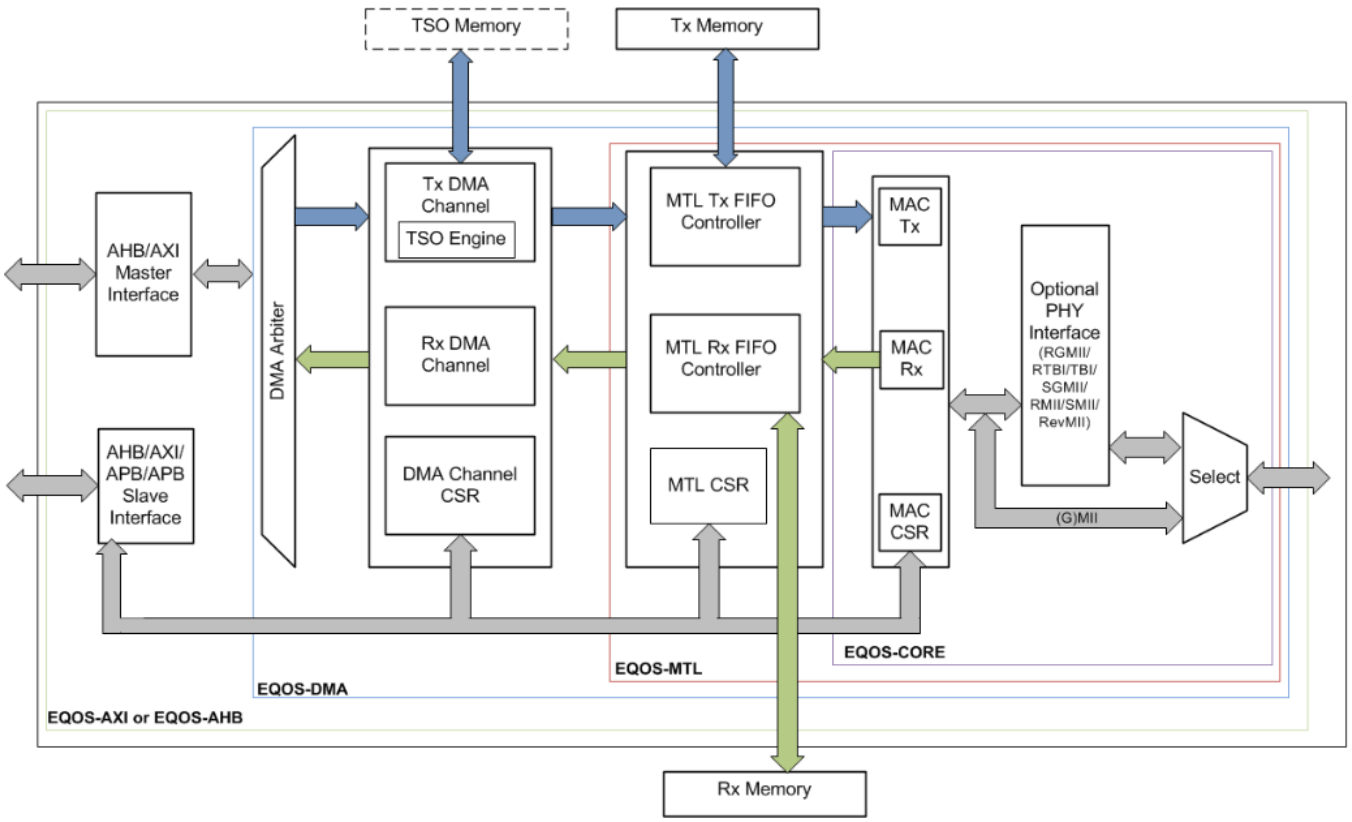

Figure 61-1. System-Level Block Diagram

61.2.2 Features

This module supports the following features in addition to the default features defined in IEEE802.3 specification

- MII (10/100Mbps), RMII (10/100Mbps), RGMII (10/100/1000Mbps)
- Time aware shaper (IEEE802.1Qbv), Time synchronization (IEEE1588-2008), and Frame pre-emption (IEEE802.1Qbu) for Time-Sensitive Networking (TSN)
- Media clock recovery and generation for AVB
- RMII specification version 1.2 from RMII consortium
- RGMII specification version 2.6 from HP/Marvell
- Separate interface for Transmit, Receive and Control path

- Broadcast/Multicast Packet duplication
- Full duplex flow control operations (IEEE 802.3x pause packet and priority flow control)
- Network statistics with MAC management (RMON) counters
- Flexibility to control the Pulse per second (PPS) output signal
- MDIO (clause 22 and Clause 45) interface for configuration and management of PHY device
- Preamble and start of packet data (SFD) insertion/deletion
- Automatic CRC and pad generation/stripping option, option to disable CRC checking
- Programmable inter-packet gap
- Source address insertion/replacement
- VLAN insertion, replacement and deletion in transmitted packets with per-packet or static-global control
- Insertion, replacement and deletion of up to two VLAN tags
- Insertion, replacement and deletion of queue/channel based VLAN tags
- IEEE802.1Q VLAN tag detection and option to delete from received packets
- Programmable safety watchdog timeout limits
- Flexible address filtering modes:
  - Up to 2 additional 48-bit perfect (DA) address filters with masks for each byte
  - Up to 2 48-bit SA address comparison check with masks for each byte
  - 64-bit Hash filter for multicast and unicast (DA) addresses
  - Option to pass all multi-cast addressed packets
  - Promiscuous mode to pass all packets without any filtering for network monitoring
  - Pass all incoming packets (as per filter) with a status report
- Additional packet filtering:
  - VLAN tag-based: Perfect match and Hash-based filtering. Filtering based on either outer or inner VLAN tag is possible
  - Layer 3 and Layer 4-based: TCP or UDP over IPv4 or IPv6
  - Extended VLAN tag based filtering 4 filter selections

61.3 Functional description

NOTE

This section and all its sub-sections are Synopsys Proprietary.
Used with permission.

The following sections describe functional details of the ENET module.

61.3.1 Architecture

This section describes the interfaces, protocols, and functionality. Following are the main blocks of the ENET QOS block.

- DMA Controller
- MAC Transaction Layer (MTL)
- MAC
- Interrupts

61.3.1.1 DMA controller

The DMA has independent Transmit (Tx) and Receive (Rx) engines, and a control and status register (CSR) space. The Tx engine transfers data from the system memory to the MTL interface, whereas the Rx engine transfers data from the MTL interface to the system memory. The DMA engine uses descriptors to efficiently move data from source to destination with minimal Host intervention. The DMA is designed for packet-oriented data transfers such as packets in Ethernet. The DMA controller can be programmed to interrupt the Host for situations such as Packet Transmit and Receive Transfer completion, and other normal or error conditions.

The DMA and Host communicate through the following two data structures:

- Control and Status registers (CSR)
- Descriptor lists and data buffers

The DMA supports up to 5 Tx and 5 Rx Descriptor lists (or DMA channels). The base address of each list is written to the respective Tx Descriptor List Address register and Rx Descriptor List Address register. The descriptor list is forward linked and the next descriptor is always considered at a fixed offset to the current one. The offset is controlled by the DSL field of DMA_Ch[n]_Control register. The number of descriptors in the list is programmed in the respective Tx (or Rx) Descriptor Ring Length register. Once the DMA processes the last descriptor in the list, it automatically jumps back to the descriptor in the List Address register to create a descriptor ring.

The descriptor lists reside in the physical memory address space of the application. Each descriptor can point to a maximum of two buffers in the system memory. This enables two buffers to be used, physically addressed, rather than contiguous buffers in memory.

A data buffer resides in the application physical memory space and consists of an entire packet or part of a packet but cannot exceed a single packet. Buffers contain only data. Buffer status is maintained in the descriptor. Data chaining refers to packets that span multiple data buffers. However, a single descriptor cannot span multiple packets. The DMA skips to the data buffer of next packet when end of packet (EOP) is detected.

This module supports the ring structure for the DMA descriptor. For more information on Descriptor, see the Descriptors.

Following sections describes the operation of DMA Controller.

61.3.1.1.1 DMA Controller Bus Burst Access

The DMA engines attempt to transfer data in a burst of maximum size as programmed in the PBL bit fields of Transmit Control and Receive Control registers of the respective DMA. The Rx and Tx descriptors are always accessed in the maximum possible (limited by PBL or 16 * 8/bus width) burst length for 16 bytes to be read. The burst transfers initiated by the DMA can be split into multiple burst transfers as per the AHB requirements and the settings of DMA_SysBus_Mode register.

The Tx DMA initiates a data transfer only when sufficient space is available in the MTL Tx Queue to accommodate either of the following:

- Bytes corresponding to the configured burst (PBL * bus_width/8)
- Remaining bytes in Tx Buffer without EOP
- Number of bytes till EOP

The Rx DMA initiates a data transfer in the following conditions:

- Sufficient data is available in MTL Rx Queue to accommodate the configured burst
- EOP (when it is less than the configured burst length) is detected in the Rx Queue

61.3.1.1.2 DMA application data buffer alignment

The Tx and Rx data buffers do not have any restrictions on start address alignment. For example, in systems with 32-bit memory, the start address for buffers can be aligned to any of the four bytes. However, the DMA always initiates write transfers with address aligned to the bus width and dummy data (old data) in the invalid byte lanes. This typically happens during the transfer of the beginning or end of an Ethernet packet. For the receiver, the software driver should discard the dummy bytes based on the start address of the buffer and size of the packet.

Table 61-2. Data buffer alignment examples

Examples	
Buffer Read	If the Tx buffer address is 32'h00000FF2 (for 32-bit data bus), and 15 bytes need to be transferred, the DMA reads five full words from address 32'h00000FF0, but when transferring data to the MTL Tx queue, the extra bytes (the first two bytes) are dropped or ignored. Similarly, the last 3 bytes of the last transfer are also ignored. The DMA always ensures that it transfers a full 32-bit data to the MTL Tx queue, unless it is the end of packet.

Table continues on the next page...

Table 61-2. Data buffer alignment examples (continued)

Buffer Write	If the Rx buffer address is 32'h0000FF2 (for 64-bit data bus) and 16 bytes of a received packet need to be transferred, the DMA writes 3 full words from address 32'h00000FF0. However, the first 2 bytes of the first transfer and the last 6 bytes of the third transfer have dummy data. The DMA considers the offset address only if it is the first Rx buffer of the packet. The DMA ignores the offset address and performs full word writes for the middle and the last Rx buffer of the packet.

61.3.1.1.3 DMA buffer size calculations

The DMA does not update the size fields in the Tx and Rx descriptors. The DMA updates only the status fields (RDES and TDES) of the descriptors. The driver has to perform the size calculations.

The Tx DMA transfers the exact number of bytes (indicated by buffer size field of TDES2) towards the MAC. If a descriptor is marked as first (FD bit of TDES3 is set), the DMA marks the first transfer from the buffer as SOP. If a descriptor is marked as last (LD bit of TDES3), the DMA marks the last transfer from that data buffer as EOP to the MTL.

The Rx DMA transfers data to a buffer until the buffer is full or the end of packet is received from the MTL. When the FD bit of a descriptor is set, the amount of valid data in a buffer is accurately indicated by the buffer size field (programmed in DMA Channel Receive Control register) minus the data buffer pointer offset. The offset is zero when the data buffer pointer is aligned to the data bus width. If a descriptor is marked as last, the buffer may not be full (as indicated by the buffer size in Bits [14:1] of Receive Control register). To compute the amount of valid data in this final buffer, the driver must read the packet length (PL bits of RDES3[14:0]) and subtract the sum of the buffer sizes of the preceding buffers in this packet. The Rx DMA always transfers the start of next packet with a new descriptor.

61.3.1.2 MAC transaction layer

The MAC Transaction Layer (MTL) provides the FIFO memory Interface to buffer and regulate the packets between system memory and the MAC. It also enables the data to be transferred between the system clock and MAC clock domains. The MTL layer has two data paths: Transmit path and Receive Path. The size of the FIFO is 8 Kb for Tx and Rx. The MTL communicates with the host through Application Transmit Interface (ATI) on the Transmit path and Application Receive Interface (ARI) on the receive path.

61.3.1.2.1 Transmit path

Internal DMA handles all transactions for the transmit path through ATI. Internal DMA pushes the Ethernet packets read from system memory into the corresponding queue. The packet is then popped out and transferred to the MAC when the queue threshold is reached (threshold mode) or complete packet is in the queue (store-and-forward mode). When EOP is transferred, the status of the transmission is taken from the MAC and transferred back to the internal DMA.

61.3.1.2.1.1 Transmit control word

The following control information related to packet transmission is provided as a part of the Control Word through ATI interface:

- Packet Length (if DCB is enabled with WFQ scheduling algorithm)
- CRC Pad Control
- Source Address Insertion Control
- VLAN Insertion and Replacement Control and VLAN Tag for Outer and Inner VLAN Tags
- TCP/IP Checksum Insertion Control
- One-step Timestamping Control Correction
- Transmit Timestamp Enable

61.3.1.2.1.2 Transmit operation

The following two modes of operation triggers reading of the data towards the MAC:

- Threshold mode: In Threshold (or cut-through) mode, as soon as the number of bytes in the Queue cross the configured threshold level (or when the end of packet is written before the threshold is crossed), the data is ready to be popped out and forwarded to the MAC. The threshold level is configured by using the TTC bits of MTL_TxQ0_Operation_Mode register corresponding to an MTL queue.
- Store-and-forward mode:

In store-and-forward mode, the MTL pops out the packet towards the MAC only when one or more of the following conditions are true:

- A complete packet is stored in the Queue
- The Tx FIFO becomes almost full
- The ATI watermark becomes low

The watermark becomes low when the requested queue does not have space to accommodate the requested burst length on the ATI. Therefore, the MTL when operating in the store-and-forward mode allows packet transmission even if the packet length is bigger than the Tx queue size.

The application can flush complete content of the Tx queue by setting Bit 0 (FTQ) of Transmit Operation Mode register corresponding to an MTL queue. This bit is self-clearing and initializes the Queue pointers to the default state. If the FTQ bit is set during a packet transfer from the MTL to the MAC, the MTL stops further transfer because the queue is considered to be empty. Therefore, an underflow event occurs at the MAC transmitter.

61.3.1.2.1.3 Initialization flow

Upon reset, the MTL is ready to manage the flow of data to and from the DMA, and MAC. For configurations with a single Transmit Queue, there are no initialization requirements for enabling the MTL. For configurations with multiple Transmit Queues, initialize the queue size for each of the queues by programming the TQS bits of MTL_TxQ0_Operation_Mode register corresponding to a Transmit queue. Also, initialize the MAC block. Internal DMA controllers must be individually enabled through their respective CSRs.

61.3.1.2.2 Receive path

The MTL Rx module receives the packets from the MAC and pushes them into the Rx Queue. The status (fill level) of the queue is indicated to DMA when it crosses the configured Receive threshold (RTC bits[1:0] of MTL_RxQ0_Operation_Mode register of corresponding MTL queue), or the complete packet is received. The MTL also indicates the fill level of the queue so that the DMA can initiate preconfigured burst transfers towards the AHB interface.

For more information on queues, see Multiple Channels and Queues Support.

61.3.1.2.2.1 Receive Operation

During a Receive operation, the MTL is a slave for the MAC. The general sequence of events is as follows:

1. When the MAC receives a packet, it indicates the availability of receive data.
2. The MAC indicates the SOP and EOP delimiters.
3. The MTL accepts the data and pushes it into corresponding Rx queue.
4. After the EOP is transferred, the MAC drives the status word which is also pushed into the corresponding Rx queue by the MTL.
5. If IEEE 1588 timestamp feature is enabled and the 64-bit timestamp is available along with the packet status, it is pushed into the Rx queue as a part of the status word. Therefore, two additional locations are taken per packet to store the timestamp in the Rx queue.

6. The MTL takes the data out of the queue and sends it to the DMA depending on the following modes:

61.3.1.2.2.1.1 Threshold mode

In the (default) Threshold mode, the MTL reads the data and indicates its availability to the application or DMA when one of the following occurs:

- Data bytes equal to the threshold amount are written to the Rx queue (RTC bits[1:0] of MTL_RxQ0_Op-eration_Moderegister of corresponding MTL queue)
- A full packet of data is received into the queue

61.3.1.2.2.1.2 Store and forward mode

In the store-and-forward mode (when Bit 5 of MTL_RxQ0_Operation_Mode register of a queue is set to 1), the initial Rx queue locations are reserved for the status words before writing the SOP. A packet is read out only after it is completely written into the Rx queue. In this mode, all error packets are dropped (if configured through Bit 4 of MTL_RxQ0_Operation_Mode register of a queue) such that only valid packets are read and forwarded to the application.

61.3.1.2.2.2 Multi packet receive operation

In Threshold mode, the packet status is available immediately after the packet data. In store-and-forward mode, the packet data is available after the packet status. The MTL is capable of storing any number of packets into the queue as long as it is not full.

If the MAC receives a packet when the corresponding Rx queue is full, the MTL ignores that packet and overflow pulse is generated on the corresponding Rx queue. In addition, the MTL increments the overflow counter in the MTL_RxQ0_Missed_Packet_Overflow_Cnt of corresponding queue.

61.3.1.2.2.3 Error handling in receive operation

Following things would happen, If the MTL Rx queue is full before it receives the EOP data from the MAC.

1. An overflow is declared
2. The whole packet (including the status word) is dropped
3. The overflow counter in the DMA (Overflow Counter register of corresponding MTL queue) is incremented.

This is true even if Bit 4 (FEP) of MTL_RxQ0_Operation_Mode register of corresponding MTL queue is set.

If the start address of such a packet has already been transferred to the Read Controller, the rest of the packet is dropped and a dummy EOP is written to the queue along with the status word with overflow status. The status indicates a partial packet because of overflow. In such packets, the Packet Length field is invalid. If the MTL Receive Queue is configured to operate in the store-and-forward mode and the length of the received packet is more than the queue size, overflow occurs and all such packets are dropped.

The MTL Rx Control logic can filter error and undersized packets, if enabled by using the FEP and FUP bits of MTL_RxQ0_Operation_Mode register of corresponding MTL queue. If the start address of such a packet has already been transferred to the Rx Queue Read Controller, that packet is not filtered. The start address of the packet is transferred to the Read Controller after the packet crosses the receive threshold set by Bits[1:0] of MTL_RxQ0_Operation_Mode register of corresponding MTL queue.

If the MTL Receive Queue is configured to operate in the store-and-forward mode, all error packets can be filtered and dropped. For the application or DMA to flush the error packet being read from the queue, it must assert the flush signal. The MTL then stops transferring data to the application (DMA). It internally reads the rest of the packet and drops it. The MTL then starts the transfer of next packet (if available).

61.3.1.3 MAC

MAC can support MII, RMII or RGMII Phy interface. MAC consists of Mac Transmit interface (MTI), MAC Receive Interface (MRI) and MAC Control Interface (MCI).

61.3.1.3.1 MAC transmission

The MAC transmission process is as follows:

1. Transmission is initiated when the MAC Transaction Layer (MTL) pushes in data with the SOP signal asserted.
2. When the SOP signal is detected, the MAC accepts the data and begins transmitting to the MII, RMII or RGMII.
3. After the EOP is transferred to the MAC, the MAC does one of the following:
    - The MAC completes the normal transmission and gives the transmission status to the MTL.
    - If a normal collision (in half-duplex mode) occurs during transmission, the MAC gives the Transmit Status with retry bit set to the MTL. The MAC gives the Retry request till one of the following is true:
        - Packet is successfully transmitted

        - Maximum retry requests expire
        - When maximum retry requests expire, the MAC aborts the packet transmission with Excessive Collision Transmit Status. The MAC accepts and drops all further data until the next SOP is received. The MTL block should retransmit the same packet from SOP on observing a Retry request (in the Status) from the MAC.
    - If any one of the following happens, the MAC aborts the packet transmission:
        - No carrier (half-duplex mode)
        - Loss of carrier (half-duplex mode)
        - Excessive deferral (half-duplex mode)
        - Late collisions (half-duplex mode)
        - Jabber
        - The MAC accepts and drops all further data until the next SOP is received
4. The MAC issues an underflow status if the MTL is not able to provide the data continuously during the transmission. The MAC accepts and drops all further data until the next SOP is received.
5. During the normal transfer of a packet from MTL, if the MAC receives a SOP without getting an EOP for the previous packet, it ignores the SOP and considers the new packet as continuation of the previous packet.

61.3.1.3.2 MAC reception

A receive operation is initiated when the MAC detects an SFD on RMII, RGMII, or MII. The MAC strips the preamble and SFD before proceeding to process the packet. The header fields are checked for filtering and the FCS field used to verify the CRC for the packet. The received packet is stored in a shallow buffer until the address filtering is performed. The packet is dropped in the MAC if it fails the address filter.

61.3.2 Using PHY interfaces

This module support the following modes:

- RMII 10/100 Mbps interface
- MII 10/100 Mbps interface
- RGMII 10/100/1000 Mbps interface

The internal Phy_intf_sel input signal decides which mode has been selected. Phy_intf_sel signal gets sampled at reset. PS and FES bit of MAC configuration register selects the speed of mode.

The module supports the IEEE802.3-2015 specification for MII, RMII (RMII specification version 1.2 from the RMII consortium) and RGMII specification.

NOTE

RMII reference clock (50 MHz) can be fed to IP from an external source or internally from PLL on SoC.

The module supports can access the phy registers through Station Management Agent (SMA) which is a two wire Station management interface (MIM). One wire is management data clock (MDC) and other wire is management data input/output (MDIO). As per IEEE 802.3 specification, maximum operating frequency of MDC is 2.5 Mhz which can be derived from system clock using a divider. The CR bit of MAC_MDIO_Address register can be programmed to generate different MDC clock frequency.

SMA supports both MDIO clause 45 and clause 22 frame structure as per IEEE802.3 specification. The C45E bit of MAC_MDIO_Address register can be set to enable the clause 45 frame structure.

If the MII interface is overclocked to run at 200 Mbps, it reduces the accuracy of the 1588 timestamp. This is because the MAC logic uses the MII interface speed, as specified in MAC_Configuration[FES], to adjust or compensate for the timestamps taken at MII, as compared to the time generated in the PTP clock domain.

61.3.3 VLAN and double VLAN insertion, deletion, replacement and tagging

These sections describes the VLAN and Double VLAN features.

61.3.3.1 Double VLAN processing

The module can support processing of two VLAN tags in double VLAN tagging processing. These two VLAN tags can also be named as inner (C-VLAN) and outer (S-VLAN) VLAN tag. If packet is having only one tag then it would be considered as outer tag.

It supports the following function in Double VLAN processing feature using the MAC_VLAN_Incl, MAC_Inner_VLAN_Incl and MAC_VLAN_Tag registers.

- Insertion, replacement, or deletion of up to two VLAN tags in the Transmit path.
- Packet filtering and stripping based on any one of the two VLAN Tags in the Receive path. Stripping and providing up to two VLAN Tags in the Receive path as a part of the Receive status.

61.3.3.1.1 Transmit path

Following table describes the features supported by the MAC on the Transmit side.

Table 61-3. Double VLAN Processing Features in Transmit Path

Feature	Description
Support for C-VLAN and S-VLAN Tag types	The inner or outer VLAN tag can be of C-VLAN and S-VLAN type. The VLAN type is specified through the CSVL bit of MAC_VLAN_INCL and MAC_INNER_VLAN_INCL registers. The module supports processing of any sequence of outer and inner VLAN tags. **NOTE:** The module does not support the C-VLAN S-VLAN sequence. The MAC does not check whether the packet provided by the application has a valid sequence of the VLAN Tag types or the insertion or replacement operation results in invalid sequence of VLAN Tag type. Therefore, the application must provide correct sequence of VLAN Tag types and program the MAC in such a way that it results in correct sequence of VLAN Tag types in the transmitted packet. The application must ensure the following: • The inner tag should not be S-VLAN when outer C-VLAN Tag insertion is enabled. • The outer tag should not be C-VLAN when inner S-VLAN Tag insertion is enabled. • The inner tag should not be S-VLAN when outer tag should be replaced with C-VLAN. • The outer tag should not be C-VLAN when inner tag should be replaced with S-VLAN.
VLAN Tag deletion	VLAN tag deletion for outer or inner tag can be enabled through VLC field in the MAC_VLAN_Incl or MAC_Inner_VLAN_Incl register, respectively. When VLAN deletion is enabled, the MAC deletes the tag present at the corresponding position. When a packet has only one tag, it is considered as the outer tag. If inner tag deletion is enabled and the packet has only one tag, the MAC does not delete the inner tag.
VLAN Tag Insertion or Replacement	VLAN tag insertion or replacement for outer or inner tag can be enabled through VLC field in the MAC_VLAN_Incl or MAC_Inner_VLAN_Incl register, respectively. When VLAN tag insertion or replacement is enabled, the VLTI bit in the MAC_VLAN_Incl or MAC_Inner_VLAN_Incl register is used to determine whether the VLAN tag should be taken from the register or the Control Word.

61.3.3.1.2 Receive path

Following table describes the features supported by the MAC on the receive side and the corresponding bits in the MAC_VLAN_Tag register.

Table 61-4. Double VLAN Processing in Receive Path

Feature	Description
Outer or inner VLAN tag-based filtering	The MAC can filter packets based on the outer or inner VLAN tag through the ERIVLT bit.
C-VLAN or S-VLAN tag-based filtering	The MAC can filter packets based on the C-VLAN or S-VLAN type based on the ERSVLM bit.
Outer and Inner VLAN Tag stripping	The MAC can strip the outer and inner VLAN Tags from received frame based on the EVLS and EIVLS bits.
16-bit outer and inner VLAN Tag and Type in Rx status	The MAC can provide the 16-bit outer and inner VLAN Tag and Type in the Rx status based on the EVLRXS and EIVLRXS bits, respectively.
Disabling or skipping checking of outer VLAN Tag type	The MAC can disable or skip checking of outer VLAN Tag type to match C-VLAN or SVLAN based on the DOVLTC bit.

61.3.3.1.3 Source address and VLAN insertion, replacement, or deletion

The module supports the SA and VLAN insertion, replacement and deletion. The source address (SA) and VLAN fields are Tx packet-related control information that are provided as part of the control word through interfaces. IP supports the feature to insert or replace the source address based on the information in the MAC Address Registers, and also the feature to insert, replace or delete the VLAN fields (VLAN Type and VLAN Tag) based on the setting of the VLTI bit in the MAC_VLAN_Incl register. SA insertion or replacement feature can be enabled for all Transmit packets or selective packets. Similarly, VLAN insertion, replacement, or deletion feature can be enabled for all Tx packets or selective packets.

61.3.3.1.4 Programming source address insertion or replacement

The software can use the SA insertion or replacement feature to instruct the MAC to do the following for Tx packets:

- Insert the content of the MAC Address Registers in the SA field
- Replace the content of the SA field with the content of the MAC Address Registers

When SA insertion is enabled, the application must ensure that the packets sent to the MAC do not have the SA field. The MAC does not check whether the SA field is present in the Transmit packet and it inserts the content of MAC Address Registers in the SA field. Similarly, when SA replacement is enabled, the application must ensure that the SA field is present in the packets sent to the MAC.

The MAC replaces the six bytes following the Destination Address field in the Transmit packet with the content of the MAC Address Registers.

- SARC bit of MAC_Configuration register can be program to enable the SA insertion or replacement for all Tx packets.
- SA insertion for selective packet can be enabled by programming the SA Insertion Control field (bits [25:23] of TDES3) in the first Transmit descriptor of the packet. When Bit 25 of TDES3 is set, the SA Insertion Control field indicates insertion or replacement by MAC Address1 registers. When Bit 25 of TDES3 is reset, it indicates insertion or replacement by MAC Address 0 registers.

If MAC Address1 Registers are not enabled, the MAC Address0 registers are used for insertion or replacement irrespective of the value of the most-significant bit of the SA Insertion Control field.

61.3.3.1.5 Programming VLAN insertion, replacement, or deletion

The software can use the VLAN insertion, replacement, or deletion feature to instruct the MAC to do the following for Tx packets:

- Delete the VLAN Type and VLAN Tag fields
- Insert or replace the VLAN Type and VLAN Tag fields

Insertion or replacement is done based on the setting of VLTI bit in the MAC_VLAN_Incl register as described in the following table:

Table 61-5. VLAN Insertion or Replacement Based on VLTI Bit

Condition	Description
VLTI bit is set	The MAC inserts or replaces the following: • VLAN Type field (C-VLAN or S-VLAN as indicated by the CSVL bit of MAC_VLAN_Incl register) • VLAN Tag field depending on the Content of the VT field of Transmit context descriptor of the packet
VLTI bit is reset	The MAC inserts or replaces the following: • VLAN Type field (C-VLAN or S-VLAN as indicated by the CSVL bit of MAC_VLAN_Incl register) • VLAN Tag field with the VLT field of MAC_VLAN_Incl register

When VLAN replacement or deletion is enabled, the MAC checks if the VLAN Type field (0x8100 or 0x88a8) is present after the DA and SA fields in the Transmit packet. The replace or delete operation does not occur if the VLAN Type field is not detected in two bytes following the DA and SA fields. However, when VLAN insertion is enabled, the MAC does not check the presence of VLAN Type field in the Transmit packet and just inserts the VLAN Type and VLAN Tag fields.

VLAN insertion, replacement, or deletion feature can be enabled for all Tx packets by programming the VLC and VLP fields of MAC_VLAN_Incl register.

VLAN insertion, replacement, or deletion for selective packets can be enabled by programming the VTIR field of TDES2 Normal Descriptor.

In addition, the VLP (VLAN Priority control) bit must be reset in MAC_VLAN_Incl register (for outer VLAN) and MAC_Inner_VLAN_Incl register (in inner VLAN) for the MAC to take the control inputs from the host, depending on the configuration.

61.3.3.1.6 Queue/Channel Based VLAN Tag Insertion on Tx

This module supports channel/queue based VLAN tag insertion on all transmitted packets.

61.3.3.1.6.1 Accessing Queue/Channel Specific VLAN Tag Registers

Queue/Channel specific VLAN tag registers are accessed using indirect addressing through the MAC_VLAN_Incl register. VLAN type and tag value can be independently programmed for each queue/channel.

61.3.4 Packet Filtering

There are various packets filtering scheme available in MAC receiver. Filtering sequence in their precedence order of received packet is shown in the following figure.

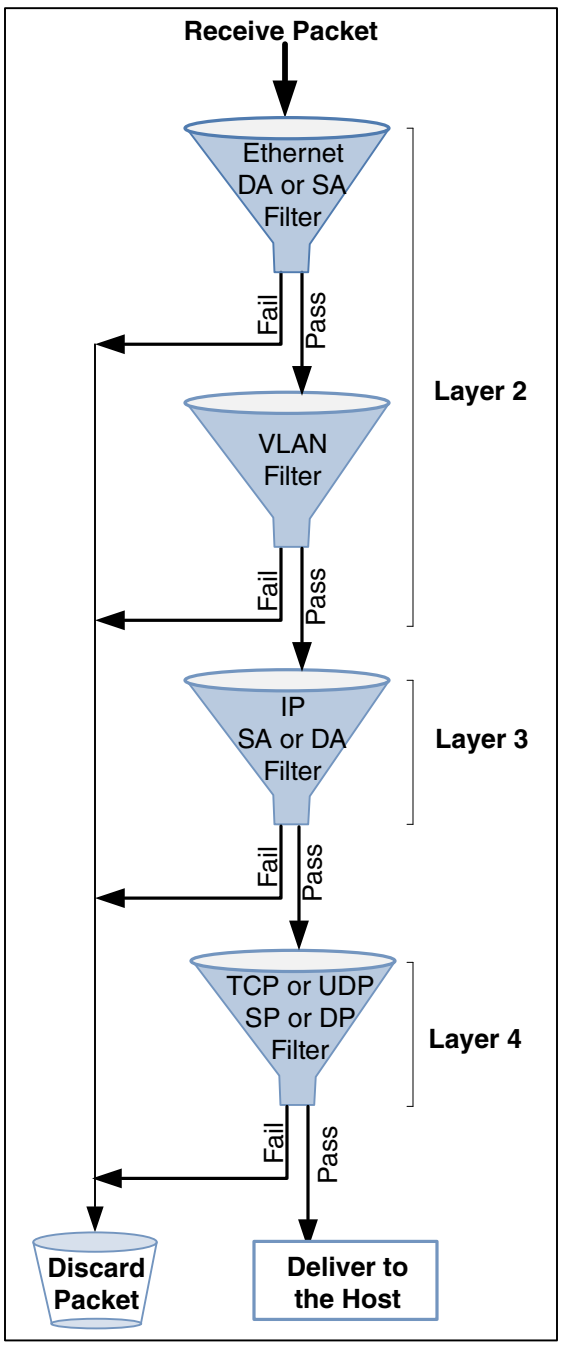

Figure 61-2. Packet Filtering Sequence

If any of the Layer filters are not enabled, that filter is bypassed and the subsequent filter is applied. A packet that fails any of the filters, is discarded. However, depending on the entry address and the number of parsed entries of the frame offset, discarded packets can be routed to RX_DMA_CH0 and a parser interrupt can be generated.

Even if no parser matched, the frame can be routed into the DMA channel indicated in DMA_CH_NO[2:0].

61.3.4.1 Source address or destination address filtering

The Address Filtering Module of the MAC checks the source address (SA) and destination address (DA) fields of each incoming packet. Programming of different type of address filtering is described in the following sections.

61.3.4.1.1 Unicast destination address filtering

MAC supports up to 64 MAC addresses for unicast perfect filtering. If perfect filtering is selected (HUC bit of MAC_Packet_Filter register is reset), the MAC compares all 48 bits of received unicast address with the programmed MAC address for any match. Default MacAddr0 is always enabled. The MacAddr1 to MacAddr63 addresses are selected with an individual enable bit. Each byte of MacAddr1 to MacAddr31 can be masked during comparison with corresponding received DA byte by setting the corresponding Mask Byte Control bit in the register. This enables group address filtering for the DA.

In hash filtering mode (when HUC bit is set), the MAC performs imperfect filtering for unicast addresses using a 64-bit Hash table. For hash filtering, the MAC uses the upper 6 bits CRC(by CRC32) of the received destination address to index the content of the Hash table. A value of 000000 selects Bit 0 of selected register, and a value of 111111 selects Bit 63 of Hash Table register. If the corresponding bit (indicated by the 6-bit CRC) is set to 1, the unicast packet is considered to have passed the Hash filter; otherwise, the packet is considered to have failed the Hash filter.

61.3.4.1.2 Multicast destination address filtering

PM bit of MAC_Packet_Filter register can be enabled to pass all multicast packets or disabled to do multicast addresses filtering based on HMC bit of MAC_Packet_Filter register. The multicast address is compared with the programmed MAC Destination Address registers (1–31). Also, Group address filtering is supported.

In Hash filtering mode, the MAC performs imperfect filtering using a 64-bit Hash table. The MAC uses the upper 6-bits CRC(by CRC32) of received multicast address to index the content of the Hash table. A value of 000000 selects Bit 0 of selected register and a value of 111111 selects Bit 63 of the Hash Table register. If the corresponding bit is set to 1, the multicast packet is considered to have passed the Hash filter. Otherwise, the packet is considered to have failed the Hash filter.

61.3.4.1.3 Hash or perfect address filtering

HPF bit of MAC_Packet_Filter register must be configured for enabling or disabling the destination address filtering by either Hash filter or Perfect filter. HUC and HMC bit of MAC_Packet_Filter register must be configured to select the Hash filtering or Perfect filtering for Unicast/Multicast packet.

61.3.4.1.4 Broadcast address filtering

The MAC does not filter any broadcast packets by default. DBF bit of MAC_Packet_filter register must be set to reject the broadcast packets.

61.3.4.1.5 Unicast source address filtering

By default, MAC compares the source address field with the value programmed in the source address registers. Bit 30 of MAC address register [1-2] can be configure to use it for source address instead of destination address comparison. The MAC also supports group filtering with source address(SA) . You can filter a group of addresses by masking one or more bytes of the address. The MAC drops the packets that fail the SA filter if the SAF bit is set in MAC_Packet_Filter register. Otherwise, the result of the SA filter is given as a status bit in the Receive Status word. When the SAF bit is set, the SA filter and DA filter result is AND'ed to decide whether the packet needs to be forwarded. This means that the packet is dropped if either filter fails. The packet is forwarded to the application only if the packet passes both filters in-order.

61.3.4.1.6 Inverse filtering

For DA and SA filtering, you can invert the filter-match result at the final output by setting the DAIF and SAIF bits of MAC_Packet_Filter register. The DAIF bit is applicable for both Unicast and Multicast DA packets. The result of the unicast or multicast destination address filter is inverted in this mode. Similarly, when the SAIF bit is set, the result of unicast SA filter is reversed.

Following two tables summarize the DA and SA filtering based on the type of packets received.

Table 61-6. Destination Address Filtering

Packet Type	PR	HPF	HUC	DAIF	HMC	PM	DBF	DA Filter Operation
Broadcast	1	X	X	X	X	X	X	Pass
	0	X	X	X	X	X	0	Pass
	0	X	X	X	X	X	1	Fail

Table continues on the next page...

Table 61-6. Destination Address Filtering (continued)

Unicast	1	X	X	X	X	X	X	Pass all packets
	0	X	0	0	X	X	X	Pass on Perfect/ Group filter match
	0	X	0	1	X	X	X	Fail on Perfect/ Group filter match
	0	0	1	0	X	X	X	Pass on Hash filter match
	0	0	1	1	X	X	X	Fail on Hash filter match
	0	1	1	0	X	X	X	Pass on Hash or Perfect/ Group filter match
	0	1	1	1	X	X	X	Fail on Hash or Perfect/ Group filter match
Multicast	1	X	X	X	X	X	X	Pass all packets
	X	X	X	X	X	1	X	Pass all packets
	0	X	X	0	0	0	X	Pass on Perfect/ Group filter match and drop Pause packets if PCF = 0x
	0	0	X	0	1	0	X	Pass on Hash filter match and drop Pause packets if PCF = 0x
	0	1	X	0	1	0	X	Pass on Hash or Perfect/ Group filter match and drop Pause packets if PCF = 0x
	0	X	X	1	0	0	X	Fail on Perfect/ Group filter

Table continues on the next page...

Table 61-6. Destination Address Filtering (continued)

								match and drop Pause packets if PCF = 0x
	0	0	X	1	1	0	X	Fail on Hash filter match and drop Pause packets if PCF = 0x
	0	1	X	1	1	0	X	Fail on Hash or Perfect/ Group filter match and drop Pause packets if PCF = 0x

Table 61-7. Source Address Filtering

Packet Type	PR	SAIF	SAF	SA Filter Operation
Unicast	1	X	X	Pass all packets.
	0	0	0	Pass status on Perfect or Group filter match but do not drop packets that fail
	0	1	0	Fail status on Perfect or Group filter match but do not drop packet
	0	0	1	Pass on Perfect or Group filter match and drop packets that fail
	0	1	1	Fail on Perfect or Group filter match and drop packets that fail

NOTE

When the RA bit of MAC_Packet_Filter register is set, all packets are forwarded to the system along with the correct result of the address filtering in the Rx Status.

61.3.4.2 VLAN Filtering

VLAN tag filter can be done by either perfect match or hash table. Depending upon the configuration, MAC can compare either lower 12 bits or all 16 bits of received VLAN tag for perfect match. MAC forwarded the VLAN tagged packet with match status while it drops all the packets which don't matches.

MAC uses 16-bit VLAN hash table for group address filtering based on the VLAN tag. If hash filtering is enabled then most significant 4-bit of CRC-32 of VLAN tag are used to index the content of the VLAN Hash Table Register. A value of 1 in the VLAN Hash Table register, corresponding to the index, indicates that the VLAN tag of the packet matched and the packet should be forwarded. A value of 0 indicates that VLAN-tagged packet should be dropped.

The MAC also supports the inverse matching for VLAN packets. In the inverse matching mode, when the VLAN tag of a packet matches the perfect or hash filter, the packet should be dropped. If the VLAN perfect and VLAN hash match are enabled, a packet is considered as matched if either the VLAN hash or the VLAN perfect filter matches. When inverse match is set, a packet is forwarded only when both perfect and hash filters indicate mismatch.

Table below shows the different possibilities for VLAN matching and the final VLAN match status. When the RA bit of MAC_Packet_Filter register is set, all packets are received and the VLAN match status is indicated in the VF bit of RDES2 Normal Descriptor (Write-Back Format). When the RA bit is not set and the VTFE bit is set in MAC_Packet_Filter register, the packet is dropped if the final VLAN match status is Fail.

When VLAN VID is programmed to 0 in the VL field of MAC_VLAN_Tag register, all VLAN-tagged packets are considered as perfect matched but the status of the VLAN hash match depends on the VTHM and VTIM bits in MAC_VLAN_Tag register.

Table 61-8. VLAN Match Status

VID	VLAN Perfect Filter Match Result	VTHM Bit	VLAN Hash Filter Match Result	VTIM Bit	Final VLAN Match Status
VID = 0	Pass	0	X	X	Pass
	Pass	1	X	0	Pass
	Pass	1	Fail	1	Pass
	Pass	1	Pass	1	Fail
VID!= 0	Pass	X	X	0	Pass
	Fail	0	X	0	Fail
	Fail	1	Fail	0	Fail
	Fail	1	Pass	0	Pass

Table continues on the next page...

Table 61-8. VLAN Match Status (continued)

VID	VLAN Perfect Filter Match Result	VTHM Bit	VLAN Hash Filter Match Result	VTIM Bit	Final VLAN Match Status
	Fail	0	X	1	Pass
	Pass	X	X	1	Fail
	Fail	1	Pass	1	Fail
	Fail	1	Fail	1	Pass

In this table, X represents any value.

61.3.4.3 VLAN Filter Fail Packets Queue

When VLAN filtering is enabled, the VLAN Filter Fail Packets can be routed to a programmable Queue (VFFQ) when Bit RA = 1 or VTFE = 0 of MAC_Packet_Filter register and the enable bit (VFFQE of MAC_RXQ_CTRL4) for the queue is set.

The packets that passes the VLAN filtering, are routed to Rx queues based on the VLAN TAG priority field by programming the PSRQ in the corresponding MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 registers. The packets that fail the VLAN filter are discarded if RA=0 or VTFE=1. However, when RA=1 or VTFE=0, the VLAN filter fail packets are still forwarded to the application. In such a scenario, when the VLAN Filter Fail Queue Enable (VFFQE) bit is set, the VLAN filter fail packets are forwarded to the Rx queue number programmed in the VFFQ bit. If VFFQE=0, the Rx queue number is determined by the VLAN priority mapping as per the PSRQ fields.

Table below shows the Rx Queue routing table for Unicast tagged packets, with DA/SA Filter enabled.

Table 61-9. Rx Queue Routing table for Unicast Tagged Packets

RA	VFTE	SA/DA Filter Result	VLAN Filter Result	VFFQE	Queue Routing
X	X	PASS	PASS	X	PSRQ
0	0	PASS	FAIL	0	PSRQ
0	0	PASS	FAIL	1	VFFQ
0	X	FAIL	X	X	DROPPED
0	1	PASS	FAIL	X	DROPPED
1	X	FAIL	X	0	UFFQ*/PSRQ
1	X	FAIL	X	1	UFFQ*/VFFQ
1	X	PASS	FAIL	0	PSRQ
1	X	PASS	FAIL	1	VFFQ

X : Don't care condition * : When UFFQE is enabled else PSRQ

61.3.4.4 Extended Receive VLAN Filtering and Routing

When Extended Rx VLAN filtering and routing is enabled then both perfect filtering and Hash filtering can be enabled. The overall VLAN filter result is based on the Perfect filter result and Hash filter result (if enabled). Filter result is passed to application/software as part of the status bit. Extended Routing will happen only if VLAN filter has passed. Routing is only based on Perfect filter result. Each Perfect filter has a DMA channel enable and DMA channel number filed which should be programmed for routing.

For more details about routing, see details on 'Extended VLAN Based DMA Selection' in Dynamic (Per Packet) Mapping.

61.3.4.4.1 Comparison mode

Software/Application has following comparison option for each VLAN tag filter

- It can program the MAC to compare the inner or outer VLAN tag with either 12 bits or 16 bits programmed VID.
- It can choose that VID comparison is for SVLAN or CVLAN type frames, if type check is enabled for a filter.

61.3.4.4.2 Filtering

Perfect Filtering is done based on the MAC_VLAN_Tag_Filter registers. For each VLAN Tag Filter, the MAC will compare the relevant VLAN Tag ID and gives a result. If any one of the VLAN Tag Filters gives a match then the frame is considered to have passed the VLAN Tag Filters. If the frame mismatches all the filters, then the frame is considered to have failed the VLAN filter. This behavior is applicable only when the Inverse Filtering is not enabled in MAC_VLAN_Tag_Ctrl Register.

If inverse Filtering is enabled and the frame has mis-matched all the relevant filters then it is considered to have passed the VLAN filter. If the frame matches any one of the relevant filters then it is considered as a fail. If none of the enabled filters can perform a comparison or if none of the filters are enabled, then the frame is bypassed to the application.

The overall filter result and the programming on the VTFE and RA bits of the MAC Filter Register determine if the frame will be dropped or forwarded to the application. If RA = 1 or VTFE = 0, it does not matter if the filter result is a pass or fail. The frame is

always forwarded. If RA = 0 and VTFE = 1, only then, if the VLAN Tag Filter result is a pass does the MAC forward the frame. If the frame is forwarded to the application, then the relevant filter result is indicated through the Status bits.

61.3.4.4.3 Filter Status

The Extended Receive VLAN Filtering and Routing feature provides two status bits to indicate the comparison result of the VLAN tags.

By default, the MAC indicates the VLAN Filter Status through one bit in the status – VF field in RDES2. When Extended RX VLAN Filtering and Routing is enabled, two status bits are used to indicate the comparison result of VLAN tags. The Outer VLAN Tag Filter Pass and Inner VLAN Tag Filter Pass bits are defined in the following positions. The status indicated through these bits is highly dependent on the programming as explained below.

In RDES2:

- Bit 15 – Outer VLAN Tag Filter Status
- Bit 14 – Inner VLAN Tag Filter Status

In ARI status: MAC Filter Status:

- Bit 15 – Outer VLAN Tag Filter Status
- Bit 14 – Inner VLAN Tag Filter Status

In MRI Status:

- Bit 47 – Outer VLAN Tag Filter Status
- Bit 46 – Inner VLAN Tag Filter Status

Outer VLAN Tag Filter Status (OTS)

- In perfect Filtering, without inverse filtering enabled, if this bit is set, it indicates that the frame's Outer VLAN Tag has matched one of the VLAN Tag Filters.
- If this bit is reset, it indicates that the frame's Outer VLAN Tag has either failed the relevant Outer VLAN Tag Filters or bypassed them.
- If none of the filters are enabled for Outer VLAN Tag Comparison, then this bit is reset.

- If Inverse Filtering is enabled and this bit is set, then the frame's VLAN Tag has passed all the relevant VLAN Tag Filters. If it is reset, then it has failed at least one of or bypassed all the Filters programmed for Outer VLAN Tag Comparison.
- This bit is valid for both Single and Double VLAN Tagged frames.

Inner VLAN Tag Filter Status (ITS)

- In perfect Filtering, without inverse filtering enabled, if this bit is set, it indicates that the frame's Inner VLAN Tag has matched one of the VLAN Tag Filters.
- If this bit is reset, it indicates that the frame's Inner VLAN Tag has either failed the relevant Inner VLAN Tag Filters or bypassed them.
- If none of the filters are enabled for Inner VLAN Tag Comparison, then this bit is reset.
- If Inverse Filtering is enabled and this bit is set, then the frame's VLAN Tag has passed all the relevant VLAN Tag Filters. If it is reset, then it has failed at least one of or bypassed all the Filters programmed for Inner VLAN Tag Comparison.
- This bit is valid for only Double VLAN Tagged frames, when Double VLAN Processing is enabled.

The application must look at the status bits and the programming to determine if the Frame has passed or failed the VLAN Filter.

Following two tables 'OTS and ITS Bit Values with At Least 1 Perfect Filter Enabled' and 'OTS and ITS Bit Values with Only VLAN Hash Filter Enabled' show the possible Filter combinations and the corresponding filter results. These tables explain the scenarios when Double VLAN Processing and Hash VLAN filter are enabled in the design.

Legend for the table 'OTS and ITS Bit Values with At Least 1 Perfect Filter Enabled'

- VTIM: VLAN Tag Inverse Match Enable – bit 17 in VLAN_Tag_Ctrl Register.
- HFO: Hash Filter enabled for Outer VLAN Tag Comparison - bit 25 and bit 27 in VLAN_Tag_Ctrl Register.
- HFI: Hash Filter enabled for Inner VLAN Tag Comparison – bit 25 and bit 27 in VLAN_Tag_Ctrl Register.
- PFO – Perfect Filter comparison enabled for Outer VLAN Tag - Any of the MAC_VLAN_Tag_Filter Registers is enabled (bit 16 is set) and programmed for Outer VLAN Tag comparison (bit 20 is set to 0).

- PFI – Perfect Filter comparison enabled for Inner VLAN Tag - Any of the MAC_VLAN_Tag_Filter Registers is enabled (bit 16 is set) and programmed for Inner VLAN Tag comparison (bit 20 is set to 1).
- OTS – Outer VLAN Tag Filter Status
- ITS – Inner VLAN Tag Filter Status

Following table shows the possible values of status bits (OTS and ITS) when at least one Perfect filter is enabled.

Table 61-10. OTS and ITS Bit Values with At Least 1 Perfect Filter Enabled

VTIM	HFO	HFI	PFO	PFI	OTS	ITS
0	0	0	0	1	0	1/0
0	0	0	1	0	1/0	0
0	0	0	1	1	1/0	1/0
0	1	0	1	1	1/0	1/0
0	1	0	1	0	1/0	0
0	1	0	0	1	1/0	1/0
0	0	1	1	1	1/0	1/0
0	0	1	1	0	1/0	1/0
0	0	1	0	1	0	1/0
1	0	0	0	1	0	1/0
1	0	0	1	0	1/0	0
1	0	0	1	1	1/0	1/0
1	1	0	1	1	1/0	1/0
1	1	0	1	0	1/0	0
1	1	0	0	1	1/0	1/0
1	0	1	1	1	1/0	1/0
1	0	1	1	0	1/0	1/0
1	0	1	0	1	0	1/0

Following table shows the possible values of status bits (OTS and ITS) when none of the perfect filters are enabled and only the VLAN Hash Filter is enabled.

Table 61-11. OTS and ITS Bit Values with Only VLAN Hash Filter Enabled

VTIM	HFO	HFI	OTS	ITS
0	0	0	0	0
0	1	0	1/0	0
0	0	1	1/0	1/0
1	0	0	1/0	0
1	1	0	1/0	0

Table continues on the next page...

Table 61-11. OTS and ITS Bit Values with Only VLAN Hash Filter Enabled (continued)

VTIM	HFO	HFI	OTS	ITS
1	0	1	1/0	1/0

With no perfect filters enabled, any VLAN packet is considered to have bypassed the perfect filter. If Hash Filter is enabled for one of the Tags, then the respective Status bit depends on the Filter's result. The Status bits are set to 0 if VLAN Hash Filter is also not enabled.

If the value of ITS/OTS is shown as 1/0; then it indicates that the final result is dependent on the enabled relevant filter's result.

Example 1: The second row of table 'OTS and ITS Bit Values with Only VLAN Hash Filter Enabled' indicates that at least one Perfect Filter is enabled for Outer VLAN tag comparison and none of the filters are enabled for Inner VLAN tag comparison. Inverse VLAN Filtering is not enabled. The bit OTS is given as 1/0. If the received frame passes at least one of the enabled Outer VLAN Tag filters then the bit is set to 1. If the frame doesn't pass any of the enabled Outer VLAN Tag filters, then the bit is set to 0.

Example 2: Last Row of table 'OTS and ITS Bit Values with Only VLAN Hash Filter Enabled' indicates that Inverse Filtering is enabled, Hash Filter and at least one perfect filter is enabled for Inner VLAN Tag comparison, then if the received frame's Inner VLAN tag mismatches with both the Hash Filter and all the enabled Perfect filters, then the frame will have the ITS bit set to 1 else it is set to 0. OTS will be set to 0 as no comparison is performed.

61.3.4.4.4 Stripping

Each of the VLAN Tags has individual control over stripping. The programming options of always strip, never strip, strip on pass and strip on fail are available. Inner or Outer VLAN Tag Stripping is based on the pass or fail results of the individual tag. If a tag is bypassed by all the relevant filters, stripping is not applicable for the tag.

- If strip on Pass is enabled for the outer VLAN Tag, then the stripping occurs only if the Outer VLAN tag has passed the relevant filters. The Outer VLAN Tag Filter Result bit will be set.
- If strip on Fail is enabled for the outer VLAN Tag, then stripping occurs only if the Outer VLAN Tag has failed relevant filters. The Outer VLAN Tag Filter Result Bit will be reset.

- If the Outer VLAN tag of the received frame is bypassed by the entire filter (no comparison has been made), then the tag is not stripped, though the Status Bit is still 0.
- As multiple filters are enabled, it is possible that the received VLAN frame could have matched any one or more of the filters. The VLAN Tag's value is not always deterministic from the filter status bits.

If the software/application strips the VLAN Tag based on the filter result, it might lose the VID. So the suggested use is, if stripping is enabled for any of the tags, the tag can be put in the status. For this the software/application will have to enable the respective "VLAN Tag in Status" bit - 24 or 31 in the MAC VLAN Tag Control Register.

See section Programming Guidelines for Extended VLAN Filtering and Routing on Receive

61.3.4.5 Layer 3 and Layer 4 Filtering

IP supports the Layer 3 based packet filtering which is IP Source or Destination Address filtering in the IPv4 or IPv6 packets, and Layer 4 based packet filtering which is Source or Destination Port number filtering in TCP or UDP. When layer 3 and layer 4 packet filtering is enabled then packets are filtered in the following manner.

- Matched Packets: The MAC forwards the packets that match all enabled fields to the application along with the status. The MAC gives the matched field status only if the IPC bit of MAC_Configuration register is set and one of the following conditions is true:
  - All enabled Layer 3 and Layer 4 fields match
  - At least one of the enabled field matches and other fields are bypassed or disabled

When multiple Layer 3 and Layer 4 filters are enabled, any filter match is considered as a match. If more than one filter matches, the MAC provides the status of the lowest filter where Filter 0 is the lowest filter and Filter 3 is the highest filter.

- Unmatched Packets: The MAC drops the packets that do not match any of the enabled fields. You can use the inverse match feature to block or drop a packet with specific TCP or UDP over IP fields and forward all other packets.

- Non-TCP or UDP IP Packets: By default, all non-TCP or UDP IP packets are bypassed from the Layer 3 and Layer 4 filters. MAC can optionally be programmed to drop all non-TCP or UDP over IP packets.
- IP has a control register “MAC_L3_L4_Control” to control the Layer L3 and L4 packet filtering along with address registers to program the Layer L3 and L4 fields to be matched.

61.3.4.6 Flexible Receive Parser

When this function is enabled, all incoming packets are parsed as per the programmable instruction stored in memory. It does the following function

- Packet Filter (Accept or Reject)
- DMA Channel Selection

Flexible receive parser block operates over the first 128 bytes data of receive packet based on 64 bytes of instruction on each packet. Following figure shows the functional block diagram of Flexible Receive Parser.

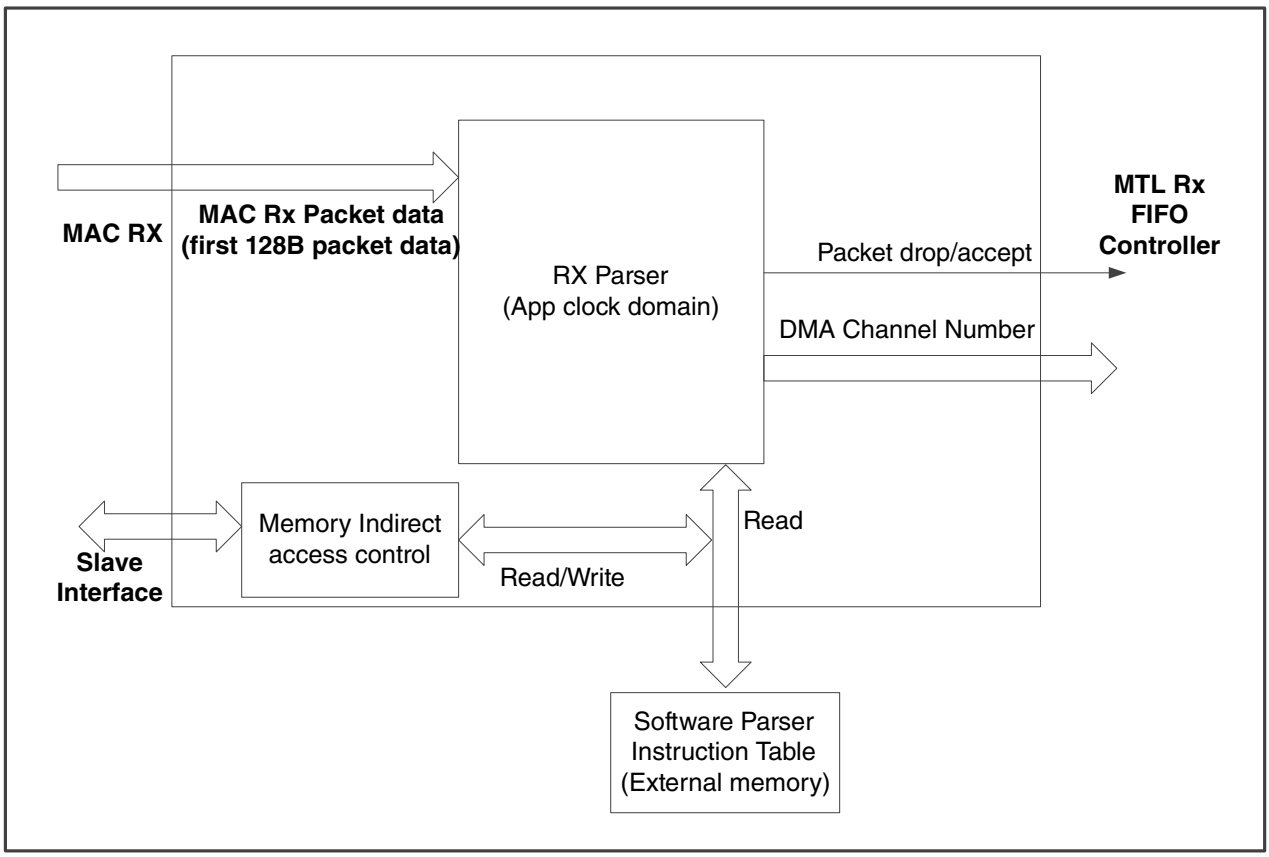

Figure 61-3. Functional block diagram of flexible recieve parser

61.3.4.6.1 Instruction Table Format of the Flexible Receive Parser

Software must build the 96-bit wide instruction before enabling the receive parser feature. Each instruction is programmed as an entry in the instruction memory.

The format of each entry in the Instruction table is shown in the following table.

Table 61-12. Rx Parser Instruction Entry Format

Field	Field Name	Description
31:0	MATCH_DATA	The 4-byte data. This data is used for comparing with incoming packet data starts at the frame offset as defined in [79:72] of the entry. The comparison is done only on those bits whose corresponding mask bits are set to 1 (MATCH_EN bits of [63:32]). See the Notes (below this table) on the byte order relative to Ethernet arrival data

Table continues on the next page...

Table 61-12. Rx Parser Instruction Entry Format (continued)

Field	Field Name	Description
		and endianness supported by QoS IP on the slave interface. The programming of this instruction table should adhere to the same.
62:32	MATCH_EN	When the MATCH_EN is set to 1, the corresponding Packet data bit is used for comparing. Otherwise, corresponding data bit is don't care.
64	AF	Accept frame
65	RF	Reject frame
66	IM	Inverse match
67	NIC	Next instruction control
71:68	Reserved	-
79:72	Frame Offset	[77:72] indicates the frame offset in terms of 4 bytes. (Here [79:78] always 0)Frame offset in the packet data to be compared for Match.This is in terms of 4 bytes. Value Actual Frame offset in bytes 0 01 42 8… ..63 252 The max value programmed in this Instruction Table is 128 B. The 'Actual Frame Offset' should not cross this limit.
87:80	OK Index	If (NIC==0) Memory Index to be used next when ENTRY_MATCH==1 and neither AF or RF is set to 1. If (NIC==1) Memory Index to be used next when ENTRY_MATCH==0 Note: ENTRY_MATCH is a calculated value based on MATCH_DATA, MATCH EN, and IM. It is not a field.
92:88	DMA CH NO	Indicates the DMA Channel Number (1-bit for each). This will be used when ENTRY_MATCH==1 and AF==1 (Accept frame). The encoding is as follows: • bit[0]- DMA Channel Number 0 • bit[1]- DMA Channel Number 1 • bit[2]- DMA Channel Number 2 • bit[3]- DMA Channel Number 3 • bit[4]- DMA Channel Number 4. Note: The DMA Channel number is encoded using bit wise as QoS IP support multicasting/broadcast across DMA Channels. See section 3.3.12 for more details and proper usage.
128:93	Reserved	0 (This field is only for software view and reserved for future enhancements. The memory width remains as 93-bits for now)

The parser begins parsing from the 0th entry, for each received packet. The subsequent parsing entry location (next entry or OK_INDEX[]) depends on the parser result of the current entry. Following figure shows the detailed flow.

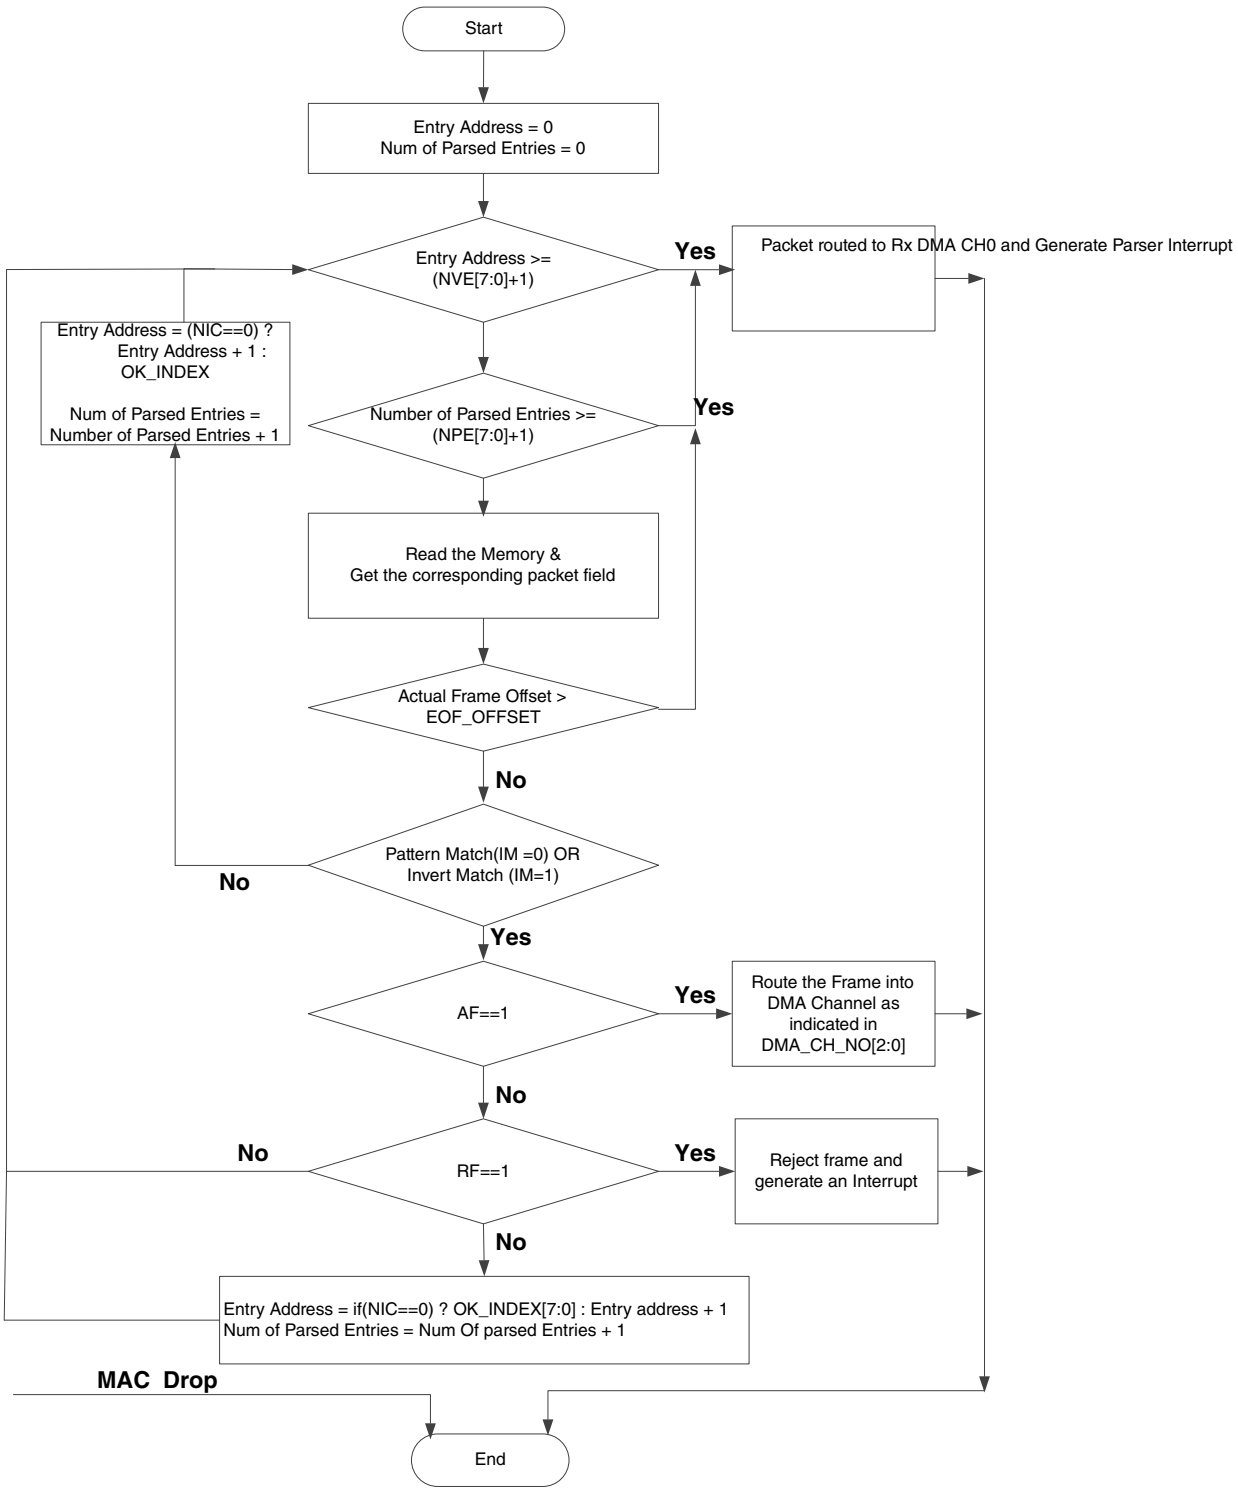

Figure 61-4. Flexible recieve parser flow chart

In the above figure, MAC Drop means the packet is dropped by the MAC due to another filter condition (for example, DA filter) and will not reach the Flexible Receive Parser.

The EOF_OFFSET shown in the figure is equal to the least among the following:

- Actual Packet size
- 128 Byte when frame pre-emption feature is not enabled/configured
- 128 Byte when frame pre-emption feature is enabled and packet is pre-emptible.
- 64 Byte when frame pre-emption feature is enabled and packet is Express Packet

61.3.4.6.2 Number of Valid Entries (NVE)

NVE indicates the number of valid entries in the instruction table. The default value is 64. Software can change this value by writing into MTL_RXP_Control_Status registers field NVE[7:0].

While parsing, if the Entry address is found to be is greater than NVE[7:0]+1, an error is flagged in the MTL_RXP_Interrupt_Control_Status register bit[0], NVEOVIS (Number of Valid Entries overflow status). IP generates an interrupt status (MTL_Interrupt_Status, bit[23], MTLPIS (MTL Parser Interrupt Status)).

61.3.4.6.3 Number of Parsable Entries (NPE)

NPE indicates the number of entries that can be parsed on an incoming packet. The default value is 64. Software can change this value by writing into MTL_RXP_Control_Status registers field NPE[7:0] (Number of Parsable Entries) bits [21:16].

While parsing, if the number of parsed entries is more than NPE[7:0]+1, an error is flagged in the MTL_RXP_Interrupt_Control_Status register bit[1], NPEOVIS (Number of Parsable Entries overflow status). IP generates an interrupt status (MTL_Interrupt_Status, bit[23], MTLPIS (MTL Parser Interrupt Status).

While NVE[] indicates is the number of valid entries in the Rx parser memory built by software, NPE[] indicates the worstcase parsable entries considering the various possible paths that the parser can take. (NVE[] >= NPE[]).

61.3.4.6.4 Frame Offset

It indicates the frame offset, in terms of 4 bytes which is used while comparing against the current table entry.

In an entry, an error is flagged in the TL_RXP_Interrupt_Control_Status register bit[2], FOOVIS (Frame Offset Overflow Interrupt Status) in any of the following cases:

When Frame Offset is more than

- Packet size
- 128B if pre-emption is disabled
- 128B if pre-emption is enabled and packet is pre-empitble
- 64B if pre-emption is enabled and packet is an Express packet

IP generates an interrupt status (MTL_Interrupt_Status bit[23]) and MTLPIS (MTL Parser Interrupt Status).

NOTE

If the frame ends after the (frame_offset *4) bytes but before ((frame_offset *4)+4) bytes, the Receive parser declares Frame Offset Error if comparison is enabled (via MASK bits) for the non-received bytes; from (frame_offset *4) to ((frame_offset *4)+4).

61.3.4.6.5 Frame Reject

In cases where an Entry matches (considering the Inverse match, IM bit in the instruction table) and Frame Accept bit is not set, and Frame Reject bit (RF) is set, the frame is dropped.

When a frame is dropped due to RF = 1, IP generates an interrupt status (MTL_Interrupt_Status, bit[23], MTLPIS (MTL Parser Interrupt Status).

61.3.4.6.6 Out of Order Processing

The Rx parser flow can be out of order. The decision tree need not be based on the order in which packet arrives. That is, the decision tree can be out of order; the decision tree need not be based on the same order as the packet data arrival (data within one packet). This implies that the next entry and next frame offset (OK_INDEX[]/ FRAME_OFFSET[]) can be less than the current entry address and current Frame Offset.

61.3.4.6.7 DMA Channel Selection

When the Rx parser is enabled (FRPE bit[16] is set to 1 in MTL_Operation_Mode register) the Rx parser overrides the DMA selection criteria of the MAC.

When the Rx parser is disabled (FRPE bit[16] is set to 0 in MTL_Operation_Mode register) the MAC/MTL determines the DMA channel number.

61.3.4.6.8 Receive Queue Selection

The Rx Queue is determined by the existing MAC functionality, irrespective of the enabling/disabling of the Rx Parser. This is because the Rx parser is mainly designed for selecting the DMA channel and Rx queuing is decided by the MAC to enable the proper functioning of the Pause/PFC feature.

NOTE

When there are multiple queues and multiple DMA Channels are enabled, a particular DMA channel might receive out of order packets. This is because queue selection is based on MAC criteria (VLAN Priority and other criteria) and Rx DMA channel selection is based on Rx parser.

61.3.4.6.9 MAC Packet Filtering/Drop/Error Handling

The MAC does the packet filtering based on the received packet fields. Disable the Packet Filtering features inside the MAC when the Rx parser is enabled. To disable the Packet Filtering features inside the MAC,

1. Set Promiscuous Mode (PR, bit[0] of MAC_Packet_Filter register)
2. Set all other bits in the MAC_Packet_Filter register to its default values

When MAC decides to drop the packet (due to Rx MAC dependent Error such as GMII Error, Receive Watch Dog Error, CRC Error and Giant Frame Error) the packet is dropped irrespective of the Rx parser decision.

61.3.4.6.10 PAD Strip/CRC Strip Handling

The pad strip and CRC strip are controlled by the software and applicable to all the received packets. When these features are enabled, software must build the Rx parser instructions accordingly.

NOTE

Enable PAD and CRC stripping in real use case.

61.3.4.6.11 VLAN Strip Handling

The MAC supports stripping the VLANs, outer as well as inner VLAN. When MAC is programmed to strip the VLAN, the Rx parser considers those VLAN tags to be part of the incoming packet.

61.3.4.6.12 Multicast and Broadcast Support

IP supports multicast and broadcast packet and the packet is routed to the highest queue number.

When Rx Parser is enabled, the packet routing is decided by the DMA Channel Numbers (DMA CH NO, Bits [95:88]) in the Instruction Table.

When Rx Parser is disabled, the packet routing is determined by DCS (DMA Channel Select) field of the MAC_AddressX_High register. For more details, see Broadcast/ Multicast Packet Duplication.

NOTE

DCS/DMA CH NO field is per DMA Channel control and therefore, multiple DMA channels can be selected for routing the packet.

61.3.4.6.13 Pre-emption Support

The MAC supports the frame pre-emption feature when the Flexible Rx parser feature is enabled. The minimum packet size for Frame Preemption is 64 bytes. This means that:

- The Rx parser can operate on 64 bytes of Express traffic.
- The Rx parser can operate on 128 bytes of pre-emptible traffic, as a 64 bytes packet of pre-emptible traffic might be interrupted by Express traffic before that packet is fully received, so the parser needs to have 64 bytes on either side of the express traffic in order to capture the full 64-bytes of a pre-empted packet.

61.3.4.6.14 Software Access to the Flexible Receive Parser Memory

Software can read/write into the Rx parser memory, using the following registers via indirect addressing.

- MTL_RXP_Indirect_Acc_Control_Status
- MTL_RXP_Indirect_Acc_data

For more details, see ENET_QOS register descriptions.

61.3.4.6.15 Statistical Counters

IP supports the following statistics counters for flexible receive parser.

1. MTL_RXP_Drop_Cnt
2. DMA_RXP_Error_Cnt

DMA_CH(#i)_Rxp_Accept_cnt (i=0; i<2)

For more details, see ENET_QOS register descriptions.

61.3.4.6.16 Changing the Instruction Table by Software

Software can update the instruction table in the memory in the following ways

- Disable the MAC Receiver and Receive Parser by setting the RE field of the MAC_Configuration register to 0 and FRPE bit of MTL_Operation_mode register to 0. Wait for Rx Parser to become inactive (RXPIA, MTL_RXP_Control_Status register bit[31]).
- (Optional) Program in the Entry address 0 to unconditionally (all MATCH_EN bit 0) skip to OK_INDEX[] (to certain location in the memory) where it is programmed to reject or accept all packets.

61.3.4.6.17 Receive Cut-Through Functionality

In the case of cut-through mode, the Rx controller attempts to transfer the received packets to DMA just after the cut-through threshold amount of packet data is received (RTC field in the MTL_RxQx_Operation_Mode register).

However due to Rx parser's result worst case arrival time can be more than the programmed cut-through threshold. So, the Rx controller delays the packet transfer to DMA accordingly. So, the cut-through functionality is re-defined as follows

The Rx controller attempts to transfer packet to DMA after at least RTC number of bytes have been received and Rx parser results are available.

61.3.4.6.18 Receive Packet Drop Indication

In most cases, the packet drops internally in the Rx Queue. However, back-to-back packets can arrive for the same queue and first packet's Rx parser result is not available when the second packet arrives. In such cases, the packet cannot be flushed internally and

forwarded to DMA or the Application Interface and status is indicated accordingly. For more details, see RDES2, bit 16(RXPD) in Receive Normal Descriptor (Write-Back Format).

61.3.4.6.19 Runt Packet Handling

The Rx parser can perform the operation with 64B minimum size packet. If the runt packet is received (should be indicated by MAC), the Rx parser assumes that it gets dropped in the MAC. This is because, back-to-back runt packets (< 64B) cannot be handled in the Rx parser.

61.3.4.6.20 Uncorrectable ECC Error Handling

When the parser detects an uncorrectable ECC error while parsing the parser memory, the packet is not dropped. Instead, the packet is sent to the application with an Error Indication. The RXPI (RX Parser Incomplete) is set in the packet status along with Error Summary (ES) bit.

For more details, see Receive Normal Descriptor (Write-Back Format).

61.3.5 IEEE 1588 Timestamp Support

The MAC supports the IEEE 1588 Precision Time Protocol (PTP). The MAC is able to do precise time stamping and capturing of incoming and outgoing frame to enable support of PTP with its associated software. The MAC supports the all clock types defined in IEEE 1588-2008. Typical frequency of PTP timestamp clock is 125 MHz. The MAC supports:

- Taking a timestamp snapshot of all packets or only PTP type packets.
- Taking a timestamp snapshot of only event messages.
- Identifying the PTP message type, version, and PTP payload in packets sent directly over Ethernet and sending the PTP message type status given by the MAC. The PTP status is finally written back to the Receive Descriptor: RDES1 Normal Descriptor (Write-Back Format).
- Measuring sub-second time in decimal or binary format.

61.3.5.1 Delay Request-Response Mechanism

The system or network is classified into the master and slave nodes for distributing the timing and clock information. Following figure shows the process that PTP uses for synchronizing a slave node to a master node by exchanging PTP messages.

Figure 61-5. Networked Time Synchronization

As shown in the figure, PTP uses the following process:

1. The master broadcasts the PTP Sync messages to all its nodes. The Sync message contains the reference time information of the master. This message leaves the system of the master at t1. This time must be captured for Ethernet ports at the internal GMII or MII interface.
2. The slave receives the Sync message and also captures the exact time, t2, using its timing reference.
3. The master sends a Follow_up message to the slave, which contains t1 information for later use.
4. The slave sends a Delay_Req message to the master and notes the exact time, t3, at which this packet leaves the internal GMII or MII interface.
5. The master receives the message, capturing the exact time t4, at which the message enters its system.
6. The master sends the t4 information to the slave in the Delay_Resp message.
7. The slave uses the four values of t1, t2, t3, and t4 to synchronize its local timing reference to the timing reference of the master.

Most of the PTP implementation is done in the software above the Ethernet layer. However, the hardware support is required to capture the exact time when specific PTP packets enter or leave the Ethernet port at the internal GMII or MII interface. This timing information must be captured and returned to the software for proper implementation of PTP with high accuracy.

61.3.5.2 Peer-to-Peer PTP Transparent Clock (P2P TC) Message Support

The IEEE 1588-2008 supports peer-to-peer PTP (Pdelay) message in addition to the SYNC, Delay Request, Follow-up, and Delay Response messages. Following figure shows the method to calculate the propagation delay in clocks supporting peer-to-peer path correction.

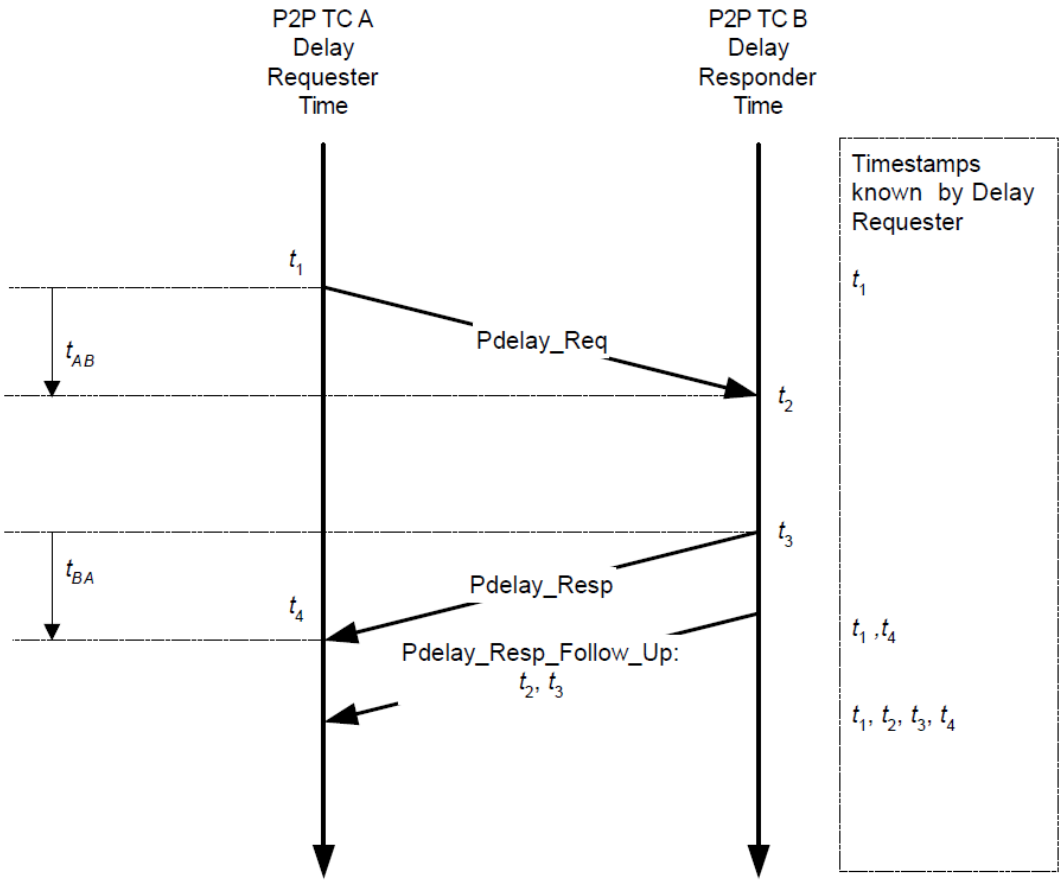

Figure 61-6. Propagation Delay Calculation in Clocks Supporting Peer-to-Peer Path Correction

As shown in the above figure, the propagation delay is calculated in the following way:

1. Port 1 issues a Pdelay_Req message and generates a timestamp (t1) for the Pdelay_Req message.
2. Port 2 receives the Pdelay_Req message and generates a timestamp (t2) for this message.
3. Port 2 returns a Pdelay_Resp message and generates a timestamp (t3) for this message. To minimize errors because of any frequency offset between the two ports, Port 2 returns the Pdelay_Resp message as quickly as possible after the receipt of the Pdelay_Req message. Port 2 returns any one of the following:
   - Difference between the timestamps t2 and t3 in the Pdelay_Resp message
   - Difference between the timestamps t2 and t3 in the Pdelay_Resp_Follow_Up message
   - Timestamps t2 and t3 in the Pdelay_Resp and Pdelay_Resp_Follow_Up messages, respectively
4. Port 1 generates a timestamp (t4) on receiving the Pdelay_Resp message.

5. Port 1 uses all four timestamps to compute the mean link delay.

61.3.5.3 Timestamp Correction

According to the IEEE 1588 specification, a timestamp must be captured when the PTP message timestamp point (leading edge of the first bit of the octet immediately following the Start Frame Delimiter octet) crosses the boundary between the node and the network. As the MAC takes the timestamp at an internal point far from the actual boundary of the node and network, this captured timestamp is corrected/updated for the ingress/egress path latency (including the delay in the PHY layers). Further correction is done for the inaccuracies/errors introduced due to the clock (internal GMII or MII Tx, Rx clock) being different at the capture point as compared to the PTP clock (clk_ptp_ref_i) that is used to generate the time. The resultant CDC (Clock Domain Crossing) circuits add error depending on the clock period of the internal GMII or MII and PTP clocks.

61.3.5.3.1 Ingress Correction

In the Receive side the timestamp captured at the internal snapshot point is delayed (later in time) as compared to the time at which that packet's SFD bit is received at the port's boundary. Therefore, the captured timestamp must be reduced by the ingress latency and the errors in CDC sampling. This correction value must be determined/calculated by the software and written into the MAC_Timestamp_Ingress_Corr_* registers.

The correction value consists of the following 3 components:

1. External latency in the PHY layer between boundary point and the input of the core.

   If the PHY is compliant to the IEEE 802.3 Clause 45 MMD registers, it has a register indicating the maximum and minimum ingress latency. The software can read these registers and determine the average ingress latency in the PHY. Alternatively (if the PHY does not support these registers), the ingress latency must be determined from its datasheet or timing characteristics.

2. Internal latency from the input of the core to the internal capture point.

   The internal ingress latency can be read from the MAC_Ingress_Timestamp_Latency register. This is a read-only register and gives the latency in scaled Nanoseconds format defined in IEEE 1588 Clause 5.3.2. The latency differs based on the active PHY interface (for example, RMII) and the operating speed. Therefore, the software must read this register after any speed change in the MAC to determine the current internal latency.

3. CDC Synchronization

The CDC synchronization error is almost equal to 2 times the clock-period of the PTP clock (clk_ptp_ref_i).

The values determined from these 3 components should be added by the software and must be written into the TSIC and TSICSNS fields of the MAC_Timestamp_Ingress_Corr_* registers.

NOTE

The value written to the register must be negative (two's complement as explained below), because it has to be subtracted from the captured timestamp. The MAC Receiver adds the value in this register to the captured timestamp and then gives the resultant value as the timestamp of the received packet.

When TSCTRLSSR bit in MAC_Timestamp_Control register is set, the nanoseconds field of the captured timestamp is in decimal format with a granularity of 1ns. So the Bit31 of TSIC must be set to 1 (for negative value) and bits[30:0] must be written with "10^9 - total ingress_correction_value[nanosecond part]" represented in binary. For example, if the required correction value is -5 ns, then the value is 0xBB9A_C9FB.

When TSCTRLSSR bit in MAC_Timestamp_Control register is reset, the nanoseconds field of the captured timestamp is in binary format with a granularity of ~0.466ns. Therefore, bits[30:0] must be written with "2^31 - total ingress_correction_value" represented in binary with bit[31] = 1.

61.3.5.3.2 Egress Correction

In the Transmit side the timestamp captured at the internal snapshot point is earlier (advanced in time) as compared to the time at which that packet's SFD bit is output at the port's boundary. Therefore, the captured timestamp must be compensated by the egress latency and the errors in CDC sampling. This correction value must be determined/ calculated by the software and written into the MAC_Timestamp_Egress_Corr_* registers.

The correction value consists of the following 3 components:

1. External latency in the PHY layer between the output of the core and the boundary of the port and the network

If the PHY is compliant to the IEEE 802.3 Clause 45 MMD registers, it has a register indicating the maximum and minimum egress latency. The software can read these registers and determine the average egress latency in the PHY. Alternatively (if the PHY does not support these registers), the egress latency must be determined from its datasheet or timing characteristics.

2. Internal latency from the internal capture point and the output of the core

   This internal egress latency can be read from the MAC_Egress_Timestamp_Latency register. This is a read-only register and gives the latency in scaledNanoseconds format defined in IEEE 1588 Clause 5.3.2. The latency will differ based on the active PHY interface (for example, RMII) and the operating speed. Hence the software must read this register after any speed change in the MAC to determine the current internal latency.

3. CDC synchronization error

   The CDC synchronization error value for one-step timestamping would be = (1 * period of clk_ptp_ref_i + 4 * period of clk_tx_i). Otherwise (Two-step timestamping mode), the value = -(2 * period of clk_ptp_ref_i).

61.3.5.3.3 Frequency Range of Reference Timing Clock

The timestamp information is transferred across asynchronous clock domains, from the MAC clock domain to the application/system clock domain. Therefore, a minimum delay is required between two consecutive timestamp captures. This delay is 4 clock cycles of MII and 3 clock cycles of PTP clocks. If the delay between two timestamp captures is less than this delay, the MAC does not take a timestamp snapshot for the second packet.

61.3.5.3.4 PTP Processing and Control

Following table shows the common message header for the PTP messages. This format is taken from the IEEE 1588-2008.

Table 61-13. Message Format Defined in IEEE 1588-2008

Bits								Octet	Offset
7	6	5	4	3	2	1	0		
transportSpecific				messageType				1	0
Reserved				versionPTP				1	1
messageLength								2	2
domainNumber								1	4
Reserved								1	5

Table continues on the next page...

Table 61-13. Message Format Defined in IEEE 1588-2008 (continued)

Bits								Octet	Offset
7	6	5	4	3	2	1	0		
flagField								2	6
correctionField								8	8
Reserved								4	16
sourcePortIdentity								10	20
sequenceId								2	30
controlField (*)								1	32
logMessageInterval								1	33

(*) – control Field is used in version 1. In version 2, message Type field is used for detecting different message types.

There are some fields in the Ethernet payload that are being use to detect the PTP packet type and control the snapshot to be taken. These fields are given below in table for PTP packets over Ethernet.

Following table provides information about the fields that are matched to control the snapshots for the PTP packets sent over Ethernet for IEEE 1588 version 1 and 2. The octet positions for the tagged packets are offset by 4. This is based on the IEEE 1588-2008, Annex D and the message format.

Table 61-14. Ethernet PTP Packet Fields Required for Control And Status

Field Matched	Octet Position	Matched Value	Description
MAC Destination Multicast Address[1]	0–5	01-1B-19-00-00-00 01-80-C2-00-00-0E	All PTP messages can use any of the following multicast addresses[2]: • 01-1B-19-00-00-00 • 01-80-C2-00-00-0E[3]
MAC Packet Type	12, 13	0x88F7	PTP Ethernet packet
PTP Control Field (IEEE 1588 version 1)	46	0x00, 0x01, 0x02, 0x03, or 0x04	• 0x00: SYNC • 0x01: Delay_Req • 0x02: Follow_Up • 0x03: Delay_Resp • 0x04: Management
PTP Message Type Field (IEEE 1588 version 2)	14 (nibble)	0x0, 0x1, 0x2, 0x3, 0x8, 0x9, 0xB, 0xC, or 0xD	• 0x0: SYNC • 0x1: Delay_Req • 0x2: Pdelay_Req • 0x3: Pdelay_Resp

Table continues on the next page...

Table 61-14. Ethernet PTP Packet Fields Required for Control And Status (continued)

Field Matched	Octet Position	Matched Value	Description
			• 0x8: Follow_Up • 0x9: Delay_Resp • 0xA: Pdelay_Resp_Follow_Up • 0xB: Announce • 0xC: Signaling • 0xD: Management
PTP Version	15 (nibble)	0x1 or 0x2	• 0x1: Supports PTP version 1 • 0x2: Supports PTP version 2

1. The unicast address match of destination addresses (DA), programmed in MAC address 0 to 31, is used if the TSENMACADDR bit of MAC_Timestamp_Control register is set.
2. IEEE 1588-2008, Annex F
3. The MAC does not consider the PTP version 1 messages with Peer delay multicast address (01-80-C2-00-00-0E) as valid PTP messages.

61.3.5.4 Transmit Path Functions

The MAC captures a timestamp when the Start Packet Delimiter (SFD) of a packet is sent on the internal GMII or MII interface. The packets, for which the timestamps has to be captured can be controlled on per-packet basis. Each Transmit packet can be marked to indicate whether a timestamp should be captured for it. The MAC does not process the transmitted packets to identify the PTP packets. You can specify the packets by using the control bits in the Transmit descriptor. The MAC returns the timestamp to the software inside the corresponding Transmit descriptor, thus connecting the time-stamp automatically to the specific PTP packet. The 64-bit timestamp information is written to the TDES0 and TDES1 fields. The TDES0 field holds the 32 least significant bits of the timestamp.

61.3.5.5 Receive Path Functions

The MAC can be programmed to capture the timestamp of all packets received on the internal GMII or MII interface or to process packets to identify the valid PTP messages. Use the following options of the MAC_Timestamp_Control register to control the snapshot of the time to be sent to the application:

- Enable snapshot for all packets
- Enable snapshot for IEEE 1588 version 1 or version 2 timestamp
- Enable snapshot for PTP packets transmitted directly over Ethernet
- Enable timestamp snapshot for the received packet for IPv4 or IPv6
- Enable timestamp snapshot only for EVENT messages (SYNC, DELAY_REQ, PDELAY_REQ, or PDELAY_RESP)
- Enable the node to be a master or slave and select the snapshot type

Table 61-15. Timestamp Snapshot Dependency on Register Bits

SNAPTYPSEL	TSMSTRENA	TSEVNTENA	PTP Messages
00	x	0	SYNC, Follow_Up, Delay_Req, Delay_Resp
00	0	1	SYNC
00	1	1	Delay_Req
01	x	0	SYNC, Follow_Up, Delay_Req, Delay_Resp,Pdelay_Req, Pdelay_Resp,Pdelay_Resp_Follow_Up
01	0	1	SYNC, Pdelay_Req, Pdelay_Resp
01	1	1	Delay_Req, Pdelay_Req, Pdelay_Resp
10	x	x	SYNC, Delay_Req
11	x	x	Pdelay_Req, Pdelay_Resp

The DMA returns the timestamp to the software inside the corresponding Receive Descriptor. The extended status, containing the timestamp message status and the IPC status, is written in normal descriptor RDES1 and the snapshot of the timestamp is written in RDES0 and RDES1 fields of context descriptor. The RDES0 field holds the 32 least significant bits of the timestamp.

NOTE

For Programming Guidelines for IEEE 1588 Timestamping (System Time Correction), see System Time Correction

61.3.5.6 IEEE 1588 System Time Source

The ENET QOS block supports both external and internal time source for reference timestamping.

- External Time source uses the 64-bit external time reference and clock as input in IP. The clock input is used to synchronize the external timing reference into MAC clock domain. Upper 32-bit indicates the time in seconds while lower 32-bit indicates the time in nanoseconds.
- Internal time source takes only the reference clock input and uses it to internally generate the Reference time (also called the system time) and capture timestamps.
  - UInteger48 seconds Field: The seconds field is the integer portion of the timestamp in units of seconds. It is 48-bits wide.

    For example, 2.000000001 seconds are represented as seconds Field = 0x0000_0000_0002.

  - UInteger32 nano secondsField The nanoseconds field is the fractional portion of the timestamp in units of nanoseconds.

    For example, 2.000000001 seconds are represented as nanoSeconds = 0x0000_0001. The nanoseconds field supports the following two modes:

    - Digital rollover mode: In this mode, the maximum value in the nanoseconds field is 0x3B9A_C9FF, that is, (10e9-1) nanoseconds.
    - Binary rollover mode: In this mode, the nanoseconds field rolls over and increments the seconds field after value 0x7FFF_FFFF. Accuracy is ~0.466 ns per bit.

There is a system time register module which is being used when internal time reference is being used. The 80-bit time is maintained in this module and updated using the input reference clock (clk_ptp_ref_i). This time is the source for taking snapshots (timestamps) of Ethernet packets being transmitted or received at the internal GMII or MII interface.

The system time counter can be initialized or corrected using the coarse correction method. In this method, the initial value or the offset value is written to the Timestamp Update register. For initialization, the system time counter is written with the value in the Timestamp Update register. For system time correction, the offset value is added to or subtracted from the system time.

In the fine correction method, the frequency offset and/or frequency drift of a slave clock (clk_ptp_ref_i) with respect to the master clock (as defined in IEEE 1588-2002) is corrected over a period of time instead of in one clock, as in coarse correction. This helps maintain linear time and does not introduce drastic changes (or a large jitter) in the reference time between PTP Sync message intervals.

NOTE

For Programming Guidelines for IEEE 1588 Timestamping (For Internal Time-stamp Source Configuration). see Initialization Guidelines for System Time Generation

61.3.5.7 IEEE 1588 Higher Word Register

If system time source is internal, then higher word register can be invoked. MAC timestamp is 64-bit wide. The values of the upper 16-bits of the seconds field can be read from the CSR register.

61.3.5.8 Flexible Pulse-Per-Second Output

The ENET QOS block supports the flexibility of programming the start or stop time, width and interval of pulse generated on pulse per second (PPS) output. IP supports 4 such output signals. By default, the block is in fixed pulse per second output mode with an interval of 1 second.

Initially. the start time should be programmed in target time registers "MAC_PPSx_Target_Time_Seconds and MAC_PPSx_Target_Time_Nanoseconds" for all desired/enabled PPS output. Reprogramming the start or stop time must be done after the synchronization of the earlier programmed value. Bit 31 of the MAC_PPS#_Target_Time_Nanoseconds register indicates that the synchronization is complete. If the application programs a start or stop time that has already elapsed, the MAC sets an error status bit indicating the programming error. If enabled, the MAC also sets the Target Time Reached interrupt event. The application can cancel the start or stop request only if the corresponding start or stop time has not elapsed. If the time has elapsed, the cancel command has no effect.

The PPS width and interval are programmed in terms of granularity of system time, that is, number of the units of sub-second increment value. For example, to have a PPS pulse width of 40 ns and interval of 100 ns with PTP reference clock of 50 MHz, you should program the width and interval to values 2 and 5, respectively. You can achieve smaller granularity by using a faster PTP reference clock. Before giving the command to trigger a pulse or pulse train on the PPS output, you should program or update the interval and width of the PPS signal output.

NOTE

See Programming Guidelines for Flexible Pulse-Per-Second Output

61.3.5.9 Media Clock Generation and Recovery

Media clock recovery and generation needs a dedicated hardware and software to complete the operation. IP generates a reference clock with the help of dedicated hardware which is then multiplied to get the desired media clock. Software extracts the presentation time from the incoming PTP 1722 frames and programs these value into CSR registers so IP can read them for media clock recovery.

As shown in the following figure, the timestamp array and the DMA module are external to IP. IP supports a 32-bit presentation time counter in nanoseconds that wraps at the full32 bit value to match up with 1722 presentation time format and an handshake mechanism with external application(such as DMA) to program the presentation time into CSR register.

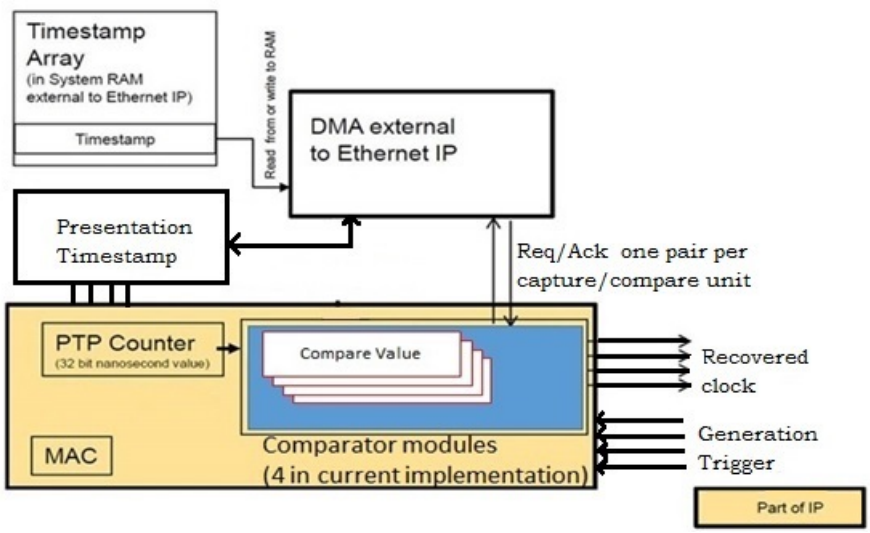

Figure 61-7. Block Diagram of Media Clock Generation and Recovery

61.3.5.9.1 Presentation Time Counter

Presentation time counter is another view of the PTP System time (1588 timer). For a given PTP System time (PTP[63:32] represents time in seconds and PTP[31:0] represents time in nanoseconds), there exists a corresponding Presentation Time (32-bit value in nanosecond). The Presentation time computed is referred to as Current Presentation Time (CPT).

The Current Presentation Time (CPT) can be viewed as derived from 64bit PTP System Time. PTPNS[63:0] = (PTP[63:32] * 32'd1,000,000,000) + PTP[31:0] where, PTPNS is the PTP system time converted into a 64bit nanosecond value.

Current Presentation Time[31:0] = PTPNS[31:0]

Media Clock Recovery is possible when the System Time is internally generated in IP and CPT is computed in the same way as the Internal PTP System Time generation. Because CPT and System Time values are in nanoseconds, and must be synchronous, the increment cycle of both the timers are same. The timer is updated at the same instance, but the updated value could be different. The software must compute a separate 32-bit update value in nanoseconds for the CPT update. CPT sampled at different edges of a triggering input results in the generation of Media Clock timestamps which are inserted in 1722 based AVBTP packets, to recover the clock at the destination.

61.3.5.9.2 Comparator Modules

As shown in the figure 'Block Diagram of Media Clock Generation and Recovery' the module supports four comparator modules to handle multiple media clocks that might be required. The Comparator modules hand shake with the application to

Program the timestamps into the MAC_PPS(#i)_Target_Time_Seconds register when PTGE field of MAC_Timestamp_Control register is set.

Set the Presentation Time Control bits of the particular instance for recovery mode.

The timestamps received from the application are referred as Target Presentation Time (TPT).

When MCGREN#i field of MAC_PPS_Control register is set to 1, the IP operates in MCGR mode. The comparator module sends up to two requests to the application for TPT write, when PTGE field of MAC_Timestamp_Control register is set and the Presentation time control bits of the particular instance is set for MCGR mode. Subsequent requests are generated each time a Presentation Time match occurs. (CPT transitions from a value less than TPT, to a value greater than or equal to CPT). The first request is asserted when a specific comparator instance is set to MCGR mode with a non-zero Presentation Time Control and an additional request is made when the first data is received into the Comparator. This allows the application to write the next TPT value while IP processes the previous TPT value for a match.

The TPT read from the MAC_PPS(#i)_Target_Time_Second is considered as a future time. A toggle/pulse is generated in the next cycle when a match is detected. When a match is detected, the mcgr_dma_req_o#i request for that comparator is asserted (to obtain next TPT) until the corresponding application acknowledgment is set.

The presentation control bits (PPSCMD#i field of MAC_PPS_Control register) determine the shape of the generated waveform. Also, these bits can be programmed to either toggle or generate a high/low pulse for one PTP clock cycle, upon match.

Media Clock Recovery: A match is when the free-running CPT value matches the received TPT value. A output signal EMAC_TMR signal as shown in the IO mux sheet is asserted (toggle, low pulse, or high pulse) based on the presentation control value programmed.

Media Clock Generation: Based on the presentation control value programmed in MAC_PPS_Control register, the particular comparator captures the presentation time and programs it into MAC_PPS(#i)_Target_Time_Second register. A request is raised to the application to read the captured timestamp. Until the acknowledgment is received from the application, acknowledging that the read operation is complete, no new timestamps are captured.

61.3.5.9.3 Media Clock Generation and Recovery Flow

Following figure shows the media clock generation and recovery flow. For both media clock generation and recovery, set the PTGE field of MAC_Timestamp register for CPT generation and set the MCGREN#i field of MAC_PPS_Control Register for the corresponding instance to be enabled in the MCGR mode.

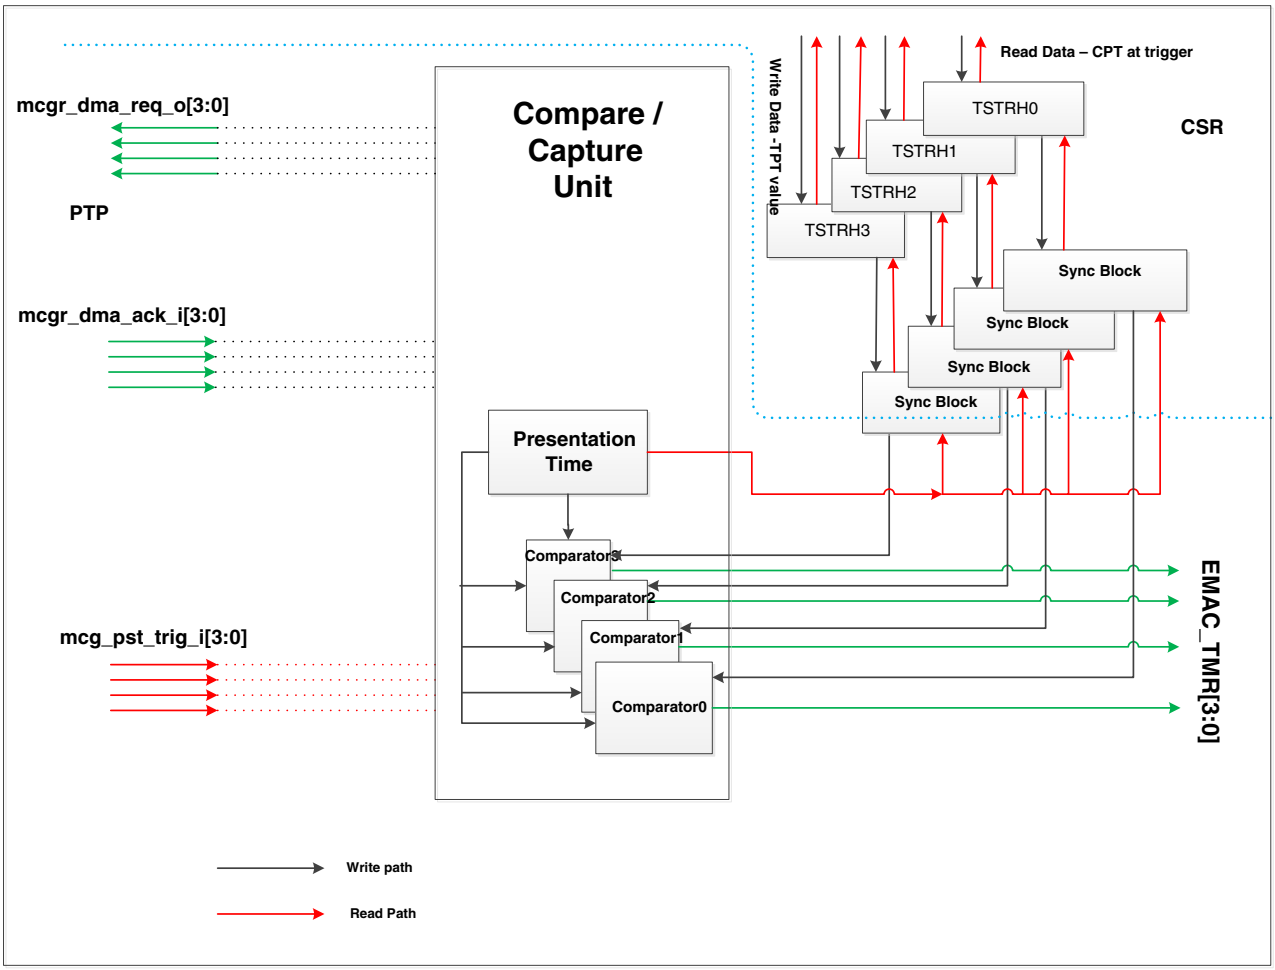

Figure 61-8. Media Clock Generation and Recovery Flow

NOTE

1. The consecutive triggers to sample the presentation time should always be asserted after a few PTP clock cycles to allow for synchronization delays. (This is not an issue when the input trigger maximum frequency is 8KHz and the PTP clock is running at least at 1MHz)
2. DMA acknowledgment can be both posted as well as non-posted, in the Media Clock Recovery Mode.
3. See "Programming Guidelines for Media Clock Generation and Recovery"

61.3.5.10 One step timestamp

IP supports the one step time stamp feature. It can be enabled for a packet by setting the Bit 20 (OSTC) in the control word.

NOTE

See Programming Guidelines for IEEE 1588 Timestamping.

61.3.5.11 IEEE 1588 Sub Nanoseconds Timestamp

The ENET QOS block supports the ingress and egress correction accuracy in sub-nanoseconds. It is programmed in the TSICSNS and TSECSNS fields of the MAC Timestamp Ingress Correction Subnanosecond and MAC Timestamp Egress Correction Subnanosecond registers, respectively. In this case, the correction has an unit of nanosecond, multiplied by 2^8. The least significant 8 bits of the value should be programmed in the sub-nanoseconds register.

For example, if the required egress correction is 3.6 nS and TSCTRLSSR bit is set, then TSEC must be 0x3 and TSECSNS must be 0x99 (0.6 * 256). Similarly, if the required ingress correction is -3.6 ns and TSCTRLSSR bit is set, then TSIC must be 0xBB9A_C9FC and TSICSNS must be 0x66 (fractional part of (10^9 - 3.6) * 256).

61.3.6 Multiple Channels and Queues Support

IP supports the five queues and channel on Tx and Rx paths.

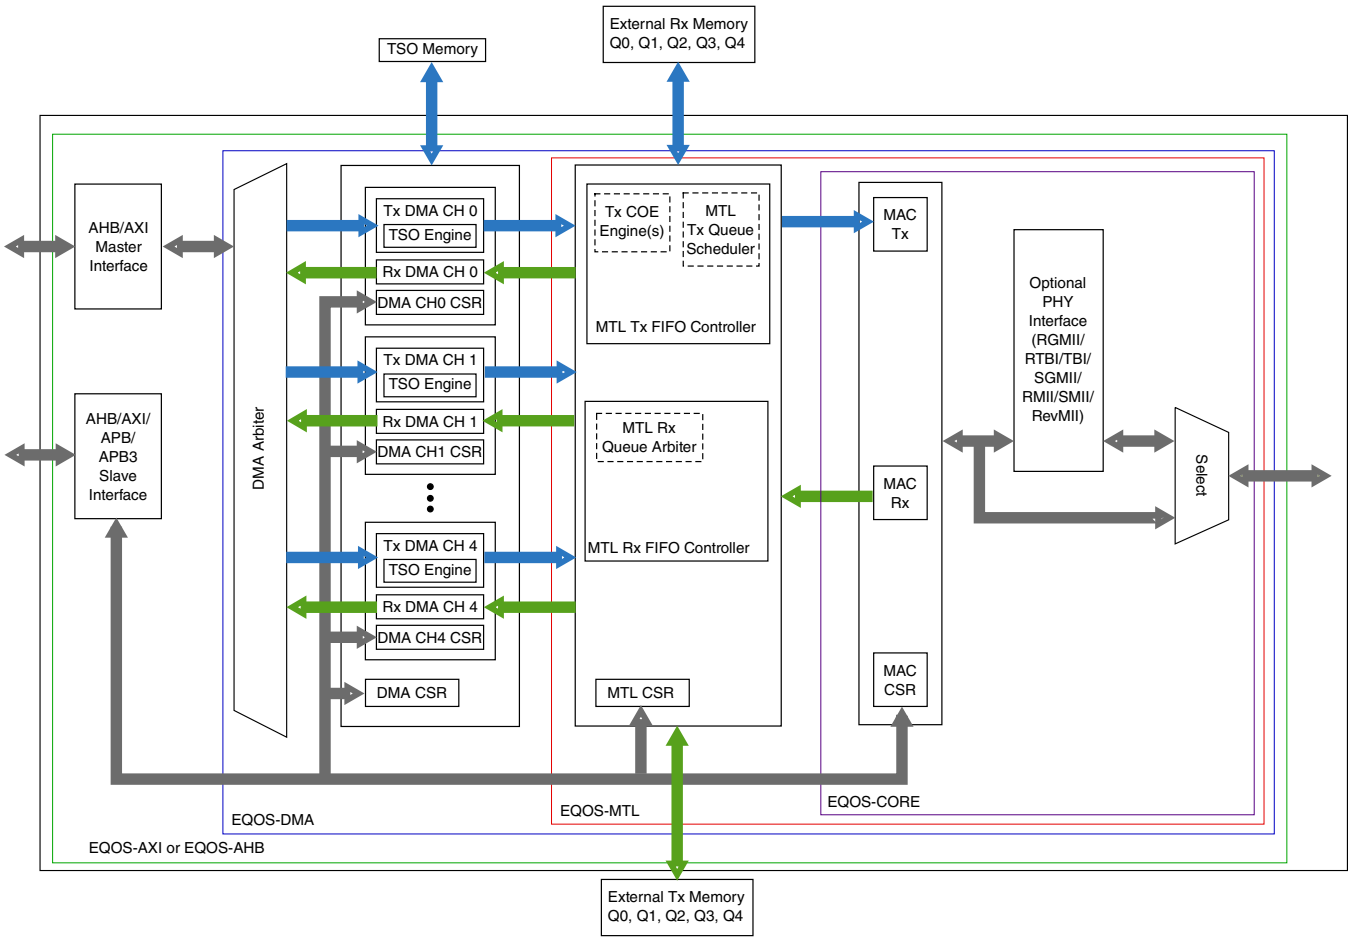

Figure 61-9. Module with Multiple Channels and Queues Block Diagram

DMA arbiter of IP supports two types of arbitration scheme, fixed priority and weighted round-robin. The DMA arbiter performs the arbitration between the Tx and Rx paths of DMA channels for accessing descriptors and data buffers. The DA bit of the DMA_Mode register specifies the arbitration scheme (fixed or weighted round-robin) between the Tx and Rx DMA of a channel.

Priority between the corresponding Tx DMA and Rx DMA can be set by using TXPR field of the DMA_Mode register. PR field of the DMA_Mode register can be set to specify the weighted priority between the Tx DMA and Rx DMA in round robin arbitration scheme.

Following table provides information about the priority scheme between Tx DMA and Rx DMA.

Table 61-16. Priority Scheme for Tx DMA and Rx DMA

Bit 14	Bit 13	Bit 12	Bit 11	Bit 10	Priority Schemes
x	x	x	0	1	Rx always has priority over Tx

Table continues on the next page...

Table 61-16. Priority Scheme for Tx DMA and Rx DMA (continued)

Bit 14	Bit 13	Bit 12	Bit 11	Bit 10	Priority Schemes
0	0	0	0	0	Tx and Rx have equal priority. Rx gets the access first on simultaneous requests
0	0	1	0	0	Rx has priority over Tx in ratio 2:1
0	1	0	0	0	Rx has priority over Tx in ratio 3:1
0	1	1	0	0	Rx has priority over Tx in ratio 4:1
1	0	0	0	0	Rx has priority over Tx in ratio 5:1
1	0	1	0	0	Rx has priority over Tx in ratio 6:1
1	1	0	0	0	Rx has priority over Tx in ratio 7:1
1	1	1	0	0	Rx has priority over Tx in ratio 8:1
x	x	x	1	1	Tx always has priority over Rx
0	0	0	1	0	Tx and Rx have equal priority. Tx gets the access first on simultaneous requests
0	0	1	1	0	Tx has priority over Rx in ratio 2:1
0	1	0	1	0	Tx has priority over Rx in ratio 3:1
0	1	1	1	0	Tx has priority over Rx in ratio 4:1
1	0	0	1	0	Tx has priority over Rx in ratio 5:1
1	0	1	1	0	Tx has priority over Rx in ratio 6:1
1	1	0	1	0	Tx has priority over Rx in ratio 7:1
1	1	1	1	0	Tx has priority over Rx in ratio 8:1

61.3.6.1 Multiple Queues and Channels Support in the Transmit Path

IP supports the five transmit queues and five channels.

NOTE

See Programming Guidelines for Multi-Channel Multi-Queuing

61.3.6.2 Multiple Queues and Channels Support in the Receive Path

IP supports five receive channels and five queues.

In the Receive direction, the MTL Rx Controller selects the Rx DMA for which it is transferring or reading the data from the Rx FIFO memory. This scheduling is based on the programming done in the respective MTL_RxQ[x]_Control register.

Each Rx DMA indicates when it is ready to transfer data and the size of the burst-length (number of beats) that it has to transfer. The scheduler checks whether sufficient data (of requested burst length) is available to be transferred to these DMAs and then selects the Rx DMA that gets serviced using the programmed priorities.

NOTE

See Programming Guidelines for Multi-Channel Multi-Queuing.

61.3.6.3 Rx Queue to DMA Mapping

The packets in the MTL Rx Queues can be routed to any one of the multiple DMA channels by programming the register MTL_RxQ_DMA_Map0 Register for queues 0 through 3, and MTL_RxQ_DMA_Map1 for queue 4.

The following types of Rx Queue to DMA mapping are possible through programming.

61.3.6.3.1 Static Mapping

In this mode, all of the packets of an Rx Queue are connected to a specific DMA channel. For example, all the packets from Rx Queue 0 can be routed to a DMA channel by programming Q0MDMACH (bit[3:0]) and Q0DDMACH (bit[7] = 0) of the MTL_RxQ_DMA_Map0 Register.

Similarly, packets from other Rx Queues can be routed to any DMA channel by programming register fields corresponding to each Queue.

61.3.6.3.2 Dynamic (Per Packet) Mapping

In this mode, the destination DMA channel of a packet being read from a Rx Queue is not constant but decided independently for each packet. For example, if you set the Q1DDMACH bit of the MTL_RxQ_DMA_Map0 register, the static mapping is disabled for Rx Queue 1 and the value in Q1MDMACH is ignored. The destination DMA channel is decided by the MAC receiver for each packet, depending on the following in decreasing order of priority:

1. L3-L4 filter Based DMA Selection: The TCP/UDP and IP header fields of the received packet are matched against the corresponding values programmed and enabled for comparison in the MAC_L3_L4_Address_Control register. If the match is successful, the DMA channel number programmed in the DMCHN field of the MAC_L3_L4_Ad-dress_Control register is selected as the destination DMA channel number provided DMCHEN bit of the same register is set. If none of the L3-L4 Registers give a comparison match, then the module proceeds to the next step below.
2. Extended VLAN Based DMA Selection: Extended routing is applicable only if the VLAN Filter has passed. Routing is only based on Perfect Filter Result. Each perfect filter has a DMA Channel Enable and a DMA Channel Number field which can be programmed. Routing is applicable for a filter, only if the DMA Channel Enable bit is set. The frame is routed to the smallest Matching Filter's DMA Channel provided it is enabled. If that filter's DMA Channel number is not enabled, the frame gets routed to Channel 0. For example, if a frame's VLAN tag matches filters 7, 3, and 1. Then the MAC checks if Filter 1's DMA Channel Number is enabled through programming. If yes, the frame gets routed to the programmed value; otherwise it gets routed to DMA. When the inverse filter is enabled; is routed to the least mismatched filter's DMA channel number provided it is enabled. If the DMA Channel enable bit is not set, then the frame is routed based on DA based addressing or to Channel 0.

   If Hash Filter is also enabled, it is used to determine the Filter result only. Routing will still depend on the Perfect Filters enabled. If none of the perfect filters are enabled or if all of them are bypassed, then the VLAN Filter based routing will not take place. The frame will be routed via DA Based addressing or to Channel 0. If all the perfect filters give a fail result and the Hash Filter has passed, then the VLAN Filter result is a pass but routing will be based on DA Based Addressing or to Channel 0. Similar behavior is seen when inverse Filtering is enabled as well.

3. Ethernet DA-Based DMA Selection: The DA address of the received packet is compared against the programmed DA values in MAC Address Registers. If the address matches any of the programmed values, the corresponding DCS field (when enabled) determines the destination DMA channel number.

If none of the previous operations is able to make a successful match/decision, then the packet is routed to DMA Channel 0 by default.

61.3.6.3.2.1 Broadcast/Multicast Packet Duplication

Broadcast/Multicast Packet Duplication feature provides a mechanism to send the received Broadcast/Multicast packets to multiple DMA channels.

The DCS field of the of MAC_Address0_High and other optional MAC_Address(#i)_High (i=1 to 2) registers determines the DMA channel number to which the received packet (that matches the MAC Address present in that register) must be routed.

Packet duplication is not supported in other DMA channel routing mechanisms such as Extended VLAN, or L3-L4 based routing.

The Packet Duplication feature is supported only on the highest MTL Queue configured. Therefore, packet duplication for Broadcast/Multicast packets requires that the MCBCQ field of MAC_RxQ_Ctrl1 register is programmed to the highest RxQ present in the configuration.

61.3.6.4 Selection of Tag Priorities Assigned to Rx Queues

The VLAN Tag priorities can be assigned to Rx Queues by programming the PSRQ field in the corresponding MAC_RxQ_Ctrl2 registers. The bit corresponding to the VLAN Tag priority can be set in the PSRQ field for assigning that priority to the Rx Queue. For example, if you want to assign VLAN Tag priority of 3 to Rx Queue 0, set bit [3] in PSRQ field of MAC_RxQ_Ctrl2 register. The VLAN Tag priority assigned to particular Rx Queue must be unique, that is, more than one Rx Queue cannot be assigned the same VLAN Tag priority. However, more than one VLAN Tag priorities can be assigned to same Rx Queue.

The settings in the PSRQ field is used for VLAN Tagged Rx packet routing to Rx Queues as well as for PFC based Tx flow control. The received VLAN Tagged Rx packet is routed to Rx Queue that has the VLAN Tag priority match. In PFC based Tx flow control, PSRQ field corresponding to a particular Rx Queue is used for enabling VLAN Tag priorities in the PFC packet transmitted when corresponding Rx Queue threshold levels are reached.

61.3.6.5 Rx Side Routing from MAC to Queues

IP supports Rx Side Routing from the MAC to Queues. The MAC routes the Rx packets to the Rx Queues based on following packet types in that order

- Unicast/Multicast destination address packets that fail the destination address filter
- Multicast/Broadcast destination address packets that pass the destination address filter
- VLAN Tag Priority field in VLAN Tagged AV data packets
- AV Control packets
- VLAN Tagged IEEE 1588 PTP over Ethernet packets
- Untagged IEEE1588 PTP over Ethernet packets
- VLAN Tag Priority field in VLAN Tagged packets
- Untagged packets

The outer C-VLAN Tagged AV data Rx packets can be routed based on the priorities assigned to Rx Queues through PSRQ field in corresponding MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 registers and the corresponding Rx Queue is enabled for AV through RXQ#EN field in MAC_RxQ_Ctrl0 register. These packets may be single VLAN Tagged with C-VLAN type or Double VLAN Tagged with outer VLAN Tag of C-VLAN type when Double VLAN feature is enabled (EDVLP bit in MAC_VLAN_Tag register is set) with inner C-VLAN Tagged or inner S-VLAN Tagged when SVLAN processing is enabled (ESVL bit in MAC_VLAN_Tag register is set). This type of Rx packet routing is available when AV feature and Multiple Rx Queues are selected in the configuration.

The AV Control Rx packets can be routed based on the Rx Queue number specified in the AVCPQ field in MAC_RxQ_Ctrl1 register and corresponding Rx Queue is enabled for AV through RXQ#EN field in MAC_RxQ_Ctrl0 register. These packets may be single VLAN Tagged with C-VLAN type or Double VLAN Tagged with outer VLAN Tag of C-VLAN type when Double VLAN feature is enabled (EDVLP bit in MAC_VLAN_Tag register is set) with inner C-VLAN Tagged or inner S-VLAN Tagged when SVLAN processing is enabled (ESVL bit in MAC_VLAN_Tag register is set). This type of Rx packet routing is available when AV feature and Multiple Rx Queues are selected in the configuration.

The VLAN Tagged Rx packets can be routed based on the priorities assigned to Rx Queues through PSRQ field in corresponding MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 registers and the corresponding Rx Queue is enabled for DCB/generic through RXQ#EN field in MAC_RxQ_Ctrl0 register. This type of Rx packet routing is available when Multiple Rx Queues are selected in the configuration.

The untagged IEEE 1588 PTP over Ethernet Rx packets can be routed based on the Rx Queue number specified in the PTPQ field in MAC_RxQ_Ctrl1 register and the corresponding Rx Queue is enabled through RXQ#EN field in MAC_RxQ_Ctrl0 register.

The VLAN tagged IEEE 1588 PTP over Ethernet Rx packets can be routed based on the priorities assigned to Rx Queues through PSRQ field in corresponding MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 registers or the Rx Queue number specified in the PTPQ field in MAC_RxQ_Ctrl1 register and the corresponding Rx Queue is enabled through RXQ#EN field in MAC_RxQ_Ctrl0 register. This is determined by programming in TPQC field of MAC_RxQ_Ctrl1 register. This type of Rx packet routing is available when IEEE 1588 Timestamp feature support and Multiple Rx Queues are selected in the configuration. The VLAN Tagged IEEE 1588 PTP over Ethernet Rx packets are detected only when 802.1AS mode is disabled (AV8021ASMEN bit in MAC_Timestamp_Control register is set to 0), otherwise this type of Rx packets are routed as generic VLAN Tagged Rx packets.

The multicast/broadcast destination address Rx packets that pass the destination address filter can be routed based on the Rx Queue number specified in the MCBCQ field of MAC_RxQ_Ctrl1 register when enabled through MCBCQEN bit of MAC_RxQ_Ctrl1 register and the corresponding Rx Queue is enabled through RXQ#EN field in MAC_RxQ_Ctrl0 register. This type of Rx packet routing is available when Multiple Rx Queues are selected in the configuration.

The untagged Rx packets can be routed based on the Rx Queue number specified in the UPQ field of MAC_RxQ_Ctrl1 register and the corresponding Rx Queue is enabled through RXQ#EN field in MAC_RxQ_Ctrl0 register. This type of Rx packet routing is available when Multiple Rx Queues are selected in the configuration.

The unicast destination address Rx packets that fail the destination address filter can be routed based on the Rx Queue number specified in the UFFQ field of MAC_RxQ_Routing_Ctrl register when enabled through UFFQE bit of MAC_RxQ_Routing_Ctrl register, RA bit of MAC_Packet_Filter register is set to 1 and the corresponding Rx Queue is enabled through RXQ#EN field in MAC_RxQ_Ctrl0 register. This type of Rx packet routing is available when Multiple Rx Queues are selected in the configuration.

The multicast destination address Rx packets that fail the destination address filter can be routed based on the Rx Queue number specified in the MFFQ field of MAC_RxQ_Routing_Ctrl register when enabled through MFFQE bit of MAC_RxQ_Routing_Ctrl register, RA bit of MAC_Packet_Filter register is set to 1 and the corresponding Rx Queue is enabled through RXQ#EN field in MAC_RxQ_Ctrl0 register. This type of Rx packet routing is available when Multiple Rx Queues are selected in the configuration.

If the Rx packet cannot be classified in any of the defined packet type for routing, it will be routed through Rx Queue 0.

61.3.6.6 Rx Side Arbitration Between DMA and MTL

IP controller supports Rx side arbitration between the DMA and the MTL.

After completing the current packet processing, the DMA Channel Controller fetches the next descriptor. After the descriptor fetching is complete, the DMA Channel Controller evaluates the amount of data to be to be transferred to the Rx Buffer based on the programmed PBL and Rx Buffer Length. Accordingly, it requests the MTL to transfer the data.

After servicing the current request, the MTL Rx Queue arbitration scheme selects Rx Queue based on the arbitration scheme (RAA field of the MTL_Operation_Mode register) and the weights programmed in the Queue <n> Receive Control Register. The arbitration is done among Queues for which DMA is ready to service. After the Rx Queue is selected, PBL (Programmable Burst Length) amount of data is read out from that Queue and is routed to the Rx DMA Channel based on the Rx Channel selection criteria.

The arbitration takes place when every PBL data transfer is completed and descriptors are ready for the processing from at least one DMA Channel.

61.3.6.7 Tx Side Arbitration between DMA and MTL

IP support Tx side arbitration between the DMA and the MTL. Since the number of Tx DMA channels is always equal to the number of Tx Queues in the MTL, they are always mapped directly. For instance, each Tx DMA pushes data into its respective Tx Queue assigned to it.

The data inside each Tx Queue is stored in packets. Hence, if two DMAs are allowed to transfer data into the same queue, when a Tx DMA starts a packet transfer, the other DMA cannot transfer data unless the previous packet is completely pushed-in. This means that the second DMA remains idle until the first packet is transferred. Hence, each DMA is always connected directly to its corresponding Tx Queue.

61.3.6.8 Time-Sensitive Networking (TSN)

The ENET QOS block supports TSN in 100 Mbps or 1000 Mbps mode, which enables the transfer of time-sensitive traffic over a network. The block implements the IEEE 802.1Qbv-2015 (Enhancements to Scheduling Traffic), IEEE 802.3br (Interspersing Traffic) and IEEE 802.1Qbu (Frame Preemption) TSN protocol.

The Transmit path of Queue 0 supports the strict priority algorithm and is used for best-effort traffic while transmit paths of additional queues support traffic management by using the credit-based shaper algorithm. For a queue, the credit-based shaper algorithm determines that a queue is available for transmission if the following conditions are true:

- The queue contains one or more packets.
- The credit for the queue is positive as per the algorithm.
- AV traffic can be received on all queues. The block can also receive untagged PTP packets in addition to AV traffic on any queue.

61.3.6.8.1 Enhancements to Scheduled Traffic (EST)

The IEEE 802.1Qbv-2015 defines the schedule for each of the queues on every egress port which makes the implementation aware of traffic arrival schedule. This information can be used to block the lower priority traffic from transmission in this time window/slot. This ensures that scheduled traffic is forwarded from sender to receiver through all the network nodes with a deterministic delay.

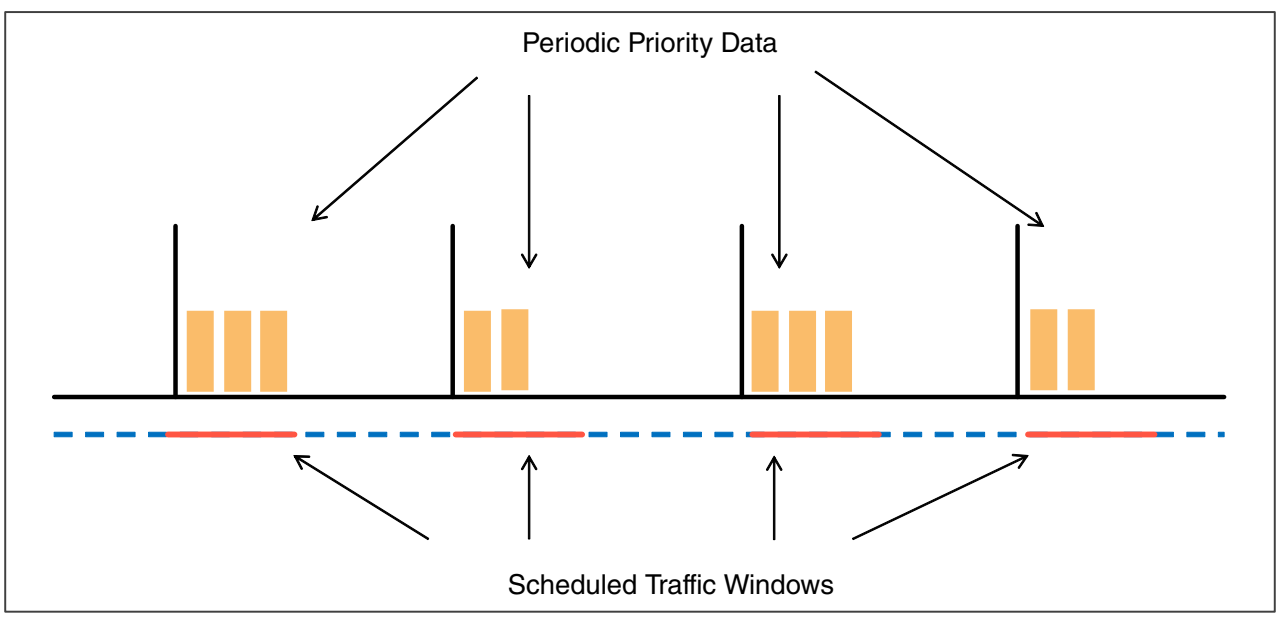

Figure 61-10. Time Aware Shaper Implementation for Traffic Scheduling

One of the important requirements to achieve a low latency is to ensure there are no interfering frames during the scheduled windows that are reserved for high priority traffic. The use of scheduled traffic imposes limitations while starting a transmission.

As shown in the following figure, if an interfering frame begins transmission just before the start of a reserved time period, it can extend transmission into the reserved window, and potentially interfere with higher priority traffic. Therefore, a guard band whose size is equal to the largest possible interfering frame is required before the window starts.

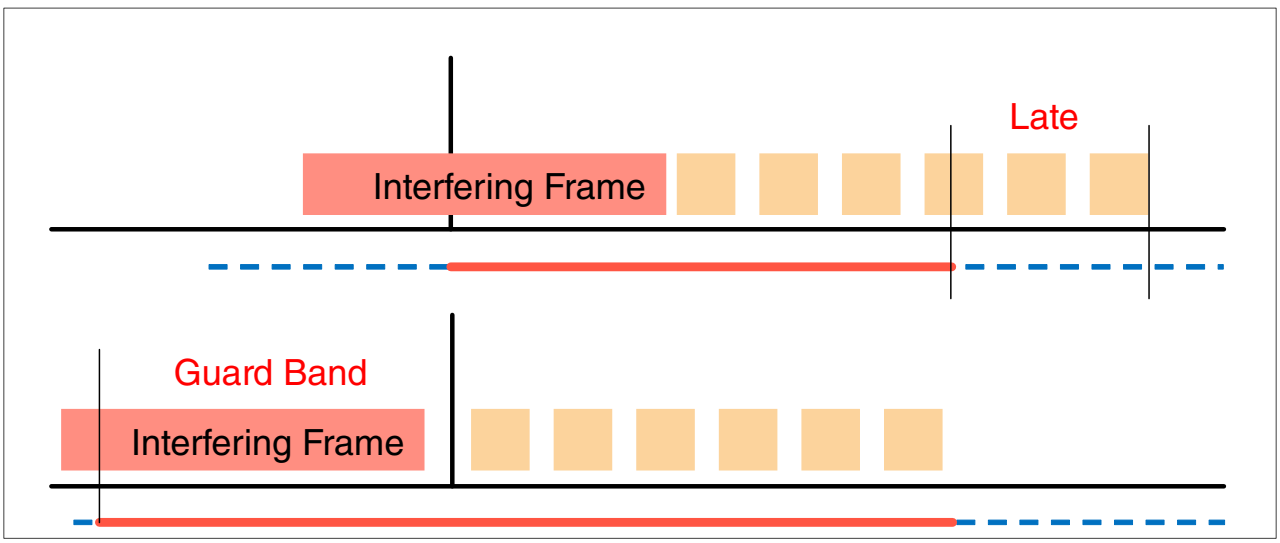

Figure 61-11. Implementing a Guard Band to Avoid Delays Due to Interfering Frames

A larger guard band equates to a less efficient use of network bandwidth. However, with the implementation of IEEE802.1Qbu (frame preemption), this issue is addressed. Frame preemption breaks the interfering frame into smaller fragments. Therefore, the guard band needs to be only as large as the largest possible interfering fragment instead of the largest possible interfering frame.

During the guard band, only the frames that can complete the transmission of the entire frame before the next gate close event are permitted. This ensures that the high priority traffic can always start at the beginning of the window reserved for it.

61.3.6.8.1.1 Frequently Used Terms in EST

- Gate Control List: The list in the hardware memory that holds the gate controls and the associated time intervals.
- Gate Controls: For a given schedule (row in gate control list) there is a Gate Open (O) and Gate Close (C) state associated with each traffic class. The set of O or C values, whose width is same as configured TCs is called the Gate Controls. Example: CCOCO means TC4=C, TC3=C, TC2=O and so on.

- Time Interval: Time interval (in nanoseconds) is a 16, 20, or 24-bit configurable field in the Gate Control list that indicates the time for which the associated gate controls are valid.
- Base Time Register: Each Gate Control List is associated with a 64-bit Base Time Register that holds the start time (in PTP format) for the list.

61.3.6.8.1.2 Updates to the Transmit Scheduling to Support EST

To support EST, following updates are required to the transmit scheduling:

- Implementation of Gate Control List (GCL)
- Enforcing gate controls in the scheduler
- Accounting for Gate Open (O) duty cycle in the computation of idleSlope (CBS)

61.3.6.8.1.2.1 Implementation of Gate Control List (GCL)

Following figure shows block diagram from the IEEE 802.1Qbv spec that illustrates how the gate control list governs the gate close(C) and open(O) events based on the schedule provided for each event. GCL has the following two parts:

- Time Interval: Defines the time in nano seconds for which the gate controls are valid and should be applied before reading the next gate controls from the list. Configurable width of 16, 20 or 24 to represent a maximum of 64us, 1ms, or 16ms schedule interval respectively. Supports left shift of the time interval upto 7 bits to be able to apply a multiplication factor from 1 to 128ns (in steps of 2(power)n). The maximum value (post shifting) of this field must be 999,999,999 ns.
- Gate Control: Defines the Open (O) represented by logic 1 or Close (C) represented by logic 0 state for the gate of each TC.

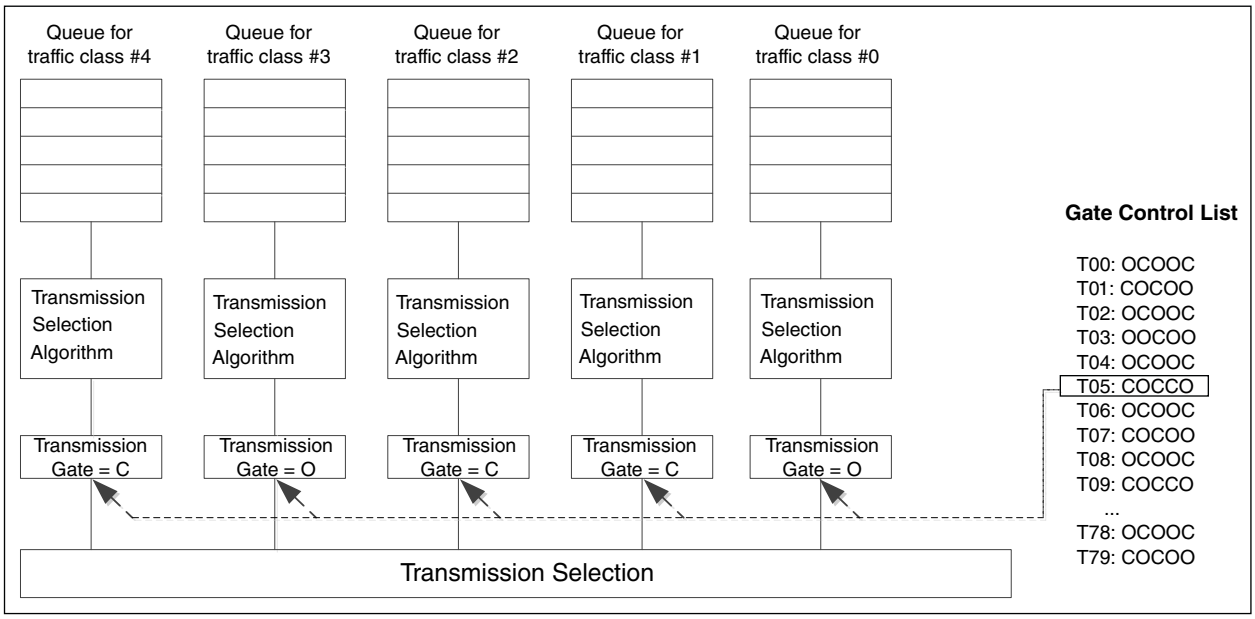

Figure 61-12. Block Diagram from IEEE 802.1 Qbv Specification - GCL Governing Gate Close and Open Events

The implementation of GCL consists of the following two Gate Control Lists:

- HWOL - Hardware Owned List which is a list for hardware access.
- SWOL - Software Owned List which is a list for software access.

The access to these lists is mutually exclusive. The ownership to the list is set by hardware in the SWOL field of MTL_EST_Status register. Following table provides the implementation details of GCL.

Table 61-17. External Memory Used for Holding the Two Gate-Control Lists

Gate Control (up to 5 bits)	Time Interval (ns) 16, 20, or 24 bits	
OOCCC	T0	HWOL or SWOL
OOOOC	T1	
CCCCO	T2	
CCCCC	T3

61.3.6.8.1.2.2 Registers Related to Gate Control List

Following are the set of 4 registers (one for each GCL) related to GCL. These registers are implemented through Indirect Addressing using the GCL_Control and GCL_Data registers.

1. 64-bit Base Time Register (BTR)

2. 40-bit Cycle Time (CTR)

3. m-bit Time Extension (TER)

4. n-bit [Gate Control] List Length (LLR) (n depends of the configured GCL depth)

61.3.6.8.1.2.2.1 Base Time Register (BTR)

Base Time Registers is a 64-bit register that holds the start time to execute the GCL. The format of the BTR is same as the PTP format (upper 32-bits holds time in seconds and lower 32 bits hold time in nano seconds). Once the execution of a given list begins, the implementation can update the value in BTR to indicate the next list execution begin time.

61.3.6.8.1.2.2.2 Cycle Time Register (CTR)

Cycle Time Register is a 40-bit register that holds the time at which the execution of the GCL should be repeated. The Cycle Time Register consists of an 8-bit value in seconds, and a 32-bit value in nano seconds (similar to the PTP time format with truncated seconds register). For a given Gate Control List the start time is "Base Time" + N * "Cycle Time" where N is an integer value representing the iteration number starting with 0 for first iteration. If the Gate Control List execution takes longer than the Cycle time, then the list is truncated at the Cycle Time and the subsequent loop begins at Cycle Time.

61.3.6.8.1.2.2.3 Time Extension Register (TER)

Time Extension Register (TER) is a m-bit (where m = Configured Time Interval width + 7) register that holds the amount of time (in nano seconds) the current Gate Control List can be extended before switching to the new Gate Control List. This will be useful in avoiding small fragments of the current list being executed before switching to a new list.

61.3.6.8.1.2.2.4 List Length Register (LLR)

List Length Register (LLR) is an n-bit register (when n is 7, 8, 9, 10, or 11 for a GCL configured depth of 64, 128, 256, 512, or 1024 respectively) that holds the integer value of the length of the GCL (that is the number of valid rows in each GCL). The processing of the GCL stops after the number of rows read equals to the LLR value.

61.3.6.8.1.2.3 Transmission Gating Implementation

A Bridge or an end station can be enhanced to allow transmission from each TC that is yet to be scheduled relative to a known timescale. To achieve this, a transmission gate is associated with each TC; the state of the transmission gate determines if the queued frames can be selected for transmission.

For a TC, the transmission gate can be in one of the following two states:

1. OPEN:Queued frames are selected for transmission, in accordance with the definition of the transmission selection algorithm associated with the TC.
2. CLOSED: Queued frames are not selected for transmission.

A frame on a traffic class queue is not available for transmission if the transmission gate is in the closed state or if there is insufficient time available to transmit the entirety of that frame before the next gate-close event associated with that queue.

The implementation has visibility to the current schedule of gate controls and the immediate next schedule of the gate controls. So the maximum Gate Open period does not exceed the sum of the two Time Intervals. This is because, a frame is selected for transmission only if the gate is currently Open and the duration of gate open interval is greater than the time taken to transfer the entire frame.

The implementation must know the frame size before the transmission, so that the transmission overruns can be avoided and only the frames that can complete are scheduled at all times.

The implementation adequately compensates for the implementation delays in the data transfer from the buffer to the line by offsetting the current time with all the relevant delays (provided by the CTOV field of MTL_EST_Control register). This ensures that the schedule provided is always accurately implemented at the line.

61.3.6.8.1.3 Idle Slope Computation Updates

When EST is enabled, credit is accumulated only when the gate is open; therefore, the effective data rate of the idleSlope must be increased to reflect the duty cycle for the transmission gate associated with the queue.

The idleSlope is computed based on the GateOpenTime and OperCycleTime values. Program the idleSlope registers (implemented one per CBS enabled TC) based on the following equation. The existing MTL register has sufficient bit width to accommodate the new values for idleSlope.

idleSlope = (operIdleSlope(N) * OperCycle/GateOpenTime)

61.3.6.8.1.4 Operational Details of GCL

Set the switch to software List, the SSWL field of the MTL_EST_Control Register, so that hardware can access the programmed gate control list. The first set of gate controls are applied when the current time is equal to the value in the Base Time Register (BTR) and is held until the programmed "Time Interval" value.

To avoid transmission overruns, one additional gate control event is always read ahead from the list. This enables the GCL to determine the next gate close events (if any) for the TCs that are open.

The scheduling based on the Gate Open state and Time Interval of only the current and subsequent schedule. An internal accumulator is used to add the time intervals when gate controls are applied. BTR + Accumulator holds the time at which the next set of gate controls are to be applied.

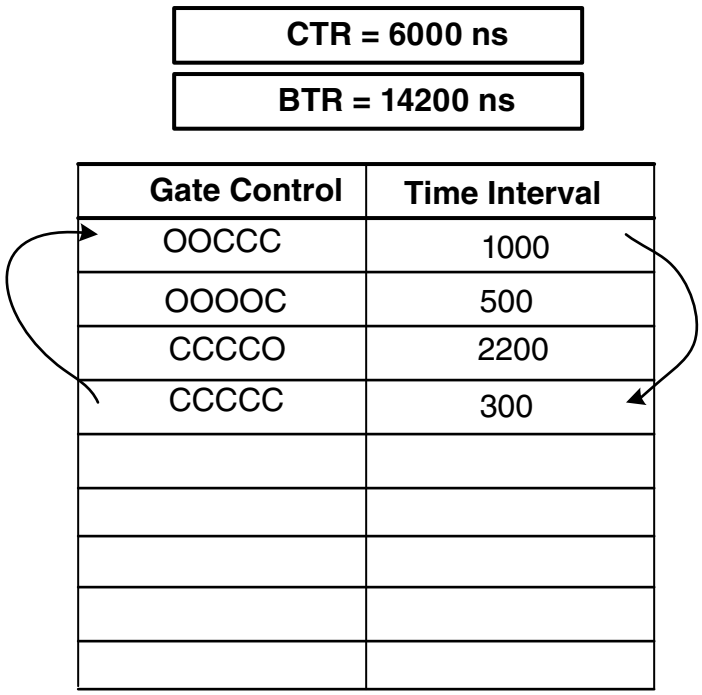

Figure 61-13. GCL and Associated Registers - BaseTime and CycleTime

The GCL is read progressively from the first row adhering to the schedule. The read operations continue until the List Length (from LLR Register) is reached and the execution of the list restarts at BTR + CTR time. At this point the BTR is incremented by value in CTR to mark the beginning of a new cycle. In the absence of any gate controls, all the gates are deemed to be in Open state, during the execution of the list.

In cases where the execution time of the list is greater than the CycleTime, the list is truncated and the next iteration starts when the current time equals BTR + CTR.

Table 61-18. GCL and Associated Registers - BTR and CTR

Current Time	Gate Control Applied	Accumulator Value	BTR (with updates)
14200	OOCCC	1000	14200
15200	OOOOC	1500	14200
15700	CCCCO	3700	14200
17900	CCCCC	4000	14200
18200	OOOOO	0	20200
20200	OOCCC	1000	20200
21200	OOOOC	1500	20200

In the example in table, the execution starts at 14200 and the first set of Gate Controls "OOCCC" are applied immediately. As the time interval is 1000ns the next set of gate controls are applied at 14200 (BTR) + 1000 (Accumulator) = 15200 ns . As there are no gate controls available after the execution of the last gate control and before the next iteration of the loop, the gates are deemed to be in open state during that time period as depicted at time 18200 in the table.

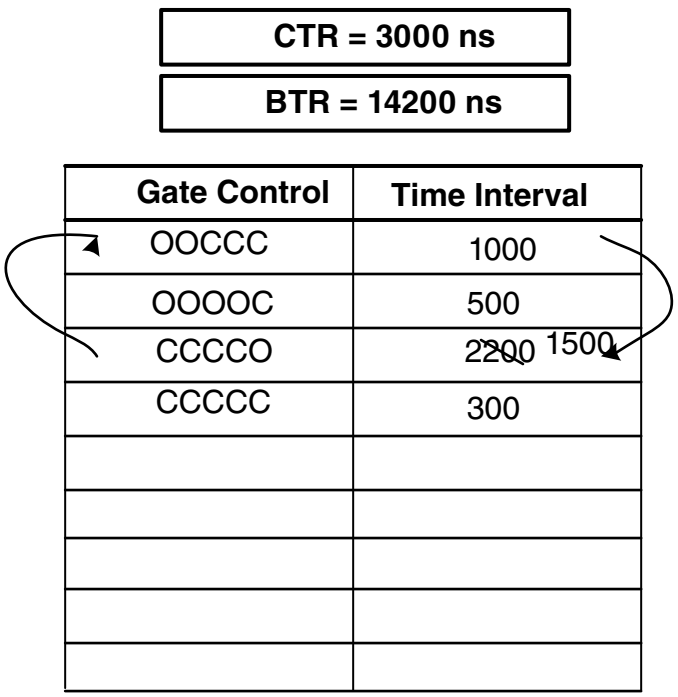

Figure 61-14. GCL and Associated Registers - BaseTime and CycleTime List Execution Time > CycleTime

As the list execution takes longer than the allocated CycleTime, the list is truncated and the list is started from the BTR+CTR as shown in the following table.

Table 61-19. GCL and Associated Registers - BTR and CTR, Execution Time > Cycle Time

Current Time	Gate Control Applied	Accumulator Value	BTR (with updates)
14200	OOCCC	1000	14200
15200	OOOOC	1500	14200
15700	CCCCO	3700	14200
17200	OOCCC	1000	17200
18200	OOOOC	1500	17200
18700	CCCCO	3700	17200

While applying the third set of gate controls, the BTR + CycleTime (17200) < BTR + Accumulator (17900), so the list is truncated and execution switches to a new iteration at 17200.

61.3.6.8.1.5 Installing a New GCL

When a new software programmed GCL is available and must be executed at the new BTR value, the switch to the new GCL can happen in one of the following ways.

- New Base Time aligned with current schedule
- New Base Time unaligned with current schedule

61.3.6.8.1.5.1 New Base Time Aligned with Current Schedule

If the choice of cycle time for the new gating cycle is unchanged from the cycle time for the current gating cycle, and if the BTR chosen for the new gating cycle (new BTR) is an integer multiple of the current cycle time (+ current BTR), then the new gating cycle exactly lines up with the old gating cycle, that is, the cycle start times for the new gating cycle is same as they would have been for the old configuration. This could be considered to be the ideal case and allows the new gating cycle to be installed and executed with no timing issues. The implementation completes the execution of an iteration of the current list and switches to the new list at the beginning of the BaseTime listed in the new list.

If (New BaseTime > = Current Time)

ConfigChangeTime = New BaseTime

Else If (New BaseTime < Current Time)

1. Set the BTRError

2. ConfigChangeTime = (New BaseTime + N* New CycleTime)

where N is the smallest integer for which the relation ConfigChangeTime >= CurrentTime and (N =< 8) is TRUE.

When N > 8 the hardware cannot auto recover and the loop count value in BTRError reporting is set to 1111 requiring the software to reprogram the New Base Time.

Following figure illustrates the installation of the new GCL along with the timelines.

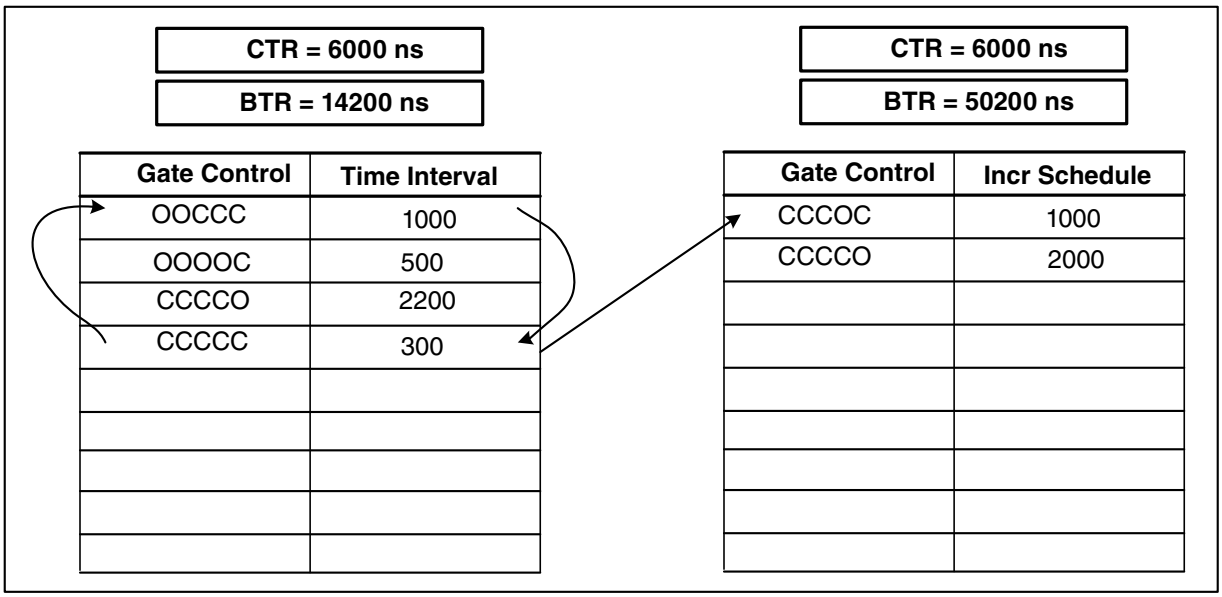

Figure 61-15. Switching to a New Configuration that is Aligned with the Existing Configuration

In the above example, after the sixth iteration of the first GCL, the BTR values of the old and new GCL are equal. At that point the new GCL is processed as a natural extension to the existing GCL.

Table 61-20. GCL and Associated Registers - BTR and CTR

Current Time	Gate Control Applied	Accumulator Value	BTR (with updates)
44200	OOCCC	1000	44200
45200	OOOOC	1500	44200
45700	CCCCO	3700	44200
47900	CCCCC	4000	44200
48200	OOOOO	0	50200
50200	CCCOC	1000	50200
51200	CCCCO	3000	50200
53200	OOOOO	0	56200

61.3.6.8.1.5.2 New Base Time Unaligned with Current Schedule

If new CycleTime differs from current CycleTime or New BaseTime is in the future and is not an integer multiple of current CycleTime, then the old and new cycles do not line up; when new BaseTime is reached (when the new configuration is installed and starts to execute), the last old cycle is normally truncated to start the first new cycle. This could be undesirable if it results in a very short last old cycle; arguably it would be better to simply extend the penultimate old cycle by that small amount, rather than starting a very short

cycle. The Cycle Time Extension Register (related to the current config list) allows this extension of the last old cycle to be done in a defined way; if the last complete old cycle ends normally in less than current Cycle Time Extension (TER) ns before the new base time, then the last complete cycle before new BaseTime is reached is extended so that it ends at new BaseTime.

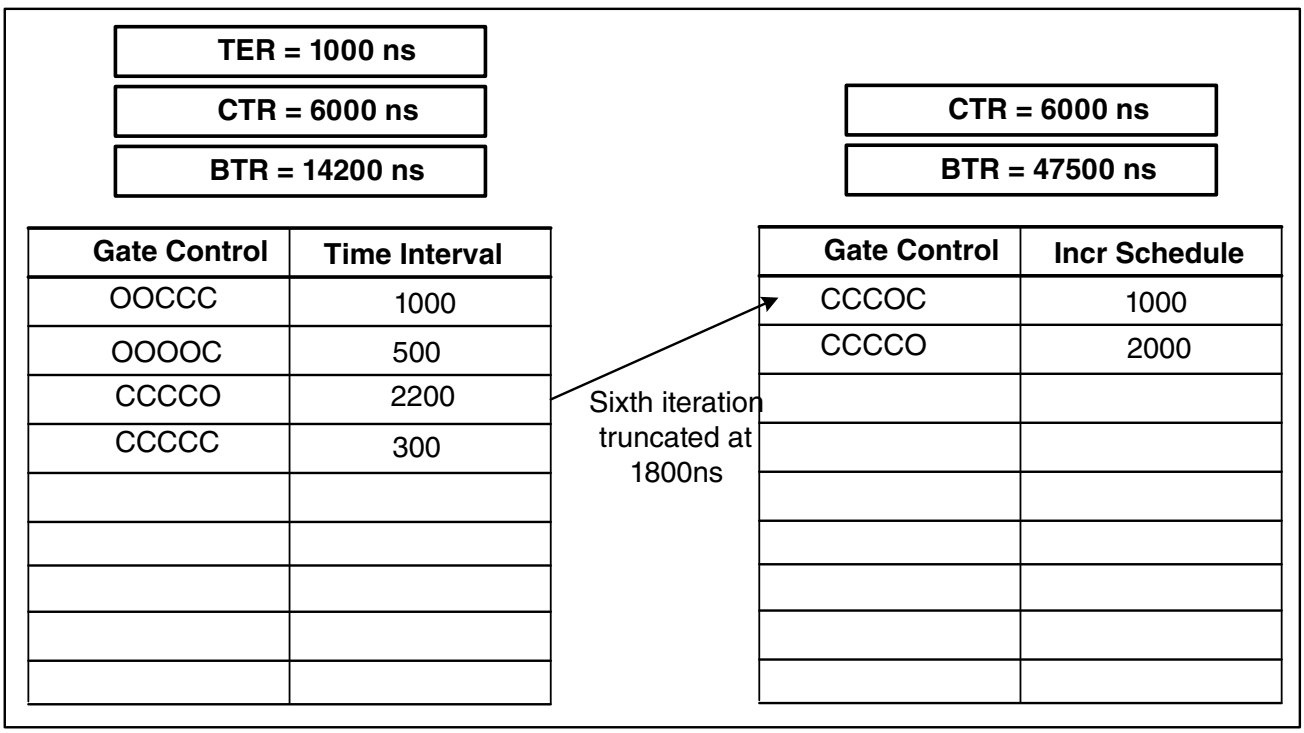

Figure 61-16. Switching to New List Truncating the Current List

At the end of the fifth iteration the Current time + Cycle time extension (TER) < New BTR so the sixth iteration of current configuration is started. During the sixth iteration of the current list when the new BTR value is smaller than the next schedule in the current list, it switches to the new list.

Table 61-21. Extending to New List By Truncating the Current List

Current Time	Gate Control Applied	Accumulator Value	BTR (with updates)
44200	OOCCC	1000	44200
45200	OOOOC	1500	44200
45700	CCCCO	3700	44200
47500	CCCOC	4000	44200
48500	CCCCO	0	50200
50500	OOOOO	1000	50200

Below is an example where the current config list is extended instead of starting a new iteration as the extension time of 800ns is less than the allowed cycle extension time (TER) of 1000ns.

Figure 61-17. Switching to New List By Extending the Current List

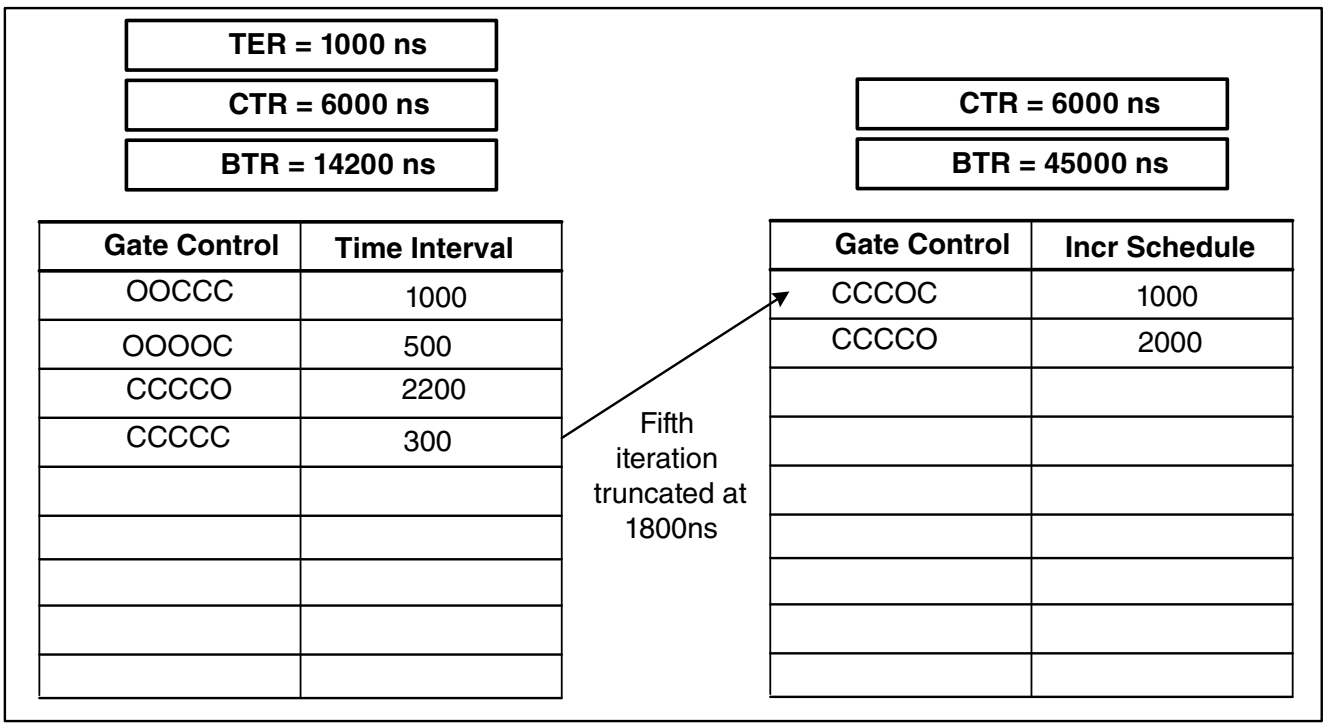

Table 61-22. Switching to New List By Extending the Current List

Current Time	Gate Control Applied	Accumulator Value	BTR (with updates)
38200	OOCCC	1000	38200
39200	OOOOC	1500	38200
39700	CCCCO	3700	38200
41900	CCCCC	4000	38200
42200	OOOOO	0	44200
45000	CCCOC	1000	45000
46000	CCCCO	3000	45000
48000	OOOOO	0	51000

61.3.6.8.1.6 Impact of Transmit Scheduling Algorithms on EST

When EST is used in isolation, the Gate Control List manages the final open/close state of the Queues along with the checks carried out by the Transmission Selection Algorithm in MTL. As the Gate Controls operate on a predefined repetitive schedule, it is recommended to use Strict Priority or Credit Based Shaper (CBS) scheduling algorithms.

Other algorithms such as the Weighted Round Robin (WRR), Deficit Weighted Round Robin (DWRR) and Weighted Fair Queuing (WFQ) implement masking of the queues based on the current winning queue. The algorithm is applied only among the group of queues that open simultaneously. To ensure Queues whose gates are "Open" get priority, these algorithms are modified to treat "gate open" queues and "gate closed" queues as separate groups giving priority to gate open queues.

For example, consider 4 queues (Q3, Q2, Q1, Q0) with weights 4:3:2:1; Q3 and Q2 are in Open state in slot one slot, while Q1 and Q0 are in Open state in another slot. In this case, the scheduler works as follows:

1. In the first slot, the Q3 and Q2 are serviced in the ratio of 4:3 for the duration the slot is open.
2. In the second slot, the queues Q1 and Q0 are serviced in the ratio of 2:1.
3. Fresh arbitration is started every time a slot is opened.

In other words, the traffic does not get distributed in the intended ratio of 4:3:2:1; but as two groups with different ratios and only for the duration of the slot when the gates are open continuously

NOTE

See Programming Guidelines for EST

61.3.6.8.2 Frame Preemption (FPE)

Frame preemption breaks the interfering frame into smaller fragments. Therefore, the guard band needs to be only as large as the largest possible interfering fragment instead of the largest possible interfering frame. During the guard band, only the frames that can complete the transmission of the entire frame before the next gate close event are permitted. This ensures that the high priority traffic can always start at the beginning of the window reserved for it.

Preemption allows one or more higher priority (express) frames to interrupt the transmission of a lower priority (preemptable) frame; the preemptable frame transmission is resumed and completed after the express frame transmission is complete. To support frame preemption, the following two abstractions of the MAC are used:

- A preemptable MAC, called pMAC, which carries the preemptable traffic.
- An express MAC, called eMAC, which carries the express traffic.

In the implementation, only the parts of the MAC that hold the state during preemption are replicated and represented as pMAC and eMAC. The MAC uses the following two ways to put the transmission of the preemtable traffic on hold, in the presence of express traffic:

- The MTL scheduler interrupts the preemptable traffic that is currently being transmitted. When the preemption capability is active, the MAC interrupts the transmission and reception of preemptable frames. A preempted fragment can be followed by zero or more express frames, before the continuation fragments. The preemptable frame can be fragmented any number of times, however, the minimum final and non-final fragment length criterion must be met. However, interleaving of more than 1 preemptable packet is not permitted. This implies that if a preemptable packet is fragmented by an express packet, another preemptable packet cannot be transferred until all the remaining fragments of the first preempted packet are transferred.
- The MTL scheduler prevents starting the transmission of preemptable traffic. When the preemption capability is inactive, the pMAC entity is disabled and only express traffic is transmitted or received. Frame preemption feature can be enabled by setting EFPE field of the MAC_FPE_CTRL_STS register.

61.3.6.8.2.1 GCL Modification to Support FPE

In the EST-only configuration, the GCL entry has up to 24 bits of Time Interval and up to 8 high order bits representing the Gate Open/Close state requirements as shown in the following figure.

Gate Control (up to 5 bits)	Time Interval(ns) 16, 20 , or 24 bits
OOCCC	T0
OOOOC	T1
CCCCO	T2
CCCCC	T3
|	|
|	|
OCOCO	T126
OOOOC	T127

Figure 61-18. Gate Control List When FPE is Disabled

EST only supports SetGate operation, which implies that the gates are set to either open or close at a given time interval. However, when both Frame Preemption (FPE) and EST are enabled, the GCL also supports Set-and-Hold-MAC and Set-and-Release-MAC operations, in addition to the SetGate operation. To enable the support of hold and release

operations, the format of the GCL is slightly changed while configuring and enabling the FPE. The first Queue (Q0) is always programmed to carry preemption traffic and therefore it is always Open. The bit corresponding to Q0 is renamed as Release/Hold MAC control. The TX Queues whose packets are preemptable are indicated by setting the PEC field of the MTL_FPE_CTRL_STS register. The GCL bit of the corresponding Queue are ignored and considered as always "Open". So, even if the software writes a "0" ("C"), it is ignored for such queues.

Gate Control (up to 4 bits)	Release/Hold Indication	Time Interval(ns) 16, 20, or 24 bits
CCCO	0	T0
CCCC	0	T1
OCCC	1	T2
COCC	1	T3
CCOC	1	T4
CCCO	0	T5
CCCC	0	T6

Figure 61-19. Gate Control List When FPE is Enabled

When the Release/Hold bit transitions from a '0' to '1', a Set-and-Hold-MAC operation is performed. This marks the cease of the preemptable traffic. This is achieved by sending a Hold request to MTL "ha" ns in advance (where ha is the time interval mentioned in the Hold Advance (HADV) field of the MTL_FPE_Advance register). When the Release/ Hold bit transitions from a '1' to '0' a Set-and-Release-MAC operation is performed. This marks the resuming of the preemptable traffic. This is achieved by sending a Release request to MTL "ra" ns in advance (where ra is the time interval mentioned in the Release Advance (RADV) field of the MTL_FPE_Advance register). The preemptable traffic is blocked for the time duration the Release/Hold bit is set to a '1' in the Gate Control List.

61.3.6.8.2.2 Impact of Preemption on CBS

In Credit Based Shaper (CBS), the definition of "Transmit" is:

- TRUE for the duration of frame transmission from the queue.
- FALSE when frame transmission from the queue is complete.
- When CBS algorithm is used with frame preemption, the value of "Transmit" is TRUE only while the frame is being transmitted by the MAC. If the frame

transmission is delayed or interrupted (for instance, a preemptable frame transmission is interrupted to allow the transmission of an express frame from a different queue, or the start of an express frame is delayed because a preemptable frame is being transmitted) the value of "Transmit" is FALSE until transmission of the frame commences or is resumed.

Also, the value of "Transmit" is FALSE during the transmission of any overhead that is a consequence of frame preemption, (for example, when additional frame overhead, such as mCRC or Fragment Count, is added to the preemptable frame.

At any given time, if there are no frames in the queue, and the value of Transmit is FALSE, and credit is positive value, the credit value is set to zero if there is no preemptable frame from the queue for which transmission is in progress but has been interrupted.

61.3.6.8.2.3 mPacket Format

When the preemption capability is active, MAC sends mPackets to the PHY. An mPacket can be one of the following:

1. A express packet
2. A preemptable packet
3. An initial fragment of a preemptable packet
4. A continuation fragment of a preemptable packet

Start mPacket Delimiter (SMD)

The value of the SMD indicates whether the mPacket contains an express packet, the start of a preemptable packet (initial fragment or complete packet), or any of continuation fragments of a preemptable packet. Following table shows the valid SMD values.

Table 61-23. Possible SMD Values of mPacket

mPacket Type	Notation	Frame Count	Value
verify packet	SMD-V	-	0x07
respond packet	SMD-R	-	0x19
express packet	SMD-E	-	0xD5
preemptable packet start	SMD-S0	0	0xE6
	SMD-S1	1	0x4C
	SMD-S2	2	0x7F
	SMD-S3	3	0xB3
continuation fragment	SMD-C0	0	0x61
	SMD-C1	1	0x52
	SMD-C2	2	0x9E
	SMD-C3	3	0x2A

frag_count

A frag_count is a modulo-4 counter that increments for each continuation fragment of the preemptable packet. The frag_count protects against mPacket reassembly errors by enabling detection of the loss of up to 3 packet fragments.

The frag_count field is present only in mPackets with SMD-C notation (continuation fragment). The frag_count is zero in the first continuation fragment of each preemptable packet.

Table 61-24. Possible frag_count Values

frag_count	Value
0	0xE6
1	0x4C
2	0x7F
3	0xB3

mData

The contents of the packet from the MAC, starting with the first byte after the SFD to the last byte before the FCS are sent in the mData fields of one or more mPackets for that frame. The minimum size of the mData field is 60 bytes.

CRC The CRC field contains a cyclic redundancy check (CRC) and has an indication of the final mPacket of a frame. In the final mPacket of a frame, the CRC field contains the last 4 octets of the MAC frame (the FCS field).

For other mPackets, the CRC field contains an mCRC value. The mCRC is calculated on the octets of the packet from the first octet of the frame (the octet following the SFD of preemption frames) to the last octet of the packet transmitted in that mPacket by performing an XOR of the calculated 32 bit CRC value of the fragment and a value of 0x0000FFFF.

Summary of Packet Formats

- Express Packet: 7bytes of PREAMBLE, SMD-E, Data, and CRC
- Complete Preemptable Packet: 7 bytes of PREAMBLE, <Current Preemptable packet SMD>, Data, CRC
- Initial Fragment (non-final) of Preemptable Packet: 7 bytes of PREAMBLE, <Current Preemptable packet SMD>, Data, mCRC

- Continuation fragments (non-final) of Preemptable packet: 6 bytes of PREAMBLE, <Current Preemptable continuation fragment SMD>, <Current Preemptable continuation fragment FC>, Data, mCRC
- Final fragment of Preemptable packet: 6 bytes of PREAMBLE, <Current Preemptable continuation fragment SMD>, <Current Preemptable continuation fragment FC>, Data, CRC

Table 61-25. Current and Previous SMD Values

Previous Preemptable packet SMD	Current Preemptable packet SMD
SMD-S0	SMD-S1
SMD-S1	SMD-S2
SMD-S2	SMD-S3
SMD-S3	SMD-S0

SMD-C3	FC1	SMD-C3	FC2
SMD-C3	FC2	SMD-C3	FC3
SMD-C3	FC3	SMD-C3	FC0

61.3.6.8.2.4 Transmit Preemption

When FPE is enabled (setting EFPE=1 in MAC_FPE_CTRL_STS register), the MTL preempts a preemptable frame, when a "hold" request is asserted (EST/Qbv configured and enabled) express frames are available for transmission, that is, frame is present in MTL FIFO and is qualified for arbitration, after ensuring that the minimum mPacket mData field size is met. Therefore, preemption occurs only if at least 60 bytes of the preemptable frame have been transmitted and at least 64 bytes (including the frame CRC) remain to be transmitted.

The earliest starting position of preemption is controlled by the AFSZ field of the MTL_ FPE_CTRL_STS Register. Preemption does not occur until at least 64 * (1+ AFSZ) - 4 bytes of the preemptable frame have been sent.

When preemption occurs, all the preemptable queues are blocked and only the express queues are allowed to arbitrate (if more than one express queue has traffic) and transmit.

Continuation fragment of the preempted frame is the first frame to be transmitted after "release" request is asserted (EST/Qbv configured and enabled) and all the express traffic transmission completes.

NOTE

PTP packets should be transmitted as express packets.

MTL communicates the following frame-type information to the MAC using a 2-bit preemption control signal on the MTI interface qualified by SoF and EoF.

- Express Frame
- Preemption Frame (Full or Fragment)
- Continuation Fragment (non-Final or Final)

Table 61-27. Preemption Control Values on MTI Interface for Various Frame Types

Qualifier	Preemption Control Value	Frame Type
SoF	00	Start Express
SoF	01	Start Preemption
SoF	10	Continuation Fragment
SoF	11	Reserved
EoF	00	End of Frame
EoF	01	End of Fragment

MTL should wait for the previous fragment status to be received before resuming the continuation fragments of a preempted frame. Fragment status is described in detail in the Tx Fragment Status section.

61.3.6.8.2.4.1 MAC Tx Preemption

MAC supports preemption by implementing the functionality needed to generate the mPackets as described in “mPacket Format”.

Based on the Preemption Control value received on the MTI interface (qualified with SoF and EoF), MAC determines the frame type (shown in the above table 'Preemption Control Values on MTI Interface for Various Frame Types') and generates mPackets accordingly.

When the preemption capability is active, MAC replaces the SFD of a preemption packet with an SMD-S value. A 2-bit rolling frame count is encoded in the SMD-S value.

The SMD-E value is the same as the SFD value so the SFD of an express packet does not need to be replaced.

61.3.6.8.2.4.1.1 Tx Fragment Status

MAC sends Tx fragment status to indicate successful transmission of fragmented mPackets.

In case of a transmission error (underflow, jabber, and so on) the frame status is sent (and not a fragment status) with an error indication along with all other relevant status fields. In case of receiving an error status for a transmitted fragment, the MTL drops the remaining fragments and does not send any more continuation fragments.

61.3.6.8.2.5 Receive Preemption

61.3.6.8.2.5.1 MAC Receive Preemption

When FPE is enabled, the MAC Receiver pases the incoming packets and differentiates between Express packets and preemptable packets. An SMD containing an SMD-E indicates express packet, and SMD containing an SMD-S indicates the first mPacket of a preemptable packet.

If an mPacket containing an SMD-S is received when MAC has not completed receiving the previous preempted packet, MAC sets a CRC Error status for the previously received partial packet.

When an SMD-S is detected, MAC records the frame count indicated by the SMD and then begins sending data on the MRI interface.

The MAC checks the last four bytes of the mPacket . If the last four bytes of the mPacket do not match CRC, that indicates the end of the packet with or without a CRC error as per the CRC check result. If the last four octets of the mPacket match, that indicates that the packet was preempted.

An SMD containing an SMD-C indicates an mPacket that continues the data for a preempted packet. Upon receiving an SMD value of SMD-C, MAC checks the following:

1. A preempted packet is in progress
2. The frame count indicated by the SMD matches the frame count of the packet in progress
3. The frag_count value indicates the next fragment count.

If any of the above check fails, the mPacket is discarded and MAC sets a CRC Error status for the partially received packet.

If all the checks pass, the next fragment count is incremented modulo 4.

When a packet is preempted, the MAC saves the state of the partially received packet (filter check status, timestamp, length fields etc.) and will be able to process any received Express packets before the continuation fragment is received.

The MAC Receiver sends a "dummy status" for all the mPacket fragments successfully received and sends the Rx status with the final fragment. If an error is detected during any of the fragments the Rx status is sent and the fragment is marked as final fragment. All subsequent continuation fragments received for this packet are dropped in the MAC.

The MAC communicates the following frame type information to the MTL using a 2-bit preemption control signal.

1. Express Frame
2. Preemption Frame (Full or Fragment)
3. Continuation Fragment (non-Final or Final)

Table 61-28. Preemption Control Values on MRI Interface for Various Frame Types

Qualifier	Preemption Control Value	Frame Type
SoF	00	Start Express
SoF	01	Start Preemption
SoF	10	Continuation Fragment
SoF	11	Reserved
EoF	00	End of Frame
EoF	01	End of Fragment

61.3.6.8.2.5.1.1 Data Alignment

When a received frame cannot be fragmented on any byte boundary, MAC retains the unaligned bytes of data in the previous fragment and resends them with the next fragment as shown in the following figure.

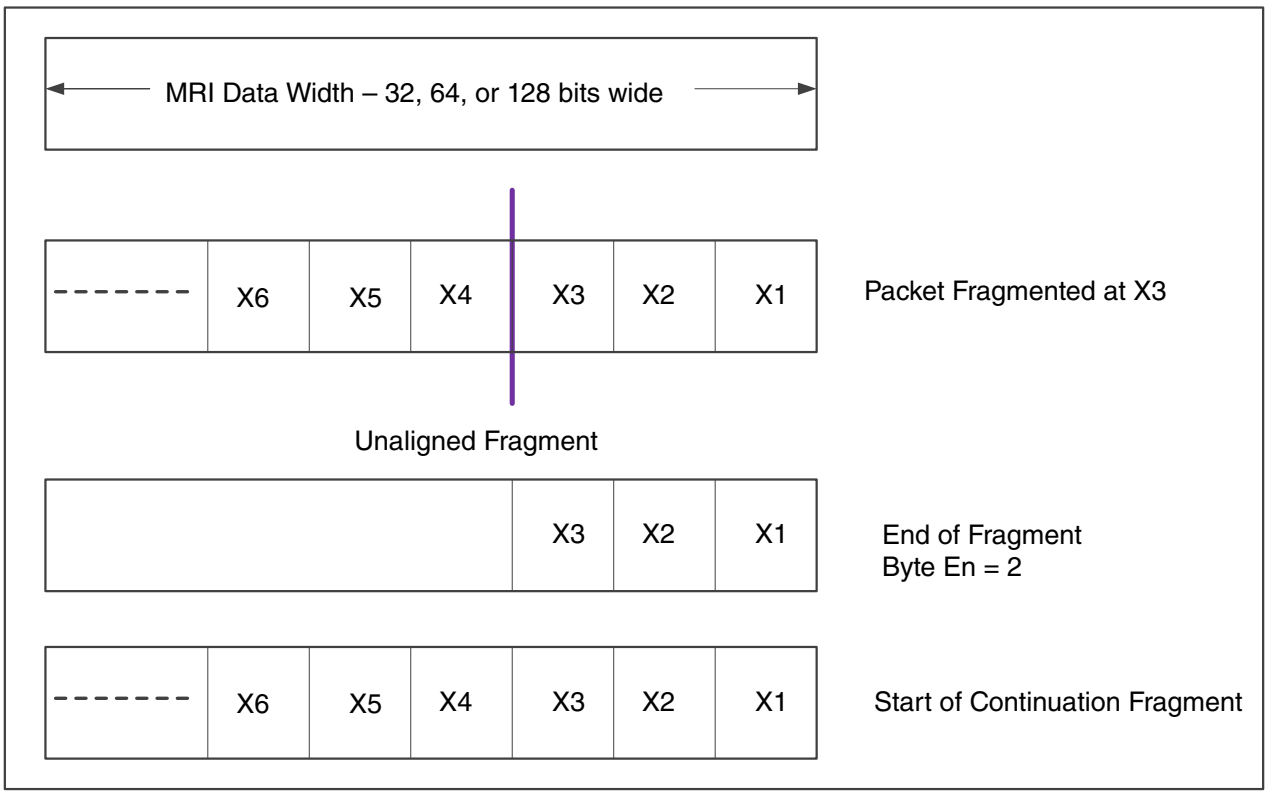

Figure 61-20. Data Alignment Feature of MAC

61.3.6.8.2.5.1.2 MTL Receive Preemption

The MTL Rx must have at least 2 Rx queues to support FPE function as the preemptable packets and the express packets must be routed to separate Rx queues. The destination Rx queue of a received packet is controlled by MAC_RxQ_Ctrl[n] registers. Program these registers such that Preemptable traffic and express traffic are not routed to the same Rx queue. As the queue mapping for tagged packets is based on VLAN user-priority field, this implies that priority of preemptable and express packets are mutually exclusive. In other words, packets of a certain priority (traffic class) are either express or preemptable but cannot be both.

For the preemptable frames, in addition to the PSRQ (Priority Selected in Rx queue) based queue routing, a programmable "Frame Preemption Residue Queue" (FPRQ) is supported to route all other Preemption Packets received (Untagged, SA/ DA or VLAN Filter Fails forwarded due to RA being set or VTFE being reset).

Table 61-29. Preemption Control Values on MRI Interface for Various Frame Types

Preemption Packet Type	Queue Routing
AV Tagged Packets passing the SA/DA and VLAN filters	PSRQ*
DCB/Generic Tagged Packets passing the SA/DA and VLAN filters	PSRQ**
Tagged Packets failing the SA/DA and VLAN filters without setting the Receive All (RA = 0) or setting VTFE = 1	Dropped
All other packets OR when RA = 1	FPRQ

61.3.6.8.2.5.1.3 MTL Receive Arbitration

On the ARI Interface, data is fetched from the MTL Rx FIFO based on the arbitration selected in the MTL_Operation_Mode register. Frame based arbitration can be used only when all the MTL Preemption Queues are operating in Store and Forward mode, else there will be loss of bandwidth on the ARI interface because all the fragments of a preemptable packet is not available. Therefore, any express packets received between the fragments are blocked until all the fragments are received and transferred; this defeats the purpose of express traffic.

When operating in either Threshold (cut through) or Store and forward modes of operation, PBL based arbitration is recommended over Frame based arbitration. In case of PBL based arbitration, the watermark check is always performed and the arbitration/ transfer of data in terms of chunks of "PBL" size of data which is almost similar to the concepts of "fragments". Therefore the express queue packets get blocked for less time as well as the ARI interface transfers the data without loss of efficiency.

61.3.6.8.2.6 Verify and Respond mPackets

When FPE function is present, the MAC can receive and detect the Verify and Respond mPackets, even when FPE is not enabled by software. When MAC detects valid Verify/ Respond mPackets, it notifies the software by setting the RVER and RRSP fields of MAC_FPE_CTRL_STS register respectively. Optionally an interrupt can be generated. As such packets have empty (all-zero) data payload, they are dropped inside the MAC and not forwarded to the MRI.

Software can set the SVER and SRSP fields of MAC_FPE_CTRL_STS register to request MAC to transmit Verify and Respond mPackets respectively. Upon successful transmission of these frames, MAC clears the SVER/SRSP bits and sets the TVER & TRSP fields of MAC_FPE_CTRL_STS register. Optionally an interrupt can be generated when these events occur.

61.3.6.8.2.7 Frame Preemption and MMC Counter and Interrupt Registers

The following MMC counters and associated Interrupt registers are instantiated/present in the MAC when Frame Preemption feature is enabled.

Table 61-30. MMC Counters and Associated Interrupt Registers

Frame Assembly Error Counter	Description	Associated MMC Counter
Frame Assembly Error Counter	A 32-bit counter that provides the number of MAC frames with reassembly errors on the Receiver, due to mismatch in the Fragment Count value.	MMC_Rx_Packet_Assembly_Err_Cntr
Frame SMD Error Counter	A 32-bit counter that provides the number of received MAC frames rejected due to arriving with an SMD-C when there was no preceding preempted frame.	MMC_Rx_Packet_SMD_Err_Cntr
Frame Assembly OK Counter	A 32-bit counter that provides the number of MAC frames that were successfully reassembled.	MMC_Rx_Packet_Assembly_Ok_Cntr
MAC Rx Fragment Counter	A 32-bit counter that provides the number of additional mPackets received due to preemption.	MMC_Rx_FPE_Fragment_Cntr
MAC Tx Fragment Counter	A 32-bit counter that provides the number of additional mPackets transmitted due to preemption.	MMC_Tx_FPE_Fragment_Cntr
Hold Request Counter	A 32-bit counter that maintains the count of number of times a hold request is given to MAC.	MMC_Tx_Hold_Req_Cntr

61.3.6.8.2.7.1 Additional Registers Associated With MMC Interrupts

Following are the additional registers associated with MMC interrupts for the MMC error counters:

- MMC_FPE_Tx_Interrupt
- MMC_FPE_Tx_Interrupt_Mask
- MMC_Rx_Interrupt
- MMC_FPE_Rx_Interrupt_Mask

61.3.6.8.3 Time-Based Scheduling

Time-based scheduling feature is suitable for traffic whose periodicity and rate are predictable. To improve the quality-of-service of such traffic,

- The transmit DMA fetches the packet from the host memory for transmission at designated time. This helps the software to setup the Transmit descriptors in advance even before packet is ready/available. It reduces the overhead on the software and

avoids constant monitoring of the time and preparing descriptors just in time when the packet is targeted to be transmitted.
- The MAC transmits the packet only at the designated/pre-determined time even if the packets are fetched in advance. This helps in maintaining a constant transmission rate that can be consumed by the receiver station; therefore avoiding congestion and excessive buffering in the network.

The time-based scheduling feature supports fetching and launching an Ethernet packet at (or after) a pre-determined time. The time-based scheduling is supported only in the following modes/configurations:

- Full duplex mode
- Link speed is 100Mbps or higher

The following figure shows the time-based scheduling flow.

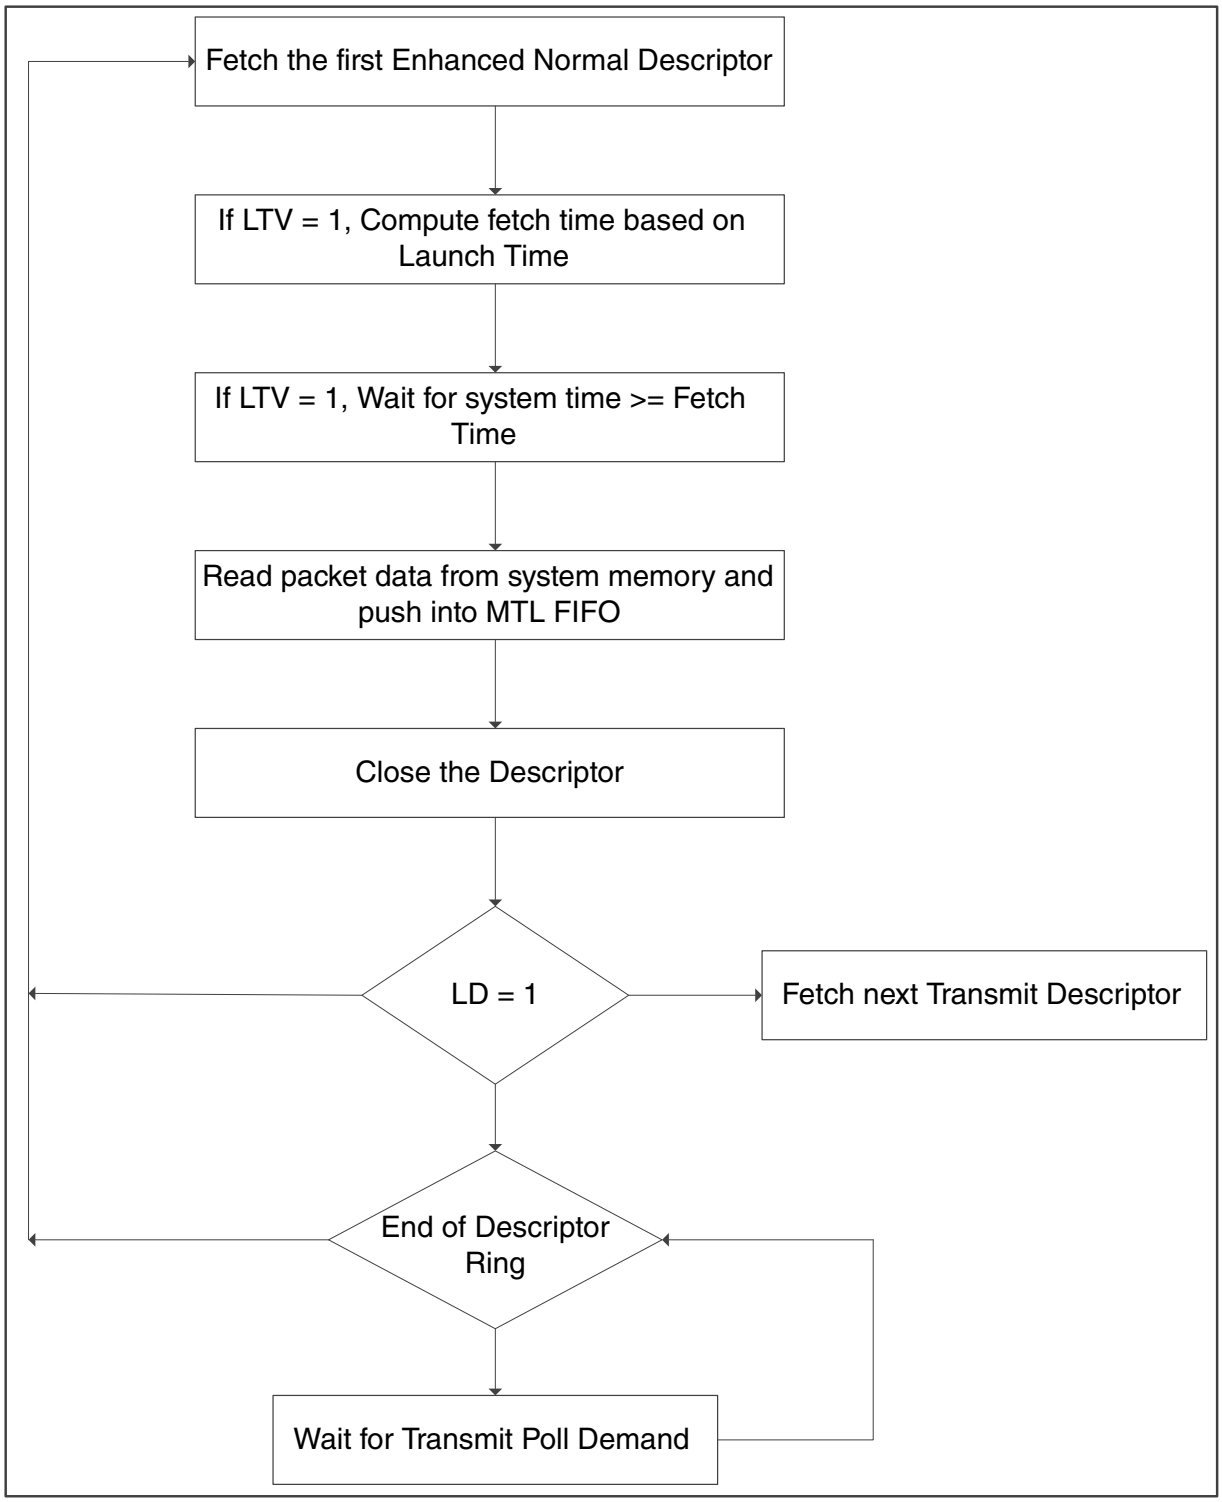

Figure 61-21. Time-Based Scheduling Flow

Following are the definitions specific to the time-based scheduling feature:

61.3.6.8.3.1 Launch Time

Launch time is the time beyond which the MTL can schedule the packet for transmission. The launch time is reset after the transmission of one frame. Following are the two formats of the launch time.

Normal/Absolute Format:

In this format, the launch time is interpreted in the Normal/Absolute format if the ESTM bit of the MTL_TBS_CTRL register is set to 0.

The launch time is a 32-bit value, where most-significant 8-bits represent the time in seconds and the rest 24 bits represent the time in 256 ns. The launch time is compared against the IEEE 1588 based System/PTP Time (bits[39:8]) and rolls over after 256 seconds.

The maximum value of the lower 32-bits of System Time is 999,999,999 decimal (0x3B9AC9FF) and it wraps to 0 when reaching this value (representing a full second). Therefore, the maximum value of the lower 24 bits of the Launch Time (after multiplying by 256) must be 0x3B9AC9.

As the maximum value of Launch time is 256 seconds,

- Launch Time is greater than current System Time when its value is between System Time[39:8] and System Time[39:8] + 128 sec
- Launch Time is less than current System Time when its value is between "System Time[39:8] + 128sec" and "System Time[39:8] + 256 sec", because this is a modulo 256 computation.

EST/Offset Format

In this format, the Launch time is an offset value relative to the time indicated by the Base Time Register (BTR) of the GCL list provided in the GCL Slot Number (GSN). The value in the BTR is always updated to the start time of the current loop of the GCL.

For each packet, the GSN value and the Launch Time value are specified in the Enhanced Transmit Descriptor in the DMA configurations, or as Control Word in the MTL configurations.

The launch time offset is a 32-bit value; the upper 8-bits represent the time in seconds and the rest 24 bits represent the time in 256 ns, which is added to the BTR value corresponding to GCL Slot Number. The value of the Launch Time Offset must be smaller than the value of the Cycle Time (specified in the CTR register that is implemented when EST is enabled). If the CTR is greater than or equal to 1s, the maximum value of the lower-24 bits of Launch Time offset should be 999,999,999 decimal (0x3B9AC9FF).

In this format, the launch time is a 64-bit value, which is interpreted as, Launch Time = Launch GSN BTR[63:0] + (Launch Time Offset[31:0] << 8), which is compared with the System Time [63:0].

GSN BTR is the Base Time value at which the Launch GSN loop started execution.

GCL Slot Number (GSN) A modulo 16 count of the GCL loop count is implemented and known as GSN. The count is incremented for every new GCL loop; installation of new GCL list does not impact the count. The current GCL slot number can be obtained by reading the CGSN field of the MTL_EST_Status register.

The maximum value of GSN is 15. Therefore GSN values between Current GSN (CGSN field of MTL_EST_Status register) and CGSN+8 represent current or future slots; all other GSN values are interpreted as elapsed slots or past slots. So, for the correct interpretation of time, GSN value must be between CGSN and CGSN+8, for correct interpretation of time.

61.3.6.8.3.2 Launch Expiry Time

Normal/Absolute Mode

In the normal mode, when the LEOV (Launch Expiry Offset Valid bit of MTL_TBS_CTRL register) is set, the Launch Expiry Offset (LEOS field of MTL_TBS_CTRL register) determines the maximum amount of time a frame is eligible for launch, starting from the time the frame becomes eligible for launch.

The Launch Expiry Offset is a 24-bit value defined in 256ns units, with a maximum possible value of 999,999,999 ns (0x3B9AC9FF).

Launch Expiry Time = (Launch Time[39:8] + LEOS[32:8]) * 256ns

The packet with a specific Launch time is considered eligible for transmission when the Launch time is less than the System Time and (if LEOV is set) the System Time is less than the Launch Expiry time.

When the System time is greater than the Launch Expiry time the frame is categorized as expired and will be dropped from the MTL FIFO.

NOTE

- For correct interpretation and meaningful operation, the Fetch, Launch, and Launch Expiry time should never be set to a value larger than Current System Time + 128 sec; such a value is interpreted as time that has already elapsed.
- In full duplex mode, the frames dropped from the MTL FIFO have Error Summary (Bit 15) and Excessive Deferral (bit 3) of TxStatus set.

EST/Offset Mode

In the EST mode of operation, when the LEOV field of the MTL_TBS_CTRL register is set, the launch expiry GSN offset (LEGOS field of the MTL_TBS_CTRL register) and Launch Expiry Offset (LEOS field of MTL_TBS_CTRL register) determine the maximum amount of time a frame remains eligible for launch, starting from the time the frame becomes eligible for launch.

Launch Expiry Offset = (LEGOS: LEOS)

LEGOS holds the GSN offset (multiples of CTR time) and LEOS holds maximum value of CTR (sub CTR values) in ns.

Launch Expiry offset is a 24-bit value defined in the units of 256 ns, with a maximum possible value of the smaller of 999,999,999ns or CTR-1 ns.

The Launch Expiry GSN is computed as follows:

Launch Expiry GSN = (Launch GSN + LEGOS + CCMA) Where, CCMA is the CTR Carry due to Modulo addition. This value is 1 if ((Launch Time Offset + LEOS) << 8) is equal to or greater than CTR.

When CCMA = 1, Launch Expiry Offset = (Launch Time Offset+ LEOS) - CTR

When CCMA = 0,

Launch Expiry Offset = (Launch Time Offset + LEOS).

Launch Expiry Time = Launch Expiry GSN BTR[63:0] + Launch Expiry Time Offset.

When LEOV is not set, Launch Expiry Time is not checked.

When LEOV is set, and

- the system time is greater than the Launch Expiry time, the frame is dropped from MTL FIFO. The frame is considered as expired.
- the launch time is smaller than the System Time and Launch Expiry Time is greater than system time, the frame is considered eligible for launch.

NOTE

- Max value of LEGOS is 7. This implies that when LEOV is set, the frame has a maximum life time of <8 GCL loop iterations after it becomes eligible for Launch.
- The slot number of the First GCL List executed each time after EST is enabled, is zero.

61.3.6.8.3.3 Fetch Time

The fetch time accounts for all possible delays in the DMA fetch operation and ensures that the frame is present in the MTL FIFO before the launch time.

If FTOV field of DMA_TBS_CTRL register is set, then fetch time can be indicated for each packet. If the FTOV filed is not set, the Fetch Time Offset is not valid and the DMA fetches packets without any time constraints.

61.3.6.8.3.3.1 Normal/Absolute Mode

In the Normal mode fetch time derived/calculated by reducing the time specified in the Fetch Time Offset (FTOS) field of DMA_TBS_CTRL register from the given Launch time.

Normal mode of operation, the Fetch Launch Time is computed as:

Fetch Time[39:8] = (Launch Time[39:8] - FTOS[31:8])

The Fetch time is 32-bits and is compared against System Time[39:8] to determine the Eligible for fetching the frame:

- The Fetch time is defined as "greater" than System Time if the Fetch Time is in the range of "System Time[39:8]" and "System Time[39:8] + 128 sec". The frame is considered as not-eligible for fetch.
- The Fetch time is defined as "smaller" than the System Time if the Fetch time is in the range of "System Time[39:8] + 128 sec" and "System Time[39:8] + 256 sec". The frame is considered as eligible for fetch.

This is a modulo 256 computation.

61.3.6.8.3.3.2 EST/Offset Mode

In the EST/Offset mode, the Fetch GSN Offset (FGOS field of MTL_TBS_CTRL register) provides the Slot Number offset to be deducted from the Launch GSN. In this case the FTOS value should be the smaller of 999,999,999ns or CTR-1 ns.

If (Launch Time Offset >= FTOS):

Fetch Time Offset = ((Launch Time Offset - FTOS) * 256ns)

CBFS(CTR Borrow for Fetch Subtraction) = 0

If (Launch Time Offset < FTOS) Fetch Time Offset = CTR + ((Launch Time Offset - FTOS) * 256ns)

CBFS (CTR Borrow for Fetch Subtraction) = 1

The Fetch GSN is computed as follows:

Fetch GSN = Launch GSN - FGOS - CBFS

Fetch Time = Fetch GSN BTR[63:0] + Fetch Time Offset

The frame is marked eligible for DMA fetch when the fetch time is smaller than the System Time.

61.3.6.8.3.3.3 DMA Operations Sequence

Following is the sequence of operation when FTOV = 1:

1. Fetch the first Enhanced Normal Descriptor (FD is set)
2. If LTV is set and Fetch enabled, compute the Fetch Time based on the Launch Time Wait for the System Time to be greater than Fetch Time
3. Read the Frame (Data) from the host memory and transfer to MTL FIFO
4. Close the Normal Descriptor
5. Fetch the next Normal Descriptor (if the previous Descriptor was not the Last)
6. Repeat steps 4 to 6, until the last descriptor of the frame (LD is set)

After the Last Descriptor of a frame, the next enhanced normal descriptor should be programmed with a new Launch Time and with LTV bit set. Otherwise, the subsequent frames will be processed without any time restrictions.

NOTE

See Programming the Launch Time in Time-Based Scheduling

61.3.6.8.4 Credit-Based Shaper Algorithm

The MTL Queue Scheduler (shown in Figure 61-1) uses the credit-based shaper algorithm to arbitrate the AV traffic in all queues and the legacy Ethernet traffic in Queue 0. You can program the additional queues to use the credit-based shaper algorithm.

The following sections provide information about how you can implement the credit-based shaper algorithm:

- Credit Value
- idleSlopeCredit and sendSlopeCredit Values
- Bandwidth Status

61.3.6.8.4.1 Credit Value

The credit value is part of the credit-based sharper algorithm used by the MTL Queue Scheduler.

The credit value is accumulated every transmit clock cycle, that is, 40 ns for 100 Mbps and 8 ns for 1000 Mbps. The credit to be added or subtracted per cycle can be fractional based on the required idleSlope and sendSlope values, as described in the table below.

Table 61-31. Credit Value Per Transmit Cycle Example

Mode	Values	Description
100 Mbps	• portTransmitRate = 100 Mbps • idleSlope = 70 Mbps (assuming 70% bandwidth reserved for a higher priority traffic class) • sendSlope = 30 Mbps	• credit = 2.8 bits accumulates per cycle (40 ns) for the higher priority traffic class when best-effort packet is being transmitted. • credit = 1.2 bits drains per cycle (40 ns) when higher priority traffic class packet is being transmitted.

The DMA stores the queue traffic in the respective part of the Tx FIFO based on the slot number in the transmit descriptor (if enabled) or the bandwidth availability on the AMBA AHB application bus.

The credit for a queue builds up only when the packet is available but it cannot be transmitted because the MAC is sending a packet from another queue. The module supports another mode in which the credit can build up in advance for a queue in which no packet is available in respective part of the FIFO. This enables sending a burst of high priority traffic in a queue as soon as the data is available. You can enable this mode with Bit 3 of the CBS Control registers of corresponding queues.

When reset, the accumulated credit parameter in the credit-based shaper algorithm is set to zero if there is positive credit, and there is no packet to transmit in a queue. The credit does not accumulate when there is no packet waiting in a queue and other queues are transmitting. When set, the accumulated credit parameter in the credit-based shaper algorithm is not reset to zero if there is positive credit and no packet to transmit in a queue. The credit accumulates even when there is no packet waiting in a queue and other queues are transmitting.

61.3.6.8.4.2 idleSlopeCredit and sendSlopeCredit Values

The idleSlopeCredit and sendSlopeCredit values are programmable.

The software must program the idleSlopeCredit and sendSlopeCredit values. The programmed values should be the credit accumulated or drained per clock cycle scaled by 1024, such as, 2.8 x 1024 = 2867 and 1.2 x 1024 = 1229. In addition, the software must program the hiCredit and loCredit values, scaled by 1024, to adjust for scaling of the idleSlopeCredit and sendSlopeCredit values. This means that if computed hiCredit and

loCredit values are 12,000 bits and 3,036 bits respectively, the values to be programmed in the hiCredit and loCredit registers of the corresponding channel are 12000 x 1024 bits and two's complement of 3036 x 1024, respectively.

61.3.6.8.4.3 Bandwidth Status

The hardware maintains the status of the actual bandwidth consumed by each higher priority queue in the CBS status registers. This enables the software to estimate the average bandwidth consumed by numerically higher traffic classes as compared to the reserved bandwidth.

The CBS status register gives the average number of bits transmitted during the previous programmed slot interval (1, 2, 4, 8, or 16 slots of 125 μs) in a queue. The status register is updated even if the credit-based shaper algorithm is not enabled for a queue. The number of slots over which the average bits transmitted per slot are computed is programmed in Bits[6:4] of the CBS control register of the respective queue. For example, if you have programmed two slots, the average bits are computed over slot numbers 0–1, 2–3, 4–5, and so on.

The value programmed in the idleSlopeCredit register of a queue is proportional to the bandwidth reserved for the queue. The software can allocate any bandwidth that is not used by the higher priority queue to the reserved bandwidth of the lower priority queue.

A lower priority queue, which is using the credit-based shaper algorithm, cannot use the unused reserved bandwidth of any higher priority queue that is using the credit-based shaper algorithm. However, a lower priority queue, which is using the strict-priority algorithm, can use the unused reserved bandwidth of any higher priority queue that uses the credit-based shaper algorithm. For example, Queue 1 and Queue 2 use the credit-based shaper algorithm (with reserved bandwidth of 50% and 25%, respectively) and Queue 0 uses the strict-priority algorithm. If Queue 1 uses only 40% of reserved bandwidth, the remaining 10% is used by Queue 0. Queue 2 cannot exceed the reserved bandwidth of 25%.

61.3.6.9 Queue Modes

Both Tx and Rx queues can handle AV traffic.

Queueing is based on WRR (Weighted Round Robin) or WSP (Weighted Strict Priority) algorithm for generic traffic while it is based on CBS (Credit Base Shaper) and SP (Strict Priority) algorithm for AV traffic.

Whether an Rx Queue is configured for generic or AV-based routing depends on the RXQ#EN field of corresponding queue. Queueing is done based on VLAN tag priority. The VLAN tag priority should match the PSRQ field of the MAC_RXQ_CTRL2 registers. The Rx packets can also be routed to a particular DMA channel based on the DCS field of perfectly-matched MAC Address register.

By default, untagged packets in generic traffic are routed to Receive queue specified in UPQ field of MAC_RXQ_CTRL1 register. Queue 0 is the default value of UPQ field. You can override the default value with any other value, for the UPQ field.

AV control packets (tagged or untagged) are routed based on the AVCPQ field of the MAC_RXQ_CTRL1 register. The PTP over Ethernet packets are routed based on the AVPTPQ field of MAC_RXQ_CTRL1 register.

61.3.6.10 Queue Priorities

Priority of an Rx queue can be programmed in corresponding field of MAC_RxQ_Ctrl2 registers. AV queue (high priority) should be programmed as higher priority than the Best-effort queue (low priority).

61.3.7 TCP/IP Offloading Features

61.3.7.1 Transmit Checksum Offload Engine

The MAC has a Checksum Offload Engine (COE) to support checksum calculation and insertion in the Transmit path, using which, the software can offload the task of checksum insertion to the hardware. In the transmit path MAC calculates the checksum and inserts it in the Tx packet. This feature helps in reducing the load on the software and can improve the overall throughput of the system. This feature is supported for only Q0 queue.

The checksum offload engine module supports two types of checksum calculation and insertion. The checksum engine can be controlled for each packet by setting the CIC bits (TDES3 Bits[17:16]).

Note: The checksum for TCP, UDP, or ICMP is calculated over a complete packet, and then inserted into its corresponding header field. Because of this requirement, when this function is enabled, the Tx FIFO automatically operates in the store-and-forward mode even if IP is configured for Threshold (cut-through) mode.

61.3.7.1.1 IP Header Checksum Engine

In IPv4 datagrams, the integrity of the header fields is indicated by the 16-bit Header Checksum field (the eleventh and twelfth bytes of the IPv4 datagram). The COE detects an IPv4 datagram when the Type field of Ethernet packet has the value 0x0800 and the Version field of IP datagram has the value 0x4. The checksum field of the input packet is ignored during calculation and replaced with the calculated value.

NOTE

IPv6 headers do not have a checksum field. Therefore, the COE does not modify the IPv6 header fields.

The result of this IP header checksum calculation is indicated by the IP Header Error status bit in the Transmit status (TDES3[0]). This status bit is set whenever the values of the Ethernet Type field and the Version field of IP header are not consistent, or when the Ethernet packet does not have enough data, as indicated by the IP header Length field. In other words, this bit is set when an IP header error is asserted under the following circumstances:

- For IPv4 datagrams:
  - The received Ethernet type is 0x0800, but the Version field of IP header is not equal to 0x4.
  - The IPv4 Header Length field indicates a value less than 0x5 (20 bytes).
  - The total packet length is less than the value given in the IPv4 Header Length field.
- For IPv6 datagrams:
  - The Ethernet type is 0x86dd but the IP header Version field is not equal to 0x6.
  - The packet ends before the IPv6 header (40 bytes) or extension header (as given in the corresponding Header Length field in an extension header) is completely received.

61.3.7.1.2 TCP/UDP/ICMP Checksum Engine

The TCP/UDP/ICMP Checksum Engine processes the IPv4 or IPv6 header (including extension headers) and determines whether the encapsulated payload is TCP, UDP, or ICMP. The checksum is calculated for the TCP, UDP, or ICMP payload and inserted into its corresponding field in the header. The Tx COE can work in the following two modes:

- The TCP, UDP, or ICMPv6 pseudo-header is not included in the checksum calculation and is assumed to be present in the Checksum field of the input packet.

This engine includes the Checksum field in the checksum calculation, and then replaces the Checksum field with the final calculated checksum.
- The engine ignores the Checksum field, includes the TCP, UDP, or ICMPv6 pseudo-header data into the checksum calculation, and overwrites the checksum field with the final calculated value.

NOTE

For ICMP-over-IPv4 packets, the Checksum field in the ICMP packet must always be 16'h0000 in both modes, because pseudo-headers are not defined for such packets. If it does not equal 16’h0000, an incorrect checksum may be inserted into the packet.

The result of this operation is indicated by the Payload Checksum Error status bit in the Transmit Status vector (TDES3[12]). This engine sets the Payload Checksum Error status bit when:

- It detects that the packet has been forwarded to the MAC Transmitter engine in the store-and-forward mode without the end of packet (EOP) being written to the FIFO.
- when the packet ends before the number of bytes indicated by the Payload Length field in the IP Header is received.

When the packet is longer than the indicated payload length, the COE ignores them as stuff bytes and no error is reported. When this engine detects the first type of error, it does not modify the TCP, UDP, or ICMP header. For the second error type, it still inserts the calculated checksum into the corresponding header field. The following table describes the functions supported by Transmit Checksum Offload engine based on the packet type. When the MAC does not insert the checksum, it is indicated as "No" in the table.

NOTE

You should not enable checksum insertion for IPv4 or IPv6 packets that are greater than the frame size constraint specified in Description of Transmit Checksum Offload Engine because it may result in incorrect checksum insertion or unexpected behavior.

Table 61-32. Transmit Checksum Offload Engine Functions for Different Packet Types

Packet Type	Hardware IP headerchecksum insertion	Hardware TCP/UDPchecksum insertion
Non-IPv4 or IPv6 packet	No	No
IPv4 packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in	Yes	Yes

Table continues on the next page...

Table 61-32. Transmit Checksum Offload Engine Functions for Different Packet Types (continued)

Packet Type	Hardware IP headerchecksum insertion	Hardware TCP/UDPchecksum insertion
MAC) but less than or equal to the frame size constraint specified in Transmit Checksum Offload Engine.		
IPv6 packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in MAC) but less than or equal to the frame size constraint specified in Transmit Checksum Offload Engine.	Not Applicable	Yes
IPv4 with TCP, UDP, or ICMP	Yes	Yes
IPv4 packet has IP options (IP header is longer than 20 bytes)	Yes	Yes
Packet is an IPv4 fragment	Yes	No
IPv6 packet with the following next header fields in main or extension headers:		
Hop-by-hop options (in IPv6 main header)	Not Applicable	Yes
Hop-by-hop options (in IPv6 extension header)	Not Applicable	No
Destinations options	Not Applicable	Yes
Routing (with segment left 0)	Not Applicable	No
Routing (with segment left > 0)	Not Applicable	No
TCP, UDP, or ICMP	Not Applicable	Yes
Authentication	Not Applicable	No
Any other next header field in main or extension headers	Not Applicable	No
IPv4 packet has TCP header with Options fields	Yes	Yes
IPv4 Tunnels:	#160;	#160;
IPv4 packet in an IPv4 tunnel	Yes (IPv4 tunnel header)	No
IPv6 packet in an IPv4 tunnel	Yes (IPv4 tunnel header)	No
IPv6 Tunnels:	#160;	#160;
IPv4 packet in an IPv6 tunnel	Not applicable	No
IPv6 packet in an IPv6 tunnel	Not applicable	No
IPv4 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled).	Yes	Yes
IPv6 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled).	Not applicable	Yes
IPv4 frames with security features (such as encapsulated security payload)	Yes	No

Table continues on the next page...

Table 61-32. Transmit Checksum Offload Engine Functions for Different Packet Types (continued)

Packet Type	Hardware IP headerchecksum insertion	Hardware TCP/UDPchecksum insertion
IPv6 frames with security features (such as encapsulated security payload)	Not applicable	No

61.3.7.2 Receive Checksum Offload Engine

IP provides the Checksum Offload Engine that is used to detect any error in an IPv4 or IPv6 packet in the receive path. The MAC verifies the checksum field of the received packet with the internally calculated checksum and provides the status.

The Receive Checksum Offload engine is used to detect errors in IP packets by calculating the header checksum and further matching it with the received header checksum. This engine also identifies a TCP, UDP, or ICMP payload in received IP packets and calculates the checksum of such payloads appropriately.

Here, the IPv4 or IPv6 packets in the received Ethernet packets are detected and processed for data integrity. The MAC receiver identifies IPv4 or IPv6 packets by checking for value 0x0800 or 0x86DD, respectively, in the Type field of the received Ethernet packet. This identification is applicable to single VLAN-tagged packets. It is also applicable to double VLAN-tagged packets when the Enable Double VLAN Processing option is selected and the EDVLP bit of the MAC_VLAN_Tag register is set.

The Rx COE calculates the IPv4 header checksums and checks that they match the received IPv4 header checksums. The result of this operation (pass or fail) is given to the RFC module for insertion into the receive status word. The IP Header Error bit is set for any mismatch between the indicated payload type (Ethernet Type field) and the IP header version, or when the received packet does not have enough bytes, as indicated by the Length field of the IPv4 header (or when fewer than 20 bytes are available in an IPv4 or IPv6 header).

This engine also identifies a TCP, UDP, or ICMP payload in the received IP datagrams (IPv4 or IPv6) and calculates the checksum of such payloads properly, as defined in the TCP, UDP, or ICMP specifications. This engine includes the TCP, UDP, or ICMPv6 pseudo-header bytes for checksum calculation and checks whether the received checksum field matches the calculated value. The result of this operation is given as a Payload Checksum Error bit in the receive status word. This status bit is also set if the length of the TCP, UDP, or ICMP payload does not match the expected payload length given in the IP header.

Following table describes the functions supported by the Rx COE based on the packet type. When the payload of an IP packet is not processed (indicated as "No" in the table), the information (whether the checksum engine is bypassed or not) is given in the receive status.

NOTE

The MAC does not append any payload checksum bytes to the received Ethernet packets.

Table 61-33. Receive Checksum Offload Engine Functions for Different Packet Types

Packet type	Hardware IP header checksum checking	Hardware TCP/UDP/ICMP checksum checking
Non-IPv4 or IPv6	No	No
IPv4 packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in the MAC)	Yes	Yes
IPv6 packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in the MAC)	Not Applicable	Yes
IPv4 with TCP, UDP, or ICMP	Yes	Yes
IPv4 header's protocol field contains a protocol other than TCP, UDP, or ICMP	Yes	No
IPv4 packet has IP options (IP header is longer than 20 bytes)	Yes	Yes
Packet is an IPv4 fragment	Yes	No
IPv6 packet with the following next header fields in main or extension headers: • Hop-by-hop options (in IPv6 main header) • Hop-by-hop options (in IPv6 extension header) • Destinations options • Routing (with segment left 0) • Routing (with segment left > 0) • TCP, UDP, or ICMP • Any other next header field in main or extension headers	• Not Applicable • Not Applicable • Not Applicable • Not Applicable • Not Applicable • Not Applicable • Not Applicable	• Yes • No • Yes • Yes • No • Yes • No
IPv4 packet has TCP header with Options fields	Yes	Yes
IPv4 Tunnels: • IPv4 packet in an IPv4 tunnel • IPv6 packet in an IPv4 tunnel	• Yes (IPv4 tunnel header) • Yes (IPv4 tunnel header)	• No • No

Table continues on the next page...

Table 61-33. Receive Checksum Offload Engine Functions for Different Packet Types (continued)

Packet type	Hardware IP header checksum checking	Hardware TCP/UDP/ICMP checksum checking
IPv4 Tunnels: • IPv4 packet in an IPv6 tunnel • IPv6 packet in an IPv6 tunnel	• Not Applicable • Not Applicable	• No • No
IPv4 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled)	Yes	Yes
IPv6 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled)	Not Applicable	Yes
IPv4 frames with security features (such as encapsulated security payload)	Yes	No
IPv6 frames with security features (such as encapsulated security payload)	Not Applicable	No

Set the IPC bit of the MAC_Configuration register for enabling Receive Checksum offload.

61.3.8 MAC Management Counters

IP supports storing the statistics about the received and transmitted packets in registers that are accessible through the application/software. The MMC module maintains a set of registers for gathering statistics on the received and transmitted packets. The MMC counters are free running.

For MMC register details, see registers "MMC_Control" to "MMC_Rx_FPE_Fragment_Cntr" in ENET_QOS register descriptions.

61.3.9 Flow Control

61.3.9.1 Transmit Flow Control

The Transmit Flow Control involves transmitting Pause packets in full-duplex mode and backpressure in half-duplex mode to control the flow of packets from the remote end.

61.3.9.1.1 Flow control in Full duplex mode

IP supports the IEEE802.3x Pause Packets.

Pause packet structure is shown in the following table.

Table 61-34. Pause Packet Fields

Field	Description
DA	Contains the special multicast address
SA	Contains the MAC address 0
Type	Contains 8808
MAC Control opcode	Contains 0001 for IEEE 802.3x Pause Control packets; 0101 for PFC packets
PT	Contains Pause time specified in the PT field of the MAC_Q#_Tx_Flow_Ctrl register

61.3.9.1.2 Pause Packet Control

When the FCB bit is set, the MAC generates and transmits a single Pause packet. If the FCB bit is set again after the Pause packet transmission is complete, the MAC sends another Pause packet irrespective of whether the pause time is complete or not. To extend the pause or terminate the pause prior to the time specified in the previously-transmitted Pause packet, the application should program the Pause Time register with appropriate value and then again set the FCB bit.

61.3.9.1.3 Flow Control in Half-Duplex Mode

In half-duplex mode, the MAC uses the deferral mechanism for the flow control (backpressure). When the application requests to stop receiving packets, the MAC sends a JAM pattern of 32 bytes when it senses a packet reception, provided the transmit flow control is enabled. This results in a collision and the remote station backs off. If the application requests a packet to be transmitted, it is scheduled and transmitted even when the backpressure is activated. If the backpressure is kept activated for a long time (and more than 16 consecutive collision events occur), the remote stations abort the transmission because of excessive collisions.

Following table describes the flow control in the Tx path for Queue 0 based on the setting of the following bits:

- EHFC bit of MTL_RxQ0_Operation_Mode register
- TFE bit of MAC_Q0_Tx_Flow_Ctrl register
- DM bit of MAC_Configuration register

Flow control is similar for all queues.

Table 61-35. Tx MAC Flow Control

EHFC	TFE	DM	Description
x	0	x	The MAC transmitter does not perform the flow control or backpressure operation.
0	1	0	The MAC transmitter performs back-pressure when Bit 0 of MAC_Q0_Tx_Flow_Ctrl register is set or the sideband signal sbd_flowctrl_i is 1.
1	1	0	The MAC transmitter performs back-pressure when Bit 0 of MAC_Q0_Tx_Flow_Ctrl register is set or the sideband signal sbd_flowctrl_i is 1. In addition, the MAC Tx performs back-pressure when Rx Queue level crosses the threshold set by Bits[10:8] of MTL_RxQ0_Operation_Mode register.
0	1	1	The MAC transmitter sends the Pause packet when Bit 0 of MAC_Q0_Tx_Flow_Ctrl register is set or the sideband signal sbd_flowctrl_i is 1.
1	1	1	The MAC transmitter sends the Pause packet when Bit 0 of MAC_Q0_Tx_Flow_Ctrl register is set or the sideband signal sbd_flowctrl_i is 1. In addition, the MAC Tx sends a Pause packet when Rx Queue level crosses the threshold set by Bits[10:8] of MTL_RxQ0_Operation_Mode register.

61.3.9.1.4 Enabling Transmit Flow Control

To independently enable Transmit Flow Control for each Tx queue, set the TFE bit in the MAC_Q#_Tx_Flow_Ctrl register.

61.3.9.2 Receive Flow Control

In the Receive path, the Flow Control is functional only in the full-duplex mode. If any Pause packet is received in the half-duplex mode, the packet is considered as a normal control packet.

NOTE

Receive pause packets should have a frame size of 64 bytes.

The Receive Flow Control is implemented by the MAC based on the bit value of the respective register, and the destination address and different fields of the received packet.

Following table describes the flow control in the Rx path based on the setting of the following bits:

- RFE bit of MAC_RX_FLOW_CTRL register
- DM bit of MAC_CONFIGURATION register

Table 61-36. Rx MAC Flow Control

RFE	DM	Description
0	x	The MAC receiver does not detect the received Pause packets.
1	0	The MAC receiver does not detect the received Pause packets but recognizes such packets as Control packets.
1	1	The MAC receiver detects or processes the Pause packets and responds to such packets by stopping the MAC transmitter.

61.3.9.2.1 Enabling Receive Flow Control

To enable Pause Flow Control, set the RFE bit in the MAC_Rx_Flow_Ctrl register.

61.3.10 Loopback Mode

The MAC supports Loopback of transmitted packets to its receiver.

The following are some guidelines for using the loopback mode:

- Enable loopback only with the full-duplex mode. In half-duplex mode, the carrier sense signal (crs) or collision (col) signal inputs get sampled which may result into issues such as packet dropping.
- If the loopback mode is enabled without connecting a PHY chip (for example, in FPGA setup), you should externally generate the Tx and Rx clocks and provide these clocks to the MAC.
- Do not loop back big packets. Big packets (>1522 bytes) may get corrupted in the loopback FIFO.

To enable this feature, program the LM bit of the MAC_Configuration register.

You can enable loopback for all PHY interfaces. The data is always looped back through internal asynchronous FIFO on to the internal Receive MII or GMII interface, irrespective of which PHY interface is selected. The loopback data is also passed through the corresponding transmit PHY interface block, on to the Ethernet line.

61.3.11 Descriptors

61.3.11.1 Overview

The DMA in the Ethernet subsystem transfers data based on a linked list of descriptors. The application creates the descriptors in the system memory. The module supports the following two types of descriptors:

- Normal Descriptor: Normal descriptors are used for packet data and to provide control information applicable to the packets to be transmitted.
- Context Descriptor: Context descriptors are used to provide control information applicable to the packet to be transmitted.

Each normal descriptor contains two buffers and two address pointers. These buffers enable the adapter port to be compatible with various types of memory management schemes.

NOTE

There is no limit for the number of descriptors that can be used for a single packet.

61.3.11.2 Descriptor Structure

The module supports the ring structure for DMA descriptor as shown in the following figure.

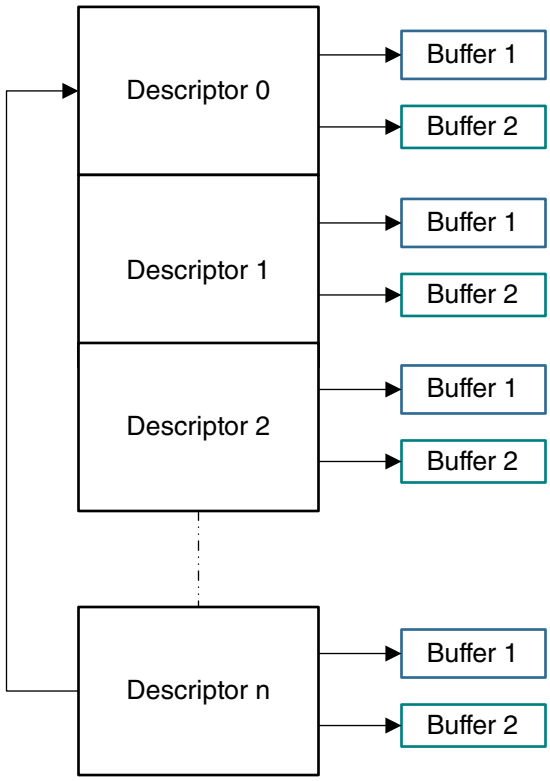

Figure 61-22. Descriptor Ring Structure

In Ring structure, descriptors are separated by the Word, DWord, or LWord number programmed in the DSL field of the DMA_CH#_Control register. The application needs to program the total ring length, that is, the total number of descriptors in ring span in the following registers of a DMA channel:

- Transmit Descriptor Ring Length Register (DMA_CH#_TxDesc_Ring_Length)
- Channel n Receive Control 2 register (DMA_CH#_RX_CONTROL2)

The Descriptor Tail Pointer Register contains the pointer to the descriptor address (N). The base address and the current descriptor pointer decide the address of the current descriptor that the DMA can process. The descriptors up to one location less than the one indicated by the descriptor tail pointer (N – 1) are owned by the DMA. The DMA continues to process the descriptors until the following condition occurs:

Current Descriptor Pointer == Descriptor Tail Pointer;

The DMA goes into the Suspend mode when this condition occurs. The application must perform a write to the Descriptor Tail pointer register and update the tail pointer so that the following condition is true:

Current Descriptor Pointer < Descriptor Tail Pointer;

The DMA automatically wraps around the base address when the end of ring is reached, as shown in the following figure.

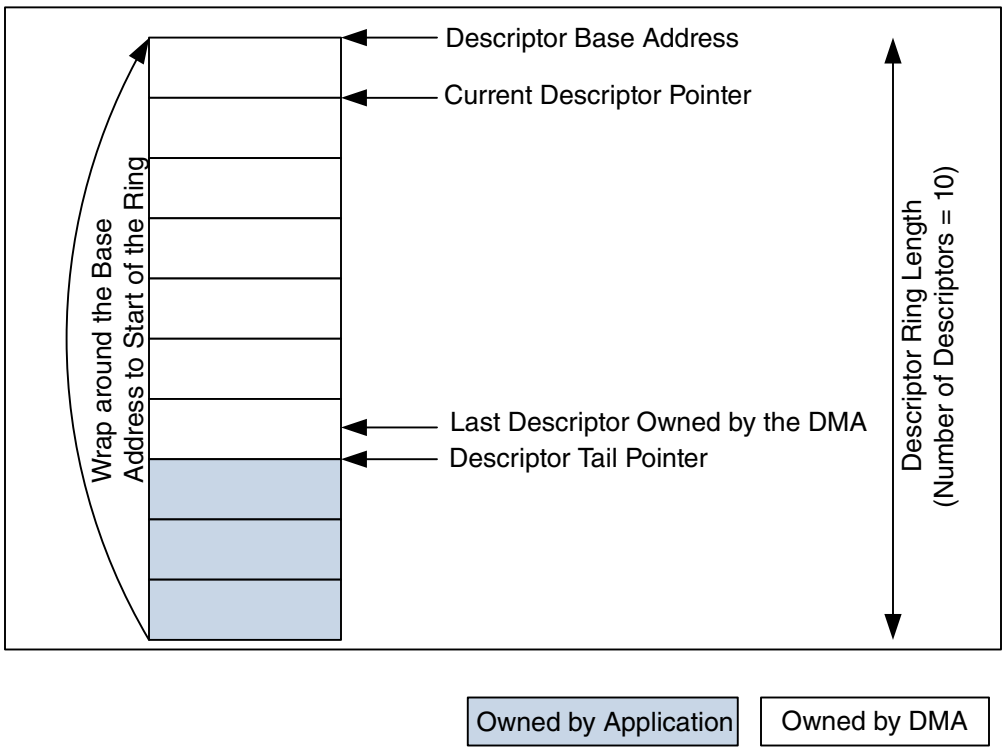

Figure 61-23. DMA Descriptor Ring

For descriptors owned by the application, the OWN bit of DES3 is reset to 0. For descriptors owned by the DMA, the OWN bit is set to 1. If the application has only one descriptor in the beginning, the application sets the last descriptor address (tail pointer) to Descriptor Base Address + 1. The DMA processes the first descriptor and then waits for the application to advance the tail pointer.

61.3.11.3 Transmit Descriptor

The DMA in the module requires at least one descriptor for a transmit packet. In addition to two buffers, two byte-count buffers, and two address pointers, the transmit descriptor has control fields which can be used to control the MAC operation on per-transmit packet basis. The Transmit Normal descriptor has two formats: Read format and Write-Back format

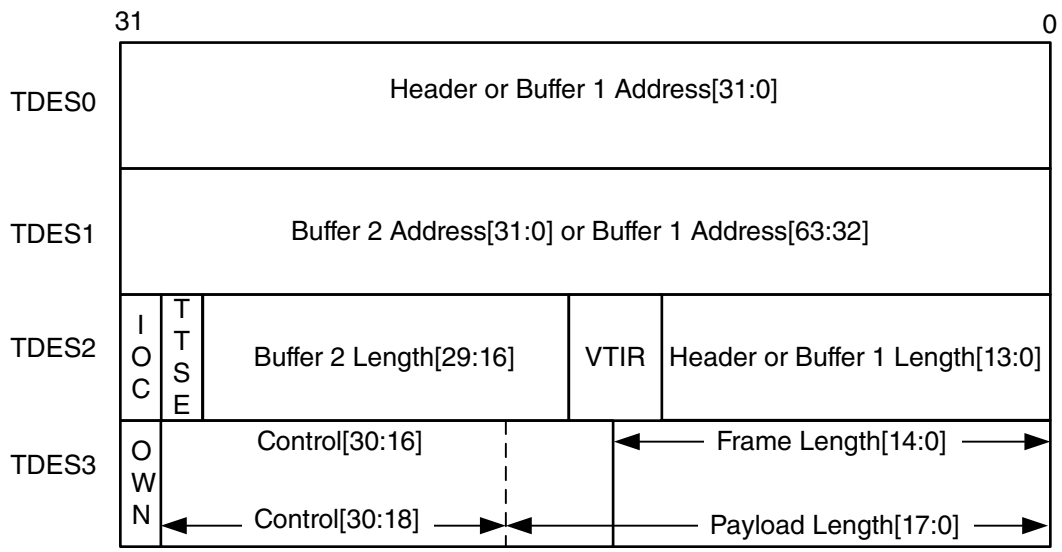
NOTE

TSO Split header is not supported.

61.3.11.3.1 Transmit Normal Descriptor (Read Format)

Following figure shows the Read Format for a Transmit normal descriptor. Table: 'TDES0 Normal Descriptor (Read Format)' through Table: 'TDES3 Normal Descriptor (Read Format)' describe the read format for the Transmit Normal Descriptors: TDES0, TDES1, TDES2, and TDES3.

Figure 61-24. Transmit Descriptor Read Format



61.3.11.3.1.1 TDES0 Normal Descriptor (Read Format)

Table 61-37. TDES0 Normal Descriptor (Read Format)

Bit	Name	Description
31:0	BUF1AP	Buffer 1 Address Pointer or TSO Header Address Pointer These bits indicate the physical address of Buffer 1. These bits indicate the TSO Header Address pointer when the following bits are set: • TSE bit of TDES3 • FD bit of TDES3

61.3.11.3.1.2 TDES1 Normal Descriptor (Read Format)

Table 61-38. TDES1 Normal Descriptor (Read Format)

Bit	Name	Description
31:0	BUF2AP	Buffer 2 or Buffer 1 Address Pointer

Table 61-38. TDES1 Normal Descriptor (Read Format)

Bit	Name	Description
		This bit indicates the physical address of Buffer 2 when a descriptor ring structure is used. There is no limitation for the buffer address alignment. In 40- or 48-bit addressing mode, these bits indicate the most-significant 8- or 16- bits of the Buffer 1 Address Pointer.

61.3.11.3.1.3 TDES2 Normal Descriptor (Read Format)

Table 61-39. TDES2 Normal Descriptor (Read Format)

31	30	29-16	15:14	13:0
IOC	TTSE/ TMWD	B2L	VTIR	HL or B1L

Table 61-40. TDES2 Normal Descriptor (Read Format)

Bits	Name	Description
31	IOC	Interrupt on Completion This bit controls the setting of TI and ETI status bits in the DMA_CH#_Status register. When ETIC = 1 and TDES2[LD] = 0, this bit sets the ETI bit. When TDES3[LD] = 1, this bit sets the TI status bit.
30	TTSE/TMWD	Transmit Timestamp Enable or External TSO Memory Write Enable This bit enables the IEEE1588 time stamping for Transmit packet referenced by the descriptor, if TSE bit is not set. If TSE bit is set and external TSO memory is enabled, setting this bit disables external TSO memory writing for this packet.
29:16	B2L	Buffer 2 Length The driver sets this field. When set, this field indicates Buffer 2 length.
15:14	VTIR	VLAN Tag Insertion or Replacement These bits request the MAC to perform VLAN tagging or untagging before transmitting the packets. The application must set the CRC Pad Control bits appropriately when VLAN Tag Insertion, Replacement, or Deletion is enabled for the packet. The following list describes the values of these bits:

Table continues on the next page...

Table 61-40. TDES2 Normal Descriptor (Read Format) (continued)

Bits	Name	Description
		• 2'b00: Do not add a VLAN tag. • 2'b01: Remove the VLAN tag from the packets before transmission. This option should be used only with the VLAN packets. • 2'b10: Insert a VLAN tag with the tag value programmed in the MAC_VLAN_Incl register or context descriptor. • 2'b11: Replace the VLAN tag in packets with the tag value programmed in the MAC_VLAN_Incl register or context descriptor. This option should be used only with the VLAN packets. These bits are valid when the Enable SA and VLAN Insertion on Tx option is selected while configuring the core.
13:0	HL or B1L	Header Length or Buffer 1 Length For Header length only bits [9:0] are taken. The size 13:0 is applicable only when interpreting buffer 1 length. If the TCP Segmentation Offload feature is enabled through the TSE bit of TDES3, this field is equal to the header length. When the TSE bit is set in TDES3, the header length includes the length in bytes from Ethernet Source address till the end of the TCP header. The maximum header length supported for TSO feature is 1023 bytes. The maximum header length supported for TSO feature is 1023 bytes. If the TCP Segmentation Offload feature is not enabled, this field is equal to Buffer 1 length.

61.3.11.3.1.4 TDES3 Normal Descriptor (Read Format)

Table 61-41. TDES3 Normal Descriptor (Read Format)

31	30	29	28	27:26	25:23	22:19	18	17:16	15	14:0
OWN	CTXT	FD	LD	CPC	SAIC	SLOTNUM or THL	TSE	CIC/TPL	TPL	FL/TPL

Table 61-42. TDES3 Normal Descriptor (Read Format)

Bits	Name	Description
31	OWN	Own Bit When this bit is set, it indicates that the DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit after it completes the transfer of data given in the associated buffer(s).
30	CTXT	Context Type This bit should be set to 1'b0 for normal descriptor.
29	FD	First Descriptor When this bit is set, it indicates that the buffer contains the first segment of a packet.
28	LD	Last Descriptor When this bit is set, it indicates that the buffer contains the last segment of the packet. When this bit is set, the B1L or B2L field should have a non-zero value.
27:26	CPC	CRC Pad Control This field controls the CRC and Pad Insertion for Tx packet. This field is valid only when the first descriptor bit (TDES3[29]) is set. The following list describes the values of Bits[27:26]: • 2'b00: CRC and Pad Insertion The MAC appends the cyclic redundancy check (CRC) at the end of the transmitted packet of length greater than or equal to 60 bytes. The MAC automatically appends padding and CRC to a packet with length less than 60 bytes. • 2'b01: CRC Insertion (Disable Pad Insertion) The MAC appends the CRC at the end of the transmitted packet but it does not append padding. The application should ensure that the padding bytes are present in the packet being transferred from the Transmit Buffer, that is, the packet being transferred from the Transmit Buffer is of length greater than or equal to 60 bytes. • 2'b10: Disable CRC Insertion

Table continues on the next page...

Table 61-42. TDES3 Normal Descriptor (Read Format) (continued)

Bits	Name	Description
		The MAC does not append the CRC at the end of the transmitted packet. The application should ensure that the padding and CRC bytes are present in the packet being transferred from the Transmit Buffer. • 2'b11: CRC Replacement The MAC replaces the last four bytes of the transmitted packet with recalculated CRC bytes. The application should ensure that the padding and CRC bytes are present in the packet being transferred from the Transmit Buffer. This field is valid only for the first descriptor. Note: When the TSE bit is set, the MAC ignores this field because the CRC and pad insertion is always done for segmentation.
25:23	SAIC	SA Insertion Control These bits request the MAC to add or replace the Source Address field in the Ethernet packet with the value given in the MAC Address 0 or 1 register. The application must set the CRC Pad Control bits appropriately when SA Insertion Control is enabled for the packet. Bit 25 specifies the MAC Address Register (1 or 0) value that is used for Source Address insertion or replacement. The following list describes the values of Bits[24:23]: • 2'b00: Do not include the source address • 2'b01: Include the source address. For reliable transmission, the application must provide frames without source addresses. • 2'b10: Replace the source address. For reliable transmission, the application must provide frames with source addresses. • 2'b11: Reserved

Table continues on the next page...

Table 61-42. TDES3 Normal Descriptor (Read Format) (continued)

Bits	Name	Description
		These bits are valid in the EQOS-DMA, EQOS-AXI, and EQOS-AHB configurations when the Enable SA and VLAN Insertion on Tx option is selected while configuring the core and when the First Segment control bit (TDES3 [29]) is set. This field is valid only for the first descriptor.
22:19	SLOTNUMor THL	SLOTNUM: Slot Number Control Bits in AV Mode These bits indicate the slot interval in which the data should be fetched from the corresponding buffers addressed by TDES0 or TDES1. When the Transmit descriptor is fetched, the DMA compares the slot number value in this field with the slot interval maintained in the RSN field DMA_CH#_Slot_Function_Control_Status. It fetches the data from the buffers only if a value matches. These bits are valid only for the AV channels. THL: TCP/UDP Header Length If the TSE bit is set, this field contains the length of the TCP/UDP header. The minimum value of this field must be 5 for TCP header. The value must be equal to 2 for UDP header. This field is valid only for the first descriptor.
18	TSE	TSO Split header is not supported. The value of this bit is always zero.
17:16	CIC/TPL	Checksum Insertion Control or TCP Payload Length These bits control the checksum calculation and insertion. The following list describes the bit encoding: • 2'b00: Checksum Insertion Disabled. • 2'b01: Only IP header checksum calculation and insertion are enabled.

Table continues on the next page...

Table 61-42. TDES3 Normal Descriptor (Read Format) (continued)

Bits	Name	Description
		• 2'b10: IP header checksum and payload checksum calculation and insertion are enabled, but pseudo-header checksum is not calculated in hardware. • 2'b11: IP Header checksum and payload checksum calculation and insertion are enabled, and pseudo-header checksum is calculated in hardware. This field is valid when the Enable Transmit TCP/IP Checksum Offload option is selected and the TSE bit is reset. When the TSE bit is set, this field contains the upper bits [17:16] of the TCP Payload (or IP Payload for UDP fragmentation). This allows the TCP/UDP packet length field to be spanned across TDES3[17:0] to provide 256 KB packet length support. This field is valid only for the first descriptor.
15	TPL	Reserved or TCP Payload Length When the TSE bit is reset, this bit is reserved. When the TSE bit is set, this is Bit 15 of the TCP payload length [17:0]. This field is valid only when the Enable TCP Segmentation Offloading for TCP/IP Packets option is selected while configuring the core.
14:0	FL/TPL	Frame Length or TCP Payload Length This field is equal to the length of the packet to be transmitted in bytes. When the TSE bit is not set, this field is equal to the total length of the packet to be transmitted: Ethernet Header Length + TCP /IP Header Length – Preamble Length – SFD Length + Ethernet Payload Length When the TSE bit is set, this field is equal to the lower 15 bits of the TCP payload length in case of segmentation and IP payload in case of UDP fragmentation.

Table 61-42. TDES3 Normal Descriptor (Read Format)

Bits	Name	Description
		In case of segmentation, this length does not include Ethernet header or TCP/UDP/IP header length. In case of fragmentation, this length does not include Ethernet header and IP header. When DWRR/WFQ algorithm is NOT enabled, value written into this field is not used when TSE = 0.

61.3.11.3.2 Transmit Normal Descriptor (Write-Back Format)

The write-back format of the Transmit Descriptor includes timestamp low, timestamp high, OWN, and Status bits.

The write-back format is applicable only for the last descriptor of the corresponding packet. The LD bit (TDES3[28]) is set in the descriptor where the DMA writes back the status and timestamp information for the corresponding Transmit packet.

Following figure illustrates the write-back format of the Transmit Descriptor.

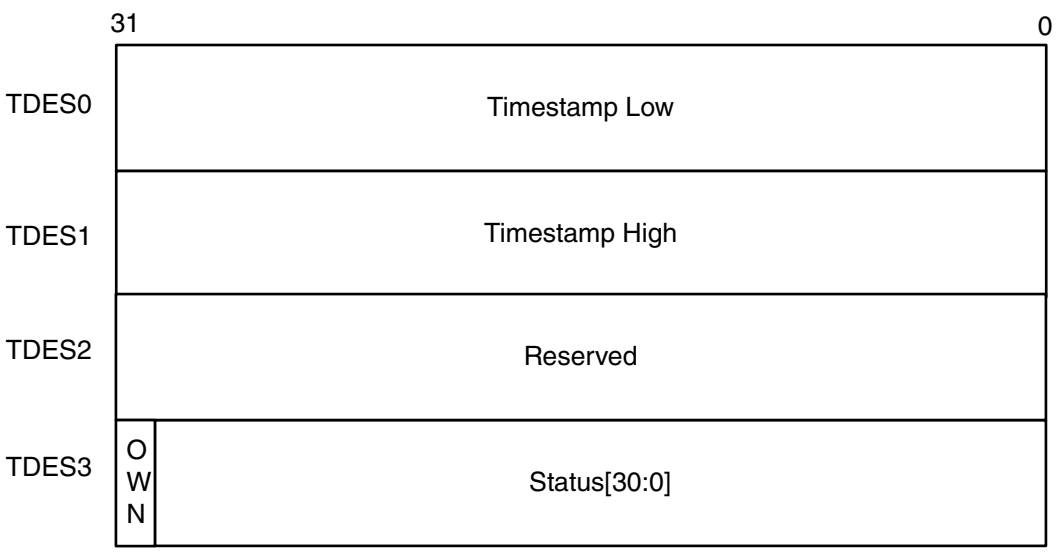


Figure 61-25. Transmit Descriptor Write-Back Format

TDES0 Normal Descriptor (Write-Back Format)

As described in following table, this format is only applicable to the last descriptor of a packet.

Table 61-43. TDES0 Normal Descriptor (Write-Back Format)TDES0 Normal Descriptor (Write-Back Format)

Bit	Name	Description
31:0	TTSL	Transmit Packet Timestamp Low The DMA updates this field with least significant 32 bits of the timestamp captured for the corresponding Transmit packet. The DMA writes the timestamp only if TTSE bit of TDES2 is set in the first descriptor of the packet. This field has the timestamp only if the Last Descriptor bit (LD) in the descriptor is set and the Timestamp status (TTSS) bit is set.

TDES1 Normal Descriptor (Write-Back Format)

As mentioned in the following table, this format is only applicable to the last descriptor of a packet.

Table 61-44. TDES1 Normal Descriptor (Write-Back Format)

Bit	Name	Description
31:0	TTSH	Transmit Packet Timestamp High The DMA updates this field with the most significant 32 bits of the timestamp captured for corresponding transmit packet. The DMA writes the timestamp only if the TTSE bit of TDES2 is set in the first descriptor of the packet. This field has the timestamp only if the Last Descriptor bit (LD) in the descriptor is set and Timestamp status (TTSS) bit is set.

TDES2 Normal Descriptor (Write-Back Format)

This format is applicable only to the last descriptor of a packet.

Table 61-45. TDES2 Normal Descriptor (Write-Back Format)

Bit	Description
31:0	Reserved

TDES3 Normal Descriptor (Write-Back Format)

This format is applicable only to the last descriptor of a packet.

Table 61-46. TDES3 Normal Descriptor (Write-Back Format)

31	30	29	28	27:24	23	22:18	17	16	15	14	13	12	11	10	9	8	7:4	3	2	1	0
OWN	CTXT	FD	LD	Rsvd	DE	Rsvd	TTSS	EUE	ES	JT	FF	PCE	LoC	NC	LC	EC	CC	ED	UF	DB	IHE

Table 61-47. TDES3 Normal Descriptor (Write-Back Format)

Bit	Name	Description
31	OWN	Own Bit When this bit is set, it indicates that the the module DMA owns the descriptor. The DMA clears this bit when it completes the packet transmission. After the write-back is complete, this bit is set to 'b0.
30	CTXT	Context Type This bit should be set to 'b0 for Normal descriptor.
29	FD	First Descriptor This bit indicates that the buffer contains the first segment of a packet.
28	LD	Last Descriptor This bit is set 'b1 for last descriptor of a packet. The DMA writes the status fields only in the last descriptor of the packet.
27:24	Rsvd	Reserved
23	DE	Descriptor Error When this bit is set, it indicates that the descriptor content is incorrect. The DMA sets this bit during write-back while closing the descriptor. Descriptor Errors can be: • Incorrect sequence from the context descriptor. For example, a location after the first descriptor for a packet. • All 1s • CTXT, LD, and FD bits set to 1. Note 1: When Descriptor Error occurs due to All 1s or CTXT, LD, and FD bits set to 1, the Transmit DMA closes the transmit descriptor with DE and LD bits set to 1. When IOC bit in TDES2 of corresponding first descriptor is set to 1, Transmit DMA will set the TI bit in the DMA_CH#_Status register

Table continues on the next page...

Table 61-47. TDES3 Normal Descriptor (Write-Back Format) (continued)

Bit	Name	Description
		Note 2: Based on CTXT, LD, and FD bits of the transmit descriptor, the subsequent descriptor might be considered as the First Descriptor (even if FD bit is not set) and partial packet is sent.
22:18	Rsvd	Reserved
17	TTSS	Tx Timestamp Status This status bit indicates that a timestamp has been captured for the corresponding transmit packet. When this bit is set, TDES0 and TDES1 have timestamp values that were captured for the Transmit packet. This field is valid only when the Last Segment control bit (TDES3 [28]) in a descriptor is set. This bit is valid only when IEEE1588 timestamping feature is enabled; otherwise, it is reserved.
16	EUE	ECC Uncorrectable Error Status Indicates the ECC uncorrectable error in the TSO memory. Note: Uncorrectable error in Transmit FIFO memory is reported with (Bit 13) FF = 1. This is because, all such packets are flushed by the module.
15	ES	Error Summary This bit indicates the logical OR of the following bits: • TDES3[0]: IP Header Error • TDES3[14]: Jabber Timeout • TDES3[13]: Packet Flush • TDES3[12]: Payload Checksum Error • TDES3[11]: Loss of Carrier • TDES3[10]: No Carrier • TDES3[9]: Late Collision • TDES3[8]: Excessive Collision • TDES3[3]: Excessive Deferral • TDES3[2]: Underflow Error This bit is also set when EUE (bit 16) is set.
14	JT	Jabber Timeout

Table continues on the next page...

Table 61-47. TDES3 Normal Descriptor (Write-Back Format) (continued)

Bit	Name	Description
		This bit indicates that the MAC transmitter has experienced a jabber time-out. This bit is set only when the JD bit of the MAC_Configuration register is not set.
13	FF	Packet Flushed This bit indicates that the DMA or MTL flushed the packet because of a software flush command given by the CPU.
12	PCE	Payload Checksum Error This bit indicates that the Checksum Offload engine had a failure and did not insert any checksum into the encapsulated TCP, UDP, or ICMP payload. This failure can be either because of insufficient bytes, as indicated by the Payload Length field of the IP Header or the MTL starting to forward the packet to the MAC transmitter in Store-and-Forward mode without the checksum having been calculated yet. This second error condition only occurs when the Transmit FIFO depth is less than the length of the Ethernet packet being transmitted to avoid deadlock, the MTL starts forwarding the packet when the FIFO is full, even in the store-and-forward mode. This error can also occur when Bus Error is detected during packet transfer. When the Full Checksum Offload engine is not enabled, this bit is reserved.
11	LoC	Loss of Carrier This bit indicates that Loss of Carrier occurred during packet transmission (that is, the gmii_crs_i signal was inactive for one or more transmit clock periods during packet transmission). This is valid only for the packets transmitted without collision and when the MAC operates in the half-duplex mode.
10	NC	No Carrier This bit indicates that the carrier sense signal form the PHY was not asserted during transmission.
9	LC	Late Collision

Table continues on the next page...

Table 61-47. TDES3 Normal Descriptor (Write-Back Format) (continued)

Bit	Name	Description
		This bit indicates that packet transmission was aborted because a collision occurred after the collision window (64 byte times including Preamble in MII mode and 512 byte times including Preamble and Carrier Extension in GMII mode). This bit is not valid if Underflow Error is set.
8	EC	Excessive Collision This bit indicates that the transmission was aborted after 16 successive collisions while attempting to transmit the current packet. If the DR bit is set in the MAC_Configuration register, this bit is set after first collision and the transmission of the packet is aborted.
7:4	CC	Collision Count This 4-bit counter value indicates the number of collisions occurred before the packet was transmitted. The count is not valid when the EC bit is set.
3	ED	Excessive Deferral This bit indicates that the transmission ended because of excessive deferral of over 24,288 bit times (155,680 bits times in 1000 Mbps mode or Jumbo Packet enabled mode) if DC bit is set in the MAC_Configuration register. When TBS is enabled in full duplex mode and this bit is set, it indicates that the frame has been dropped after the expiry time has reached.
2	UF	Underflow Error This bit indicates that the MAC aborted the packet because the data arrived late from the system memory. The underflow error can occur because of either of the following conditions: • The DMA encountered an empty Transmit Buffer while transmitting the packet • The application filled the MTL Tx FIFO slower than the MAC transmit rate The transmission process enters the suspended state and sets the underflow bit corresponding to a queue in the MTL_Interrupt_Status register.
1	DB	Deferred Bit

Table continues on the next page...

Table 61-47. TDES3 Normal Descriptor (Write-Back Format) (continued)

Bit	Name	Description
		This bit indicates that the MAC deferred before transmitting because of presence of carrier. This bit is valid only in the half-duplex mode.
0	IHE	IP Header Error When IP Header Error is set, this bit indicates that the Checksum Offload engine detected an IP header error. This bit is valid only when Tx Checksum Offload is enabled. Otherwise, it is reserved. If COE detects an IP header error, it still inserts an IPv4 header checksum if the Ethernet Type field indicates an IPv4 payload. In full duplex mode, when EST/Qbv is enabled and this bit is set, it indicates the frame drop status due to Frame Size error or Schedule Error.

61.3.11.3.3 Transmit Context Descriptor

The context descriptor is used to provide the timestamps for one-step timestamp correction, VLAN Tag ID for VLAN insertion feature.

The Transmit Context descriptor can be provided any time before a packet descriptor. The context is valid for the current packet and subsequent packets. The context descriptor is used to provide the timestamps for one-step timestamp correction and VLAN Tag ID for VLAN insertion feature. Write back is done on a context descriptor only to reset the OWN bit.

NOTE

The VLAN Tag IDs and MSS values, provided by the application in a context descriptor with their corresponding Valid bits set, are stored internally by the DMA. When the outer or inner VLAN tag is provided with the Valid bit set, the DMA always passes the last valid VLAN tag to the MTL. The application cannot invalidate the valid VLAN tag stored by the DMA. The VLAN tag is inserted or replaced based on the control inputs provided for the packet.

The Inner VLAN Tag Control input is used only for the next packet that immediately follows the context descriptor. The application must provide a context descriptor before the normal descriptor of each packet for which the DMA should use the inner VLAN Tag control input.

The following figure shows the format of the Transmit Context descriptor.

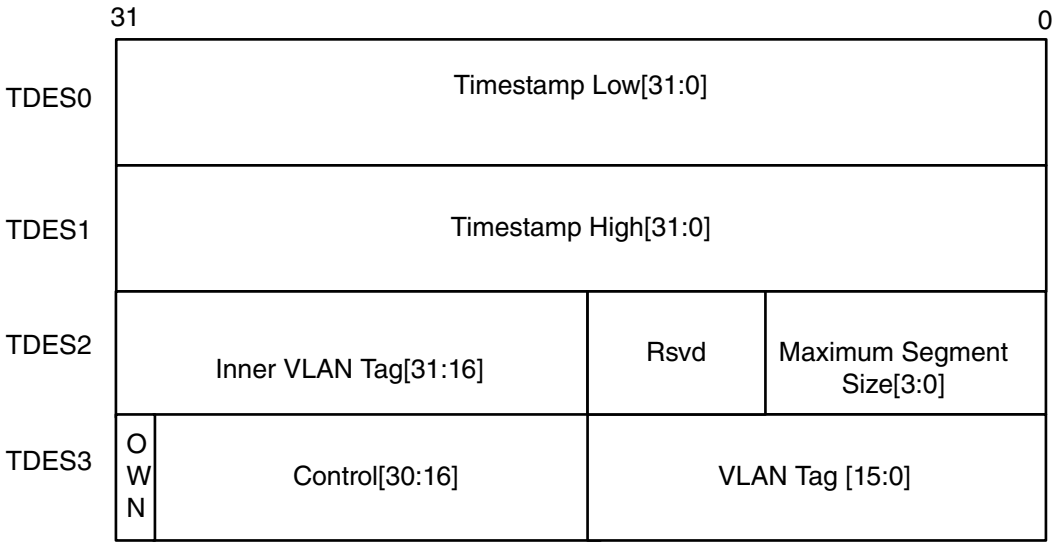

Figure 61-26. Transmit Context Descriptor Format

61.3.11.3.3.1 TDES0 Context Descriptor

Following table describes the format of the TDES0 Context descriptor.

Table 61-48. TDES0 Context Descriptor

Bit	Name	Description
31:0	TTSL	Transmit Packet Timestamp Low For one-step correction, the driver can provide the lower 32 bits of timestamp in this descriptor word. The DMA uses this value as the low word for doing one-step timestamp correction. This field is valid only if the OSTC and TCMSSV bits of TDES3 context descriptor are set.

61.3.11.3.3.2 TDES1 Context Descriptor

Following table describes the format of the TDES1 Context descriptor.

Table 61-49. TDES1 Context Descriptor

Bit	Name	Description
31:0	TTSH	Transmit Packet Timestamp High For one-step correction, the driver can provide the upper 32 bits of timestamp in this descriptor. The DMA uses this value as the high word for doing one-step timestamp correction. This field is valid only if the OSTC and TCMSSV bits of TDES3 context descriptor are set.

61.3.11.3.3.3 TDES2 Context Descriptor

Following table explains the format of the TDES2 Context descriptor.

Table 61-50. TDES2 Context Descriptor

Bit	Name	Description
31:16	IVT	Inner VLAN Tag When the IVLTV bit of TDES3 context descriptor is set and the TCMSSV and OSTC bits of TDES3 context descriptor are reset, TDES2[31:16] contains the inner VLAN Tag to be inserted in the subsequent Transmit packets.
15:14	Rsvd	Reserved
13:0	MSS	TSO Split header is not supported. The value of this bit is always zero.

61.3.11.3.3.4 TDES3 Context Descriptor

Table 61-51. TDES3 Context Descriptor

31	30	29:28	27	26	25:24	23	22:18	17	16	15:0
OWN	CTXT	Rsvd	OSTC	TCMSSV	Rsvd	CDE	Rsvd	IVLTV	VLTV	VT

Follwoing table details the format of the TDES3 Context descriptor.

Table 61-52. TDES3 Context Descriptor

Bit	Name	Description
31	OWN	Own Bit When this bit is set, it indicates that the module DMA owns the descriptor. When this bit is reset, it indicates that the

Table continues on the next page...

Table 61-52. TDES3 Context Descriptor (continued)

Bit	Name	Description
		application owns the descriptor. The DMA clears this bit immediately after the read.
30	CTXT	Context Type This bit should be set to 1'b1 for Context descriptor.
29:28	Rsvd	Reserved
27	OSTC	One-Step Timestamp Correction Enable When this bit is set, the DMA performs a one-step timestamp correction with reference to the timestamp values provided in TDES0 and TDES1.
26	TCMSSV	One-Step Timestamp Correction Input or MSS Valid When this bit and the OSTC bit are set, it indicates that the Timestamp Correction input provided in TDES0 and TDES1 is valid. When the OSTC bit is reset and this bit and the TSE bit of TDES3 are set in subsequent normal descriptor, it indicates that the MSS input in TDES2 is valid.
25:24	Rsvd	Reserved
23	CDE	Context Descriptor Error When this bit is set, it indicates that the descriptor content is incorrect.The DMA sets this bit during write-back while closing the context descriptor. Descriptor Errors can be: • Incorrect sequence from the context descriptor. For example, a location before the first descriptor for a packet. • All 1s. • CD, LD, and FD bits set to 1. Note 1: When Descriptor Error occurs due to All 1s or CTXT, LD, and FD bits set to 1, the Transmit DMA closes the transmit descriptor with DE and LD bits set to 1. When IOC bit in TDES2 of corresponding first descriptor is set to 1, Transmit DMA will set the TI bit in the DMA_CH#_Status register Note 2: Based on CTXT, LD, and FD bits of the transmit descriptor, the subsequent descriptor might be

Table continues on the next page...

Table 61-52. TDES3 Context Descriptor (continued)

Bit	Name	Description
		considered as the First Descriptor (even if FD bit is not set) and partial packet is sent.
22:20	Rsvd	Reserved
19:18	IVTIR	Inner VLAN Tag Insert or Replace When this bit is set, these bits request the MAC to perform Inner VLAN tagging or un-tagging before transmitting the packets. If the packet is modified for VLAN tags, the MAC automatically recalculates and replaces the CRC bytes. The following list describes the values of these bits: • 2'b00: Do not add the inner VLAN tag. • 2'b01: Remove the inner VLAN tag from the packets before transmission. This option should be used only with the VLAN frames. • 2'b10: Insert an inner VLAN tag with the tag value programmed in the MAC_In-ner_VLAN_Incl register or context descriptor. • 2'b11: Replace the inner VLAN tag in packets with the tag value programmed in the MAC_Inner_VLAN_Incl register or context descriptor. This option should be used only with the VLAN frames. These bits are valid when the Enable SA and VLAN Insertion on Tx and Enable Double VLAN Processing options are selected.
17	IVLTV	Inner VLAN Tag Valid When this bit is set, it indicates that the IVT field of TDES2 is valid.
16	VLTV	VLAN Tag Valid When this bit is set, it indicates that the VT field of TDES3 is valid.
15:0	VT	VLAN Tag This field contains the VLAN Tag to be inserted or replaced in the packet. This field is used as VLAN Tag only when the VLTI bit of the MAC_VLAN_Incl register is reset.

61.3.11.4 Receive Descriptor

The DMA in the module attempts to read a descriptor only if the Tail Pointer is different from the Base Pointer or current pointer. It is recommended to have a descriptor ring with a length that can accommodate at least two complete packets received by the MAC. Otherwise, the performance of the DMA is impacted greatly because of the unavailability of the descriptors. In such situations, the RxFIFO in MTL becomes full and starts dropping packets.

The following Receive Descriptors are present:

- Normal descriptors
- Context descriptors

All RX descriptors are prepared by the software and given to the DMA as "Normal" Descriptors with the content as shown in Receive Normal Descriptor (Read Format). The DMA reads this descriptor and after transferring a received packet (or part of) to the buffers indicated by the descriptor, the Rx DMA will close the descriptor with the corresponding packet status. The format of this status is given in the "Receive Normal Descriptor (Write-Back Format)".

For some packets, the normal descriptor bits are not enough to write the complete status. For such packets, the RX DMA writes the extended status to the next descriptor (without processing or using the Buffers/ Pointers embedded in that descriptor). The format and content of the descriptor write back is described in "Receive Context Descriptor".

61.3.11.4.1 Receive Normal Descriptor (Read Format)

The read format for a Receive Normal descriptor is made up of a header or Buffer 1 address, reserved field, payload or Buffer 2 or Next Descriptor address, a 30-bit reserved filed, OWN bit, and an interrupt bit.

Following figure shows the Read Format for a Receive Normal Descriptor.

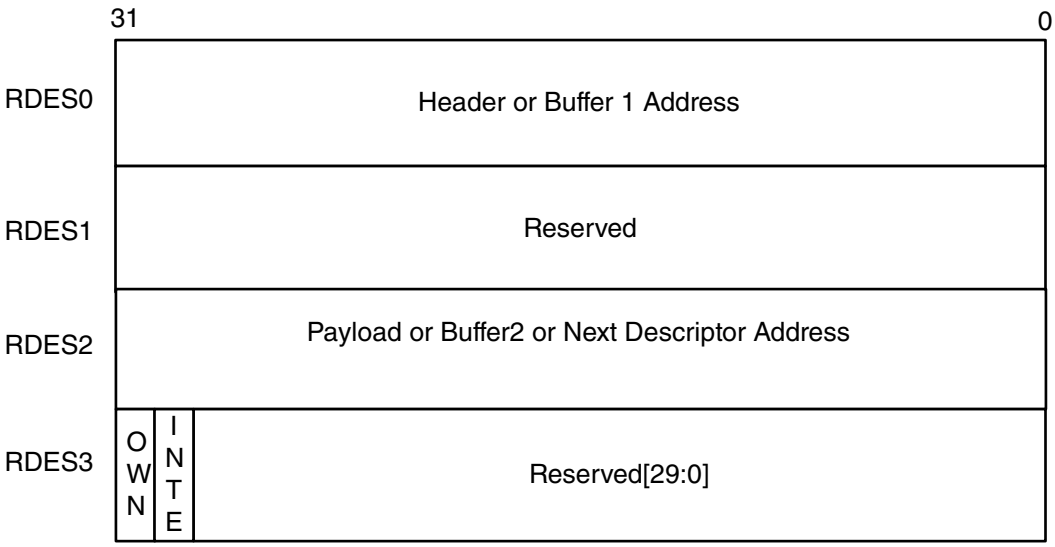

Figure 61-27. Receive Normal Descriptor Read Format

NOTE

In the Receive Descriptor (Read Format), if the Buffer Address field is all 0s, the module does not transfer data to that buffer and skips to the next buffer or next descriptor.

61.3.11.4.1.1 RDES0 Normal Descriptor (Read Format)

Following table explains the read format of the RDES0 Normal Descriptor.

Table 61-53. RDES0 Normal Descriptor (Read Format)

Bit	Name	Description
31:0	BUF1AP	Header or Buffer 1 Address Pointer When the SPH bit of Control register of a channel is reset, these bits indicate the physical address of Buffer 1. When the SPH bit is set, these bits indicate the physical address of Header Buffer where the Rx DMA writes the L2/L3/L4 header bytes of the received packet. The application can program a byte-aligned address for this buffer which means that the LS bits of this field can be non-zero. However, while transferring the start of packet, the DMA performs a Write operation with RDES0[1:0] (or RDES0[2:0]/[3:0] in case of 64-/128-bit configuration) as zero. However, the packet data is shifted as per actual offset as given by buffer address pointer.

Table 61-53. RDES0 Normal Descriptor (Read Format)

Bit	Name	Description
		If the address pointer points to a buffer where the middle or last part of the packet is stored, the DMA ignores the offset address and writes to the full location as indicated by the data-width.

61.3.11.4.1.2 RDES1 Normal Descriptor (Read Format)

Following table describes the read format of the RDES1 Normal Descriptor.

Table 61-54. RDES1 Normal Descriptor (Read Format)

Bit	Name	Description
31:0	Reserved or BUF1AP	In 64-bit addressing mode, this field contains the most-significant 32 bits of the Buffer 1 Address Pointer. Otherwise, this field is reserved.

61.3.11.4.1.3 RDES2 Normal Descriptor (Read Format)

Following table provides the read format of the RDES2 Normal Descriptor.

Table 61-55. RDES2 Normal Descriptor (Read Format)

Bit	Name	Description
31:0	BUF2AP	Buffer 2 Address Pointer These bits indicate the physical address of Buffer 2. When the SPH bit of the DMA_CH#_Control register is set, the buffer address pointer must be bus width-aligned, that is, RDES2[3:0, 2:0, or 1:0] = 0 corresponding to 128, 64, or 32 bus width. LSBs are ignored internally. When the SPH bit of the DMA_CH#_Control register is reset, there is no limitations on the RDES2 value. However, the RxDMA uses the LS Bits of the pointer address only while transferring the start bytes of a packet. If the BUF2AP is giving the address of a buffer in which the middle or last part of a packet is stored, the DMA ignores BUF2AP[3:0 or 2:0 or 1:0] (corresponding to 128- or 64- or 32-bit data-bus) and writes to the complete location.

61.3.11.4.1.4 RDES3 Normal Descriptor (Read Format)

Following table describes the read format of the RDES3 Normal Descriptor.

31	30	19-26	25	24	23:0
OWN	IOC	Rsvd	BUF2V	BUF1V	Rsvd

Table 61-56. RDES3 Normal Descriptor (Read Format)

Bit	Name	Description
31	OWN	Own Bit When this bit is set, it indicates that the module DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit when either of the following conditions is true: • The DMA completes the packet reception • The buffers associated with the descriptor are full
30	IOC	Interrupt Enabled on Completion When this bit is set, an interrupt is issued to the application when the DMA closes this descriptor.
29:26	Rsvd	Reserved
25	BUF2V	Buffer 2 Address Valid When this bit is set, it indicates to the DMA that the buffer 2 address specified in RDES2 is valid. The application must set this bit so that the DMA can use the address, to which the Buffer 2 address in RDES2 is pointing, to write received packet data.
24	BUF1V	Buffer 1 Address Valid When set, this indicates to the DMA that the buffer 1 address specified in RDES1 is valid. The application must set this value if the address pointed to by Buffer 1 address in RDES1 can be used by the DMA to write received packet data.
23:0	Rsvd	Reserved

61.3.11.4.2 Receive Normal Descriptor (Write-Back Format)

The following figure illustrates the write-back format for a Receive Normal descriptor.

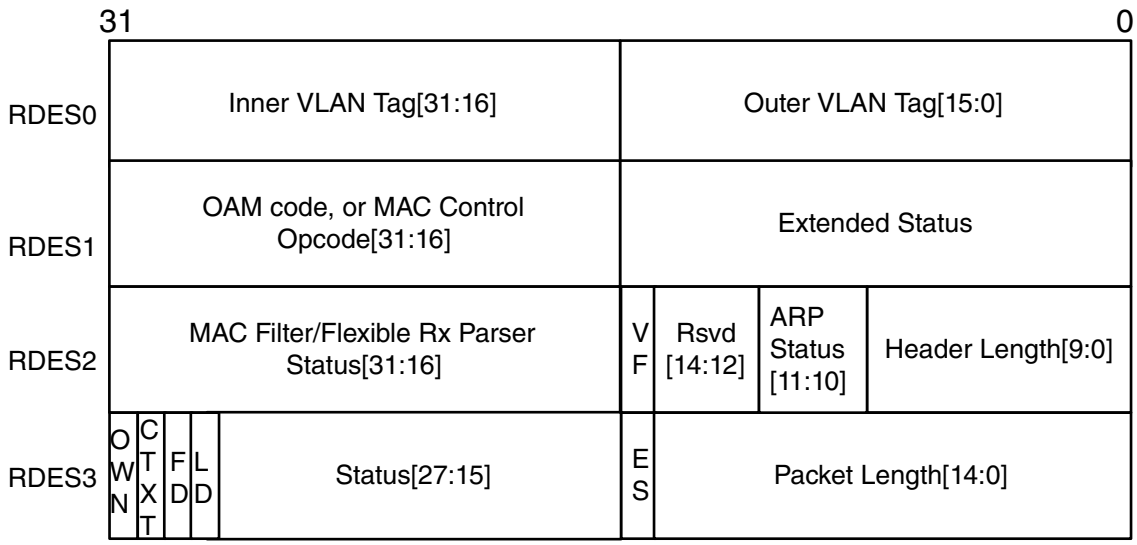

Figure 61-28. Receive Normal Descriptor (Write-Back Format)

NOTE

When Flexible RX Parser is enabled, RDES2[31:16] indicates Parser status, and not the MAC filter status. MAC filter status is not available when Flexible RX parser is enabled.

61.3.11.4.2.1 RDES0 Normal Descriptor (Write-Back Format)

Following table describes the write-back format for the RDES0 Normal Descriptor.

Table 61-57. RDES0 Normal Descriptor (Write-Back Format)

Bit	Name	Description
31:16	IVT	Inner VLAN Tag This field contains the Inner VLAN tag of the received packet if the RS0V bit of RDES3 is set. This is valid only when Double VLAN tag processing and VLAN tag stripping are enabled.
15:0	OVT	Outer VLAN Tag This field contains the Outer VLAN tag of the received packet if the RS0V bit of RDES3 is set.

61.3.11.4.2.2 RDES1 Normal Descriptor (Write-Back Format)

The Status fields in write-back format are valid only for the last descriptor (RDES3[28] is set). Following table provides the details of the write-back format for RDES1 Normal Descriptor.

31:16	15	14	13	12	11:8	7	6	5	4	3	2:0
OPC	TD	TSA	PV	PFT	PMT	IPCE	IPCB	IPV6	IPV4	IPHE	PT

Table 61-58. RDES1 Normal Descriptor (Write-Back Format)

Bit	Name	Description
31:16	OPC	OAM Sub-Type Code, or MAC Control Packet opcode OAM Sub-Type Code If Bits[18:16] of RDES3 are set to 3'b111, this field contains the OAM sub-type and code fields. MAC Control Packet opcode The bits[15:8] of RDES3 contains the subtype and bits [7:0] contains the code.
15	TD	Timestamp Dropped This bit indicates that the timestamp was captured for this packet but it got dropped in the MTL Rx FIFO because of overflow. This bit is available only when you select the Timestamp feature. Otherwise, this bit is reserved.
14	TSA	Timestamp Available When Timestamp is present, this bit indicates that the timestamp value is available in a context descriptor word 2 (RDES2) and word 1(RDES1). This is valid only when the Last Descriptor bit (RDES3 [28]) is set. The context descriptor is written in the next descriptor just after the last normal descriptor for a packet.
13	PV	PTP Version This bit indicates that the received PTP message has the IEEE 1588 version 2 format. When this bit is reset, it indicates the IEEE 1588 version 1 format. This bit is available only when you select the Timestamp feature. Otherwise, this bit is reserved.

Table continues on the next page...

Table 61-58. RDES1 Normal Descriptor (Write-Back Format) (continued)

Bit	Name	Description
12	PFT	PTP Packet Type This bit indicates that the PTP message is sent directly over Ethernet. This bit is available only when you select the Timestamp feature. Otherwise, this bit is reserved.
11:8	PMT	PTP Message Type These bits are encoded to give the type of the message received: • 0000: No PTP message received • 0001: SYNC (all clock types) • 0010: Follow_Up (all clock types) • 0011: Delay_Req (all clock types) • 0100: Delay_Resp (all clock types) • 0101: Pdelay_Req (in peer-to-peer transparent clock) • 0110: Pdelay_Resp (in peer-to-peer transparent clock) • 0111: Pdelay_Resp_Follow_Up (in peer-to-peer transparent clock) • 1000: Announce • 1001: Management • 1010: Signaling • 1011–1110: Reserved • 1111: PTP packet with Reserved message type These bits are available only when you select the Timestamp feature.
7	IPCE	IP Payload Error When this bit is set, it indicates either of the following: • The 16-bit IP payload checksum (that is, the TCP, UDP, or ICMP checksum) calculated by the MAC does not match the corresponding checksum field in the received segment.

Table continues on the next page...

Table 61-58. RDES1 Normal Descriptor (Write-Back Format) (continued)

Bit	Name	Description
		• The TCP, UDP, or ICMP segment length does not match the payload length value in the IP Header field. • The TCP, UDP, or ICMP segment length is less than minimum allowed segment length for TCP, UDP, or ICMP. Bit 15 (ES) of RDES3 is not set when this bit is set.
6	IPCB	IP Checksum Bypassed This bit indicates that the checksum offload engine is bypassed. This bit is available when you select the Enable Receive TCP/IP Checksum Check feature.
5	IPV6	IPv6 header Present This bit indicates that an IPV6 header is detected. When the Enable Split Header Feature option is selected and the SPH bit of Control Register of a channel is set, the IPV6 header is available in the header buffer area to which RDES0 is pointing.
4	IPV4	IPV4 Header Present This bit indicates that an IPV4 header is detected. When the SPH bit of RDES3 is set, the IPV4 header is available in the header buffer area to which RDES0 is pointing.
3	IPHE	IP Header Error When this bit is set, it indicates either of the following: • The 16-bit IPv4 header checksum calculated by the MAC does not match the received checksum bytes. • The IP datagram version is not consistent with the Ethernet Type value. • Ethernet packet does not have the expected number of IP header bytes. This bit is valid when either Bit 5 or Bit 4 is set. This bit is available when you select the Enable Receive TCP/IP Checksum Check feature.
2:0	PT	Payload Type

Table 61-58. RDES1 Normal Descriptor (Write-Back Format)

Bit	Name	Description
		These bits indicate the type of payload encapsulated in the IP datagram processed by the Receive Checksum Offload Engine (COE): • 3'b000: Unknown type or IP/AV payload not processed • 3'b001: UDP • 3'b010: TCP • 3'b011: ICMP • 3'b110: AV Tagged Data Packet • 3'b111: AV Tagged Control Packet • 3'b101: AV Untagged Control Packet • 3'b100: IGMP if IPV4 Header Present bit is set else DCB (LLDP) Control Packet If the COE does not process the payload of an IP datagram because there is an IP header error or fragmented IP, it sets these bits to 3'b000.

61.3.11.4.2.3 RDES2 Normal Descriptor (Write-Back Format)

31:29	28	27	26:19	18	17	16	15	14	13:11	10	9:0
L3L4FM	L4FM	L3FM	MADRM	HF	DAF	SAF	OTS	ITS	Rsvd	ARPNR	HL

Table 61-59. RDES2 Normal Descriptor (Write-Back Format)

Bit	Name	Description
31:29	L3L4FM	Layer 3 and Layer 4 Filter Number Matched These bits indicate the number of the Layer 3 and Layer 4 Filter that matched the received packet: • 000: Filter 0 • 001: Filter 1 • 010: Filter 2 • 011: Filter 3 • 100: Filter 4 • 101: Filter 5

Table continues on the next page...

Table 61-59. RDES2 Normal Descriptor (Write-Back Format) (continued)

Bit	Name	Description
		• 110: Filter 6 • 111: Filter 7 This field is valid only when Bit 28 or Bit 27 is set high. When more than one filter matches, these bits give the number of lowest filter. Note: This status is not available when Flexible RX Parser is enabled.
28	L4FM	Layer 4 Filter Match When this bit is set, it indicates that the received packet matches one of the enabled Layer 4 Port Number fields. This status is given only when one of the following conditions is true: • Layer 3 fields are not enabled and all enabled Layer 4 fields match • All enabled Layer 3 and Layer 4 filter fields match When more than one filter matches, this bit gives the layer 4 filter status of filter indicated by Bits[31:29]. Note: This status is not available when Flexible RX Parser is enabled.
27	L3FM	Layer 3 Filter Match When this bit is set, it indicates that the received packet matches one of the enabled Layer 3 IP Address fields. This status is given only when one of the following conditions is true: • All enabled Layer 3 fields match and all enabled Layer 4 fields are bypassed • All enabled filter fields match When more than one filter matches, this bit gives the layer 3 filter status of filter indicated by Bits[31:29]. Note: This status is not available when Flexible RX Parser is enabled.
26:19	MADRM	MAC Address Match or Hash Value When the HF bit is reset, this field contains the MAC address register number that matched the Destination address of the received packet. This field is valid only if the DAF bit is reset.

Table continues on the next page...

Table 61-59. RDES2 Normal Descriptor (Write-Back Format) (continued)

Bit	Name	Description
		When the HF bit is set, this field contains the hash value computed by the MAC. A packet passes the hash filter when the bit corresponding to the hash value is set in the hash filter register. Note: This status is not available when Flexible RX Parser is enabled.
18	HF	Hash Filter Status When this bit is set, it indicates that the packet passed the MAC address hash filter. Bits[26:19] indicate the hash value. Note: This status is not available when Flexible RX Parser is enabled.
17	DAF/RXPI	Destination Address Filter Fail When Flexible RX Parser is disabled, and this bit is set, it indicates that the packet failed the DA Filter in the MAC. When Flexible RX Parser is enabled, this bit is set to indicate that the packet parsing is incomplete (RXPI) due to ECC error. Note: When this bit is set, ES bit of RDES3 is also set.
16	SAF/RXPD	SA Address Filter Fail When Flexible RX Parser is disabled, and this bit is set, it indicates that the packet failed the SA Filter in the MAC. When Flexible RX Parser is enabled, this bit is set to indicate that the packet is dropped (RXPD) by the parser. Note: When this bit is set, ES bit of RDES3 is also set.
15	OTS	VLAN Filter Status When set, this bit indicates that the VLAN Tag of the received packed passed the VLAN filter. This bit is redefined as Outer VLAN Tag Filter Status (OTS). This bit is valid for both Single and Double VLAN Tagged frames
14	ITS	Inner VLAN Tag Filter Status (ITS) This bit is valid only for Double VLAN Tagged frames, when Double VLAN Processing is enabled. For more information, see Filter Status.
13:11	Rsvd	Reserved

Table continues on the next page...

Table 61-59. RDES2 Normal Descriptor (Write-Back Format) (continued)

Bit	Name	Description
10	ARPNR	ARP Reply Not Generated When this bit is set, it indicates that the MAC did not generate the ARP Reply for received ARP Request packet. This bit is set when the MAC is busy transmitting ARP reply to earlier ARP request (only one ARP request is processed at a time). This bit is reserved when the Enable IPv4 ARP Offload option is not selected.
9:0	HL	L3/L4 Header Length This field contains the length of the header of the packet split by the MAC at L3 or L4 header boundary as identified by the MAC receiver. This field is valid only when the first descriptor bit is set (FD = 1). The header data is written to the Buffer 1 address of corresponding descriptor. If header length is zero, this field is not valid. It implies that the MAC did not identify and split the header. This field is valid when the Enable Split Header Feature option is selected.

61.3.11.4.2.4 RDES3 Normal Descriptor (Write-Back Format)

Following table describes the write-back format for the RDES3 Normal Descriptor.

31	30	29	28	27	26	25	24	23	22	21	20	19	18:16	15	14:0
OWN	CTXT	FD	LD	RS2V	RS1V	RS0V	CE	GP	RWT	OE	RE	DE	LT	ES	PL

Table 61-60. RDES3 Normal Descriptor (Write-Back Format)

Bit	Name	Description
31	OWN	Own Bit When this bit is set, it indicates that the module DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit when either of the following conditions is true:

Table continues on the next page...

Table 61-60. RDES3 Normal Descriptor (Write-Back Format) (continued)

Bit	Name	Description
		• The DMA completes the packet reception • The buffers associated with the descriptor are full
30	CTXT	Receive Context Descriptor When this bit is set, it indicates that the current descriptor is a context type descriptor. The DMA writes 1'b0 to this bit for normal receive descriptor. When CTXT and FD bits are used together, {CTXT, FD} • 2'b00: Intermediate Descriptor • 2'b01: First Descriptor • 2'b10: Reserved • 2'b11: Descriptor Error (due to all 1s) Note: When Descriptor Error occurs, the Receive DMA closes the receive descriptor indicating Descriptor Error. This receive descriptor is skipped and the buffer addresses are not used to write the packet data Receive DMA will set the CDE bit in DMA_CH#_Status register but not the RI bit even when IOC is set, as this is not marked as last receive descriptor for the packet. The subsequent valid receive descriptor is used to write the packet data.
29	FD	First Descriptor When this bit is set, it indicates that this descriptor contains the first buffer of the packet. If the size of the first buffer is 0, the second buffer contains the beginning of the packet. If the size of the second buffer is also 0, the next descriptor contains the beginning of the packet. See the CTXT bit description for details of using the CTXT bit and FD bit together.
28	LD	Last Descriptor When this bit is set, it indicates that the buffers to which this descriptor is pointing are the last buffers of the packet.
27	RS2V	Receive Status RDES2 Valid

Table continues on the next page...

Table 61-60. RDES3 Normal Descriptor (Write-Back Format) (continued)

Bit	Name	Description
		When this bit is set, it indicates that the status in RDES2 is valid and it is written by the DMA. This bit is valid only when the LD bit of RDES3 is set.
26	RS1V	Receive Status RDES1 Valid When this bit is set, it indicates that the status in RDES1 is valid and it is written by the DMA. This bit is valid only when the LD bit of RDES3 is set.
25	RS0V	Receive Status RDES0 Valid When this bit is set, it indicates that the status in RDES0 is valid and it is written by the DMA. This bit is valid only when the LD bit of RDES3 is set.
24	CE	CRC Error When this bit is set, it indicates that a Cyclic Redundancy Check (CRC) Error occurred on the received packet. This field is valid only when the LD bit of RDES3 is set.
23	GP	Giant Packet When this bit is set, it indicates that the packet length exceeds the specified maximum Ethernet size of 1518, 1522, or 2000 bytes (9018 or 9022 bytes if jumbo packet enable is set). Note: Giant packet indicates only the packet length. It does not cause any packet truncation.
22	RWT	Receive Watchdog Timeout When this bit is set, it indicates that the Receive Watchdog Timer has expired while receiving the current packet. The current packet is truncated after watchdog timeout.
21	OE	Overflow Error When this bit is set, it indicates that the received packet is damaged because of buffer overflow in Rx FIFO. Note: This bit is set only when the DMA transfers a partial packet to the application. This happens only when the Rx FIFO is operating in the threshold mode. In the store-and-forward mode, all partial packets are dropped completely in Rx FIFO.
20	RE	Receive Error

Table continues on the next page...

Table 61-60. RDES3 Normal Descriptor (Write-Back Format) (continued)

Bit	Name	Description
		When this bit is set, it indicates that the gmii_rxer_i signal is asserted while the gmii_rxdv_i signal is asserted during packet reception. This error also includes carrier extension error in the GMII and half-duplex mode. Error can be of less or no extension, or error (rxd!= 0f) during extension.
19	DE	Dribble Bit Error When this bit is set, it indicates that the received packet has a non-integer multiple of bytes (odd nibbles). This bit is valid only in the MII Mode.
18:16	LT	Length/Type Field This field indicates if the packet received is a length packet or a type packet. The encoding of the 3 bits is as follows: • 3'b000: The packet is a length packet • 3'b001: The packet is a type packet. • 3'b011: The packet is a ARP Request packet type • 3'b100: The packet is a type packet with VLAN Tag • 3'b101: The packet is a type packet with Double VLAN Tag • 3'b110: The packet is a MAC Control packet type • 3'b111: The packet is a OAM packet type • 3'b010: Reserved
15	ES	Error Summary When this bit is set, it indicates the logical OR of the following bits: • RDES3[24]: CRC Error • RDES3[19]: Dribble Error • RDES3[20]: Receive Error • RDES3[22]: Watchdog Timeout • RDES3[21]: Overflow Error • RDES3[23]: Giant Packet • RDES2[17]: Destination Address Filter Fail, when Flexible RX Parser is enabled

Table continues on the next page...

Table 61-60. RDES3 Normal Descriptor (Write-Back Format) (continued)

Bit	Name	Description
		• RDES2[16]: SA Address Filter Fail, when Flexible RX Parser is enabled • RDES2[13:11]: Receive Parser Overflow Errors (3'b010) This field is valid only when the LD bit of RDES3 is set.
14:0	PL	Packet Length These bits indicate the byte length of the received packet that was transferred to system memory (including CRC). This field is valid when the LD bit of RDES3 is set and Overflow Error bits are reset. The packet length also includes the two bytes appended to the Ethernet packet when IP checksum calculation is enabled and the received packet is not a MAC control packet. This field is valid when the LD bit of RDES3 is set. When the Last Descriptor and Error Summary bits are not set, this field indicates the accumulated number of bytes that have been transferred for the current packet.

61.3.11.4.3 Receive Context Descriptor

This descriptor is read-only for the application. Only the DMA can write to this descriptor. The context descriptor provides information about the extended status related to the last received packet. The Bit 30 of RDES3 indicates the context type descriptor.

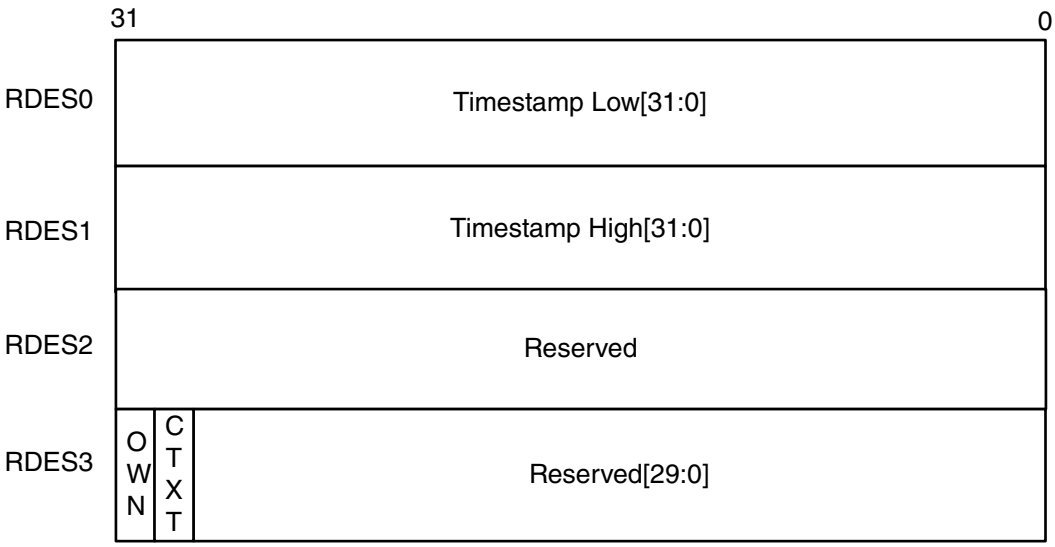

Figure 61-29. Receive Context Descriptor Format

61.3.11.4.3.1 RDES0 Context Descriptor

Table 61-61. RDES0 Context Descriptor

Bit	Name	Description
31:0	RTSL	Receive Packet Timestamp Low The DMA updates this field with least significant 32 bits of the timestamp captured for corresponding Receive packet. When this field and the RTSH field of RDES1 show all-ones value, the timestamp must be considered as corrupt.

61.3.11.4.3.2 RDES1 Context Descriptor

Table 61-62. RDES1 Context Descriptor

Bit	Field	Description
31:0	RTSH	Receive Packet Timestamp High The DMA updates this field with most significant 32 bits of the timestamp captured for corresponding receive packet. When this field and the RTSL field of RDES0 show all-ones value, the timestamp must be considered as corrupt.

61.3.11.4.3.3 RDES2 Context Descriptor

Bit	Name	Description
		register but not the RI bit even when IOC is set, as this is not marked as last receive descriptor for the packet. The subsequent valid receive descriptor is used to write the packet data.
29	DE	Descriptor Error See the CTXT bit description for details of using theDE bit along with CTXT bit.
28:0	Rsvd	Reserved

61.3.11.5 Enhanced Descriptor for Time-Based Scheduling

The time-based scheduling feature needs 32 bytes Enhanced Descriptors to be enabled on all the DMA channels that intend to use the feature (by setting the EDSE bit of DMA_CH(#i)_TX_Control register).

The structure of 32-byte Descriptor for the Context and the Normal Descriptor in Read and Write formats are described in the following sections.

61.3.11.5.1 Enhanced Normal Descriptor - Read (32-Bit Mode)

The fields present in the first 16 bytes of the Enhanced Descriptor format of normal descriptor are as follows:

- LTV

  Launch Time Valid indicates the Launch Time (LT) and GSN fields present in the descriptor are valid. The LTV must be set only if the FD bit of the descriptor is not.
- GSN

  This field indicates the GCL slot number associated with the packet.
- Launch Time (LT)

  This field indicates the Launch Time associated with the packet.

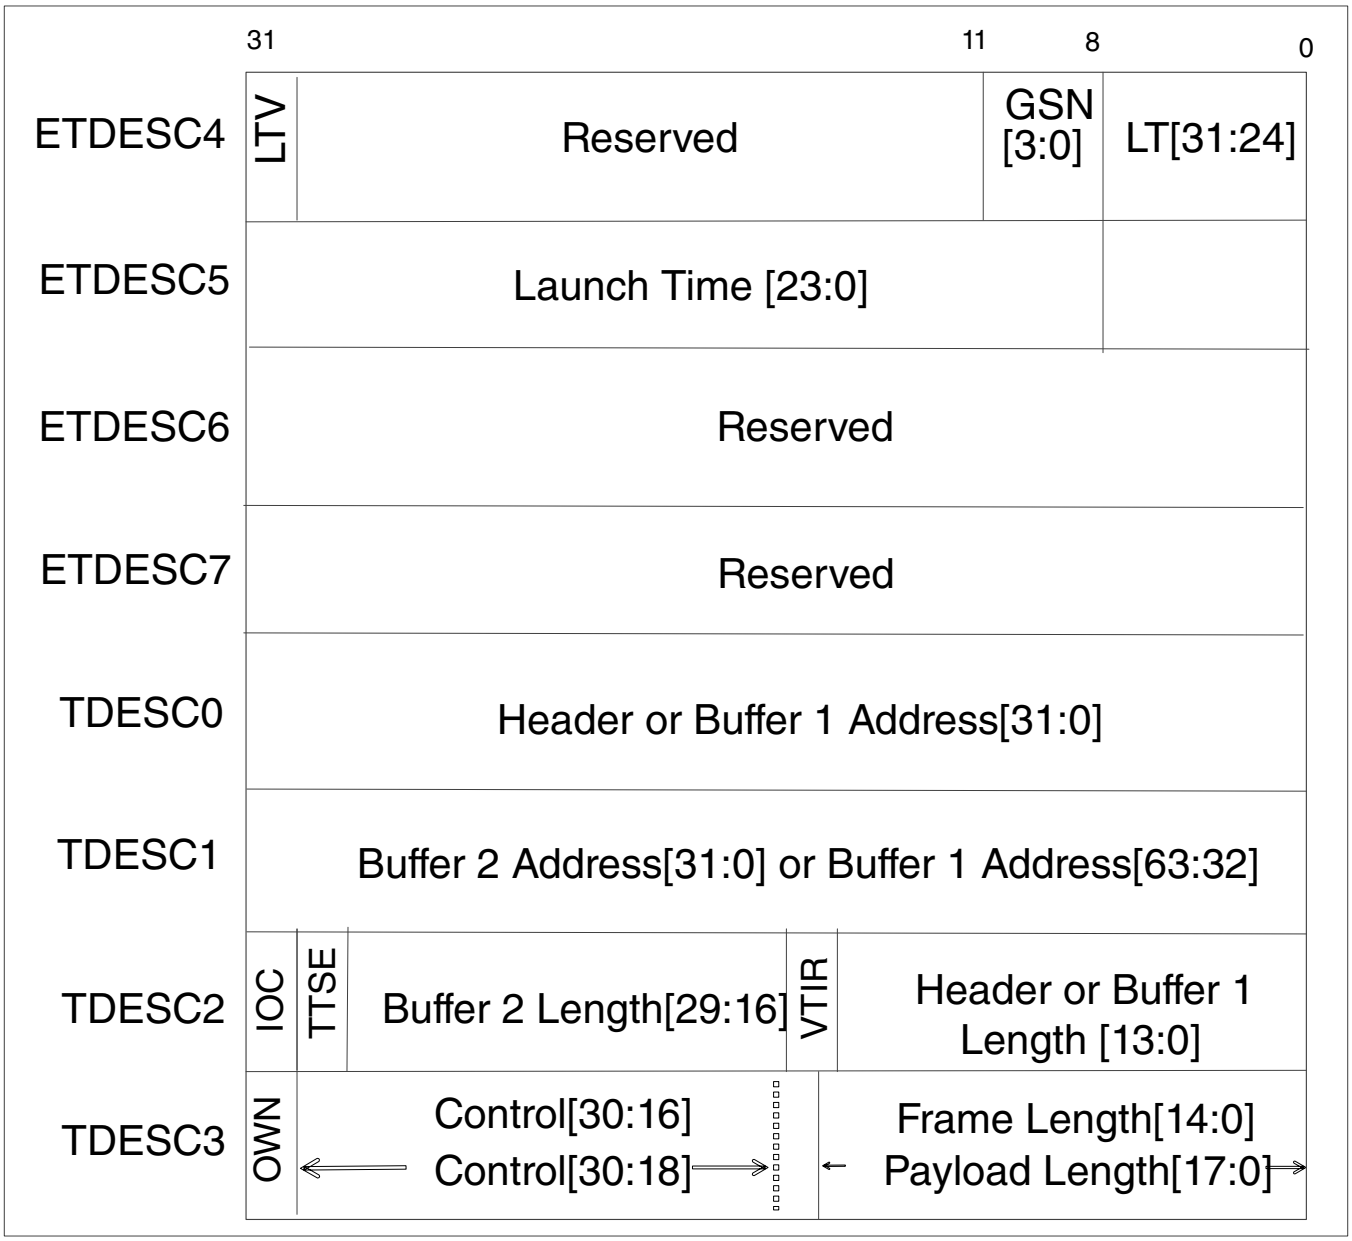

Figure 61-30. Enhanced Normal Descriptor - Read (32-Bit Mode)

61.3.11.5.2 Enhanced Normal Descriptor (Write, 32-Bit Mode)

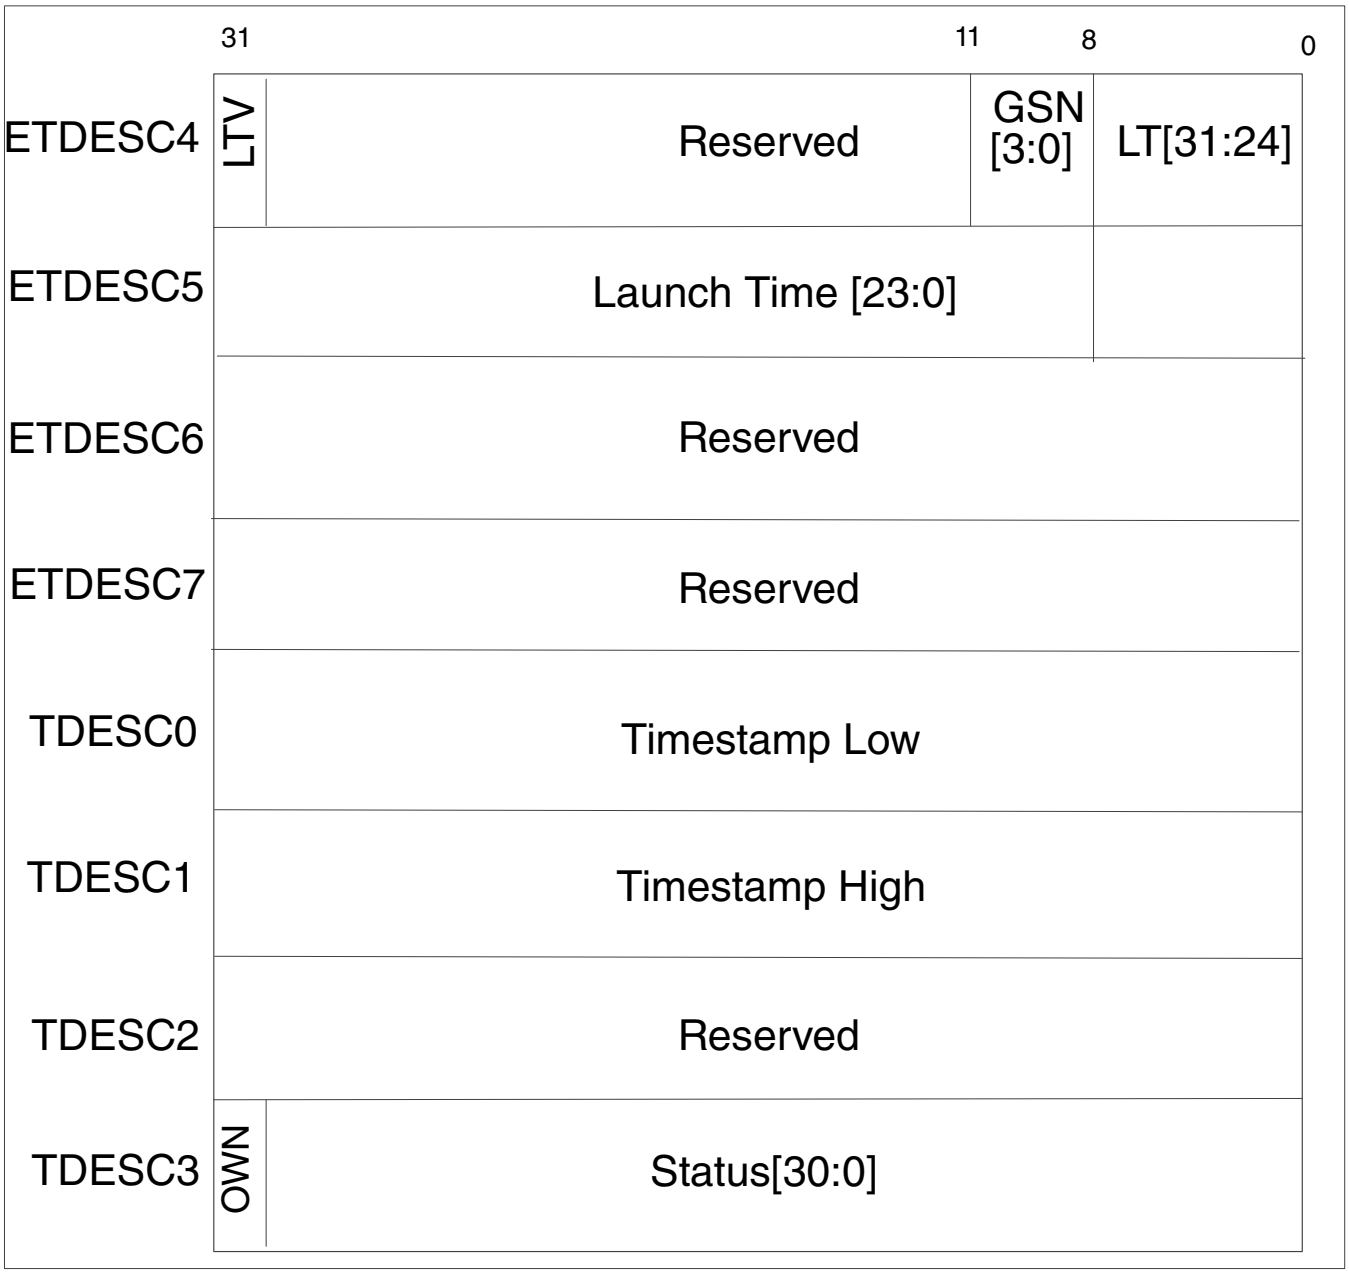

Figure 61-31. Enhanced Normal Descriptor Write (32-Bit Mode)

NOTE

- All the enhanced descriptor examples, assumes a 32-bit data width configurations. However, the same definitions are valid in 64 and 128 bit configurations.

- In both the write back formats, no modifications can be done to the extended 16 bytes. The rest of the 16 bytes (TDESC0 to TDESC3) are written back as per the previous 16 bytes Descriptor format.
- Fetch time when enabled overrides the AV slot function
- When an unaligned new GCL list (with a different CTR) is installed it is recommended not to have traffic during the installation of the new list. Any traffic during the switching of the lists might have unpredictable behavior regarding Fetch, Launch, and Launch expiry as the CTR and BTR values get updated while the frame is being processed

61.3.11.5.3 Enhanced Context Descriptor (Read, 32-bit Mode)

The first 16 bytes of the Enhanced context descriptor (ETDESC4 to ETDESC7) are reserved and must be zeros. The fields present in last bytes of the Descriptor (TDESC0 to TDESC3) are same as the context descriptor (TDESC0 to TDESC3) in 16 byte format.

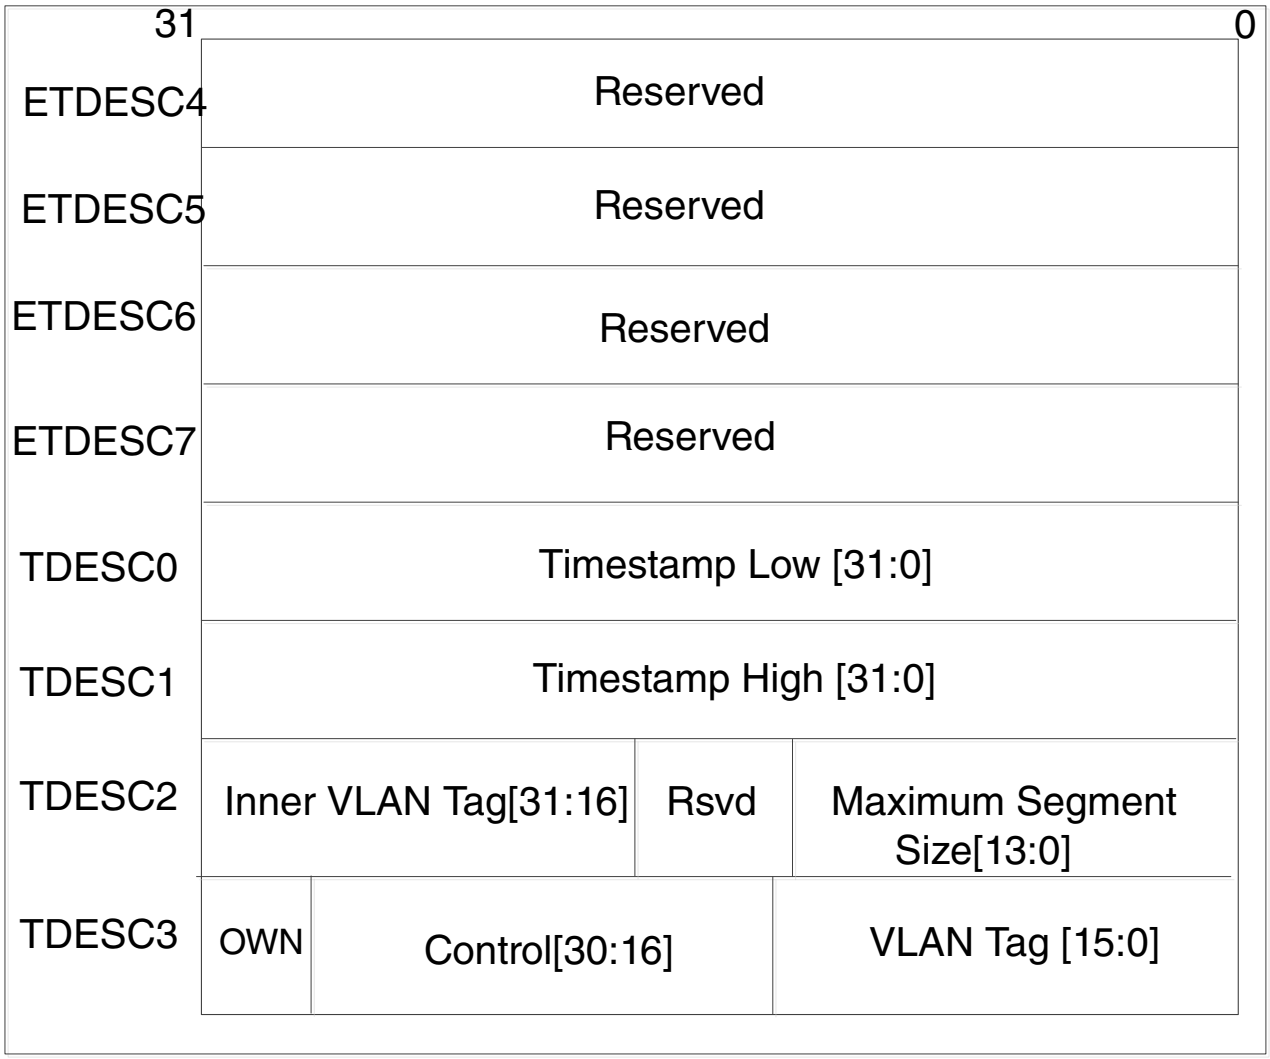

Figure 61-32. Enhanced Context Descriptor - Read

61.3.11.5.4 Enhanced Context Descriptor (Write, 32 Bit Mode)

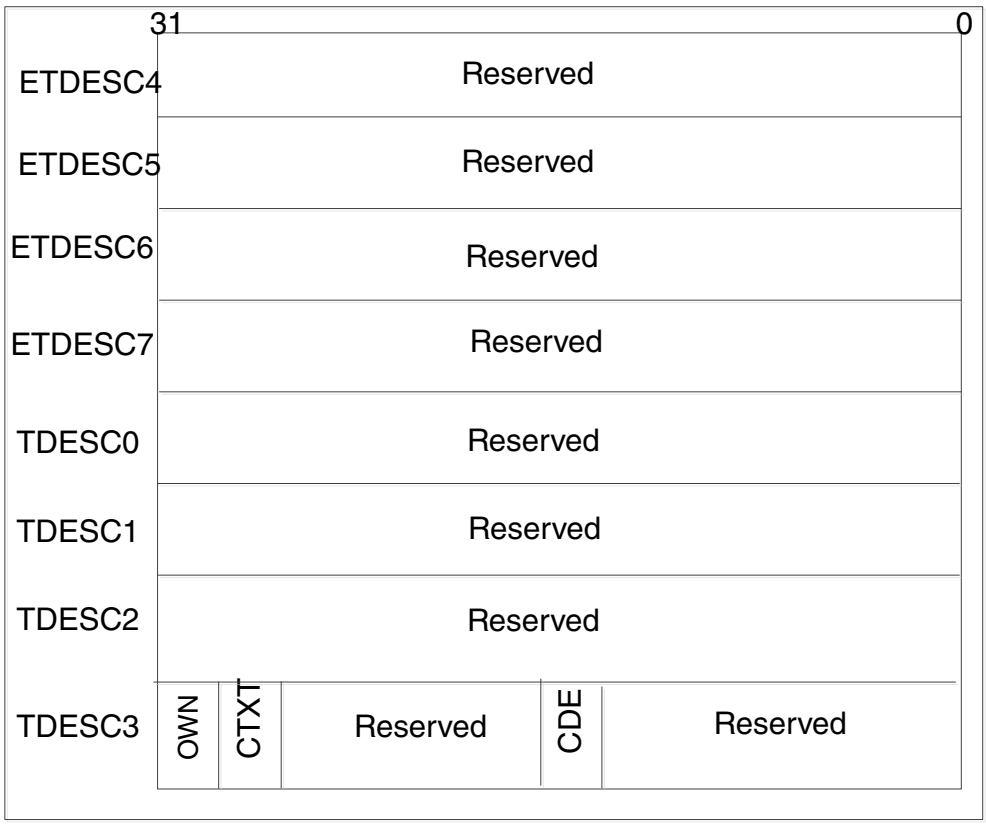

Figure 61-33. Enhanced Context Descriptor - Write

61.3.12 Power management and low power modes

This section describes the power management (PMT) mechanisms supported by the MAC. PMT supports the reception of network (remote) wake-up frames and magic packet frames. PMT does not perform the clock gate function, but generates interrupts for wake-up frames and magic packets received by the MAC. The PMT block sits on the receiver path of the MAC and is enabled with remote wake-up frame enable and magic packet enable. These enables are in the PMT control and status register and are programmed by the application.

When the power-down mode is enabled in the PMT, then all received frames are dropped by the Ethernet core and they are not forwarded to the application. The Ethernet comes out of the power-down mode only when either a magic packet or a remote wake-up frame is received and the corresponding detection is enabled.

61.3.12.1 Energy Efficient Ethernet

Energy Efficient Ethernet (EEE) is an operational mode that enables the IEEE 802.3 MAC sublayer along with a family of physical layers to operate in the Low-Power Idle (LPI) mode. The EEE operational mode supports the IEEE 802.3 MAC operation at 100 Mbps. The Ethernet module supports the IEEE 802.3az-2010 for EEE. The LPI mode allows power saving by switching off the parts of the communication device functionality when there is no data to be transmitted and received. The systems on both sides of the link can disable some functionality to save power during periods of low-link utilization. The MAC controls whether the system should enter or exit the LPI mode and communicates this to the PHY. The EEE specifies the capabilities negotiation methods that the link partners can use to determine whether EEE is supported, and then select the set of parameters that are common to both devices.

61.3.12.1.1 Transmit path functions

In the transmit path, the software must set the LPIEN bit of the MAC LPI control status register to indicate to the MAC to stop transmission and initiate the LPI protocol. The MAC completes the transmission in progress, generates its transmission status, and starts transmitting the LPI pattern instead of the IDLE pattern if the link status has been up continuously for a period specified in the LPI LS TIMER(LST) field of MAC LPI timers control register. The PHY link status bit of the LPI control and status register indicates the link status of the PHY.

According to the Energy Efficient Ethernet standard (IEEE 802.3az-2010), the PHY must not stop the transmit clock during the LPI state in the MII (10 or 100) mode.

To make the PHY enter the LPI state, the MAC performs the following tasks:

1. De-asserts transmit enable (TX_EN).
2. Asserts transmit error (TX_ER). Sets TXD[3:0] to 0x1 The MAC maintains the same state of the TX_EN, TX_ER, and TXD signals for the entire duration during which the PHY remains in the LPI state.
3. Updates the status (TLPIEN bit of MAC LPI control status register and generates an interrupt. To bring the PHY out of the LPI state, that is, when the software resets the LPIEN bit, the MAC performs the following tasks:
4. Stops transmitting the LPI pattern and start transmitting the IDLE pattern

5. Starts the LPI TW TIMER
6. Updates the LPI exit status (TLPIEX bit of the MAC LPI control status register and generates an interrupt

The MAC cannot start the transmission until the wake-up time specified for the PHY expires. The auto-negotiated wake-up interval is programmed in the TWT field of the MAC LPI Timers control register.

61.3.12.1.2 Automated entry/exit of LPI mode in TX path

The MAC transmitter can be programmed to enter and exit LPI IDLE mode automatically based on whether it is IDLE for a specific period or has a packet to transfer. These modes are enabled and controlled by the MAC LPI control status register.

When the LPITXA (bit 19) and LPITXEN (bit 16) of the MAC LPI control status register are set, the MAC transmitter enters the LPI IDLE state when the MAC transmit path (including the MTL layers and DMA layers) are idle. The MAC transmitter exits the LPI IDLE state and clears the LPITXEN bit as soon as any of the functions in the TX path (DMA, MTL, or MAC) becomes non-idle due to initiation of a packet transfer. In addition to the above, when bit 20 (LPIATE) is also set, the MAC transmitter enters LPI IDLE state only when the transmit path remains in an idle state (no activity) for the time indicated by the value in MAC LPI Entry Timer. In this mode also, the MAC transmitter exits the LPI IDLE state as soon as any of the functions becomes non-idle. However, the LPITXEN bit is not cleared but remains active so that reentry to LPI IDLE state is possible without any software intervention when the MAC becomes idle again.

When both LPIATE and LPITXA bits are cleared, you can directly control the entry and exit of the LPI IDLE state by programming the LPITXEN bit.

61.3.12.1.3 Receive path functions

In the receive path, when the PHY receives the signals from the link partner to enter into the LPI state, the PHY and MAC perform the following tasks:

1. The PHY asserts RX_ER.
2. The PHY sets RXD[7:0] to 0x01.
3. The PHY de-asserts RX_DV. The PHY maintains the same state of the RX_ER, RXD, and RX_DV signals for the entire duration during which it remains in the LPI state.
4. The MAC updates the RLPIEN bit of the MAC LPI control status register and immediately generates an interrupt.

When the PHY receives signals from the link partner to exit the LPI state, the PHY and MAC perform the following tasks:

1. The PHY de-asserts RX_ER and returns to a normal inter-packet state.
2. The MAC updates the RLPIEX bit of the MAC LPI control status register and generates an interrupt immediately. The sideband signal (synchronous to Rx clock) is also asserted.

61.3.12.1.4 LPI timers

The transmitter maintains the following two timers that are loaded with the respective values from the MAC_LPI_Timers_Control register:

- LPI LS Timer
  - The LPI LS TIMER counts, in milliseconds, the time expired since the link status is up. You can enable the monitoring of the LUD bit of the MAC_PHYIF_Control_Status register by setting the PLSEN bit of the MAC_LPI_Control_Status register. The link status is indicated to the MAC by the LNKSTS bit of the MAC_PHYIF_Control_Status register or the value programmed by the software in the PLS bit of the MAC_LPI_Control_Status register. If the link status is not available in the MAC_PHYIF_Control_Status, the software should get the PHY link status by reading the PHY register and accordingly update the PLS bit. This timer is cleared every time the link goes down. It starts to increment when the link is up again and continues to increment until the value of the timer becomes equal to the terminal count. Once the terminal count is reached, the timer remains at the same value as long as the link is up. The terminal count is the value programmed in bits 25:16 of the MAC_LPI_Timers_Control register. The GMII interface does not assert the LPI pattern unless the terminal count is reached. This ensures a minimum time for which no LPI pattern is asserted after a link is established with the remote station. This period is defined as 1 second in the IEEE 802.3-az-2010. The LPI LS TIMER is 10-bit wide. Therefore, the software can program up to 1,023 ms.
- LPI TW Timer
  - The LPI TW TIMER counts, in microseconds, the time expired since the de-assertion of LPI. The terminal count should be programmed in bits 15:0 of MAC register 53 (LPI timers control register). The terminal count of the timer is the value of resolved transmit TW that is the auto-negotiated time after which the MAC can resume the normal transmit operation. After exiting the LPI mode, the MAC resumes its normal operation after the TW timer reaches the terminal count. The MAC supports the LPI TW TIMER in units of a microsecond. The LPI TW TIMER is 16-bits wide. Therefore, the software can program up to 65,535 µs.

61.3.12.1.5 LPI interrupt

The MAC generates the LPI interrupt when the Tx or Rx side enters or exits the LPI state. The low-power interrupt is asserted when the LPI interrupt status is set. The LPI interrupt can be cleared by reading the MAC LPI control status register.

61.3.12.2 Power management and wake-up

The power management (PMT) block supports the reception of magic packets as wake up packets, as well as the reception of network (remote) wake-up packets as wake up packets.

61.3.12.2.1 Magic packet detection

The magic packet frame is based on a method that uses Advanced Micro Device's magic packet technology to power up the sleeping device on the network. The MAC receives a specific packet of information, called a magic packet, addressed to the node on the network.

Only magic packets that are addressed to the device or a broadcast address are checked to determine whether they meet the wake-up requirements. Magic packets that pass the address filtering (unicast or broadcast)are checked to determine whether they meet the remote wake-on-LAN data format of 6 bytes of all ones followed by a MAC address appearing 16 times.

The application enables magic packet wake-up by writing a 1 to bit 1 of the PMT control and status register. The PMT block constantly monitors each frame addressed to the node for a specific magic packet pattern. Each frame received is checked for a 0xFFFF FFFF FFFF pattern following the destination and source address field. The PMT block then checks the frame for 16 repetitions of the MAC address without any breaks or interruptions. In case of a break in the 16 repetitions of the address, the 0xFFFF FFFF FFFF pattern is scanned for again in the incoming frame. The 16 repetitions can be anywhere in the frame but must be preceded by the synchronization stream (0xFFFF FFFF FFFF). The device also accepts a multicast frame, as long as the 16 duplications of the MAC address are detected.

If the MAC address of a node is 0x0011 2233 4455, then the MAC scans for the data sequence:

- 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55
- 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55
- 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55

- 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55
- ...CRC

Magic packet detection is updated in the PMT control and status register for magic packet received. A PMT interrupt to the application triggers a read to the PMT CSR to determine whether a magic packet frame is received. When you enable the power-down mode in the PMT block, the MAC drops all received packets and does not forward any packet to the MTL Rx FIFO or the application. The MAC comes out of the power-down mode only when a magic packet is received and the corresponding detection is enabled.

61.3.12.2.2 Remote wake-up detection

The PMT block supports the reception of network (remote) wake-up packets as wake-up packets.

When the MAC is in sleep mode and the remote wake-up bit is enabled in PMT control and status register (0x00C0), normal operation is resumed after receiving a remote wake-up frame. The application writes all eight wake-up filter registers by performing a sequential write to address (0x00C4). The application enables remote wake-up by writing a 1 to bit 2 of the PMT control and status register.

PMT supports 16 programmable filters that allow support of different receive frame patterns. If the incoming frame passes the address filtering of filter command, and if filter CRC-16 matches the incoming examined pattern, then the wake-up frame is received.

Filter_offset (minimum value 12, which refers to the 13th byte of the frame) determines the offset from which the frame is to be examined. Filter byte mask determines which bytes of the frame must be examined. The 31st bit of the byte mask must be set to zero.

The remote wake-up CRC block determines the CRC value that is compared with Filter CRC-16. The wake-up frame is checked only for length error, FCS error, dribble bit error, MII error, collision, and to ensure that it is not a runt frame. Even if the wake-up frame is more than 512 bytes long, if the frame has a valid CRC value, it is considered valid. Wake-up frame detection is updated in the PMT control and status register for every remote wake-up frame received. A PMT interrupt to the application triggers a read to the PMT control and status register to determine the reception of a wake-up frame.

61.3.12.3 System considerations during power-down

MAC neither gates nor stops clocks when power-down mode is enabled. Power saving by clock gating must be done outside the core by the application. The receive data path must be clocked with ENET_RX_CLK during power-down mode because it is involved in magic packet/wake-on-LAN frame detection. However, the transmit path and the application path clocks can be gated off during deep-sleep mode.

The PMT interrupt is asserted when a valid wake-up frame is received. This signal is generated in the receive clock domain.

The recommended power-down and wake-up sequences are as follows.

1. Disable the transmit DMA and wait for any previous frame transmissions to complete. These transmissions can be detected when transmit interrupt (see DMA channel status register bit TI) is received.
2. Disable the MAC transmitter and MAC receiver by clearing the appropriate bits in the MAC configuration register.
3. Wait until the receive DMA empties all the frames from the Rx FIFO. This can be done by reading the appropriate bits of Debug registers in the DMA and MTL CSR space.
4. Enable power-down mode by appropriately configuring the PMT registers.
5. Enable the MAC receiver and enter power-down mode.
6. Gate the application and transmit clock inputs to the core (and other relevant clocks in the system) to reduce power and enter sleep mode.
7. On receiving a valid wake-up frame, the MAC asserts the PMT interrupt signal and exits the power-down mode.
8. On receiving the interrupt, the system must enable the application and transmit clock inputs to the core.
9. Read the PMT status register to clear the interrupt, then enable the other modules in the system and resume normal operation.

61.3.13 Clocks

The table found here describes the clock sources for ENET_QOS. Please see the chip-specific clocking section for clock setting, configuration and gating information.

Table 61-65. ENET_QOS Clocks

Clock name	Description
aclk_i	Bus clock
clk_csr_i	CSR clock, same source as aclk_i
ptp_ref_i	PTP clock

61.3.14 Interrupts

This module supports interrupt coalescing which reduces the number of interrupts generated by IP and reduces the CPU load. Various interrupt event gets captured in status register. If interrupt enable bit of an interrupt is set then corresponding interrupt will be generated based on event status in status registers. INTM (interrupt mode) bit decides that interrupt signal is a level signal or pulse signal.

Interrupt output signals are shown below which are synchronous to control and Status register (CSR) clock.

- Sbd_intr_o – common interrupt
- Sbd_perch_tx_intr_o[max_dma_ch] – Interrupt per Tx channel
- Sbd_perch_rx_intr_o [max_dma_ch] – Interrupt per Rx channel

NOTE

max_dma_ch is equal to number of Tx/Rx queues which is 2.

The sbd_intr_o common interrupt is level signal. When sbd_intr_o interrupt is asserted, then corresponding interrupt event source can be found in DMA_Interrupt status register. DMA_Interrupt status register is read only register which contains the interrupt event source bits corresponding to each DMA channel (Tx and Rx queue pair), MAC transaction layer and MAC blocks. Software must then read the following registers corresponding to the bits that are set.

- MAC_Interrupt_Status register
- MTL_Interrupt_Status register
- DMA_CH(n)_Status register

sbd_intr_o interrupt gets de-asserted only when all the enabled interrupt events are cleared in their respective status registers and correspondingly all the bits in the DMA_Interrupt_Status register are cleared.

The DMA_CH[n]_Status register captures all the interrupt events of that Tx DMA and Rx DMA channel pair. The DMA_CH[n]_Interrupt_Enable register contains the corresponding enable bits for each of the interrupt event. There are two groups of interrupts in the DMA channel namely Normal and Abnormal interrupts. They are indicated by bits[15:14] of DMA_CH[n]_Status register respectively. The normal group is for events that happen during the normal transfer of packets (TI, RI, TBU) while the abnormal interrupt events are for error events

Interrupts are not queued. If the same interrupt event occurs again before the driver responds to the previous one, no additional interrupts are generated.

The common sbd_intr_o output signal is asserted for the transfer complete interrupts only when the corresponding interrupts are enabled in DMA_CH[n]_Interrupt_Enable register.

This module also supports the following per Channel Transfer Complete interrupt signals.

- sbd_perch_tx_intr_o[max_dma_ch] (Transmit Per Channel Interrupts)
- sbd_perch_rx_intr_o[max_dma_ch] (Receive Per Channel Interrupts)

The behavior of the RI/TI/ sbd_perch_tx_intr_o[]/sbd_perch_rx_intr_o[] changes depending on the settings of INTM field bit[17:16] in DMA_Mode. Following table explains the Transfer Complete Interrupt behavior.

Table 61-66. Transfer Complete Interrupt Behavior

Interrupt Mode	Behavior of the sbd_perch_tx_intr_o[] and sbd_perch_rx_intr_o[]	Behavior of TI/RI and sbd_intr_o
INTM=1	These signals reflect the value of corresponding TI/RI bits in DMA_CH[n]_Status register when the corresponding interrupt enable is set. Hence they are level signals and are cleared by the application by writing 1'b1 to the RI/TI status bits. This signal will not be asserted when the corresponding interrupt enable bit is not set.	The TI/RI is set as explained above. However, the sbd_intr_o signal and NIS status bit are not asserted for any RI/TI events.
INTM=2	In this mode, RI/TI interrupts are queued. These signals reflect the value of corresponding TI/RI bits inDMA_CH[n]_Status register when the corresponding interrupt enable is set. They are level signals and cleared by software by writing 1'b1 to the RI/TI status bits. However, it is set again if another TI/RI event(s) is detected before the TI/RI bits are cleared for the previous event.	The RI/TI status bits are set whenever the Transfer Complete event is detected and gets reset whenever software driver clears those bits by writing 1. However, if another Transfer Complete event is detected before it is cleared (serviced) by the software, then the module automatically set these status bits again. However, the sbd_intr_o signal is not generated based on TI/RI

61.3.14.1 PMT interrupts

The PMT interrupt signal is asserted when a valid remote wake-up packet is received. When software resets the PWRDWN bit in the remote wake-Up packet detection register, the MAC comes out of the power-down mode, but this event does not generate the PMT interrupt.

When you enable the power-down mode in the PMT block, the MAC drops all received packets and does not forward any packet to the MTL Rx FIFO or the application. The MAC comes out of the power-down mode only when a remote wake-up packet is received and the corresponding detection is enabled. The PMT block is available in the receive path of MAC.

61.4 External signals

NOTE

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

Table 61-67. External signals

Port name	Interface	I/O	Description
1588_EVENT_AUX_IN	MII/RMII	I	Auxiliary Timestamp Trigger When this signal goes high (rising edge), a snapshot of the system time is taken and stored in the auxiliary timestamp FIFO.
1588_EVENT_IN	MII/RMII	I	Media Clock Generation Trigger Input Trigger (mcg_pst_trig_i) Input to ENET_QOS to capture presentation time. Based on presentation control value of PPS Control (MAC_PPS_CONTROL), this signal can be pulse or level signal.
1588_EVENT_OUT	MII/RMII	O	Pulse Per Second Output (ptp_pps_o) This signal is high based on the PPS mode selected in PPS Control (MAC_PPS_CONTROL). When PPS is programmed in Media Clock Recovery mode, this port indicates the recovered clock. See Programming Guidelines for Flexible Pulse-Per-Second Output for details.
TX_CLK	MII, RGMII	I (for MII) O for (RGMII)	MII: The external PHY provides this transmission clock. This is 25 MHz in 100 Mbps mode, 2.5 MHz in 10 Mbps mode. All transmission signals generated by the MAC are synchronous to this clock. This clock is required for all PHY interfaces. RGMII: The transmit clock signal is always provided by the MAC on the TX_CLK line. Source-synchronous clocking is used: the clock signal that is output (by either the PHY or the MAC) is synchronous with the data signals.
RX_CLK	MII, RGMII	I	MII: The external PHY provides this receive clock. This clock is 25 MHz in 100 Mbps mode, 2.5 MHz in 10 Mbps mode. All MII receive signals received by the MAC are synchronous to this clock. This clock input is required for all PHY interfaces. RGMII: Received clock signal (recovered from incoming received data)

Table continues on the next page...

Table 61-67. External signals (continued)

Port name	Interface	I/O	Description
REF_CLK1	RMII	I/O	This 50Mhz clock used by the RMII interface. When RMII mode is selected, RX_CLK (25Mhz or 2.5Mhz) should be derived from this clock.
TX_EN	MII, RMII, RGMII	O	The MAC drives this signal. This signal has multiple functions depending on the selected PHY interface. • MII: When high, indicates that valid data is being transmitted on the phy_txd_o bus. Synchronous to TX_CLK • RMII: When high, indicates that valid data is being transmitted on the phy_txd_o bus. Synchronous to REF_CLK. • RGMII: Contains TX_EN on the rising edge of TX_CLK, and a logical derivative of TX_EN and TX_ER (TX_EN XOR TX_ER) on the falling edge of TX_CLK.
TX_DATA	MII, RMII, RGMII	O	This is a group of transmit data signals driven by the MAC. It has multiple functions depending on the selected PHY interface. • MII: Bits[3:0] provide the MII transmit data nibble. The data is valid only when the TX_EN signal is high. Synchronous to TX_CLK • RMII: Bits[1:0] provide the RMII transmit data. The data is valid only when the TX_EN signal is high. Synchronous to REF_CLK. • RGMII: Bits[3:0] provide serial output Ethernet data
TX_ER	MII	I	The PHY drives this signal. In MII, indicates an error or carrier extension in the transmitted packet the TX_DATA[3:0] bus. Synchronous to TX_CLK.
CRS	MII	I	This signal is valid only in the MII mode. The PHY drives this signal high when the Transmit or Receive medium is not idle. The PHY drives this signal low when both Transmit and Receive mediums are idle. This signal is not synchronous to any clock.
COL	MII	I	This signal is valid only in the MII mode. The PHY drives this signal high when a collision is detected on the medium. This signal is not synchronous to any clock.
RX_DATA	MII, RMII, RGMII	I	This is a group of data signals received from the PHY. It has multiple functions depending on the selected PHY interface. • MII: Bits [3:0] provide the MII receive data nibble. The data is valid only when the RX_EN signal is high. Synchronous to RX_CLK. • RMII: Bits [1:0] provide the RMII receive data. The data is valid only when the RX_EN signal is high. Synchronous to REF_CLK. • RGMII: Bits [3:0] contains the Ethernet input data transferred from the PHY to the media-access controller.
MDC	MII, RMII, RGMII	O	Management Data Clock. The MAC provides timing reference for the MDIO or MII through this periodic clock. This clock is generated from the application clock through a clock divider controlled by MAC_MDIO_ADDRESS[CR].

Table continues on the next page...

Table 61-67. External signals (continued)

Port name	Interface	I/O	Description
MDIO	MII, RMII, RGMII	I/O	Transfers control information between the external PHY and the MAC. Data is synchronous to MDC. This signal is an input after reset.
RX_ER	MII	I	The PHY drives this signal. In MII, indicates an error or carrier extension in the received packet the RX_DATA[3:0] bus. Synchronous to RX_CLK.
RX_EN	RGMII	I	The PHY drives this signal. It has multiple functions depending on the selected PHY interface. • MII: Indicates that the data on the MII_RXD bus is valid. It remains high continuously from the first recovered byte or nibble of the packet through the final recovered byte or nibble of the packet. Synchronous to RX_CLK. • RMII: Contains the CRS and data valid information of the Receive interface. Synchronous to REF_CLK. In RGMII mode, contains receive data valid on the rising edge of RX_CLK, and a logical derivative of receive data valid and RX_ER (receive data valid XOR RX_ER) on the falling edge of RX_CLK.

61.5 Initialization

NOTE

This section and all its sub-sections are Synopsys Proprietary.
Used with permission.

This section provides the instructions for initializing the DMA or MAC registers in the proper sequence.

61.5.1 Initializing DMA

Complete the following steps to initialize the DMA:

1. Provide a software reset. This resets all of the MAC internal registers and logic (bit-0 of DMA_Mode).
2. Wait for the completion of the reset process (poll bit 0 of the DMA_MODE, which is only cleared after the reset operation is completed).
3. Program the following fields to initialize the DMA_SYSBUS_MODE register:
   a. AAL
   b. Fixed burst or undefined burst
   c. Burst mode values in case of AHB bus interface, OSR_LMT in case of AXI bus interface.

   d. If fixed length value is enabled, select the maximum burst length possible on the AXI Bus (bits [7:1])
4. Create a descriptor list for transmit and receive. In addition, ensure that the descriptors are owned by DMA (set bit 31 of descriptor TDES3/RDES3). For more information about descriptors, see Descriptors
5. Program the Transmit and Receive Ring length registers (DMA_CH(#i)_TXDESC_RING_LENGTH (for i = 0; i <= 1) and DMA_CH#_RX_CONTROL2 (for i = 0; i <= 1)). The ring length programmed must be at least 4.

NOTE

The descriptor address from the start to the end of the ring must not cross the 4GB boundary.

6. Initialize receive and transmit descriptor list address with the base address of the transmit and receive descriptor (DMA_CH(#i)_TXDESC_LIST_ADDRESS (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1), DMA_CH(#i)_RXDESC_LIST_ADDRESS (for i = 0; i <= DWC_EQOS_NUM_DMA_RX_CH-1)). Also, program transmit and receive tail pointer registers indicating to the DMA about the available descriptors (DMA_CH(#i)_TXDESC_TAIL_POINTER (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) and DMA_CH(#i)_RXDESC_TAIL_POINTER (for i = 0; i <= DWC_EQOS_NUM_DMA_RX_CH-1))

NOTE

For 40-bit or 48-bit addressing mode, program the higher address List registers (DMA_CH[n]_TXDESC_LIST_HADDRESS, DMA_CH[n]_RXDESC_LIST_HADDRESS).

The tailpointer registers must be advanced to the location immediately after the descriptors that are set, for the DMA to know that additional descriptors are available.

7. Program the settings of the following registers for the parameters like maximum burst-length (PBL) initiated by DMA, descriptor skip lengths, OSP in case of TxDMA, RBSZ in case of RxDMA, and so on:
   - DMA_CH(#i)_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1)

- DMA_CH(#i)_TX_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1)
- DMA_CH(#i)_RX_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_RX_CH-1)

8. Enable the interrupts by programming the DMA_CH(#i)_Interrupt_Enable (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) register.
9. Start the Receive and Transmit DMAs by setting SR (bit 0) of the DMA_CH(#i)_RX_CONTROL (for i = 0; i <= DWC_EQOS_NUM_DMA_RX_CH-1) and ST (bit 0) of the DMA_CH(#i)_TX_CONTROL (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) register.
10. Repeat steps 4 to 9 for all the Tx DMA and Rx DMA channels selected in the hardware.

61.5.2 Initializing MTL Registers

The Transaction Layer (MTL) registers must be initialized to establish the transmit and receive operating modes and commands.

Complete the following steps to initialize the MTL registers:

1. Program the Tx Scheduling (SCHALG) and Receive Arbitration Algorithm (RAA) fields in MTL_Operation_Mode to initialize the MTL operation in case of multiple Tx and Rx queues.
2. Program the Receive Queue to DMA mapping in MTL_RxQ_DMA_Map0 and MTL_RxQ_DMA_Map1 registers.
3. Program the following fields to initialize the mode of operation in the MTL_TxQ0_Operation_Mode register.
   a. Transmit Store And Forward (TSF) or Transmit Threshold Control (TTC) in case of threshold mode
   b. Transmit Queue Enable (TXQEN) to value 2'b10 to enable Transmit Queue0
   c. Transmit Queue Size (TQS)
4. Program the following fields to initialize the mode of operation in the MTL_RxQ0_Operation_Mode register:
   a. Receive Store and Forward (RSF) or RTC in case of Threshold mode
   b. Flow Control Activation and De-activation thresholds for MTL Receive FIFO (RFA and RFD)
   c. Error Packet and undersized good Packet forwarding enable (FEP and FUP)
   d. Receive Queue Size (RQS)

5. Repeat previous two steps for all MTL Tx and Rx queues selected in the configuration.

61.5.3 Initializing MAC

The MAC configuration registers establish the operating mode of the MAC. These registers must be initialized before initializing the DMA.

The following MAC Initialization operations can be performed after DMA initialization. If the MAC initialization is completed before the DMA is configured, enable the MAC receiver (last step in the following sequence) only after the DMA is active. Otherwise, received frames fill the Rx FIFO and overflow.

1. Provide the MAC address registers: MAC_ADDRESS0_HIGH and MAC_ADDRESS0_LOW. If more than one MAC address is enabled in your configuration, program the MAC addresses appropriately.
2. Program the following fields to set the appropriate filters for the incoming frames in the MAC_PACKET_FILTER register:
   a. Receive All
   b. Promiscuous mode
   c. Hash or Perfect Filter
   d. Unicast, multicast, broadcast, and control frames filter settings
3. Program the following fields for proper flow control in the MAC_Q0_TX_FLOW_CTRL register:
   a. Pause time and other Pause frame control bits
   b. Transmit Flow control bits
   c. Flow Control Busy
4. Program the MAC_INTERRUPT_ENABLE register, as required, and if applicable, for your configuration.
5. Program the appropriate fields in the MAC_CONFIGURATION register. For ex: Inter-packet gap while transmission and jabber disable.
6. Set bit 0 and 1 in MAC_CONFIGURATION register to start the MAC transmitter and receiver.

61.6 Application Information

NOTE

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

61.6.1 Performing Normal Receive and Transmit Operation

During normal operation of the module, normal and transmit interrupts are read, descriptors polled, the DMA is suspended (if it does not own descriptors), and values of current host transmitter or receiver descriptor pointers are read for debugging.

For normal operation, complete the following steps:

1. For normal transmit and receive interrupts, read the interrupt status. Then, poll the descriptors, reading the status of the descriptor owned by the Host (either transmit or receive).
2. Set appropriate values for the descriptors, ensuring that transmit and receive descriptors are owned by the DMA to resume the transmission and reception of data.
3. If the descriptors are not owned by the DMA (or no descriptor is available), the DMA goes into SUSPEND state. The transmission or reception can be resumed by freeing the descriptors and writing the descriptor tail pointer to Tx/Rx tail pointer register (DMA_CH[n]_TXDESC_TAIL_POINTER and DMA_CH[n]_RXDESC_TAIL_POINTER).
4. The values of the current host transmitter or receiver descriptor address pointer can be read for the debug process (DMA_CH[n]_CURRENT_APP_TXDESC and DMA_CH[n]_CURRENT_APP_RXDESC).
5. The values of the current host transmit buffer address pointer and receive buffer address pointer can be read for the debug process (Register DMA_CH[n]_CURRENT_APP_TXBUFFER and DMA_CH[n]_CURRENT_APP_RXBUFFER).

61.6.2 Stopping and Starting Transmission

Complete the following steps to pause the transmission.

NOTE

The steps are provided for Channel 0.

1. Disable the Transmit DMA (if applicable) by clearing Bit 0 (ST) of DMA_CH(#i)_TX_CONTROL (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) Register.
2. Wait for any previous frame transmissions to complete. You can check this by reading the appropriate bits of MTL_TXQ0_DEBUG Register (TRCSTS is not 01 and TXQSTS=0).
3. Disable the MAC transmitter and MAC receiver by clearing Bit (RE) and Bit 1(TE) of the MAC_Config-uration Register.

4. Disable the Receive DMA (if applicable), after making sure that the data in the Rx FIFO is transferred to the system memory (by reading the appropriate bits of MTL_TXQ0_DEBUG Register, PRXQ=0 and RXQSTS=00).
5. Make sure that both Tx Queue and Rx Queue are empty (TXQSTS is 0 in MTL_TXQ0_DEBUG Register and RXQSTS is 0 in MTL_RXQ0_DEBUG Register).
6. To restart the operation, first start the DMAs, and then enable the MAC Transmitter and Receiver.

NOTE

- Do not change the configuration (such as duplex mode, speed, port, or loop back) when the MAC is actively transmitting or receiving. These parameters are changed by software only when the MAC transmitter and receiver are not active.
- Similarly, do not change the DMA-related configuration when Transmit and Receive DMA are active.

61.6.3 Programming Guidelines for Switching to New Descriptor List in RxDMA

Switching to a new descriptor list is different in the Rx DMA compared to the Tx DMA. Switching to a new descriptor list is permitted when the RxDMA is in SUSPEND state, as clarified by the following points:

- Generally, RxDMA prepares the descriptors in advance.
- If the RxDMA goes to SUSPEND due to descriptors not being available, a major failure occurs (software is not able to free the filled-up descriptors/buffers). If this issue is not rectified immediately, frames will be lost because of an RxFIFO Overflow. Therefore, the software is allowed to create a new descriptor list and program the RxDMA to start using it immediately, without going into STOP state.

61.6.4 Programming Guidelines for Multi-Channel Multi-Queuing

61.6.4.1 Transmit

1. Program the Transmit queue size in the TQS field of MTL_TXQ[n]_OPERATION_MODE register. Based on the value programmed in the TQS field, the size of the queue is determined.

   In the Transmit operation, the number of channels is equal to the number of the queues. Due to this reason, the Channel-to-Queue mapping is fixed.

2. For a queue to be used, the queue must be enabled in TXQEN in the corresponding MTL_TXQ[n]_OPERATION_MODE Register. In DMA configurations, the ST bit of DMA_CH[n]_TX_CONTROL Register and corresponding TXQEN in MTL_TXQ[n]_OPERATION_MODE Register needs to be enabled.
3. The scheduling method needs to be programmed in SCHALG of MTL_OPERATION_MODE register.
4. Program the MTL_TXQ[n]_Quantum_Weight for DCB queue as per the selected algorithm. In case of CBS algorithm in AVB queues, the MTL_TXQ[n]_ETS_CONTROL, MTL_TXQ[n]_SENDSLOPECREDIT, MTL_TXQ[n]_HICREDIT and MTL_TXQ[n]_LOCREDIT registers also need to be programmed as required.
5. If DCB is enabled and PFC function is required, program MAC_TXQ_PRTY_MAP0 Register to assign a fixed priority to the queue. This priority assigned is used for determining if the corresponding queue should stop transmitting packet based on the received PFC packet.

61.6.4.2 Receive

1. Program the Receive queue size in the RQS field of MTL_RXQ[n]_OPERATION_MODE Register. Based on the value programmed in RQS field, the size of the queue is determined.
2. Enable the Receive Queues 0 to 4 in the fields RXQ0EN to RXQ4EN in MAC_RXQ_CTRL0 Register for AV or DCB. In DMA configurations, SR bit of statically or dynamically mapped DMA_CH[n]_RX_CONTROL Register and corresponding RXQ[n]_EN in MAC_RXQ_CTRL0 Register needs to be enabled.
3. The MAC routes the Rx packets to the Rx Queues based on following packet types:
   a. AV PTP Packets: Based on the programming of AVPTPQ in MAC_RXQ_CTRL1 Register.
   b. AV Untagged Control packets: Based on the programming of AVCPQ in MAC_RXQ_CTRL1 Register.
   c. Data Center Bridging (DCB) related Link Layer Discovery Protocol (LLDP) packets. Program DCBCPQ in MAC_RXQ_CTRL1 Register to indicate to MAC which queue should get the DCB packets.

d. VLAN Tag Priority field in VLAN Tagged packets: Program PSRQ4-0 of the MAC_RXQ_CTRL2 and MAC_RXQ_CTRL3 Register for the routing of tagged packets based on the USP (user Priority) field of the received packets to the Rx Queues 0 to 4.
e. The AV tagged control and data packets are also routed based on PSRQ field of the MAC_RXQ_CTRL2 and MAC_RXQ_CTRL3 registers.

NOTE

The priorities set in PSRQ4-0 should be unique.

4. If multiple RX DMA channels are enabled, the following programming should be done for proper arbitration and mapping:
   a. Program the RAA field of MTL_OPERATION_MODE register to select the arbitration algorithm to decide which RxQ is read out from the RxFIFO memory.
   b. Program the MTL_RXQ[n]_CONTROL to decide the weights and the packet arbitration for each RxQ.
   c. If static mapping is programmed in MTL_RXQ_DMA_MAP[n] register (RXQ[n]DADMACH is reset to 0), bits RXQx2DMA and others need to be programmed to select the channel for which each queue is mapped.
   d. Set RXQ[n]DADMACH bit in MTL_RXQ_DMA_MAP0 Register to select dynamic mapping of packets in each RxQueue.
   e. In dynamic channel mapping, the routing of a packet to a specific RxDMA channel is decided by the value of DCS field in the lowest MAC Address Register.

61.6.4.2.1 Programming Guidelines for Recovering from DMA Channel Failure

When the DMA channel issues a bus error, follow these steps to recover from the failure.

Recovering from the Receive DMA Channel Failure

1. Set the RPF bit to 1. This flushes all the packets one after the other.

   This step is optional. However, setting this bit prevents HOL (head-of-line) blocking in the Rx queues when packets sent to the RXDMA are stopped due to bus error.

2. Reprogram the specific Registers of the DMA channel.
3. Start the DMA channel.

Recovering from the Transmit DMA Channel Failure

1. Stop the specific DMA channel, even if it is in active state.
2. Flush the corresponding MTL queue.
3. Reprogram the specific Registers of the DMA channel.

4. Start the DMA channel.

NOTE

Due to the known limitations in the design, reprogramming the DMA channel registers might not always be successful in recovering from a Bus Error. If the module is not fully functional after reprogramming the DMA, as a workaround, issue a Soft Reset to recover from the Bus Error.

61.6.5 Programming Guidelines for IEEE 1588 Timestamping

61.6.5.1 Initialization Guidelines for System Time Generation

You can enable the timestamp feature by setting Bit 0 of the MAC_TIMESTAMP_CONTROL Register. However, it is essential that the timestamp counter be initialized after this bit is set. Complete the following steps during the module initialization:

1. Mask the Timestamp Trigger interrupt by clearing the bit 16 of MAC_INTERRUPT_ENABLE Register.
2. Set Bit 0 of MAC_TIMESTAMP_CONTROL Register to enable timestamping.
3. Program MAC_SUB_SECOND_INCREMENT Register based on the PTP clock frequency.
4. If you are using the Fine Correction approach, program MAC_Timestamp_Addend and set Bit 5 of MAC_TIMESTAMP_CONTROL Register.
5. Poll the MAC_TIMESTAMP_CONTROL Register until Bit 5 is cleared.
6. Program Bit 1 of MAC_TIMESTAMP_CONTROL Register to select the Fine Update method (if required).
7. Program MAC_SYSTEM_TIME_SECONDS_UPDATE Register and MAC_SYSTEM_TIME_NANOSECONDS_UPDATE Register with the appropriate time value.
8. Set Bit 2 in MAC_TIMESTAMP_CONTROL Register.
9. The timestamp counter starts operation as soon as it is initialized with the value written in the Timestamp Update registers. If one-step timestamping is enabled
   a. To enable one-step timestamping, program Bit 27 of the TDES3 Context Descriptor.
   b. Program registers MAC_TIMESTAMP_INGRESS_ASYM_CORR and MAC_TIMESTAMP_EGRESS_ASYM_CORR to update the correction field in PDelay_Req PTP messages.
10. Enable the MAC receiver and transmitter for proper timestamping.

NOTE

If timestamp operation is disabled by clearing Bit 0 of MAC_TIMESTAMP_CONTROL Register, repeat all these steps to restart the timestamp operation.

61.6.5.2 System Time Correction

61.6.5.2.1 Coarse Correction Method

To synchronize or update the system time in one process (coarse correction method):

1. Set the offset (positive or negative) in the Timestamp Update registers(MAC_SYSTEM_TIME_SECONDS_UPDATE and MAC_SYSTEM_TIME_NANOSECONDS_UPDATE).
2. Set Bit 3 (TSUPDT) of MAC_TIMESTAMP_CONTROL REGISTER.

The value in the Timestamp Update registers is added to or subtracted from the system time when the TSUPDT bit is cleared.

61.6.5.2.2 Fine Correction Method

To synchronize or update the system time to reduce system-time jitter (fine correction method):

1. With the help of the algorithm, calculate the rate by which you want to make the system time increments slower or faster.
2. Update the MAC_TIMESTAMP_ADDEND with the new value and set Bit 5 of the MAC_TIMESTAMP_CONTROL Register.
3. Wait for the time for which you want the new value of the Addend register to be active. You can do this by enabling the Timestamp Trigger interrupt after the system time reaches the target value.
4. Program the required target time in MAC_PPS[n]_TARGET_TIME_SECONDS Register and MAC_PPS[n]_TARGET_TIME_NANOSECONDS Register.
5. Enable the Timestamp interrupt in bit 12 of MAC_INTERRUPT_ENABLE register.
6. Set bit 4 in Register MAC_Timestamp_Control.
7. When this trigger causes an interrupt, read MAC_INTERRUPT_STATUS Register.
8. Reprogram MAC_TIMESTAMP_ADDEND Register with the old value and set bit 5 again.

61.6.6 Programming Guidelines for AV Feature

After you enable the AV feature in the module controller, there are several programming tasks to be followed:

- Initializing the DMA for QOS-AHB configurations only
- Enabling slot number checking
- Enabling average bits per slot reporting
- Disabling flow control for AV-enabled queues (transmit and receive flow control)

61.6.6.1 Initializing the DMA in Audio Video Feature

The first step in programming the AV feature in a QOS-AHB configuration is to initialize the DMA.

Use this initialization sequence for QOS-AHB/QOS-AXI configurations with AV feature.

1. Provide a software reset to reset all QOS internal registers and logic (bit 0 in DMA_MODE register).
2. Wait for the completion of the reset process. Poll bit 0 of the DMA_MODE register), which is cleared only after the reset operation is completed.
3. Program the fields to initialize the DMA register by setting the values in DMA_MODE register.
4. Create a proper descriptor list for transmit and receive. In addition, ensure that the DMA owns the Transmit and Receive descriptors. When OSF mode is used, at least two TX descriptors are required.

   For more information about descriptors, see Descriptors.

5. Make sure that your software creates three or more different transmit or receive descriptors in the list before reusing any of the descriptors.
6. Program the Transmit and Receive Ring length registers (DMA_CH(#i)_TXDESC_RING_LENGTH (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) and DMA_CH#_RX_CONTROL2 (for i = 0; i <= DWC_EQOS_NUM_DMA_RX_CH-1)). The ring length programmed must be at least 4.
7. Initialize receive and transmit descriptor list address with the base address of the transmit and receive descriptor (DMA_CH(#i)_TXDESC_LIST_ADDRESS (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1), DMA_CH(#i)_TXDESC_LIST_ADDRESS (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1)). In addition, you must program the

Transmit and Receive tail pointer registers indicating to the DMA about the available descriptors (DMA_CH(#i)_TXDESC_TAIL_POINTER (for i = 0; i <= DWC_EQOS_NUM_D-MA_TX_CH-1) and DMA_CH(#i)_RXDESC_TAIL_POINTER (for i = 0; i <= DWC_EQOS_NUM_D-MA_RX_CH-1)).

8. Program the following fields to initialize the mode of operation in the MTL_TXQ0_OPERATION_MODE register:
   a. Transmit Store And Forward (TSF)
   b. Transmit Threshold Control (TTC)
   c. Transmit Queue Enable (TXQEN) to value 2‘b10 to enable Transmit Queue0
   d. Transmit Queue Size (TQS)
9. Enable the interrupts by programming the DMA_CH(#i)_INTERRUPT_ENABLE (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) register.
10. Repeat steps 4 through 9 for all additional channels of AV feature.
11. Program the CBS control register, idleSlope, sendSlope, hiCredit, and loCredit registers of the AV Queues.
12. Start the Receive and Transmit DMA by setting bit 0 of the DMA_CH(#i)_TX_CONTROL (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) register and bit 0 of the DMA_CH(#i)_RX_CONTROL (for i = 0; i <= DWC_EQOS_NUM_DMA_RX_CH-1) register.

61.6.6.2 Enabling Slot Number Checking

You can enable slot number checking to specify the intervals at which the DMA channels mapped to AV Queues fetch the frames from the AHB/AXI system bus.

These steps should be completed after step 11 and before step 12 of "Initializing DMA".

You can use the slot number check feature to specify the intervals at which the DMA Channels mapped to AV Queues fetch the frames from the AHB/AXI system bus. This feature is useful for a uniform and periodic transfer of the AV traffic from the host memory. The feature is available only when you enable timestamping and program the MAC_SUB_SECOND_INCREMENT register. To enable the slot number checking:

1. Enable timestamping by following the steps described in "Initialization Guidelines for System Time Generation".
2. Make sure that the SLOTNUM field (bits 22:19) of TDES3 Normal Descriptor (Read Format) contains a valid slot number. You can read the current reference slot number from the DMA_CH(#i)_Slot_Function_Control_Status (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1).

3. Set Bit 0 (ESC) of the Slot Function Control and Status register of a channel to enable the slot number checking.

61.6.6.3 Enabling Average Bits Per Slot Reporting

You can enable the reporting of the average bits that are transmitted in a slot.

The CBS Status register of the additional AV channels provides information about the average bits that are transmitted in a slot. The software can asynchronously read this register to retrieve information about the average bits transmitted per slot. To enable average bits per slot reporting:

1. Enable timestamping by following the steps described in the Initialization Guidelines for System Time Generation.
2. Program Bits [6:4], SLC, of the MTL_TXQ[n]_ETS_CONTROL register of a channel with the number of slots over which the average transmitted bits per slot need to be computed.
3. Enable Bit 9(ABPSSIE) of the MTL_Q[n]_INTERRUPT_CONTROL_STATUS register of a channel to generate the average bits per slot interrupt.

NOTE

- The frequency of this interrupt depends on the value programmed in step 2. For example, when you program value 0 in the SLC field, the interrupt is generated at every 125 microsecond.
- When not required, you can disable this interrupt to stop the interrupt flooding.

4. Read Bits [16:0], ABS, from the MTL_TXQ[n]_ETS_STATUS register of a channel on each interrupt.

NOTE

The software can read the ABS bits in polling mode even if the ABPSIE bit is not enabled. When high, bit 1 (ABPSIS) of the MTL_TXQ[n]_ETS_STATUS register indicates that a new value is updated in the ABS field.

61.6.6.4 Disabling Flow Control for AV Enabled Queues

61.6.6.4.1 Transmit Flow

Program the EHFC (Enable Hardware Flow Control) bit of corresponding Rx Queue's MTL_RXQ[n]_OPERATION_MODE register to 0.

61.6.6.4.2 Receive Flow Control

Program the PSTQ[n] field corresponding to AV enabled Tx Queue in MAC_TXQ_PRTY_MAP0/1 register to 0.

61.6.6.5 Programming Guidelines for Flexible Pulse-Per-Second Output

After you enable the Flexible Pulse-Per-Second Output feature in the module controller, you can perform the following tasks:

- Generating Single Pulse on PPS
- Generating Next Pulse on PPS
- Generating a Pulse Train on PPS
- Generating an Interrupt without Affecting the PPS

61.6.6.5.1 Generating Single Pulse on PPS

To generate single pulse on PPS:

1. Program 11 or 10 (for interrupt) in Bits [6:5], TRGTMODSEL, of MAC_PPS_CONTROL Register. This instructs the MAC to use the Target Time registers (MAC_PPS0_TARGET_TIME_SECONDS and MAC_PPS0_TARGET_TIME_NANOSECONDS) for start time of PPS signal output.
2. Program the start time value in the Target Time registers (MAC_PPS0_TARGET_TIME_SECONDS and MAC_PPS0_TARGET_TIME_NANOSECONDS).
3. Program the width of the PPS signal output in MAC_PPS(#i)_WIDTH (for i = 0; i <= 3) Register.
4. Program Bits [3:0], PPSCMD, of MAC_PPS_CONTROL to 0001. This instructs the MAC to generate single pulse on the PPS signal output at the time programmed in the Target Time registers.

61.6.6.5.2 Generating Next Pulse on PPS

When the PPSCMD is executed (PPSCMD bits = 0), you can cancel the pulse generation by giving the Cancel Start Command (PPSCMD=0011) before the programmed start time elapses. You can also program the behavior of the next pulse in advance.

To program the next pulse:

1. Program the start time for the next pulse in the Target Time registers. This time should be more than the time at which the falling edge occurs for the previous pulse.
2. Program the width of the next PPS signal output in MAC_PPS(#i)_WIDTH (for i = 0; i <= DWC_EQOS_PPS_OUT_NUM-1).
3. Program Bits [3:0], PPSCMD, of MAC_PPS_CONTROL to generate a single pulse after the time at which the previous pulse is de-asserted. This instructs the MAC to generate single pulse on the PPS signal output, at the time programmed in Target Time registers.

   If you give this command before the previous pulse becomes low, then the new command overwrites the previous command and the QOS may generate only 1 extended pulse.

61.6.6.5.3 Generating a Pulse Train on PPS

To generate a pulse train on PPS:

1. Program 11 or 10 (for interrupt) in Bits [6:5], TRGTMODSEL, of MAC_PPS_Control Register. This instructs the MAC to use the Target Time registers for start time of the PPS signal output.
2. Program the start time value in the Target Time registers.
3. Program the interval value between the train of pulses on the PPS signal output in MAC_PPS(#i)_INTERVAL (for i = 0; i <= DWC_EQOS_PPS_OUT_NUM-1) Register.
4. Program the width of the PPS signal output in MAC_PPS(#i)_WIDTH (for i = 0; i <= DWC_EQOS_PPS_OUT_NUM-1) Register.
5. Program Bits[3:0], PPSCMD, of MAC_PPS_CONTROL Register to 0010. This instructs the MAC to generate train of pulses on the PPS signal output with start time programmed in Target Time registers.

   By default, the PPS pulse train is free-running unless stopped by ‘STOP Pulse train at time’ or ‘STOP Pulse Train immediately’ commands.

6. Program the stop value in the Target Time registers. Ensure that Bit 31 (TSTRBUSY) of MAC_PPS(#i)_TARGET_TIME_NANOSECONDS (for i = 0; i

<= DWC_EQOS_PPS_OUT_NUM-1) Register is reset before programming the Target Time registers again.

7. Program the PPSCMD field (bit 3:0) of MAC_PPS_CONTROL to 0100. This stops the train of pulses on PPS signal output after the programmed stop time specified in Step 6 elapses.

   You can stop the pulse train at any time by programming 0101 in the PPSCMD field. Similarly, you can cancel the Stop Pulse train command (given in Step 7) by programming 0110 in the PPSCMD field before the time (programmed in Step 6) elapses. You can cancel the pulse train generation by programming 0011 in the PPSCMD field before the programmed start time (in Step 2) elapses.

61.6.6.5.4 Generating an Interrupt without Affecting the PPS

You can use bits[6:5], TRGTMODSEL, of the MAC_PPS_CONTROL Register to program the Target Time registers to do any one of the following:

- Generate only interrupts.
- Generate interrupts and the PPS start and stop time.
- Generate only PPS start and stop time.

To program the Target Time registers to generate only interrupt events:

1. Program 00 (for interrupt) in Bits [6:5], TRGTMODSEL, of MAC_PPS_CONTROL Register. This instructs the MAC to use the Target Time registers for target time interrupt.
2. Program a target time value in the Target Time registers. This instructs the MAC to generate an interrupt when the target time elapses.

   If Bits [6:5], TRGTMODSEL, are changed (for example, to control the PPS), then the interrupt generation is overwritten with the new mode and new programmed Target Time register value.

61.6.6.6 Programming Guidelines for VLAN Filtering on Receive

To program VLAN filtering on receive:

1. Program MAC_VLAN_TAG register for the following bit to select the filtering method:
   a. ETV: Enable 12-Bit VLAN Tag Comparison or 16-bit VLAN Tag comparison.
   b. VTHM: VLAN Tag Hash Table Match Enable.

c. ERIVLT: Enable inner VLAN Tag or outer VLAN Tag (to enable the inner or outer VLAN Tag filtering, Double VLAN Processing should enabled by setting EDVLP)
d. ERSVLM: Enable Receive S-VLAN Match or C-VLAN match (for S-VLAN processing to be enabled, set ESVL)
e. DOVLTC: Ignores VLAN Type for Tag Match
f. VTIM: to enable VLAN Tag Inverse Match instead of the normal VLAN Tag matching

2. Program VL of MAC_VLAN_Tag Register for the 12-bit or 16-bit VLAN tag.
3. If Hash filtering of VLAN tag is enabled, program MAC_VLAN_HASH_TABLE Register. When ETV bit is reset, upper 4 bits of the calculated CRC-32 of VLAN Tag are inverted and used to index the content of MAC_VLAN_Hash_Table register. When ETV bit is set, upper 4 bits of calculated CRC-32 of VLAN Tag are used to index the content of MAC_VLAN_HASH_TABLE register. For example, when ETV bit is set, a hash value of 4b'1000 selects Bit 8 of the VLAN Hash table. When ETV bit is reset a hash value of 4'b1000 selects Bit 7 of the VLAN Hash table.

61.6.6.7 Programming Guidelines for Extended VLAN Filtering and Routing on Receive

For the indirect access of the per VLAN Tag registers, follow these steps.

- Write
  a. Write the required data into the MAC VLAN Tag Data register.
  b. Program the VLAN Tag Control Register's OFS field with the required Filter Register's offset and command type to the CT field. For a write command, set this bit to 0.
  c. Write 1 to the OB field and wait till the OB bit is reset to do the next write. This will guarantee that the appropriate VLAN Tag Filter Register has been programmed.
- Read
  a. Program the VLAN Tag Control Register's OFS Field with the required register's offset and command type to the CT field. For a read command, set this bit to 1.
  b. Write 1 to the OB field and wait till the OB bit is reset. The appropriate VLAN Tag Filter register's value is available in the MAC VLAN Tag Data Register.

61.6.6.8 Programming Sequence for Queue/Channel Based VLAN Inclusion Register

To program the queue/channel-based VLAN inclusion register:

NOTE

Indirect VLAN include registers are not accessed while setting the CBTI bit.

1. Set the CBTI bit of MAC_VLAN_INCL register to 1, to enable queue/channel based VLAN Tag insertion on all transmitted packets. This bit must be set before any indirect access to the queue/channel specific MAC_VLAN_INCL(#i) register.
2. Program the VLAN Tag and VLAN Type to be inserted in packets from a particular queue/channel in VLT and CSVL fields of MAC_VLAN_INCL register; corresponding offset address in ADDR field (0 for queue/channel 0, 1 for queue/channel 1, and so on) must be set. Set the RDWR bit to 0 to indicate write access. The write to byte 0 (byte 3 in Big Endian mode) of MAC_VLAN_INCL register initiates access to indirect access MAC_VLAN_INCL(#i) register.
3. The BUSY bit of MAC_VLAN_INCL register is set by the module to indicate the progress of access to indirect access MAC_VLAN_INCL(#i) register. On completion of the access, the BUSY bit is cleared. The application must not attempt subsequent access to MAC_VLAN_INCL(#i) register when the BUSY bit is 1.
4. Repeat step 2 and step 3 to program VLAN Tag and VLAN Type to be inserted in packets from the remaining queues/channels. The application must ensure that the required VLAN Tag and VLAN Type for all the queues/channels are programmed; otherwise unintended VLAN Tag and VLAN Type might be inserted.

61.6.7 Programming Guidelines for EST

Program the gate control values and time intervals in the Software Owned Gate Control List (SWOL) along with the other EST related registers that are described in ENET_QOS register descriptions to appropriate values. The following sub-sections provide step by step details for programming the GCL and the other EST related registers.

61.6.7.1 Programming the GCL and GCL Linked Registers

To program the Gate Control List (GCL) and the four other registers implemented per GCL:

1. The GCL and the four other GCL-linked registers should be accessed via indirect addressing using the MTL_EST_GCL_CONTROL and MTL_EST_GCL_DATA

registers. The SWOL bit of the MTL_EST_STATUS register indicates if GCL0 or GCL1 is owned by software.

2. To program the GCL, write the 32-bit write data to MTL_EST_GCL_DATA register. Then program TL_EST_GCL_CONTROL register to write the write address and other control information.
3. In the MTL_EST_GCL_DATA register, Write Data consists of up to 8 bits (5 configurable, 3 reserved) of Gate Controls and up to 24 bits (configurable) of Time Interval. Gate Close is indicated by programming a '0' and Gate Open is indicated by programming a '1'. For a 4-TC and 20-bit Time Interval Configuration, the data width is 24-bits and the remaining 8-bits are reserved/read-only. The data should be written in the following format.

   {8'h0, TC3, TC2, TC1, TC0, 20-bit Time Interval} where TCx = 0 or 1.

4. MTL_EST_GCL_CONTROL register: Program the SRWO bit to 1 (to start a Write Op) and program the address and R/W fields appropriately.
5. Poll and check for the SRWO bit to be cleared by hardware to indicate the completion of the previous operation before initiating a new R/W operation via the same indirect addressing mode.
6. Repeat steps 3, 4, 5 until the programming of the GCL is completed.
7. Using the same indirect addressing method described above, program the BTR, CTR, TER and LLR registers. Set the GCRR bit in the MTL_EST_GCL_CONTROL register appropriately. The GCRR bit interprets the address field as belonging to these registers (instead of the GCL).

After programming of the GCL and the related registers, program the MTL_EST_CONTROL register to allow hardware to own and process the GCL.When the List Length (as indicated in LLR) is 1, the associated Time Interval should be smaller than the value of the Cycle Time Register. Otherwise, an error is reported (as detailed in the Error handling section) as a single set of gate controls add no value in the TSN context.

NOTE

The time unit in all the GCL related registers is seconds and nanoseconds. In cases where internally generated PTP System Time is used, the nanoseconds field must be programmed to use the Digital Rollover mode. (TSCTRLSSR field of MAC_TIMESTAMP_CONTROL must be set to value '1')

61.6.7.2 Programming the EST Registers

After completing the steps mentioned in "Programming the GCL and GCL Linked Registers" , program the MTL_EST_CONTROL register.

1. Set the Current Time Offset Value and Time Internal Left Shift fields of the MTL_EST_CONTROL register appropriately. Also, set the Enable EST (EEST) and Switch to SWOL (SWOL) bits.

   NOTE

   The CTOV recommendations for GMII for SPRAM configurations are:

   - 96 * Tx clock period, for 32 and 64 bit data width configurations.
   - 128 * Tx clock period for 128 bit data width configurations.

   The CTOV recommendations for GMII for non-SPRAM configurations are:

   - 30 * Tx clock period, when SA/VLAN insertion is enabled.
   - 22 * Tx clock period, when SA/VLAN insertion is not enabled.

2. This will enable the hardware to own and process the new GCL and make a switch to the new GCL at the BTR value. The hardware provides an interrupt (if enabled) when the switch to the new list happens.
3. Appropriate action has to be taken by software to address any other interrupts (explained in the Inter-rupts section) received during the hardware execution of the GCL.

Set the SSWL (Switch to Software Owned List) bit in the MTL_EST_CONTROL register to handoff to hardware. Software is not allowed to write to the GCL and GCL linked registers when the SSWL bit is set, because the new GCL might be in use by the hardware.

The SSWL is reset/cleared by the hardware when it successfully switches to the new list. The hardware also flips the SWOL bit to indicate the new GCL that the software owns.

To install a new GCL, program the GCL it owns (indicated by SWOL bit) as described in "Programming the GCL and GCL Linked Registers" and then program the MTL_EST_CONTROL register as described above. Ensure that the new BTR is set to an appropriate value to avoid BTRError that might need software intervention in some cases.

To avoid transmission overruns, the packet length (frame size) information should be available at all times. Therefore, in the DMA configurations, program the packet length in the first descriptor of every Tx frame. Similarly, in the MTL configuration, provide the packet length in the control word.

NOTE

To avoid transmission overruns, the Packet Length provided in the Transmit Descriptor should account for the SA and VLAN insertion, if applicable, that is, Packet Length should represent the actual packet length on the Ethernet line.

61.6.8 Programming the Launch Time in Time-Based Scheduling

The Launch Time is programmed in the Enhanced Normal Transmit Descriptors in DMA configurations and is driven as a control word in MTL configurations as follows:

The OSTC and Launch Time features are mutually exclusive and should not be used together; in case of a conflict (if OSTC = LTV = 1 in MTL configuration), priority is given to OSTC and the Launch Time is ignored.

In DMA configuration, if a context descriptor is received with a valid OSTC values immediately before receiving a first normal descriptor with LTV bit set, then the LTV is ignored.

61.6.9 Programming Guidelines for Media Clock Generation and Recovery

61.6.9.1 Programming Guidelines for Media Clock Generation

1. To set the PPS instance in Media Clock generation mode, program the appropriate Presentation Time Control (supported generation modes "1001-1011") to PPSCTRL_PPSCMD (for 0th instance)/PPSCMD#i (for 1,2,3 instances) of MAC_PPS_CONTROL register.
2. Based on the selected PPS instance, application must drive the appropriate trigger signal to the corresponding mcg_pst_trig_i[#i].

3. Based on the programmed mode, DUT captures the timestamp and programs it in the MAC_PPS(#i)_TARGET_TIME_SECONDS register. Then, mcgr_dma_req_o[#i] is set.
4. For every request generated by the DUT, the module reads the corresponding MAC_PPS(#i)_TARGET_TIME_SECONDS register and acknowledge the read request by asserting the corresponding mcgr_dma_ack_i[#i].

61.6.9.2 Programming Guidelines for Media Clock Recovery

1. Enable the Current Presentation Time (CPT) Counter by setting the PTGE field of MAC_TIMESTAMP_CONTROL register. In addition to programming the initialization values for the System Time, update the MAC_PRESN_TIME_UPDT register with the equivalent Presentation Time init value. Only then the TSINIT field of MAC_TIMESTAMP_CONTROL register is set.
2. The Increment values used for the System time is also used for the Current Presentation time. This is because, the increment value is in Sub-seconds and Sub-nanoseconds.
3. When an update is needed, along with programming the update values for the System Time, the MAC_PRESN_TIME_UPDT register should be updated with the equivalent Presentation Time update value (32-bit ns). Finally, TSUPDT field of MAC_TIMESTAMP_CONTROL register must be set for the update to happen.
4. Program the MCGREN#i of MAC_PPS_CONTROL register to enable the PPS instance to operate in MCGR mode.
5. To set the PPS instance in Media Clock recovery mode, program the appropriate Presentation Time Control (supported recovery modes "0001 - 0011") to PPSCTRL_PPSCMD (for 0th instance)/PPSCMD#i (for 1,2,3 instances) of MAC_PPS_Control register.
6. After PPS instance is set in recovery mode, corresponding mcgr_dma_req_o[#i] is set by the DUT. For every request generated by the DUT, program the target presentation time into the MAC_PPS(#i)_TARGET_TIME_SECONDS register and acknowledge the request by asserting the corresponding mcgr_d-ma_ack_i[#i]. Acknowledgment can be given before/after programming the Target presentation time.
7. Observe the recovered media clock on the corresponding ptp_pps_o[#i].

61.6.10 Programming Guidelines for ECC Protection for Memories

1. Enable the ECC feature for the respective memory by setting the appropriate bit in MTL_ECC_CONTROL register.
2. A correctable interrupt (sbd_sfty_ce_intr_o) or an uncorrectable interrupt (sbd_sfty_ue_intr_o) are generated to indicate to the application if any correctable/ uncorrectable/address errors are detected. Appropriate status is indicated in the DMA/MTL_ECC_INTERRUPT_STATUS register.
3. Debug mode is provided for each memory to specify errors.

NOTE

Enable the ECC feature before the traffic is online (or after the reset), otherwise false interrupts might be triggered.

61.6.10.1 Programming Guidelines for ECC Hardware Error Injection (Debug Mode)

1. Enable the ECC error injection feature for MTL TX/RX and DMA TSO, by setting the appropriate bit in the MTL_DBG_CTL register.
2. Enable the ECC error injection feature for the EST memory by setting the appropriate bit in the EST_GCL_CONTROL register.
3. Enable the ECC error injection for RX Parser memory by setting the appropriate bit in the MTL_RXP_INDIRECT_ACC_CONTROL_STATUS register. To access Rx Parser memory in debug mode, disable the Rx Parser feature by setting the FRPE bit of MTL_OPERATION_MODE register to 0.
4. Where multiple CSR writes are required, for writing single data word into the memory, the application should ensure that all the CSR writes corresponding to one memory write should have the same value for the error injection control word.

61.6.11 Programming Guidelines for On-Chip Datapath Parity Protection

Follow the below steps for on-chip datapath parity protection:

1. Set the EDPP bit of MTL_DPP_CONTROL register to enable the generation of parity and detection of parity Mismatch on datapath.

2. An uncorrectable interrupt (sbd_sfty_ue_intr_o) is generated to indicate to the application whether any parity Mismatches are detected and the appropriate status will be indicated in DMA/MTL_SAFETY_INTERRUPT_STATUS and MAC_DPP_FSM_INTERRUPT_STATUS register.
3. Debug mode is supported for each parity generator, to insert error.

NOTE

To avoid false safety interrupts, enable the datapath parity protection before the start of Rx or Tx traffic.

61.6.12 Programming Guidelines for FSM Parity and Timeout

To program the FSM parity and timeout:

1. Set the PRTYEN and TMOUTEN fields of MAC_FSM_CONTROL register to enable the FSM parity and timeout feature respectively.
2. For parity error detection, force the FSMs to enter into a state with even number of 1s and wait for the safety uncorrectable interrupt to be set with FSMPES of MAC_DPP_FSM_INTERRUPT_STATUS.
3. For Error Injection mode in FSM parity, select the appropriate clock domain for which parity error injection should be set using the [23:16] bits of MAC_FSM_CONTROL register. Wait for the safety uncorrectable interrupt to be set with FSMPES of MAC_DPP_FSM_INTERRUPT_STATUS.
4. For FSM Timeouts, program the large and normal mode values indicated by LTMRMD and NTMRMD of MAC_FSM_ACT_TIMER register.
5. Select large or normal mode tic generation per clock domain by using the [31:24] bits of MAC_FSM_CONTROL Register.
6. Set the TMR field of the MAC_ACT_TIMER field with the appropriate number of CSR clock cycles used to generate 1-microsecond tic.
7. Force the FSM in a particular clock domain to be in an active state for Timeout duration (for example, T-2T). Check for the safety interrupt and the status bit for the corresponding clock domain getting set in [15:8] bits of MAC_DPP_FSM_INTERRUPT_STATUS register.

8. For Error Injection mode in FSM timeout, select the appropriate clock domain for which timeout error injection must be set using the [15:8] bits of MAC_FSM_CONTROL register. Wait for the safety uncorrectable interrupt along with the corresponding error status set in MAC_DPP_FSM_INTERRUPT_STATUS.
9. For application/CSR interface timeout, only normal mode tic generation is used. Based on the timeouts of the configured interface, appropriate fields (MSTTES, SLVTES) of MAC_DPP_FSM_INTERRUPT_STATUS are set along with the safety interrupt.

61.7 Memory Map and register definition

NOTE

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

This section includes the ENET module memory map and detailed descriptions of all registers.

61.7.1 ENET_QOS register descriptions

61.7.1.2.4 Fields

Field	Function
31 —	Reserved
30-28 SARC	Source Address Insertion or Replacement Control This field controls the source address insertion or replacement for all transmitted packets. Bit 30 specifies which MAC Address register (0 or 1) is used for source address insertion or replacement based on the values of Bits[29:28]: 2'b0x: - The mti_sa_ctrl_i and ati_sa_ctrl_i input signals control the SA field generation. 2'b10: - If Bit 30 is set to 0, the MAC inserts the content of the MAC Address 0 registers in the SA field of all transmitted packets. - If Bit 30 is set to 1 and the Enable MAC Address Register 1 option is selected while configuring the core, the MAC inserts the content of the MAC Address 1 registers in the SA field of all transmitted packets. 2'b11: - If Bit 30 is set to 0, the MAC replaces the content of the MAC Address 0 registers in the SA field of all transmitted packets. - If Bit 30 is set to 1 and the MAC Address Register 1 is enabled, the MAC replaces the content of the MAC Address 1 registers in the SA field of all transmitted packets. Note:

Table continues on the next page...

Field	Function
	- Changes to this field take effect only on the start of a packet. If you write to this register field when a packet is being transmitted, only the subsequent packet can use the updated value, that is, the current packet does not use the updated value. 000b - mti_sa_ctrl_i and ati_sa_ctrl_i input signals control the SA field generation 010b - Contents of MAC Addr-0 inserted in SA field 011b - Contents of MAC Addr-0 replaces SA field 110b - Contents of MAC Addr-1 inserted in SA field 111b - Contents of MAC Addr-1 replaces SA field
27 IPC	Checksum Offload When set, this bit enables the IPv4 header checksum checking and IPv4 or IPv6 TCP, UDP, or ICMP payload checksum checking. When this bit is reset, the COE function in the receiver is disabled. The Layer 3 and Layer 4 Packet Filter and Enable Split Header features automatically selects the IPC Full Checksum Offload Engine on the Receive side. When any of these features are enabled, you must set the IPC bit. 0b - IP header/payload checksum checking is disabled 1b - IP header/payload checksum checking is enabled
26-24 IPG	Inter-Packet Gap These bits control the minimum IPG between packets during transmission. Inter-Packet Gap These bits control the minimum IPG between packets during transmission. This range of minimum IPG is valid in full-duplex mode. In the half-duplex mode, the minimum IPG can be configured only for 64-bit times (IPG = 100). Lower values are not considered. When a JAM pattern is being transmitted because of backpressure activation, the MAC does not consider the minimum IPG. The above function (IPG less than 96 bit times) is valid only when EIPGEN bit in MAC_EXT_CONFIGURATION register is reset. When EIPGEN is set, then the minimum IPG (greater than 96 bit times) is controlled as per the description given in EIPG field in MAC_EXT_CONFIGURATION register. 000b - 96 bit times IPG 001b - 88 bit times IPG 010b - 80 bit times IPG 011b - 72 bit times IPG 100b - 64 bit times IPG 101b - 56 bit times IPG 110b - 48 bit times IPG 111b - 40 bit times IPG
23 GPSLCE	Giant Packet Size Limit Control Enable When this bit is set, the MAC considers the value in GPSL field in MAC_EXT_CONFIGURATION register to declare a received packet as Giant packet. This field must be programmed to more than 1,518 bytes. Otherwise, the MAC considers 1,518 bytes as giant packet limit. When this bit is reset, the MAC considers a received packet as Giant packet when its size is greater than 1,518 bytes (1522 bytes for tagged packet). The watchdog timeout limit, Jumbo Packet Enable and 2K Packet Enable have higher precedence over this bit, that is the MAC considers a received packet as Giant packet when its size is greater than 9,018 bytes (9,022 bytes for tagged packet) with Jumbo Packet Enabled and greater than 2,000 bytes with 2K Packet Enabled. The watchdog timeout, if enabled, terminates the received packet when watchdog limit is reached. Therefore, the programmed giant packet limit should be less than the watchdog limit to get the giant packet status. 0b - Giant Packet Size Limit Control is disabled

Table continues on the next page...

Field	Function
	1b - Giant Packet Size Limit Control is enabled
22 S2KP	IEEE 802. IEEE 802.3as Support for 2K Packets When this bit is set, the MAC considers all packets with up to 2,000 bytes length as normal packets. When the JE bit is not set, the MAC considers all received packets of size more than 2K bytes as Giant packets. When this bit is reset and the JE bit is not set, the MAC considers all received packets of size more than 1,518 bytes (1,522 bytes for tagged) as giant packets. For more information about how the setting of this bit and the JE bit impact the Giant packet status, see the Table, Gaint Packet Status based on S2KP and JE Bits. Note: When the JE bit is set, setting this bit has no effect on the giant packet status. 0b - Support upto 2K packet is disabled 1b - Support upto 2K packet is Enabled
21 CST	CRC stripping for Type packets When this bit is set, the last four bytes (FCS) of all packets of Ether type (type field greater than 1,536) are stripped and dropped before forwarding the packet to the application. CRC stripping for Type packets When this bit is set, the last four bytes (FCS) of all packets of Ether type (type field greater than 1,536) are stripped and dropped before forwarding the packet to the application. Note: For information about how the settings of the ACS bit and this bit impact the packet length, see the Table, Packet Length based on the CST and ACS Bits. 0b - CRC stripping for Type packets is disabled 1b - CRC stripping for Type packets is enabled
20 ACS	Automatic Pad or CRC Stripping When this bit is set, the MAC strips the Pad or FCS field on the incoming packets only if the value of the length field is less than 1,536 bytes. Automatic Pad or CRC Stripping When this bit is set, the MAC strips the Pad or FCS field on the incoming packets only if the value of the length field is less than 1,536 bytes. All received packets with length field greater than or equal to 1,536 bytes are passed to the application without stripping the Pad or FCS field. When this bit is reset, the MAC passes all incoming packets to the application, without any modification. Note: For information about how the settings of CST bit and this bit impact the packet length, see the Table, Packet Length based on the CST and ACS Bit . 0b - Automatic Pad or CRC Stripping is disabled 1b - Automatic Pad or CRC Stripping is enabled
19 WD	Watchdog Disable When this bit is set, the MAC disables the watchdog timer on the receiver. The MAC can receive packets of up to 16,383 bytes. When this bit is reset, the MAC does not allow more than 2,048 bytes (10,240 if JE is set high) of the packet being received. The MAC cuts off any bytes received after 2,048 bytes. 0b - Watchdog is enabled 1b - Watchdog is disabled
18 BE	Packet Burst Enable When this bit is set, the MAC allows packet bursting during transmission in the GMII half-duplex mode. 0b - Packet Burst is disabled 1b - Packet Burst is enabled
17 JD	Jabber Disable

Table continues on the next page...

Field	Function
	When this bit is set, the MAC disables the jabber timer on the transmitter. The MAC can transfer packets of up to 16,383 bytes. When this bit is reset, if the application sends more than 2,048 bytes of data (10,240 if JE is set high) during transmission, the MAC does not send rest of the bytes in that packet. 0b - Jabber is enabled 1b - Jabber is disabled
16 JE	Jumbo Packet Enable When this bit is set, the MAC allows jumbo packets of 9,018 bytes (9,022 bytes for VLAN tagged packets) without reporting a giant packet error in the Rx packet status. 0b - Jumbo packet is disabled 1b - Jumbo packet is enabled
15 PS	Port Select This bit selects the Ethernet line speed. This bit, along with Bit 14, selects the exact line speed. In the 10/100 Mbps-only (always 1) or 1000 Mbps-only (always 0) configurations, this bit is read-only (RO) with appropriate value. In default 10/100/1000 Mbps configurations, this bit is read-write (R/W). The mac_speed_o[1] signal reflects the value of this bit. 0b - For 1000 or 2500 Mbps operations 1b - For 10 or 100 Mbps operations
14 FES	Speed This bit selects the speed mode. The mac_speed_o[0] signal reflects the value of this bit. 0b - 10 Mbps when PS bit is 1 and 1 Gbps when PS bit is 0 1b - 100 Mbps when PS bit is 1 and 2.5 Gbps when PS bit is 0
13 DM	Duplex Mode When this bit is set, the MAC operates in the full-duplex mode in which it can transmit and receive simultaneously. This bit is RO with default value of 1'b1 in the full-duplex-only configurations. 0b - Half-duplex mode 1b - Full-duplex mode
12 LM	Loopback Mode When this bit is set, the MAC operates in the loopback mode at GMII or MII. The (G)MII Rx clock input (clk_rx_i) is required for the loopback to work properly. This is because the Tx clock is not internally looped back. 0b - Loopback is disabled 1b - Loopback is enabled
11 ECRSFD	Enable Carrier Sense Before Transmission in Full-Duplex Mode When this bit is set, the MAC transmitter checks the CRS signal before packet transmission in the full-duplex mode. The MAC starts the transmission only when the CRS signal is low. When this bit is reset, the MAC transmitter ignores the status of the CRS signal. 0b - ECRSFD is disabled 1b - ECRSFD is enabled
10 DO	Disable Receive Own When this bit is set, the MAC disables the reception of packets when the gmii_txen_o is asserted in the half-duplex mode. When this bit is reset, the MAC receives all packets given by the PHY. This bit is not applicable in the full-duplex mode. 0b - Enable Receive Own

Table continues on the next page...

Field	Function
	1b - Disable Receive Own
9 DCRS	Disable Carrier Sense During Transmission When this bit is set, the MAC transmitter ignores the (G)MII CRS signal during packet transmission in the half-duplex mode. As a result, no errors are generated because of Loss of Carrier or No Carrier during transmission. When this bit is reset, the MAC transmitter generates errors because of Carrier Sense. The MAC can even abort the transmission. 0b - Enable Carrier Sense During Transmission 1b - Disable Carrier Sense During Transmission
8 DR	Disable Retry When this bit is set, the MAC attempts only one transmission. When a collision occurs on the GMII or MII interface, the MAC ignores the current packet transmission and reports a Packet Abort with excessive collision error in the Tx packet status. When this bit is reset, the MAC retries based on the settings of the BL field. This bit is applicable only in the half-duplex mode. 0b - Enable Retry 1b - Disable Retry
7 —	Reserved
6-5 BL	Back-Off Limit The back-off limit determines the random integer number (r) of slot time delays (4,096 bit times for 1000/2500 Mbps; 512 bit times for 10/100 Mbps) for which the MAC waits before rescheduling a transmission attempt during retries after a collision. n = retransmission attempt. The random integer r takes the value in the range 0 <= r < 2^k This bit is applicable only in the half-duplex mode. 00b - k = min(n,10) 01b - k = min(n,8) 10b - k = min(n,4) 11b - k = min(n,1)
4 DC	Deferral Check When this bit is set, the deferral check function is enabled in the MAC. The MAC issues a Packet Abort status, along with the excessive deferral error bit set in the Tx packet status, when the Tx state machine is deferred for more than 24,288 bit times in 10 or 100 Mbps mode. If the MAC is configured for 1000/2500 Mbps operation, the threshold for deferral is 155,680 bits times. Deferral begins when the transmitter is ready to transmit, but it is prevented because of an active carrier sense signal (CRS) on GMII or MII. The defer time is not cumulative. For example, if the transmitter defers for 10,000 bit times because the CRS signal is active and the CRS signal becomes inactive, the transmitter transmits and collision happens. Because of collision, the transmitter needs to back off and then defer again after back off completion. In such a scenario, the deferral timer is reset to 0, and it is restarted. When this bit is reset, the deferral check function is disabled and the MAC defers until the CRS signal goes inactive. This bit is applicable only in the half-duplex mode. 0b - Deferral check function is disabled 1b - Deferral check function is enabled

Table continues on the next page...

Field	Function
3-2 PRELEN	Preamble Length for Transmit packets These bits control the number of preamble bytes that are added to the beginning of every Tx packet. The preamble reduction occurs only when the MAC is operating in the full-duplex mode. 00b - 7 bytes of preamble 01b - 5 bytes of preamble 10b - 3 bytes of preamble 11b - Reserved
1 TE	Transmitter Enable When this bit is set, the Tx state machine of the MAC is enabled for transmission on the GMII or MII interface. When this bit is reset, the MAC Tx state machine is disabled after it completes the transmission of the current packet. The Tx state machine does not transmit any more packets. 0b - Transmitter is disabled 1b - Transmitter is enabled
0 RE	Receiver Enable When this bit is set, the Rx state machine of the MAC is enabled for receiving packets from the GMII or MII interface. When this bit is reset, the MAC Rx state machine is disabled after it completes the reception of the current packet. The Rx state machine does not receive any more packets from the GMII or MII interface. 0b - Receiver is disabled 1b - Receiver is enabled

61.7.1.3 MAC Extended Configuration Register (MAC_EXT_CONFIGURATION)

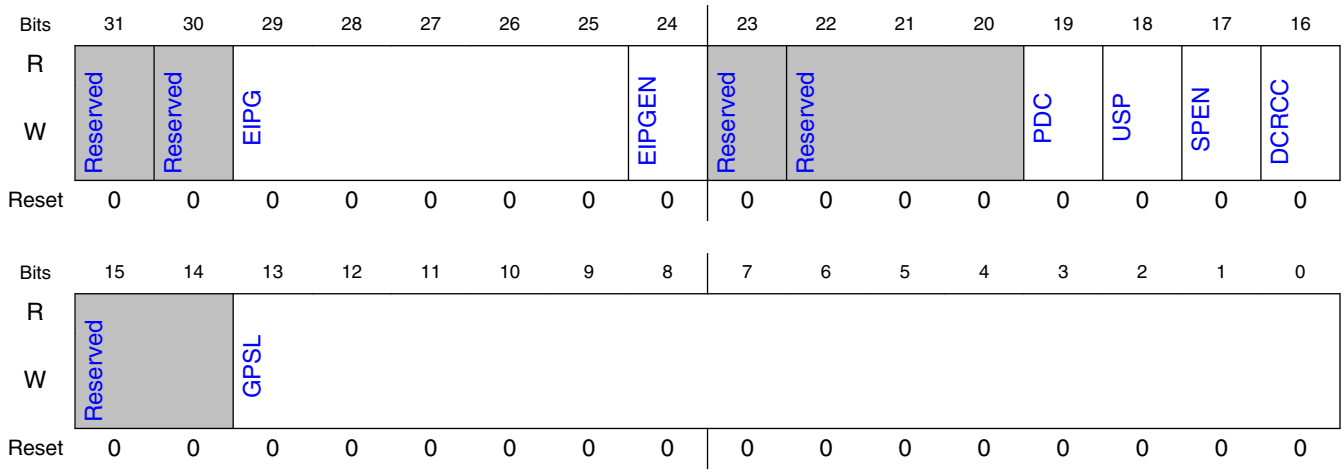
61.7.1.3.1 Offset

Register	Offset
MAC_EXT_CONFIGURATION	4h

61.7.1.3.2 Function

The MAC Extended Configuration Register establishes the operating mode of the MAC.

61.7.1.3.3 Diagram



61.7.1.3.4 Fields

Field	Function
31 —	Reserved
30 —	Reserved
29-25 EIPG	Extended Inter-Packet Gap The value in this field is applicable when the EIPGEN bit is set. This field (as Most Significant bits), along with IPG field in CONFIGURATION register, gives the minimum IPG greater than 96 bit times in steps of 8 bit times: {EIPG, IPG} 8'h00 - 104 bit times 8'h01 - 112 bit times 8'h02 - 120 bit times ---------- 8'hFF - 2144 bit times
24 EIPGEN	Extended Inter-Packet Gap Enable When this bit is set, the MAC interprets EIPG field and IPG field in CONFIGURATION register together as minimum IPG greater than 96 bit times in steps of 8 bit times. When this bit is reset, the MAC ignores EIPG field and interprets IPG field in CONFIGURATION register as minimum IPG less than or equal to 96 bit times in steps of 8 bit times. Note: The extended Inter-Packet Gap feature must be enabled when operating in Full-Duplex mode only. There may be undesirable effects on back-pressure function and frame transmission if it is enabled in Half-Duplex mode. 0b - Extended Inter-Packet Gap is disabled 1b - Extended Inter-Packet Gap is enabled
23	Reserved

Table continues on the next page...

Field	Function
—	
22-20 —	Reserved
19 PDC	Packet Duplication Control When this bit is set, the received packet with Multicast/Broadcast Destination address is routed to multiple Receive DMA Channels. The Receive DMA Channels is identified by the DCS field of MAC_ADDRESS(#i)_HIGH register corresponding to the MAC Address register that matches the Multicast/Broadcast Destination address in the received packet. The DCS field is interpreted to be a one-hot value, each bit corresponding to the Receive DMA Channel. When this bit is reset, the received packet is routed to single Receive DMA Channel. The Receive DMA Channel is identified by the DCS field of ADDRESS(#i)_High register corresponding to the MAC Address register that matches the Destination address in the received packet. The DCS field is interpreted as a binary value. 0b - Packet Duplication Control is disabled 1b - Packet Duplication Control is enabled
18 USP	Unicast Slow Protocol Packet Detect When this bit is set, the MAC detects the Slow Protocol packets with unicast address of the station specified in the MAC_ADDRESS0_HIGH and MAC_ADDRESS0_LOW registers. The MAC also detects the Slow Protocol packets with the Slow Protocols multicast address (01-80-C2-00-00-02). When this bit is reset, the MAC detects only Slow Protocol packets with the Slow Protocol multicast address specified in the IEEE 802.3-2015, Section 5. 0b - Unicast Slow Protocol Packet Detection is disabled 1b - Unicast Slow Protocol Packet Detection is enabled
17 SPEN	Slow Protocol Detection Enable When this bit is set, MAC processes the Slow Protocol packets (Ether Type 0x8809) and provides the Rx status. The MAC discards the Slow Protocol packets with invalid sub-types. When this bit is reset, the MAC forwards all error-free Slow Protocol packets to the application. The MAC considers such packets as normal Type packets. 0b - Slow Protocol Detection is disabled 1b - Slow Protocol Detection is enabled
16 DCRCC	Disable CRC Checking for Received Packets When this bit is set, the MAC receiver does not check the CRC field in the received packets. When this bit is reset, the MAC receiver always checks the CRC field in the received packets. 0b - CRC Checking is enabled 1b - CRC Checking is disabled
15-14 —	Reserved
13-0 GPSL	Giant Packet Size Limit If the received packet size is greater than the value programmed in this field in units of bytes, the MAC declares the received packet as Giant packet. The value programmed in this field must be greater than or equal to 1,518 bytes. Any other programmed value is considered as 1,518 bytes. For VLAN tagged packets, the MAC adds 4 bytes to the programmed value. When the Enable Double VLAN Processing option is selected, the MAC adds 8 bytes to the programmed value for double VLAN tagged packets. The value in this field is applicable when the GPSLCE bit is set in MAC_CONFIGURATION register.

61.7.1.4 MAC Packet Filter (MAC_PACKET_FILTER)

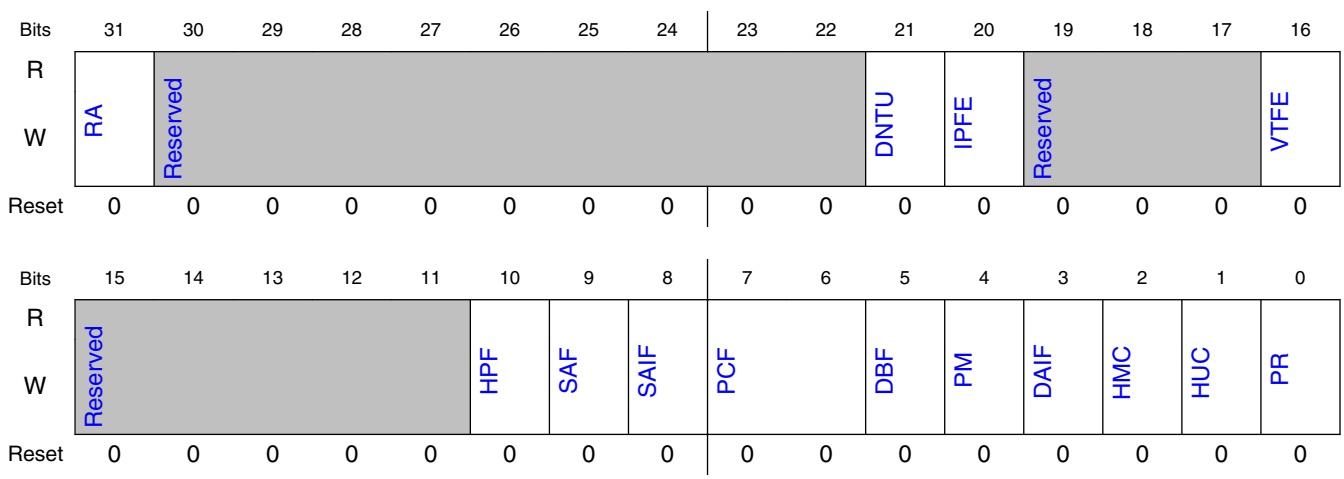
61.7.1.4.1 Offset

Register	Offset
MAC_PACKET_FILTER	8h

61.7.1.4.2 Function

The MAC Packet Filter register contains the filter controls for receiving packets. Some of the controls from this register go to the address check block of the MAC which performs the first level of address filtering. The second level of filtering is performed on the incoming packet based on other controls such as Pass Bad Packets and Pass Control Packets.

61.7.1.4.3 Diagram



61.7.1.4.4 Fields

Field	Function
31 RA	Receive All When this bit is set, the MAC Receiver module passes all received packets to the application, irrespective of whether they pass the address filter or not. The result of the SA or DA filtering is updated (pass or fail) in the corresponding bit in the Rx Status Word. When this bit is reset, the Receiver module passes only those packets to the application that pass the SA or DA address filter.

Table continues on the next page...

Field	Function
	0b - Receive All is disabled 1b - Receive All is enabled
30-22 —	Reserved
21 DNTU	Drop Non-TCP/UDP over IP Packets When this bit is set, the MAC drops the non-TCP or UDP over IP packets. The MAC forward only those packets that are processed by the Layer 4 filter. When this bit is reset, the MAC forwards all non-TCP or UDP over IP packets. 0b - Forward Non-TCP/UDP over IP Packets 1b - Drop Non-TCP/UDP over IP Packets
20 IPFE	Layer 3 and Layer 4 Filter Enable When this bit is set, the MAC drops packets that do not match the enabled Layer 3 and Layer 4 filters. If Layer 3 or Layer 4 filters are not enabled for matching, this bit does not have any effect. When this bit is reset, the MAC forwards all packets irrespective of the match status of the Layer 3 and Layer 4 fields. 0b - Layer 3 and Layer 4 Filters are disabled 1b - Layer 3 and Layer 4 Filters are enabled
19-17 —	Reserved
16 VTFE	VLAN Tag Filter Enable When this bit is set, the MAC drops the VLAN tagged packets that do not match the VLAN Tag. When this bit is reset, the MAC forwards all packets irrespective of the match status of the VLAN Tag. 0b - VLAN Tag Filter is disabled 1b - VLAN Tag Filter is enabled
15-11 —	Reserved
10 HPF	Hash or Perfect Filter When this bit is set, the address filter passes a packet if it matches either the perfect filtering or hash filtering as set by the HMC or HUC bit. When this bit is reset and the HUC or HMC bit is set, the packet is passed only if it matches the Hash filter. 0b - Hash or Perfect Filter is disabled 1b - Hash or Perfect Filter is enabled
9 SAF	Source Address Filter Enable When this bit is set, the MAC compares the SA field of the received packets with the values programmed in the enabled SA registers. If the comparison fails, the MAC drops the packet. When this bit is reset, the MAC forwards the received packet to the application with updated SAF bit of the Rx Status depending on the SA address comparison. Note: According to the IEEE specification, Bit 47 of the SA is reserved. However, in DWC_ether_qos, the MAC compares all 48 bits. The software driver should take this into consideration while programming the MAC address registers for SA. 0b - SA Filtering is disabled 1b - SA Filtering is enabled
8 SAIF	SA Inverse Filtering

Table continues on the next page...

Field	Function
	When this bit is set, the Address Check block operates in the inverse filtering mode for SA address comparison. If the SA of a packet matches the values programmed in the SA registers, it is marked as failing the SA Address filter. When this bit is reset, if the SA of a packet does not match the values programmed in the SA registers, it is marked as failing the SA Address filter. 0b - SA Inverse Filtering is disabled 1b - SA Inverse Filtering is enabled
7-6 PCF	Pass Control Packets These bits control the forwarding of all control packets (including unicast and multicast Pause packets). 00b - MAC filters all control packets from reaching the application 01b - MAC forwards all control packets except Pause packets to the application even if they fail the Address filter 10b - MAC forwards all control packets to the application even if they fail the Address filter 11b - MAC forwards the control packets that pass the Address filter
5 DBF	Disable Broadcast Packets When this bit is set, the AFM module blocks all incoming broadcast packets. In addition, it overrides all other filter settings. When this bit is reset, the AFM module passes all received broadcast packets. 0b - Enable Broadcast Packets 1b - Disable Broadcast Packets
4 PM	Pass All Multicast When this bit is set, it indicates that all received packets with a multicast destination address (first bit in the destination address field is '1') are passed. When this bit is reset, filtering of multicast packet depends on HMC bit. 0b - Pass All Multicast is disabled 1b - Pass All Multicast is enabled
3 DAIF	DA Inverse Filtering When this bit is set, the Address Check block operates in inverse filtering mode for the DA address comparison for both unicast and multicast packets. When this bit is reset, normal filtering of packets is performed. 0b - DA Inverse Filtering is disabled 1b - DA Inverse Filtering is enabled
2 HMC	Hash Multicast When this bit is set, the MAC performs the destination address filtering of received multicast packets according to the hash table. When this bit is reset, the MAC performs the perfect destination address filtering for multicast packets, that is, it compares the DA field with the values programmed in DA registers. 0b - Hash Multicast is disabled 1b - Hash Multicast is enabled
1 HUC	Hash Unicast When this bit is set, the MAC performs the destination address filtering of unicast packets according to the hash table. When this bit is reset, the MAC performs a perfect destination address filtering for unicast packets, that is, it compares the DA field with the values programmed in DA registers. 0b - Hash Unicast is disabled 1b - Hash Unicast is enabled
0	Promiscuous Mode

Field	Function
PR	When this bit is set, the Address Filtering module passes all incoming packets irrespective of the destination or source address. The SA or DA Filter Fails status bits of the Rx Status Word are always cleared when PR is set. 0b - Promiscuous Mode is disabled 1b - Promiscuous Mode is enabled

61.7.1.5 Watchdog Timeout (MAC_WATCHDOG_TIMEOUT)

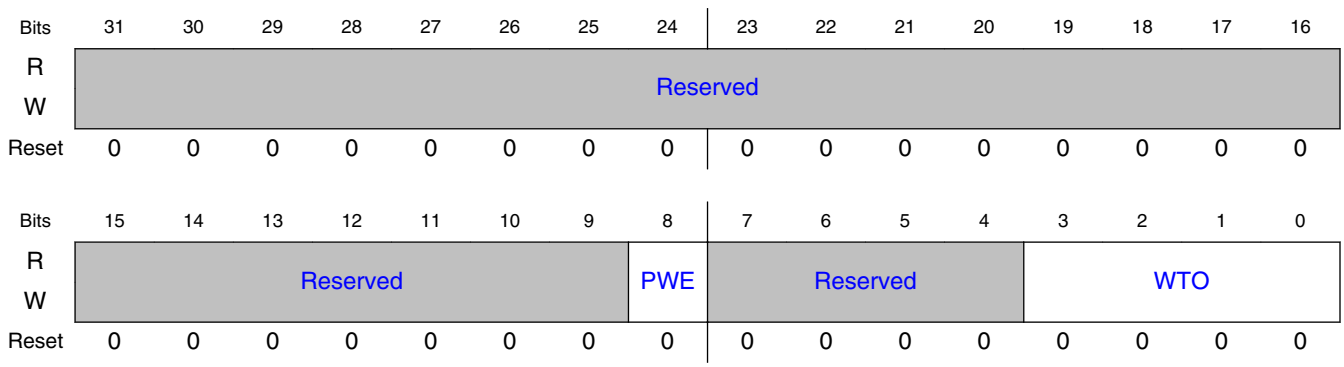
61.7.1.5.1 Offset

Register	Offset
MAC_WATCHDOG_TIMEOUT	Ch

61.7.1.5.2 Function

The Watchdog Timeout register controls the watchdog timeout for received packets.

61.7.1.5.3 Diagram



61.7.1.5.4 Fields

Field	Function
31-9 —	Reserved
8 PWE	Programmable Watchdog Enable

Table continues on the next page...

Field	Function
	When this bit is set and the WD bit of the MAC_CONFIGURATION register is reset, the WTO field is used as watchdog timeout for a received packet. When this bit is cleared, the watchdog timeout for a received packet is controlled by setting of WD and JE bits in MAC_CONFIGURATION register. 0b - Programmable Watchdog is disabled 1b - Programmable Watchdog is enabled
7-4 —	Reserved
3-0 WTO	Watchdog Timeout When the PWE bit is set and the WD bit of the MAC_CONFIGURATION register is reset, this field is used as watchdog timeout for a received packet. If the length of a received packet exceeds the value of this field, such packet is terminated and declared as an error packet. Note: When the PWE bit is set, the value in this field should be more than 1,522 (0x05F2). Otherwise, the IEEE 802.3-specified valid tagged packets are declared as error packets and then dropped. 0000b - 2 KB 0001b - 3 KB 0010b - 4 KB 0011b - 5 KB 0100b - 6 KB 0101b - 7 KB 0110b - 8 KB 0111b - 9 KB 1000b - 10 KB 1001b - 11 KB 1010b - 12 KB 1011b - 13 KB 1100b - 14 KB 1101b - 15 KB 1110b - 16383 Bytes 1111b - Reserved

61.7.1.6 MAC Hash Table Register 0 (MAC_HASH_TABLE_REG0)

61.7.1.6.1 Offset

Register	Offset
MAC_HASH_TABLE_REG0	10h

61.7.1.6.2 Function

The Hash Table Register 0 contains the first 32 bits of the hash table, when the width of the hash table is 128 or 256 bits.

The Hash table is used for group address filtering. For hash filtering, the content of the destination address in the incoming packet is passed through the CRC logic and the upper six (seven in 128-bit Hash or eight in 256-bit Hash) bits of the CRC register are used to index the content of the Hash table. The most significant bits determines the register to be used (Hash Table Register X), and the least significant five bits determine the bit within the register. For example, a hash value of 6'b100000 (in 64-bit Hash) selects Bit 0 of the Hash Table Register 1, a value of 7b'1110000 (in 128-bit Hash) selects Bit 16 of the Hash Table Register 3 and a value of 8b'10111111 (in 256-bit Hash) selects Bit 31 of the Hash Table Register 5.

The hash value of the destination address is calculated in the following way:

- Calculate the 32-bit CRC for the DA (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32).

- Perform bitwise reversal for the value obtained in Step 1.

- Take the upper 6 (or 7 or 8) bits from the value obtained in Step 2.

If the corresponding bit value of the register is 1'b1, the packet is accepted. Otherwise, it is rejected. If the PM bit is set in MAC_Packet_Filter, all multicast packets are accepted regardless of the multicast hash values.

If the Hash Table register is configured to be double-synchronized to the (G)MII clock domain, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Hash Table Register X registers are written.

If double-synchronization is enabled, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.

61.7.1.6.3 Diagram

31-0 HT31T0	MAC Hash Table First 32 Bits This field contains the first 32 Bits [31:0] of the Hash table.

61.7.1.7 MAC Hash Table Register 1 (MAC_HASH_TABLE_REG1)

61.7.1.7.1 Offset

Register	Offset
MAC_HASH_TABLE_REG1	14h

61.7.1.7.2 Function

The Hash Table Register 1 contains the second 32 bits of the hash table.

The Hash table is used for group address filtering. For hash filtering, the content of the destination address in the incoming packet is passed through the CRC logic and the upper six (seven in 128-bit Hash or eight in 256-bit Hash) bits of the CRC register are used to index the content of the Hash table. The most significant bits determines the register to be used (Hash Table Register X), and the least significant five bits determine the bit within the register. For example, a hash value of 6'b100000 (in 64-bit Hash) selects Bit 0 of the Hash Table Register 1, a value of 7b'1110000 (in 128-bit Hash) selects Bit 16 of the Hash Table Register 3 and a value of 8b'10111111 (in 256-bit Hash) selects Bit 31 of the Hash Table Register 5.

The hash value of the destination address is calculated in the following way:

- Calculate the 32-bit CRC for the DA (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32).

- Perform bitwise reversal for the value obtained in Step 1.

- Take the upper 6 (or 7 or 8) bits from the value obtained in Step 2.

If the corresponding bit value of the register is 1'b1, the packet is accepted. Otherwise, it is rejected. If the PM bit is set in MAC_Packet_Filter, all multicast packets are accepted regardless of the multicast hash values.

If the Hash Table register is configured to be double-synchronized to the (G)MII clock domain, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Hash Table Register X registers are written.

If double-synchronization is enabled, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.

61.7.1.8 MAC VLAN Tag Control (MAC_VLAN_TAG_CTRL)

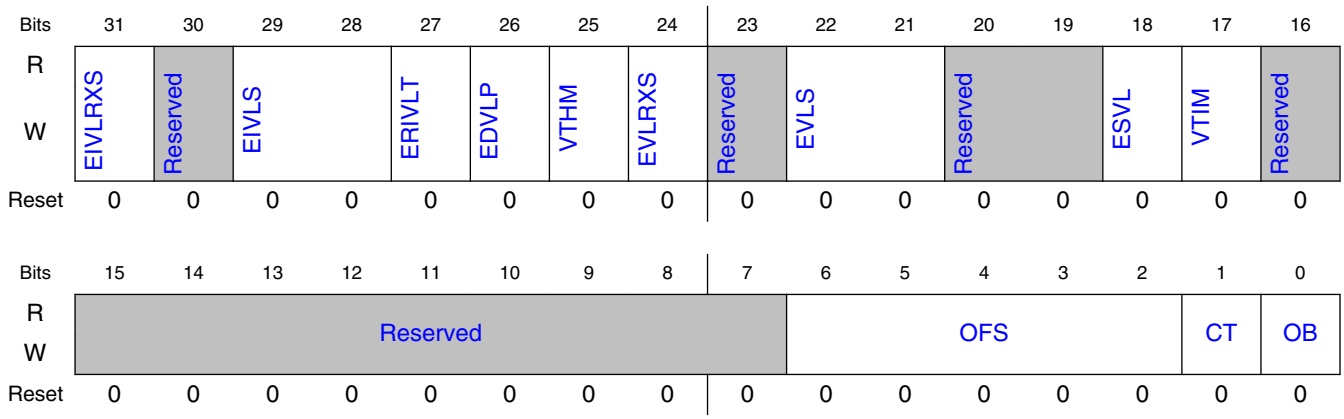
61.7.1.8.1 Offset

Register	Offset
MAC_VLAN_TAG_CTRL	50h

61.7.1.8.2 Function

This register is the redefined format of the MAC VLAN Tag Register. It is used for indirect addressing. It contains the address offset, command type and Busy Bit for CSR access of the Per VLAN Tag registers.

61.7.1.8.3 Diagram



61.7.1.8.4 Fields

Field	Function
31 EIVLRXS	Enable Inner VLAN Tag in Rx Status When this bit is set, the MAC provides the inner VLAN Tag in the Rx status. When this bit is reset, the MAC does not provide the inner VLAN Tag in Rx status. 0b - Inner VLAN Tag in Rx status is disabled 1b - Inner VLAN Tag in Rx status is enabled
30 —	Reserved
29-28 EIVLS	Enable Inner VLAN Tag Stripping on Receive This field indicates the stripping operation on inner VLAN Tag in received packet. 00b - Do not strip 01b - Strip if VLAN filter passes 10b - Strip if VLAN filter fails 11b - Always strip
27 ERIVLT	ERIVLT 0b - Inner VLAN tag is disabled 1b - Inner VLAN tag is enabled
26 EDVLP	Enable Double VLAN Processing When this bit is set, the MAC enables processing of up to two VLAN Tags on Tx and Rx (if present). When this bit is reset, the MAC enables processing of up to one VLAN Tag on Tx and Rx (if present). 0b - Double VLAN Processing is disabled 1b - Double VLAN Processing is enabled
25 VTHM	VLAN Tag Hash Table Match Enable When this bit is set, the most significant four bits of CRC of VLAN Tag (ones-complement of most significant four bits of CRC of VLAN Tag when ETV bit is reset) are used to index the content of the MAC_VLAN_Hash_Table register. A value of 1 in the VLAN Hash Table register, corresponding to the index, indicates that the packet matched the VLAN hash table. When the ETV bit is set, the CRC of the 12-bit VLAN Identifier (VID) is used for comparison. When the ETV bit is reset, the ones-complement of the CRC of the 16-bit VLAN tag is used for comparison.

Table continues on the next page...

Field	Function
	When this bit is reset, the VLAN Hash Match operation is not performed. 0b - VLAN Tag Hash Table Match is disabled 1b - VLAN Tag Hash Table Match is enabled
24 EVLRXS	Enable VLAN Tag in Rx status When this bit is set, MAC provides the outer VLAN Tag in the Rx status. When this bit is reset, the MAC does not provide the outer VLAN Tag in Rx status. 0b - VLAN Tag in Rx status is disabled 1b - VLAN Tag in Rx status is enabled
23 —	Reserved
22-21 EVLS	Enable VLAN Tag Stripping on Receive This field indicates the stripping operation on the outer VLAN Tag in received packet. 00b - Do not strip 01b - Strip if VLAN filter passes 10b - Strip if VLAN filter fails 11b - Always strip
20-19 —	Reserved
18 ESVL	Enable S-VLAN When this bit is set, the MAC transmitter and receiver consider the S-VLAN packets (Type = 0x88A8) as valid VLAN tagged packets. 0b - S-VLAN is disabled 1b - S-VLAN is enabled
17 VTIM	VLAN Tag Inverse Match Enable When this bit is set, this bit enables the VLAN Tag inverse matching. The packets without matching VLAN Tag are marked as matched. When reset, this bit enables the VLAN Tag perfect matching. The packets with matched VLAN Tag are marked as matched. 0b - VLAN Tag Inverse Match is disabled 1b - VLAN Tag Inverse Match is enabled
16-7 —	Reserved
6-2 OFS	Offset This field holds the address offset of the MAC VLAN Tag Filter Register which the application is trying to access. The width of the field depends on the number of MAC VLAN Tag Registers enabled.
1 CT	Command Type This bit indicates if the current register access is a read or a write. When set, it indicate a read operation. When reset, it indicates a write operation. 0b - Write operation 1b - Read operation
0 OB	Operation Busy This bit is set along with a read or write command for initiating the indirect access to per VLAN Tag Filter register. This bit is reset when the read or write command to per VLAN Tag Filter indirect access register is complete. The next indirect register access can be initiated only after this bit is reset. During a write operation, the bit is reset only after the data has been written into the Per VLAN Tag register.

Field	Function
	During a read operation, the data should be read from the VLAN_TAG_DATA register only after this bit is reset. 0b - Operation Busy is disabled 1b - Operation Busy is enabled

61.7.1.9 MAC VLAN Tag Data (MAC_VLAN_TAG_DATA)

61.7.1.9.1 Offset

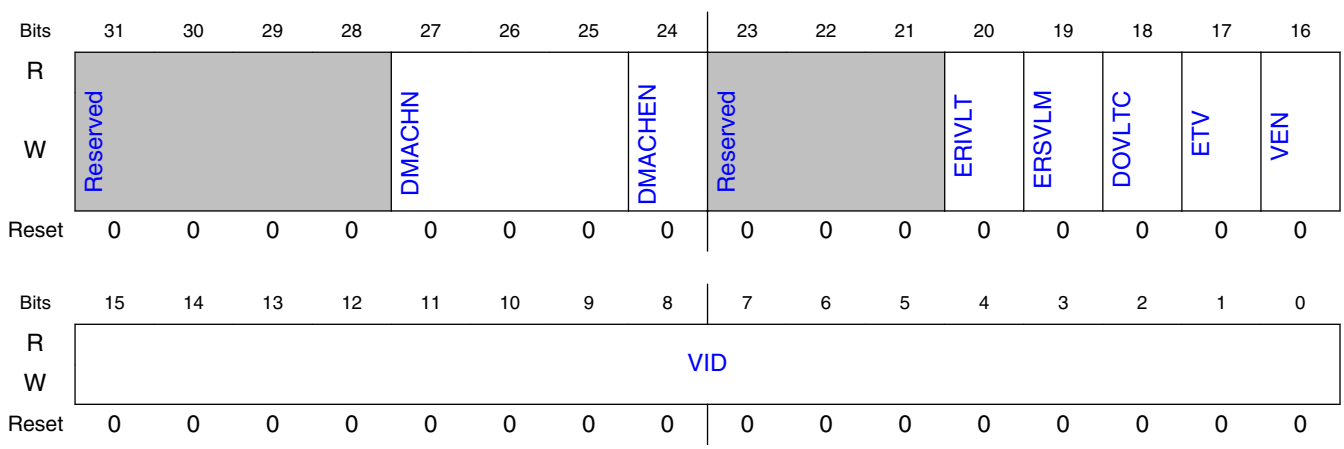
Register	Offset
MAC_VLAN_TAG_DATA	54h

61.7.1.9.2 Function

This register holds the read/write data for Indirect Access of the Per VLAN Tag registers. During the read access, this field contains valid read data only after the OB bit is reset.

During the write access, this field should be valid prior to setting the OB bit in the MAC_VLAN_Tag_Ctrl Register.

61.7.1.9.3 Diagram



61.7.1.9.4 Fields

Field	Function
31-28 —	Reserved
27-25 DMACHN	DMA Channel Number The DMA Channel number to which the VLAN Tagged Frame is to be routed if it passes this VLAN Tag Filter is programmed in this field. If the Routing based on VLAN Tag Filter is not necessary, this field need not be programmed.
24 DMACHEN	DMA Channel Number Enable This bit is the Enable for the DMA Channel Number value programmed in the field DMACH. When this bit is reset, the Routing does not occur based on VLAN Filter result. The frame is routed based on DA Based DMA Channel Routing. 0b - DMA Channel Number is disabled 1b - DMA Channel Number is enabled
23-21 —	Reserved
20 ERIVLT	Enable Inner VLAN Tag Comparison This bit is valid only when VLAN Tag Enable of the Filter is set. When this bit and the EDVLP field are set, the MAC receiver enables operation on the inner VLAN Tag (if present). When this bit is reset, the MAC receiver enables operation on the outer VLAN Tag (if present). 0b - Inner VLAN tag comparison is disabled 1b - Inner VLAN tag comparison is enabled
19 ERSVLM	Enable S-VLAN Match for received Frames This bit is valid only when VLAN Tag Enable of the Filter is set. When this bit is set, the MAC receiver enables filtering or matching for S-VLAN (Type = 0x88A8) packets. When this bit is reset, the MAC receiver enables filtering or matching for C-VLAN (Type = 0x8100) packets. 0b - Receive S-VLAN Match is disabled 1b - Receive S-VLAN Match is enabled
18 DOVLTC	Disable VLAN Type Comparison This bit is valid only when VLAN Tag Enable of the Filter is set. When this bit is set, the MAC does not check whether the VLAN Tag specified by the Enable Inner VLAN Tag Comparison bit is of type S-VLAN or C-VLAN. When this bit is reset, the MAC filters or matches the VLAN Tag specified by the Enable Inner VLAN Tag Comparison bit only when VLAN Tag type is similar to the one specified by the Enable S-VLAN Match for received Frames bit. 0b - VLAN type comparison is enabled 1b - VLAN type comparison is disabled
17 ETV	12bits or 16bits VLAN comparison This bit is valid only when VEN of the Filter is set.

Table continues on the next page...

Field	Function
	When this bit is set, a 12-bit VLAN identifier is used for comparing and filtering instead of the complete 16-bit VLAN tag. Bits [11:0] of VLAN tag are compared with the corresponding field in the received VLAN-tagged packet. 0b - 16 bit VLAN comparison 1b - 12 bit VLAN comparison
16 VEN	VLAN Tag Enable This bit is used to enable or disable the VLAN Tag. When this bit is set, the MAC compares the VLAN Tag of received packet with the VLAN Tag ID. When this bit is reset, no comparison is performed irrespective of the programming of the other fields. 0b - VLAN Tag is disabled 1b - VLAN Tag is enabled
15-0 VID	VLAN Tag ID This field holds the VLAN Tag value which is used by the MAC for perfect comparison. It is valid when VLAN Tag Enable is set.

61.7.1.10 MAC VLAN Hash Table (MAC_VLAN_HASH_TABLE)

61.7.1.10.1 Offset

Register	Offset
MAC_VLAN_HASH_TABLE	58h

61.7.1.10.2 Function

When VTHM bit of the MAC_VLAN_TAG register is set, the 16-bit VLAN Hash Table register is used for group address filtering based on the VLAN tag. For hash filtering, the content of the 16-bit VLAN tag or 12-bit VLAN ID (based on the ETV bit of MAC_VLAN_TAG Register) in the incoming packet is passed through the CRC logic. When ETV bit of MAC_VLAN_TAG register is set, the upper four bits of the calculated CRC are used to index the contents of the VLAN Hash table. When ETV bit of MAC_VLAN_TAG register is reset, the ones-complement of upper four bits of the calculated CRC are used to index the contents of the VLAN Hash table. For example, when ETV bit is set a hash value of 4b'1000 selects Bit 8 of the VLAN Hash table, whereas when ETV bit is reset a hash value of 4b'1000 selects Bit 7 of the VLAN Hash table.

The hash value of the destination address is calculated in the following way:

- Calculate the 32-bit CRC for the VLAN tag or ID (For steps to calculate CRC32, see Section 3.2.8 of IEEE 802.3).

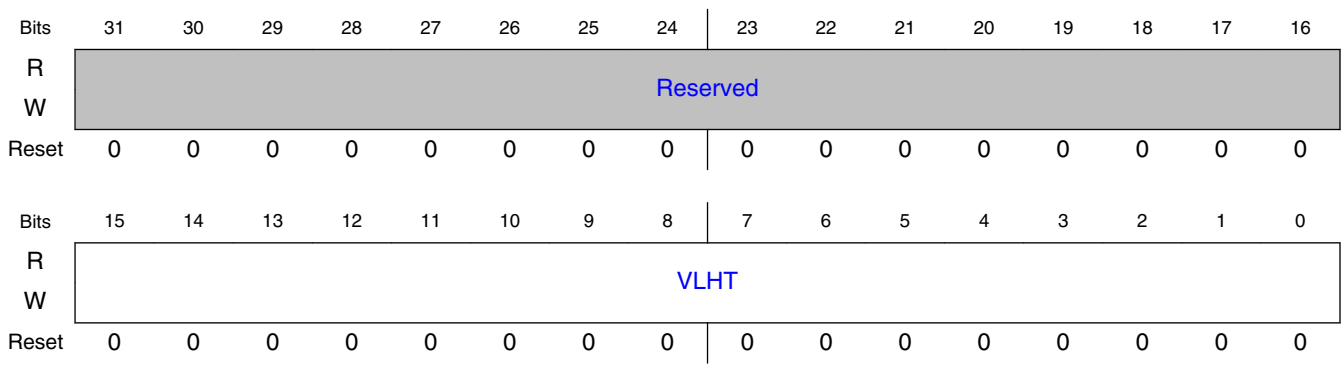
- Perform bitwise reversal for the value obtained in step 1.

- Take the upper four bits from the value obtained in step 2.

If the VLAN hash Table register is configured to be double-synchronized to the (G)MII clock domain, the synchronization is triggered only when Bits[15:8] (in little-endian mode) or Bits[7:0] (in big-endian mode) of this register are written.

- If double-synchronization is enabled, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.

61.7.1.10.3 Diagram



61.7.1.10.4 Fields

Field	Function
31-16 —	Reserved
15-0 VLHT	VLAN Hash Table This field contains the 16-bit VLAN Hash Table.

61.7.1.11 VLAN Tag Inclusion or Replacement (MAC_VLAN_INCL)

61.7.1.11.1 Offset

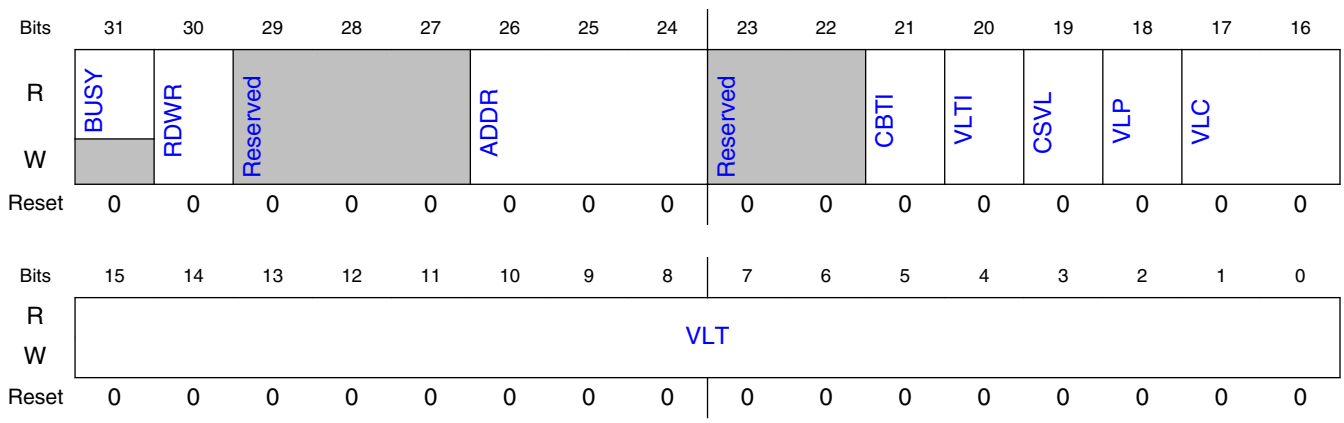
Register	Offset
MAC_VLAN_INCL	60h

61.7.1.11.2 Function

The VLAN Tag Inclusion or Replacement register contains the VLAN tag for insertion or replacement in the Transmit packets.

The VLAN Tag Inclusion or Replacement register contains the VLAN tag for insertion or replacement in the Transmit packets. It also contains the VLAN tag insertion controls.

61.7.1.11.3 Diagram



61.7.1.11.4 Fields

Field	Function
31 BUSY	Busy This bit indicates the status of the read/write operation of indirect access to the queue/channel specific VLAN inclusion register. For write operation write to a register is complete when this bit is reset. For read operation the read data is valid when the bit is reset. The application must make sure that this bit is reset before attempting subsequent access to this register. 0b - Busy status not detected 1b - Busy status detected
30 RDWR	Read write control This bit controls the read or write operation for indirectly accessing the queue/channel specific VLAN Inclusion register. When set indicates write operation and when reset indicates read operation. This does not have any effect when CBTI is reset. 0b - Read operation of indirect access 1b - Write operation of indirect access
29-27 —	Reserved

Table continues on the next page...

Field	Function
26-24 ADDR	Address This field selects one of the queue/channel specific VLAN Inclusion register for read/write access. This does not have any effect when CBTI is reset.
23-22 —	Reserved
21 CBTI	Channel based tag insertion When this bit is set, outer VLAN tag is inserted for every packets transmitted by the MAC. The tag value is taken from the queue/channel specific VLAN tag register. The VLTI, VLP, VLC, and VLT fields of this register are ignored when this bit is set. When this bit is set, a write operation to byte 3 of this register initiates the read/write access to the indirect register. When reset, outer VLAN operation is based on the setting of VLTI, VLP, VLC and VLT fields of this register. 0b - Channel based tag insertion is disabled 1b - Channel based tag insertion is enabled
20 VLTI	VLAN Tag Input When this bit is set, it indicates that the VLAN tag to be inserted or replaced in Tx packet should be taken from: - The Tx descriptor 0b - VLAN Tag Input is disabled 1b - VLAN Tag Input is enabled
19 CSVL	C-VLAN or S-VLAN When this bit is set, S-VLAN type (0x88A8) is inserted or replaced in the 13th and 14th bytes of transmitted packets. When this bit is reset, C-VLAN type (0x8100) is inserted or replaced in the 13th and 14th bytes of transmitted packets. 0b - C-VLAN type (0x8100) is inserted or replaced 1b - S-VLAN type (0x88A8) is inserted or replaced
18 VLP	VLAN Priority Control When this bit is set, the control bits[17:16] are used for VLAN deletion, insertion, or replacement. When this bit is reset, the mti_vlan_ctrl_i control input is used and bits[17:16] are ignored. 0b - VLAN Priority Control is disabled 1b - VLAN Priority Control is enabled
17-16 VLC	VLAN Tag Control in Transmit Packets - 2'b00: No VLAN tag deletion, insertion, or replacement - 2'b01: VLAN tag deletion The MAC removes the VLAN type (bytes 13 and 14) and VLAN tag (bytes 15 and 16) of all transmitted packets with VLAN tags. VLAN Tag Control in Transmit Packets - 2'b00: No VLAN tag deletion, insertion, or replacement - 2'b01: VLAN tag deletion The MAC removes the VLAN type (bytes 13 and 14) and VLAN tag (bytes 15 and 16) of all transmitted packets with VLAN tags. - 2'b10: VLAN tag insertion The MAC inserts VLT in bytes 15 and 16 of the packet after inserting the Type value (0x8100 or 0x88a8) in bytes 13 and 14. This operation is performed on all transmitted packets, irrespective of whether they already have a VLAN tag. - 2'b11: VLAN tag replacement The MAC replaces VLT in bytes 15 and 16 of all VLAN-type transmitted packets (Bytes 13 and 14 are 0x8100 or 0x88a8).

Table continues on the next page...

Field	Function
	Note: Changes to this field take effect only on the start of a packet. If you write this register field when a packet is being transmitted, only the subsequent packet can use the updated value, that is, the current packet does not use the updated value. 00b - No VLAN tag deletion, insertion, or replacement 01b - VLAN tag deletion 10b - VLAN tag insertion 11b - VLAN tag replacement
15-0 VLT	VLAN Tag for Transmit Packets This field contains the value of the VLAN tag to be inserted or replaced. The value must only be changed when the transmit lines are inactive or during the initialization phase. Bits[15:13] are the User Priority field, Bit 12 is the CFI/DEI field, and Bits[11:0] are the VID field in the VLAN tag. The following list describes the bits of this field: - Bits[15:13]: User Priority - Bit 12: Canonical Format Indicator (CFI) or Drop Eligible Indicator (DEI) - Bits[11:0]: VLAN Identifier (VID) field of VLAN tag

61.7.1.12 MAC Inner VLAN Tag Inclusion or Replacement (MAC_INNER_VLAN_INCL)

61.7.1.12.1 Offset

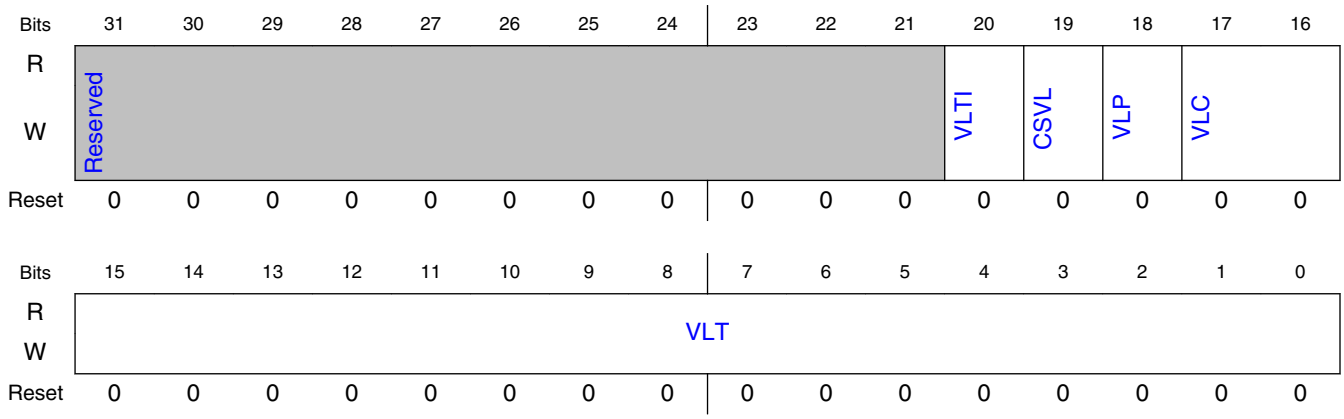
Register	Offset
MAC_INNER_VLAN_INCL	64h

61.7.1.12.2 Function

The Inner VLAN Tag Inclusion or Replacement register contains the inner VLAN tag to be inserted or replaced in the Transmit packet.

The Inner VLAN Tag Inclusion or Replacement register contains the inner VLAN tag to be inserted or replaced in the Transmit packet. It also contains the inner VLAN tag insertion controls.

61.7.1.12.3 Diagram



61.7.1.12.4 Fields

Field	Function
31-21 —	Reserved
20 VLTI	VLAN Tag Input When this bit is set, it indicates that the VLAN tag to be inserted or replaced in Tx packet should be taken from: - The Tx descriptor 0b - VLAN Tag Input is disabled 1b - VLAN Tag Input is enabled
19 CSVL	C-VLAN or S-VLAN When this bit is set, S-VLAN type (0x88A8) is inserted or replaced in the 13th and 14th bytes of transmitted packets. When this bit is reset, C-VLAN type (0x8100) is inserted or replaced in the 13th and 14th bytes of transmitted packets. 0b - C-VLAN type (0x8100) is inserted 1b - S-VLAN type (0x88A8) is inserted
18 VLP	VLAN Priority Control When this bit is set, the VLC field is used for VLAN deletion, insertion, or replacement. When this bit is reset, the mti_vlan_ctrl_i control input is used and the VLC field is ignored. 0b - VLAN Priority Control is disabled 1b - VLAN Priority Control is enabled
17-16 VLC	VLAN Tag Control in Transmit Packets - 2'b00: No VLAN tag deletion, insertion, or replacement - 2'b01: VLAN tag deletion The MAC removes the VLAN type (bytes 17 and 18) and VLAN tag (bytes 19 and 20) of all transmitted packets with VLAN tags. - 2'b10: VLAN tag insertion The MAC inserts VLT in bytes 19 and 20 of the packet after inserting the Type value (0x8100 or 0x88a8) in bytes 17 and 18. This operation is performed on all transmitted packets, irrespective of whether they already have a VLAN tag. - 2'b11: VLAN tag replacement

Table continues on the next page...

Field	Function
	The MAC replaces VLT in bytes 19 and 20 of all VLAN-type transmitted packets (Bytes 17 and 18 are 0x8100 or 0x88a8). Note: Changes to this field take effect only on the start of a packet. If you write this register field when a packet is being transmitted, only the subsequent packet can use the updated value, that is, the current packet does not use the updated value. 00b - No VLAN tag deletion, insertion, or replacement 01b - VLAN tag deletion 10b - VLAN tag insertion 11b - VLAN tag replacement
15-0 VLT	VLAN Tag for Transmit Packets This field contains the value of the VLAN tag to be inserted or replaced. The value must only be changed when the transmit lines are inactive or during the initialization phase. Bits[15:13] are the User Priority field, Bit 12 is the CFI/DEI field, and Bits[11:0] are the VID field in the VLAN tag. The following list describes the bits of this field: - Bits[15:13]: User Priority - Bit 12: Canonical Format Indicator (CFI) or Drop Eligible Indicator (DEI) - Bits[11:0]: VLAN Identifier (VID) field of VLAN tag

61.7.1.13 MAC Q0 Tx Flow Control (MAC_Q0_TX_FLOW_CTRL)

61.7.1.13.1 Offset

Register	Offset
MAC_Q0_TX_FLOW_CTRL	70h

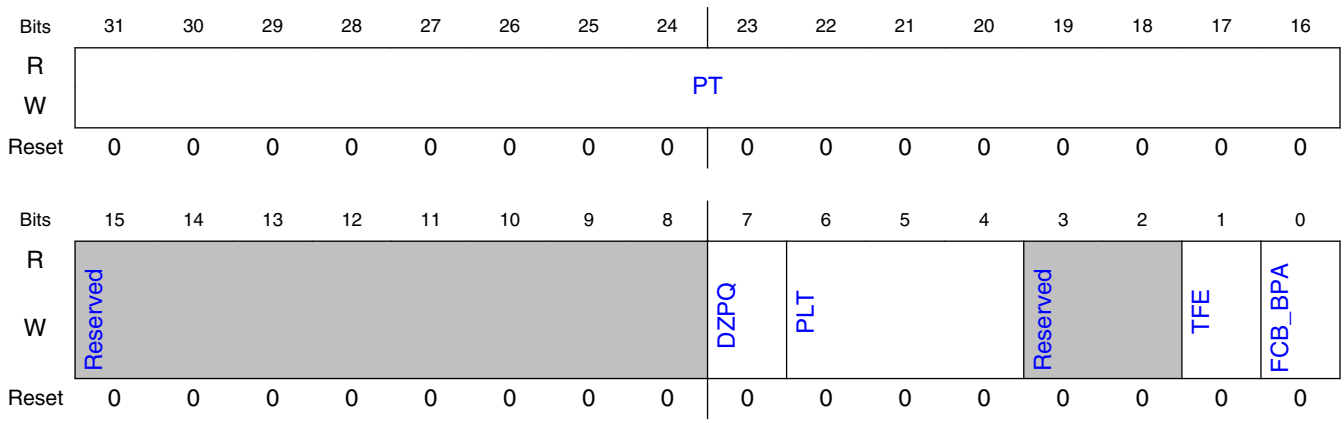
61.7.1.13.2 Function

The Flow Control register controls the generation and reception of the Control (Pause Command) packets by the Flow control module of the MAC.

The Flow Control register controls the generation and reception of the Control (Pause Command) packets by the Flow control module of the MAC. A Write to a register with the Busy bit set to 1 triggers the Flow Control block to generate a Pause packet. The fields of the control packet are selected as specified in the 802.3x specification, and the Pause Time value from this register is used in the Pause Time field of the control packet. The Busy bit remains set until the control packet is transferred onto the cable. The application must make sure that the Busy bit is cleared before writing to the register.

When the PFCE bit in the MAC_Q0_RX_FLOW_CTRL register is enabled, this register controls the generation of Priority Flow Control (PFC) frames with priorities mapped according to PSRQ0 in the MAC_Q0_RXQ_CTRL2 register.

61.7.1.13.3 Diagram



61.7.1.13.4 Fields

Field	Function
31-16 PT	Pause Time This field holds the value to be used in the Pause Time field in the Tx control packet. If the Pause Time bits are configured to be double-synchronized to the (G)MII clock domain, consecutive writes to this register should be performed only after at least four clock cycles in the destination clock domain.
15-8 —	Reserved
7 DZPQ	Disable Zero-Quanta Pause When this bit is set, it disables the automatic generation of the zero-quanta Pause packets on de-assertion of the flow-control signal from the FIFO layer (MTL or external sideband flow control signal sbd_flowctrl_i or mti_flowctrl_i). When this bit is reset, normal operation with automatic zero-quanta Pause packet generation is enabled. 0b - Zero-Quanta Pause packet generation is enabled 1b - Zero-Quanta Pause packet generation is disabled
6-4 PLT	Pause Low Threshold This field configures the threshold of the Pause timer at which the input flow control signal mti_flowctrl_i (or sbd_flowctrl_i) is checked for automatic retransmission of the Pause packet. The threshold values should be always less than the Pause Time configured in Bits[31:16]. For example, if PT = 100H (256 slot times), and PLT = 001, a second Pause packet is automatically transmitted if the mti_flowctrl_i signal is asserted at 228 (256-28) slot times after the first Pause packet is transmitted. The following list provides the threshold values for different values. The slot time is defined as the time taken to transmit 512 bits (64 bytes) on the GMII or MII interface.

Table continues on the next page...

Field	Function
	This (approximate) computation is based on the packet size (64, 1518, 2000, 9018, 16384, or 32768) + 2 Pause Packet Size + IPG in Slot Times. 000b - Pause Time minus 4 Slot Times (PT -4 slot times) 001b - Pause Time minus 28 Slot Times (PT -28 slot times) 010b - Pause Time minus 36 Slot Times (PT -36 slot times) 011b - Pause Time minus 144 Slot Times (PT -144 slot times) 100b - Pause Time minus 256 Slot Times (PT -256 slot times) 101b - Pause Time minus 512 Slot Times (PT -512 slot times) 110b - Reserved
3-2 —	Reserved
1 TFE	Transmit Flow Control Enable Full-Duplex Mode: In the full-duplex mode, when this bit is set, the MAC enables the flow control operation to Tx Pause packets. When this bit is reset, the flow control operation in the MAC is disabled, and the MAC does not transmit any Pause packets. Half-Duplex Mode: In the half-duplex mode, when this bit is set, the MAC enables the backpressure operation. When this bit is reset, the backpressure feature is disabled. 0b - Transmit Flow Control is disabled 1b - Transmit Flow Control is enabled
0 FCB_BPA	Flow Control Busy or Backpressure Activate This bit initiates a Pause packet in the full-duplex mode and activates the backpressure function in the half-duplex mode if the TFE bit is set. Full-Duplex Mode: In the full-duplex mode, this bit should be read as 1'b0 before writing to this register. To initiate a Pause packet, the application must set this bit to 1'b1. During Control packet transfer, this bit continues to be set to indicate that a packet transmission is in progress. When Pause packet transmission is complete, the MAC resets this bit to 1'b0. You should not write to this register until this bit is cleared. Half-Duplex Mode: When this bit is set (and TFE bit is set) in the half-duplex mode, the MAC asserts the backpressure. During backpressure, when the MAC receives a new packet, the transmitter starts sending a JAM pattern resulting in a collision. This control register bit is logically ORed with the mti_flowctrl_i input signal for the backpressure function. When the MAC is configured for the full-duplex mode, the BPA is automatically disabled. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0b - Flow Control Busy or Backpressure Activate is disabled 1b - Flow Control Busy or Backpressure Activate is enabled

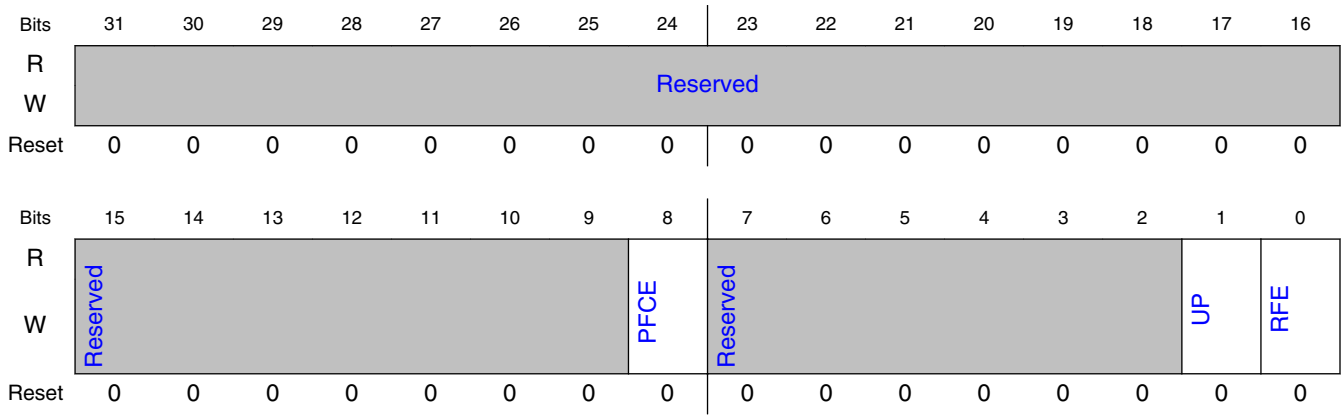
The Receive Flow Control register controls the pausing of MAC Transmit based on the received Pause packet.

61.7.1.18.3 Diagram



61.7.1.18.4 Fields

Field	Function
31-9 —	Reserved
8 PFCE	Priority Based Flow Control Enable When this bit is set, it enables generation and reception of priority-based flow control (PFC) packets. When this bit is reset, it enables generation and reception of 802.3x Pause control packets. 0b - Priority Based Flow Control is disabled 1b - Priority Based Flow Control is enabled
7-2 —	Reserved
1 UP	Unicast Pause Packet Detect A pause packet is processed when it has the unique multicast address specified in the IEEE 802.3. When this bit is set, the MAC can also detect Pause packets with unicast address of the station. This unicast address should be as specified in MAC_ADDRESS0_HIGH and MAC_ADDRESS0_LOW. When this bit is reset, the MAC only detects Pause packets with unique multicast address. Note: The MAC does not process a Pause packet if the multicast address is different from the unique multicast address. This is also applicable to the received PFC packet when the Priority Flow Control (PFC) is enabled. The unique multicast address (0x01_80_C2_00_00_01) is as specified in IEEE 802.1 Qbb-2011. 0b - Unicast Pause Packet Detect disabled 1b - Unicast Pause Packet Detect enabled
0 RFE	Receive Flow Control Enable When this bit is set and the MAC is operating in full-duplex mode, the MAC decodes the received Pause packet and disables its transmitter for a specified (Pause) time. When this bit is reset or the MAC is operating in half-duplex mode, the decode function of the Pause packet is disabled. When PFC is enabled, flow control is enabled for PFC packets. The MAC decodes the received PFC packet and disables the Transmit queue, with matching priorities, for a duration of received Pause time. 0b - Receive Flow Control is disabled 1b - Receive Flow Control is enabled

61.7.1.20.4 Fields

Field	Function
31-24 PSTQ3	Priorities Selected in Transmit Queue 3 This bit is similar to the PSTQ0 bit.
23-16 PSTQ2	Priorities Selected in Transmit Queue 2 This bit is similar to the PSTQ0 bit.
15-8 PSTQ1	Priorities Selected in Transmit Queue 1 This bit is similar to the PSTQ0 bit.
7-0 PSTQ0	Priorities Selected in Transmit Queue 0 This field holds the priorities assigned to Tx Queue 0 by the software. This field determines if Tx Queue 0 should be blocked from transmitting specified pause time when a PFC packet is received with priorities matching the priorities programmed in this field. If the content of this field is not mutually exclusive to corresponding fields of other Transmit queues, that is, same priority is mapped to multiple Tx queues, the MAC blocks all queues with matching priority for specified time.

61.7.1.21 Transmit Queue Priority Mapping 1 (MAC_TXQ_PRTY_MAP1)

61.7.1.21.1 Offset

Register	Offset
MAC_TXQ_PRTY_MAP1	9Ch

61.7.1.21.2 Function

The Transmit Queue Priority Mapping 1 register contains the priority values assigned to Tx Queue 4.

61.7.1.21.3 Diagram

61.7.1.21.4 Fields

Field	Function
31-24 —	Reserved
23-16 —	Reserved
15-8 —	Reserved
7-0 PSTQ4	Priorities Selected in Transmit Queue 4 This field holds the priorities assigned to Tx Queue 4 by the software. This field determines if Tx Queue 4 should be blocked from transmitting specified pause time when a PFC packet is received with priorities matching the priorities programmed in this field. If the content of this field is not mutually exclusive to corresponding fields of other Transmit queues, that is, same priority is mapped to multiple Tx queues, the MAC blocks all queues with matching priority for specified time.

61.7.1.22 Receive Queue Control 0 (MAC_RXQ_CTRL0)

61.7.1.22.1 Offset

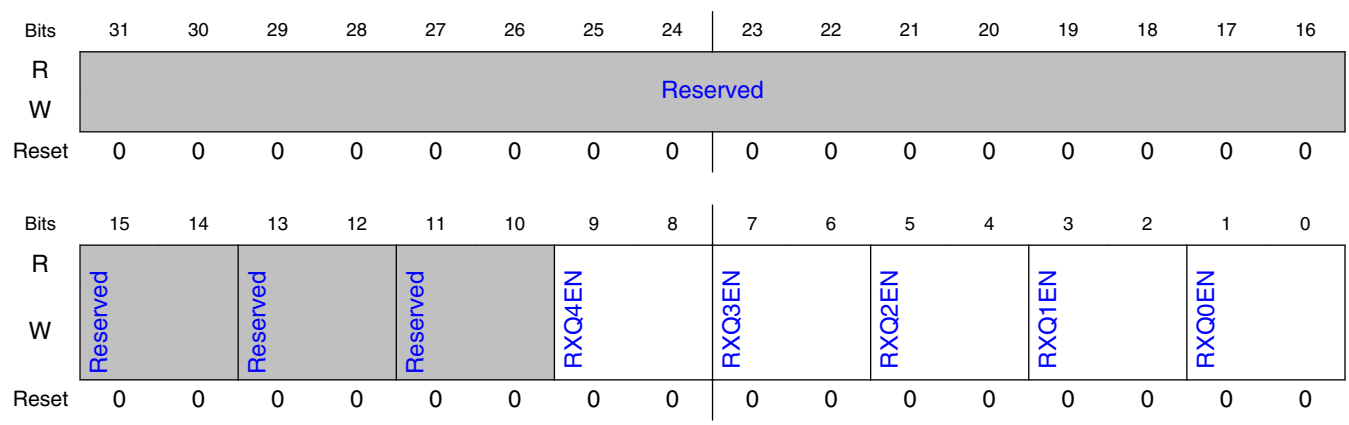
Register	Offset
MAC_RXQ_CTRL0	A0h

61.7.1.22.2 Function

The Receive Queue Control 0 register controls the queue management in the MAC Receiver.

Note: In multiple Rx queues configuration, all the queues are disabled by default. Enable the Rx queue by programming the corresponding field in this register.

61.7.1.22.3 Diagram



61.7.1.22.4 Fields

Field	Function
31-16 —	Reserved
15-14 —	Reserved
13-12	Reserved

Table continues on the next page...

Field	Function
—	
11-10 —	Reserved
9-8 RXQ4EN	Receive Queue 4 Enable This field is similar to the RXQ0EN field. 00b - Queue not enabled 01b - Queue enabled for AV 10b - Queue enabled for DCB/Generic 11b - Reserved
7-6 RXQ3EN	Receive Queue 3 Enable This field is similar to the RXQ0EN field. 00b - Queue not enabled 01b - Queue enabled for AV 10b - Queue enabled for DCB/Generic 11b - Reserved
5-4 RXQ2EN	Receive Queue 2 Enable This field is similar to the RXQ0EN field. 00b - Queue not enabled 01b - Queue enabled for AV 10b - Queue enabled for DCB/Generic 11b - Reserved
3-2 RXQ1EN	Receive Queue 1 Enable This field is similar to the RXQ0EN field. 00b - Queue not enabled 01b - Queue enabled for AV 10b - Queue enabled for DCB/Generic 11b - Reserved
1-0 RXQ0EN	Receive Queue 0 Enable This field indicates whether Rx Queue 0 is enabled for AV or DCB. 00b - Queue not enabled 01b - Queue enabled for AV 10b - Queue enabled for DCB/Generic 11b - Reserved

61.7.1.23 Receive Queue Control 1 (MAC_RXQ_CTRL1)

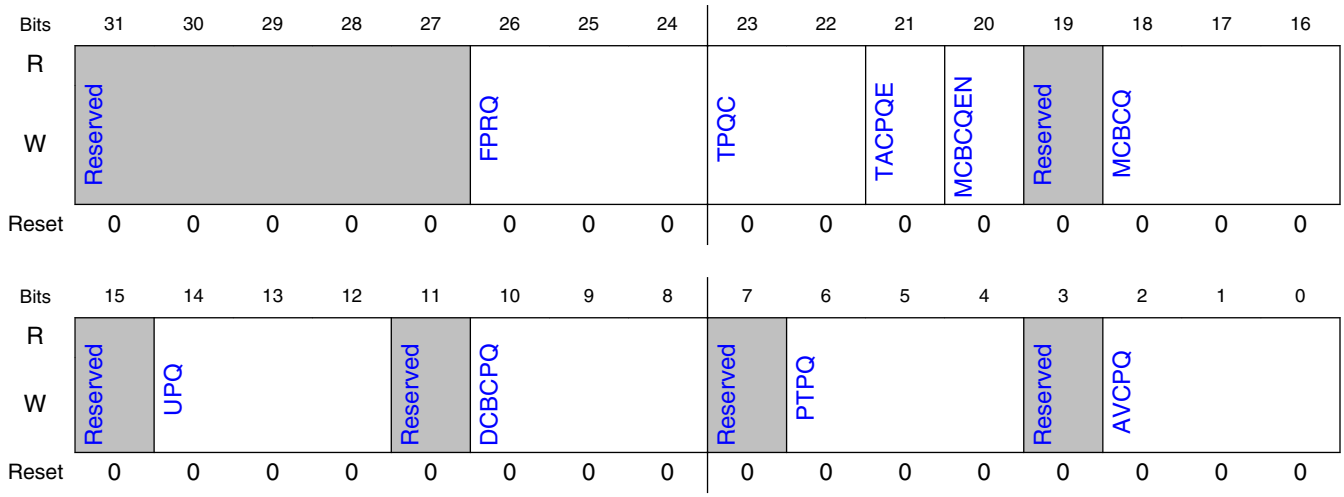
61.7.1.23.1 Offset

Register	Offset
MAC_RXQ_CTRL1	A4h

61.7.1.23.2 Function

The Receive Queue Control 1 register controls the routing of multicast, broadcast, AV, DCB, and untagged packets to the Rx queues.

61.7.1.23.3 Diagram



61.7.1.23.4 Fields

Field	Function
31-27 —	Reserved
26-24 FPRQ	Frame Preemption Residue Queue This field holds the Rx queue number to which the residual preemption frames must be forwarded. Preemption frames that are tagged and pass the SA/DA/VLAN filtering are routed based on PSRQ and all other frames are treated as residual frames and is routed to the queue number mentioned in this field. The Queue-0 is used as a default queue for express frames, so this field cannot be programmed to a value 0.
23-22 TPQC	Tagged PTP over Ethernet Packets Queuing Control. This field controls the routing of the VLAN Tagged PTPoE packets. If DWC_EQOS_AV_ENABLE is selected in the configuration, the following programmable options are allowed. - 2'b00: VLAN Tagged PTPoE packets are routed as generic VLAN Tagged packet (based on PSRQ for only non-AV enabled Rx Queues). - 2'b01: VLAN Tagged PTPoE packets are routed to Rx Queue specified by PTPQ field (That Rx Queue can be enabled for AV or non-AV traffic). - 2'b10: VLAN Tagged PTPoE packets are routed to only AV enabled Rx Queues based on PSRQ. - 2'b11: Reserved If DWC_EQOS_AV_ENABLE is not selected in the configuration, the following programmable options are allowed. - 1'b0: VLAN Tagged PTPoE packets are routed as generic VLAN Tagged packet (based on PSRQ for DCB/Generic enabled Rx Queues). - 1'b1: VLAN Tagged PTPoE packets are routed to Rx Queues specified by PTPQ field.
21 TACPQE	Tagged AV Control Packets Queuing Enable.

Table continues on the next page...

Field	Function
	When set, the MAC routes the received Tagged AV Control packets to the Rx queue specified by AVCPQ field. When reset, the MAC routes the received Tagged AV Control packets based on the tag priority matching the PSRQ fields in MAC_RXQ_CTRL2 and MAC_RXQ_CTRL3 registers. 0b - Tagged AV Control Packets Queuing is disabled 1b - Tagged AV Control Packets Queuing is enabled
20 MCBCQEN	Multicast and Broadcast Queue Enable This bit specifies that Multicast or Broadcast packets routing to the Rx Queue is enabled and the Multicast or Broadcast packets must be routed to Rx Queue specified in MCBCQ field. 0b - Multicast and Broadcast Queue is disabled 1b - Multicast and Broadcast Queue is enabled
19 —	Reserved
18-16 MCBCQ	Multicast and Broadcast Queue This field specifies the Rx Queue onto which Multicast or Broadcast Packets are routed. Any Rx Queue enabled for Generic/DCB/AV traffic can be used to route the Multicast or Broadcast Packets. 000b - Receive Queue 0 001b - Receive Queue 1 010b - Receive Queue 2 011b - Receive Queue 3 100b - Receive Queue 4 101b - Reserved 110b - Reserved 111b - Reserved
15 —	Reserved
14-12 UPQ	Untagged Packet Queue This field indicates the Rx Queue to which Untagged Packets are to be routed. Any Rx Queue enabled for Generic/DCB/AV traffic can be used to route the Untagged Packets. 000b - Receive Queue 0 001b - Receive Queue 1 010b - Receive Queue 2 011b - Receive Queue 3 100b - Receive Queue 4 101b - Reserved 110b - Reserved 111b - Reserved
11 —	Reserved
10-8 DCBCPQ	DCB Control Packets Queue This field specifies the Rx queue on which the received DCB control packets are routed. The DCB data packets are routed based on the PSRQ field of the Transmit Flow Control Register of corresponding queue. 000b - Receive Queue 0 001b - Receive Queue 1 010b - Receive Queue 2 011b - Receive Queue 3 100b - Receive Queue 4

Table continues on the next page...

Field	Function
	101b - Reserved 110b - Reserved 111b - Reserved
7 —	Reserved
6-4 PTPQ	PTP Packets Queue This field specifies the Rx queue on which the PTP packets sent over the Ethernet payload (not over IPv4 or IPv6) are routed. When the AV8021ASMEN bit of MAC_TIMESTAMP_CONTROL register is set, only untagged PTP over Ethernet packets are routed on an Rx Queue. If the bit is not set, then based on programming of TPQC field, both tagged and untagged PTPoE packets can be routed to this Rx Queue. 000b - Receive Queue 0 001b - Receive Queue 1 010b - Receive Queue 2 011b - Receive Queue 3 100b - Receive Queue 4 101b - Reserved 110b - Reserved 111b - Reserved
3 —	Reserved
2-0 AVCPQ	AV Untagged Control Packets Queue This field specifies the Receive queue on which the received AV tagged and untagged control packets are routed. The AV tagged (when TACPQE bit is set) and untagged control packets are routed to Receive queue specified by this field. 000b - Receive Queue 0 001b - Receive Queue 1 010b - Receive Queue 2 011b - Receive Queue 3 100b - Receive Queue 4 101b - Reserved 110b - Reserved 111b - Reserved

61.7.1.24 Receive Queue Control 2 (MAC_RXQ_CTRL2)

61.7.1.24.1 Offset

Register	Offset
MAC_RXQ_CTRL2	A8h

61.7.1.24.2 Function

This register controls the routing of tagged packets based on the USP (user Priority) field of the received packets to the RxQueues 0 to 3.

61.7.1.24.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

61.7.1.24.4 Fields

Field	Function
31-24 PSRQ3	Priorities Selected in the Receive Queue 3 This field decides the priorities assigned to Rx Queue 3. All packets with priorities that match the values set in this field are routed to Rx Queue 3. For example, if PSRQ3[6, 3] are set, packets with USP field equal to 3 or 6 are routed to Rx Queue 3. The software must ensure that the content of this field is mutually exclusive to the PSRQ fields for other queues, that is, the same priority is not mapped to multiple Rx queues. This field also determines the priorities to be included in the PFC packet sent to remote station when Rx Queue 3 crosses the flow control threshold settings.
23-16 PSRQ2	Priorities Selected in the Receive Queue 2 This field decides the priorities assigned to Rx Queue 2. All packets with priorities that match the values set in this field are routed to Rx Queue 2. For example, if PSRQ2[1, 0] are set, packets with USP field equal to 1 or 0 are routed to Rx Queue 2. The software must ensure that the content of this field is mutually exclusive to the PSRQ fields for other queues, that is, the same priority is not mapped to multiple Rx queues. this field also determines the priorities to be included in the PFC packet sent to remote station when Rx Queue 2 crosses the flow control threshold settings.
15-8 PSRQ1	Priorities Selected in the Receive Queue 1 This field decides the priorities assigned to Rx Queue 1. All packets with priorities that match the values set in this field are routed to Rx Queue 1. For example, if PSRQ1[4] is set, packets with USP field equal to 4 are routed to Rx Queue 1. The software must ensure that the content of this field is mutually exclusive to the PSRQ fields for other queues, that is, the same priority is not mapped to multiple Rx queues.

Table continues on the next page...

Field	Function
	this field also determines the priorities to be included in the PFC packet sent to remote station when Rx Queue 1 crosses the flow control threshold settings.
7-0 PSRQ0	Priorities Selected in the Receive Queue 0 This field decides the priorities assigned to Rx Queue 0. All packets with priorities that match the values set in this field are routed to Rx Queue 0. For example, if PSRQ0[5] is set, packets with USP field equal to 5 are routed to Rx Queue 0. The software must ensure that the content of this field is mutually exclusive to the PSRQ fields for other queues, that is, the same priority is not mapped to multiple Rx queues. this field also determines the priorities to be included in the PFC packet sent to remote station when Rx Queue 0 crosses the flow control threshold settings.

61.7.1.25 Receive Queue Control 3 (MAC_RXQ_CTRL3)

61.7.1.25.1 Offset

Register	Offset
MAC_RXQ_CTRL3	ACh

61.7.1.25.2 Function

This register controls the routing of tagged packets based on the USP (user Priority) field of the received packets to Rx Queue 4.

61.7.1.25.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

61.7.1.25.4 Fields

Field	Function
31-24 —	Reserved
23-16 —	Reserved
15-8 —	Reserved
7-0 PSRQ4	Priorities Selected in the Receive Queue 4 This field decides the priorities assigned to Rx Queue 4. All packets with priorities that match the values set in this field are routed to Rx Queue 4. For example, if PSRQ4[7:4] is set, packets with USP field equal to 7, 6, 5, or 4 are routed to Rx Queue 4. The software must ensure that the content of this field is mutually exclusive to the PSRQ fields for other queues, that is, the same priority is not mapped to multiple Rx queues. This field also determines the priorities to be included in the PFC packet sent to remote station when Rx Queue 4 crosses the flow control threshold settings.

61.7.1.26 Interrupt Status (MAC_INTERRUPT_STATUS)

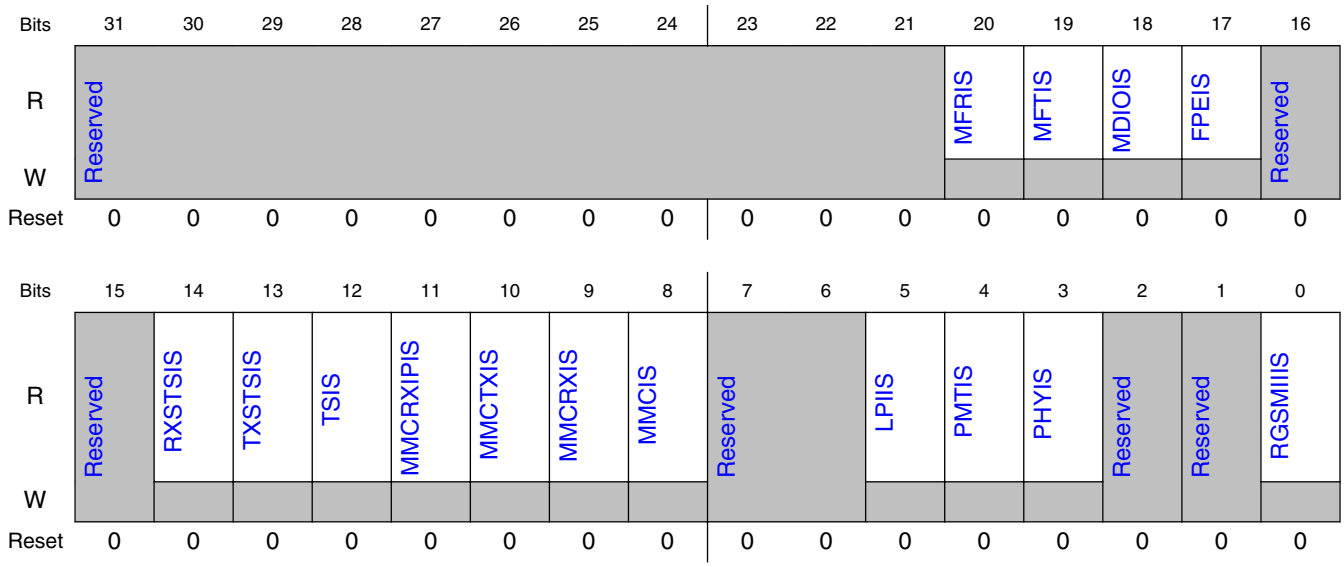
61.7.1.26.1 Offset

Register	Offset
MAC_INTERRUPT_STATUS	B0h

61.7.1.26.2 Function

The Interrupt Status register contains the status of interrupts.

61.7.1.26.3 Diagram



61.7.1.26.4 Fields

Field	Function
31-21 —	Reserved
20 MFRIS	MMC FPE Receive Interrupt Status This bit is set high when an interrupt is generated in the MMC FPE Receive Interrupt Register. This bit is cleared when all bits in this interrupt register are cleared. This bit is valid only when you select the Enable MAC Management Counters (MMC) option along with FPE support. 0b - MMC FPE Receive Interrupt status not active 1b - MMC FPE Receive Interrupt status active
19 MFTIS	MMC FPE Transmit Interrupt Status This bit is set high when an interrupt is generated in the MMC FPE Transmit Interrupt Register. This bit is cleared when all bits in this interrupt register are cleared. This bit is valid only when you select the Enable MAC Management Counters (MMC) option along with FPE support. 0b - MMC FPE Transmit Interrupt status not active 1b - MMC FPE Transmit Interrupt status active
18 MDIOIS	MDIO Interrupt Status This bit indicates an interrupt event after the completion of MDIO operation. To reset this bit, the application has to read this bit/Write 1 to this bit when RCWE bit of CSR_SW_CTRL register is set. Access restriction applies. Clears on read (or write of 1 when RCWE bit in CSR_SW_CTRL register is set). Self-set to 1 on internal event. 0b - MDIO Interrupt status not active 1b - MDIO Interrupt status active
17 FPEIS	Frame Preemption Interrupt Status

Table continues on the next page...

Field	Function
	This bit indicates an interrupt event during the operation of Frame Preemption (Bits[19:16] of MAC_FPE_CTRL_STS register is set). To reset this bit, the application must clear the event in MAC_FPE_CTRL_STS that has caused the Interrupt. 0b - Frame Preemption Interrupt status not active 1b - Frame Preemption Interrupt status active
16 —	Reserved
15 —	Reserved
14 RXSTSIS	Receive Status Interrupt This bit indicates the status of received packets. This bit is set when the RWT bit is set in the MAC_RX_TX_STATUS register. This bit is cleared when the corresponding interrupt source bit is read (or corresponding interrupt source bit is written to 1 when RCWE bit of CSR_SW_CTRL register is set) in the MAC_RX_TX_STATUS register. 0b - Receive Interrupt status not active 1b - Receive Interrupt status active
13 TXSTSIS	Transmit Status Interrupt This bit indicates the status of transmitted packets. This bit is set when any of the following bits is set in the MAC_RX_TX_STATUS register: - Excessive Collision (EXCOL) - Late Collision (LCOL) - Excessive Deferral (EXDEF) - Loss of Carrier (LCARR) - No Carrier (NCARR) - Jabber Timeout (TJT) This bit is cleared when the corresponding interrupt source bit is read (or corresponding interrupt source bit is written to 1 when RCWE bit of CSR_SW_CTRL register is set) in the MAC_RX_TX_STATUS register. 0b - Transmit Interrupt status not active 1b - Transmit Interrupt status active
12 TSIS	Timestamp Interrupt Status If the Timestamp feature is enabled, this bit is set when any of the following conditions is true: - The system time value is equal to or exceeds the value specified in the Target Time High and Low registers. - There is an overflow in the Seconds register. - The Target Time Error occurred, that is, programmed target time already elapsed. If the Auxiliary Snapshot feature is enabled, this bit is set when the auxiliary snapshot trigger is asserted. In configurations other than EQOS_CORE, when drop transmit status is enabled in MTL, this bit is set when the captured transmit timestamp is updated in the MAC_TX_TIMESTAMP_STATUS_NANOSECONDS and MAC_TXTIMESTAMP_STATUS_SECONDS registers. When PTP offload feature is enabled, this bit is set when the captured transmit timestamp is updated in the MAC_TX_TIMESTAMP_STATUS_NANOSECONDS and MAC_TX_TIMESTAMP_STATUS_SECONDS registers, for PTO generated Delay Request and Pdelay request packets.

Table continues on the next page...

Field	Function
	This bit is cleared when the corresponding interrupt source bit is read (or corresponding interrupt source bit is written to 1 when RCWE bit of CSR_SW_CTRL register is set) in the MAC_TIMESTAMP_STATUS register. 0b - Timestamp Interrupt status not active 1b - Timestamp Interrupt status active
11 MMCRXIPIS	MMC Receive Checksum Offload Interrupt Status This bit is set high when an interrupt is generated in the MMC Receive Checksum Offload Interrupt Register. This bit is cleared when all bits in this interrupt register are cleared. This bit is valid only when you select the Enable MAC Management Counters (MMC) and Enable Receive TCP/IP Checksum Check options. 0b - MMC Receive Checksum Offload Interrupt status not active 1b - MMC Receive Checksum Offload Interrupt status active
10 MMCTXIS	MMC Transmit Interrupt Status This bit is set high when an interrupt is generated in the MMC Transmit Interrupt Register. This bit is cleared when all bits in this interrupt register are cleared. This bit is valid only when you select the Enable MAC Management Counters (MMC) option. 0b - MMC Transmit Interrupt status not active 1b - MMC Transmit Interrupt status active
9 MMCRXIS	MMC Receive Interrupt Status This bit is set high when an interrupt is generated in the MMC Receive Interrupt Register. This bit is cleared when all bits in this interrupt register are cleared. This bit is valid only when you select the Enable MAC Management Counters (MMC) option. 0b - MMC Receive Interrupt status not active 1b - MMC Receive Interrupt status active
8 MMCIS	MMC Interrupt Status This bit is set high when Bit 11, Bit 10, or Bit 9 is set high. This bit is cleared only when all these bits are low. This bit is valid only when you select the Enable MAC Management Counters (MMC) option. 0b - MMC Interrupt status not active 1b - MMC Interrupt status active
7-6 —	Reserved
5 LPIIS	LPI Interrupt Status When the Energy Efficient Ethernet feature is enabled, this bit is set for any LPI state entry or exit in the MAC Transmitter or Receiver. This bit is cleared when the corresponding interrupt source bit of MAC_LPI_CONTROL_STATUS register is read (or corresponding interrupt source bit of MAC_LPI_CONTROL_STATUS register is written to 1 when RCWE bit of MAC_CSR_SW_CTRL register is set). 0b - LPI Interrupt status not active 1b - LPI Interrupt status active
4 PMTIS	PMT Interrupt Status This bit is set when a Magic packet or Wake-on-LAN packet is received in the power-down mode (RWKPRCVD and MGKPRCVD bits in MAC_PMT_CONTROL_STATUS register). This bit is cleared when corresponding interrupt source bit are cleared because of a Read operation to the MAC_PMT_CONTROL_STATUS register (or corresponding interrupt source bit of MAC_PMT_CONTROL_STATUS register is written to 1 when RCWE bit of CSR_SW_CTRL register is set).

Table continues on the next page...

Field	Function
	This bit is valid only when you select the Enable Power Management option. 0b - PMT Interrupt status not active 1b - PMT Interrupt status active
3 PHYIS	PHY Interrupt This bit is set when rising edge is detected on the phy_intr_i input. This bit is cleared when this register is read (or this bit is written to 1 when RCWE bit of CSR_SW_CTRL register is set). 0b - PHY Interrupt not detected 1b - PHY Interrupt detected
2 —	Reserved
1 —	Reserved
0 RGSMIIIS	RGMII or SMII Interrupt Status This bit is set because of any change in value of the Link Status of RGMII or SMII interface (LNKSTS bit in MAC_PHYIF_CONTROL_STATUS register). This bit is cleared when the PHYIF_CONTROL_STATUS register is read (or LNKSTS bit of MAC_PHYIF_CONTROL_STATUS register is written to 1 when RCWE bit of MAC_CSR_SW_CTRL register is set). This bit is valid only when you select the optional RGMII or SMII PHY interface. 0b - RGMII or SMII Interrupt Status is not active 1b - RGMII or SMII Interrupt Status is active

61.7.1.27 Interrupt Enable (MAC_INTERRUPT_ENABLE)

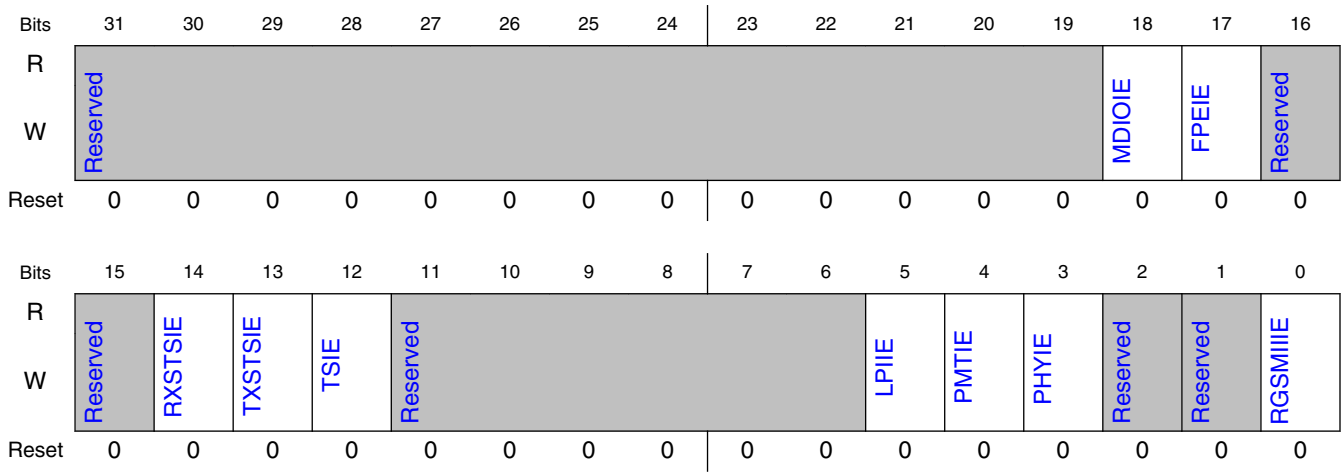
61.7.1.27.1 Offset

Register	Offset
MAC_INTERRUPT_ENABLE	B4h

61.7.1.27.2 Function

The Interrupt Enable register contains the masks for generating the interrupts.

61.7.1.27.3 Diagram



61.7.1.27.4 Fields

Field	Function
31-19 —	Reserved
18 MDIOIE	MDIO Interrupt Enable When this bit is set, it enables the assertion of the interrupt when MDIOIS field is set in the MAC_INTERRUPT_STATUS register. 0b - MDIO Interrupt is disabled 1b - MDIO Interrupt is enabled
17 FPEIE	Frame Preemption Interrupt Enable When this bit is set, it enables the assertion of the interrupt when FPEIS field is set in the MAC_INTERRUPT_STATUS. 0b - Frame Preemption Interrupt is disabled 1b - Frame Preemption Interrupt is enabled
16 —	Reserved
15 —	Reserved
14 RXSTSIE	Receive Status Interrupt Enable When this bit is set, it enables the assertion of the interrupt signal because of the setting of MAC_INTERRUPT_STATUS[RXSTSIS]. 0b - Receive Status Interrupt is disabled 1b - Receive Status Interrupt is enabled
13 TXSTSIE	Transmit Status Interrupt Enable When this bit is set, it enables the assertion of the interrupt signal because of the setting of MAC_INTERRUPT_STATUS[TXSTSIS]. 0b - Timestamp Status Interrupt is disabled 1b - Timestamp Status Interrupt is enabled
12 TSIE	Timestamp Interrupt Enable When this bit is set, it enables the assertion of the interrupt signal because of the setting of MAC_INTERRUPT_STATUS[TSIS]. 0b - Timestamp Interrupt is disabled 1b - Timestamp Interrupt is enabled
11-6 —	Reserved

Table continues on the next page...

Field	Function
5 LPIIE	LPI Interrupt Enable When this bit is set, it enables the assertion of the interrupt signal because of the setting of MAC_INTERRUPT_STATUS[LPIIS]. 0b - LPI Interrupt is disabled 1b - LPI Interrupt is enabled
4 PMTIE	PMT Interrupt Enable When this bit is set, it enables the assertion of the interrupt signal because of the setting of MAC_INTERRUPT_STATUS[PMTIS]. 0b - PMT Interrupt is disabled 1b - PMT Interrupt is enabled
3 PHYIE	PHY Interrupt Enable When this bit is set, it enables the assertion of the interrupt signal because of the setting of MAC_INTERRUPT_STATUS[PHYIS]. 0b - PHY Interrupt is disabled 1b - PHY Interrupt is enabled
2 —	Reserved
1 —	Reserved
0 RGSMIIIE	RGMII or SMII Interrupt Enable When this bit is set, it enables the assertion of the interrupt signal because of the setting of RGSMIIIS bit in MAC_INTERRUPT_STATUS register. 0b - RGMII or SMII Interrupt is disabled 1b - RGMII or SMII Interrupt is enabled

61.7.1.28 Receive Transmit Status (MAC_RX_TX_STATUS)

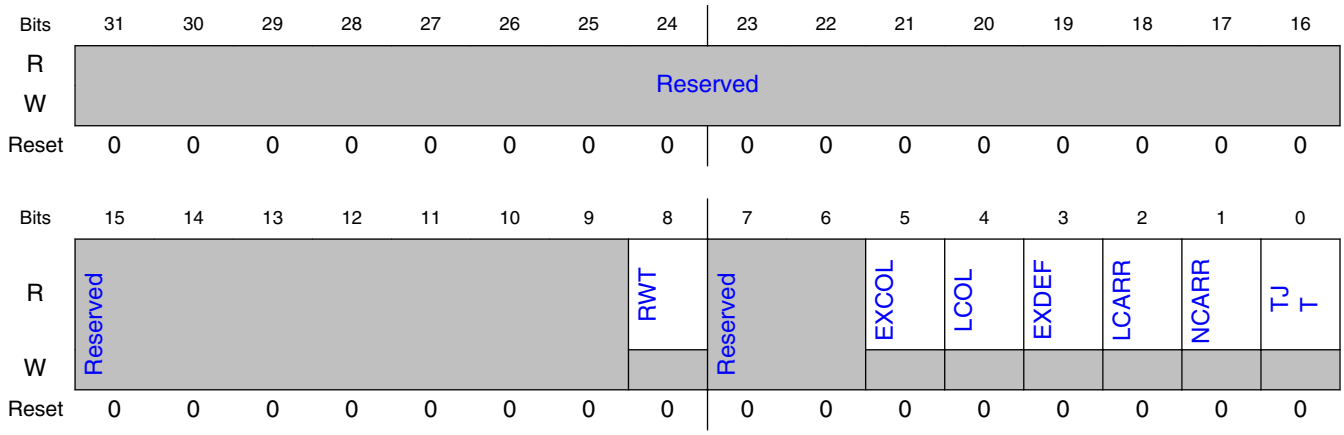
61.7.1.28.1 Offset

Register	Offset
MAC_RX_TX_STATUS	B8h

61.7.1.28.2 Function

The Receive Transmit Status register contains the Receive and Transmit Error status.

61.7.1.28.3 Diagram



61.7.1.28.4 Fields

Field	Function
31-9 —	Reserved
8 RWT	Receive Watchdog Timeout This bit is set when a packet with length greater than 2,048 bytes is received (10, 240 bytes when Jumbo Packet mode is enabled) and the WD bit is reset in the MAC_CONFIGURATION register. Receive Watchdog Timeout This bit is set when a packet with length greater than 2,048 bytes is received (10, 240 bytes when Jumbo Packet mode is enabled) and the WD bit is reset in the MAC_CONFIGURATION register. This bit is set when a packet with length greater than 16,383 bytes is received and the WD bit is set in the MAC_CONFIGURATION register. Access restriction applies. Clears on read (or write of 1 when RCWE bit in CSR_SW_CTRL register is set). Self-set to 1 on internal event. 0b - No receive watchdog timeout 1b - Receive watchdog timed out
7-6 —	Reserved
5 EXCOL	Excessive Collisions When the DTXSTS bit is set in the MAC_OPERATION_MODE register, this bit indicates that the transmission aborted after 16 successive collisions while attempting to transmit the current packet. Excessive Collisions When the DTXSTS bit is set in the MAC_OPERATION_MODE register, this bit indicates that the transmission aborted after 16 successive collisions while attempting to transmit the current packet. If the DR bit is set in the CONFIGURATION register, this bit is set after the first collision and the packet transmission is aborted. Access restriction applies. Clears on read (or write of 1 when RCWE bit in CSR_SW_CTRL register is set). Self-set to 1 on internal event. 0b - No collision 1b - Excessive collision is sensed

Table continues on the next page...

Field	Function
4 LCOL	Late Collision When the DTXSTS bit is set in the MAC_OPERATION_MODE register, this bit indicates that the packet transmission aborted because a collision occurred after the collision window (64 bytes including Preamble in MII mode; 512 bytes including Preamble and Carrier Extension in GMII mode). Late Collision When the DTXSTS bit is set in the MAC_OPERATION_MODE register, this bit indicates that the packet transmission aborted because a collision occurred after the collision window (64 bytes including Preamble in MII mode; 512 bytes including Preamble and Carrier Extension in GMII mode). This bit is not valid if the Underflow error occurs. Access restriction applies. Clears on read (or write of 1 when RCWE bit in CSR_SW_CTRL register is set). Self-set to 1 on internal event. 0b - No collision 1b - Late collision is sensed
3 EXDEF	Excessive Deferral When the DTXSTS bit is set in the MAC_OPERATION_MODE register and the DC bit is set in the MAC_CONFIGURATION register, this bit indicates that the transmission ended because of excessive deferral of over 24,288 bit times (155,680 in 1000/2500 Mbps mode or when Jumbo packet is enabled). Excessive Deferral When the DTXSTS bit is set in the MAC_OPERATION_MODE register and the DC bit is set in the MAC_CONFIGURATION register, this bit indicates that the transmission ended because of excessive deferral of over 24,288 bit times (155,680 in 1000/2500 Mbps mode or when Jumbo packet is enabled). Access restriction applies. Clears on read (or write of 1 when RCWE bit in CSR_SW_CTRL register is set). Self-set to 1 on internal event. 0b - No Excessive deferral 1b - Excessive deferral
2 LCARR	Loss of Carrier When the DTXSTS bit is set in the MAC_OPERATION_MODE register, this bit indicates that the loss of carrier occurred during packet transmission, that is, the phy_crs_i signal was inactive for one or more transmission clock periods during packet transmission. Loss of Carrier When the DTXSTS bit is set in the MAC_OPERATION_MODE register, this bit indicates that the loss of carrier occurred during packet transmission, that is, the phy_crs_i signal was inactive for one or more transmission clock periods during packet transmission. This bit is valid only for packets transmitted without collision. Access restriction applies. Clears on read (or write of 1 when RCWE bit in CSR_SW_CTRL register is set). Self-set to 1 on internal event. 0b - Carrier is present 1b - Loss of carrier
1 NCARR	No Carrier When the DTXSTS bit is set in the MAC_OPERATION_MODE register, this bit indicates that the carrier signal from the PHY is not present at the end of preamble transmission. No Carrier When the DTXSTS bit is set in the MAC_OPERATION_MODE register, this bit indicates that the carrier signal from the PHY is not present at the end of preamble transmission. Access restriction applies. Clears on read (or write of 1 when RCWE bit in CSR_SW_CTRL register is set). Self-set to 1 on internal event. 0b - Carrier is present 1b - No carrier

Field	Function
31 RWKFILTRST	Remote Wake-Up Packet Filter Register Pointer Reset When this bit is set, the remote wake-up packet filter register pointer is reset to 3'b000. Remote Wake-Up Packet Filter Register Pointer Reset When this bit is set, the remote wake-up packet filter register pointer is reset to 3'b000. It is automatically cleared after 1 clock cycle. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0b - Remote Wake-Up Packet Filter Register Pointer is not Reset 1b - Remote Wake-Up Packet Filter Register Pointer is Reset
30-29 —	Reserved
28-24 RWKPTR	Remote Wake-up FIFO Pointer This field gives the current value (0 to 7, 15, or 31 when 4, 8, or 16 Remote Wake-up Packet Filters are selected) of the Remote Wake-up Packet Filter register pointer. Remote Wake-up FIFO Pointer This field gives the current value (0 to 7, 15, or 31 when 4, 8, or 16 Remote Wake-up Packet Filters are selected) of the Remote Wake-up Packet Filter register pointer. When the value of this pointer is equal to maximum for the selected number of Remote Wake-up Packet Filters, the contents of the Remote Wake-up Packet Filter Register are transferred to the clk_rx_i domain when a Write occurs to that register.
23-11 —	Reserved
10 RWKPFE	Remote Wake-up Packet Forwarding Enable When this bit is set along with RWKPKTEN, the MAC receiver drops all received frames until it receives the expected Wake-up frame. Remote Wake-up Packet Forwarding Enable

Table continues on the next page...

Field	Function
	When this bit is set along with RWKPKTEN, the MAC receiver drops all received frames until it receives the expected Wake-up frame. All frames after that event including the received wake-up frame are forwarded to application. This bit is then self-cleared on receiving the wake-up packet. The application can also clear this bit before the expected wake-up frame is received. In such cases, the MAC reverts to the default behavior where packets received are forwarded to the application. This bit must only be set when RWKPKTEN is set high and PWRDWN is set low. The setting of this bit has no effect when PWRDWN is set high. Note: If Magic Packet Enable and Wake-Up Frame Enable are both set along with setting of this bit and Magic Packet is received prior to wake-up frame, this bit is self-cleared on receiving Magic Packet, the received Magic packet is dropped, and all frames after received Magic Packet are forwarded to application. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0b - Remote Wake-up Packet Forwarding is disabled 1b - Remote Wake-up Packet Forwarding is enabled
9 GLBLUCAST	Global Unicast When this bit set, any unicast packet filtered by the MAC (DAF) address recognition is detected as a remote wake-up packet. 0b - Global unicast is disabled 1b - Global unicast is enabled
8-7 —	Reserved
6 RWKPRCVD	Remote Wake-Up Packet Received When this bit is set, it indicates that the power management event is generated because of the reception of a remote wake-up packet. Remote Wake-Up Packet Received When this bit is set, it indicates that the power management event is generated because of the reception of a remote wake-up packet. This bit is cleared when this register is read. Access restriction applies. Clears on read (or write of 1 when RCWE bit in CSR_SW_CTRL register is set). Self-set to 1 on internal event. 0b - Remote wake-up packet is received 1b - Remote wake-up packet is received
5 MGKPRCVD	Magic Packet Received When this bit is set, it indicates that the power management event is generated because of the reception of a magic packet. Magic Packet Received When this bit is set, it indicates that the power management event is generated because of the reception of a magic packet. This bit is cleared when this register is read. Access restriction applies. Clears on read (or write of 1 when RCWE bit in CSR_SW_CTRL register is set). Self-set to 1 on internal event. 0b - No Magic packet is received 1b - Magic packet is received
4-3 —	Reserved
2 RWKPKTEN	Remote Wake-Up Packet Enable When this bit is set, a power management event is generated when the MAC receives a remote wake-up packet. 0b - Remote wake-up packet is disabled 1b - Remote wake-up packet is enabled
1	Magic Packet Enable When this bit is set, a power management event is generated when the MAC receives a magic packet.

Table continues on the next page...

Field	Function
MGKPKTEN	0b - Magic Packet is disabled 1b - Magic Packet is enabled
0 PWRDWN	Power Down When this bit is set, the MAC receiver drops all received packets until it receives the expected magic packet or remote wake-up packet. Power Down When this bit is set, the MAC receiver drops all received packets until it receives the expected magic packet or remote wake-up packet. This bit is then self-cleared and the power-down mode is disabled. The software can clear this bit before the expected magic packet or remote wake-up packet is received. The packets received by the MAC after this bit is cleared are forwarded to the application. This bit must only be set when the Magic Packet Enable, Global Unicast, or Remote Wake-Up Packet Enable bit is set high. Note: You can gate-off the CSR clock during the power-down mode. However, when the CSR clock is gated-off, you cannot perform any read or write operations on this register. Therefore, the Software cannot clear this bit. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0b - Power down is disabled 1b - Power down is enabled

61.7.1.30 Remote Wakeup Filter (MAC_RWK_PACKET_FILTER)

61.7.1.30.1 Offset

Register	Offset
MAC_RWK_PACKET_FILTER	C4h

61.7.1.30.2 Function

The Remote Wakeup Filter registers are implemented as 8, 16, or 32 indirect access registers (wkuppktfilter_reg#i) based on whether 4, 8, or 16 Remote Wakeup Filters are selected in the configuration and accessed by application through MAC_RWK_PACKET_FILTER register.

The Remote Wakeup Filter registers are implemented as 8, 16, or 32 indirect access registers (wkuppktfilter_reg#i) based on whether 4, 8, or 16 Remote Wakeup Filters are selected in the configuration and accessed by application through MAC_RWK_PACKET_FILTER register. When the Remote Wakeup Filters are to be programmed, the entire set of wkuppktfilter_reg registers must be written. The wkuppktfilter_reg register is programmed by sequentially writing the eight, sixteen or thirty-two register values in MAC_RWK_PACKET_FILTER register for wkuppktfilter_REG0, wkuppktfilter_REG1, ..., wkuppktfilter_REG31 respectively. The

wkuppktfilter_reg register is read in a similar way. The MAC updates the wkuppktfilter_reg register current pointer value in RWKPTR field of MAC_PMT_CONTROL_STATUS register.

The Remote Wakeup Filters are arranged in blocks of 4 filters each and each such block have eight 32-bit wide registers, viz. wkuppktfilter_REG0-7, wkuppktfilter_reg8-15, wkuppktfilter_REG16-23 and wkuppktfilter_REG24-31. The fields of Remote Wakeup Filter are described as follows:

Filter i Byte Mask: The filter i byte mask register defines the bytes of the packet that are examined by filter i (0, 1, 2, 3, .., 15) to determine whether or not a packet is a wake-up packet.

- The MSB (31st bit) must be zero.

- Bit j[30:0] is the byte mask.

- If Bit j (byte number) of the byte mask is set, the CRC block processes the Filter i Offset + j of the incoming packet; otherwise Filter i Offset + j is ignored.

Filter i Command: The 4-bit filter i command controls the filter i operation.

- Bit 3 specifies the address type, defining the destination address type of the pattern. When the bit is set, the pattern applies to only multicast packets; when the bit is reset, the pattern applies only to unicast packet.

- Bit 2 (Inverse Mode), when set, reverses the logic of the CRC16 hash function signal, to reject a packet with matching CRC-16 value. Bit 2, along with Bit 1, allows a MAC to reject a subset of remote wake-up packets by creating filter logic such as "Pattern 1 AND NOT Pattern 2".

- Bit 1 (And_Previous) implements the Boolean logic. When set, the result of the current entry is logically ANDed with the result of the previous filter. This AND logic allows a filter pattern longer than 32 bytes by splitting the mask among two, three, or four filters. This depends on the number of filters that have the And_Previous bit set. The details are provided below:

-- The And_Previous bit setting is applicable within a set of 4 filters.

-- Setting of And_Previous bit of filter that is not enabled has no effect, that is setting And_Previous bit of lowest number filter in the set of 4 filters has no effect. For example, setting of And_Previous bit of Filter 0 has no effect.

-- If And_Previous bit is set for filter to form AND chained filter, the AND chain breaks at the point any filter is not enabled. For example: If Filter 2 And_Previous bit is set (bit 1 in Filter 2 command is set) but Filter 1 is not enabled (bit 0 in Filter 1 command is reset), then only Filter 2 result is considered. If Filter 2 And_Previous bit is set (bit 1 in

Filter 2 command is set), Filter 3 And_Previous bit is set (bit 1 in Filter 3 command is set), but Filter 1 is not enabled (bit 0 in Filter 1 command is reset), then only Filter 2 result ANDed with Filter 3 result is considered. If Filter 2 And_Previous bit is set (bit 1 in Filter 2 command is set), Filter 3 And_Previous bit is set (bit 1 in Filter 3 command is set), but Filter 2 is not enabled (bit 0 in Filter 2 command is reset), then since setting of Filter 2 And_Previous bit has no effect only Filter 1 result ORed with Filter 3 result is considered.

-- If filters chained by And_Previous bit setting have complementary programming, then a frame may never pass the AND chained filter. For example, if Filter 2 And_Previous bit is set (bit 1 in Filter 2 command is set), Filter 1 Address_Type bit is set (bit 3 in Filter 1 command is set) indicating multicast detection and Filter 2 Address_Type bit is reset (bit 3 in Filter 2 command is reset) indicating unicast detection or vice versa, a remote wakeup frame does not pass the AND chained filter as a remote wakeup frame cannot be of both unicast and multicast address type.

- Bit 0 is the enable for filter i. If Bit 0 is not set, filter i is disabled.

Filter i Offset: The filter i offset register defines the offset (within the packet) from which the filter i examines the packets.

- This 8-bit pattern-offset is the offset for the filter i first byte to be examined.

- The minimum allowed offset is 12, which refers to the 13th byte of the packet.

- The offset value 0 refers to the first byte of the packet.

Filter i CRC-16: The filter i CRC-16 register contains the CRC-16 value calculated from the pattern and the byte mask programmed in the Remote Wakeup filter register.

- The 16-bit CRC calculation uses the following polynomial: $G(x) = x^{16} + x^{15} + x^2 + 1$

- Each mask, used in the hash function calculation, is compared with a 16-bit value associated with that mask. Each filter has the following:

-- 32-bit Mask: Each bit in this mask corresponds to one byte in the detected packet. If the bit is 1, the corresponding byte is taken into the CRC-16 calculation.

-- 8-bit Offset Pointer: Specifies the byte to start the CRC-16 computation. The pointer and the mask are used together to locate the bytes to be used in the CRC-16 calculations.

The structure of the RWK Filter registers is shown in "Figure 10-11 Remote Wake-Up Packet Filter Register".

61.7.1.30.3 Diagram

61.7.1.31 LPI Control and Status (MAC_LPI_CONTROL_STATUS)

61.7.1.31.1 Offset

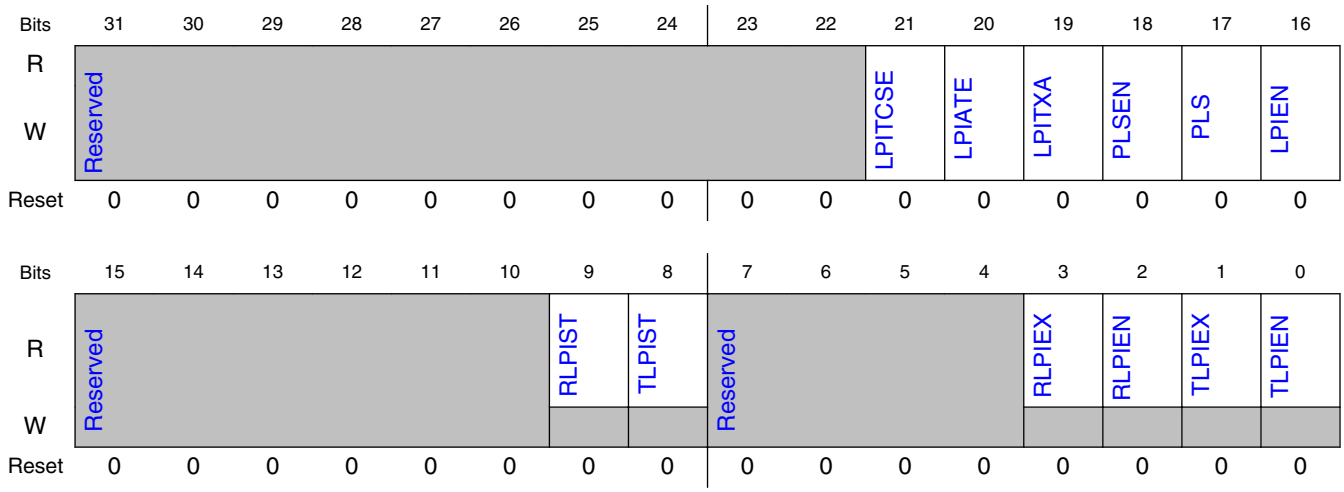
Register	Offset
MAC_LPI_CONTROL_STATUS	D0h

61.7.1.31.2 Function

The LPI Control and Status Register controls the LPI functions and provides the LPI interrupt status.

The LPI Control and Status Register controls the LPI functions and provides the LPI interrupt status. The status bits are cleared when this register is read.

61.7.1.31.3 Diagram



61.7.1.31.4 Fields

Field	Function
31-22 —	Reserved
21 LPITCSE	LPI Tx Clock Stop Enable When this bit is set, the MAC asserts sbd_tx_clk_gating_ctrl_o signal high after it enters Tx LPI mode to indicate that the Tx clock to MAC can be stopped. LPI Tx Clock Stop Enable When this bit is set, the MAC asserts sbd_tx_clk_gating_ctrl_o signal high after it enters Tx LPI mode to indicate that the Tx clock to MAC can be stopped. When this bit is reset, the MAC does not assert sbd_tx_clk_gating_ctrl_o signal high after it enters Tx LPI mode. If RGMII Interface is selected, the Tx clock is required for transmitting the LPI pattern. The Tx Clock cannot be gated and so the LPITCSE bit cannot be programmed. 0b - LPI Tx Clock Stop is disabled 1b - LPI Tx Clock Stop is enabled
20 LPIATE	LPI Timer Enable This bit controls the automatic entry of the MAC Transmitter into and exit out of the LPI state. LPI Timer Enable This bit controls the automatic entry of the MAC Transmitter into and exit out of the LPI state. When LPIATE, LPITXA and LPIEN bits are set, the MAC Transmitter enters LPI state only when the complete MAC TX data path is IDLE for a period indicated by the MAC_LPI_ENTRY_TIMER register. After entering LPI state, if the data path becomes non-IDLE (due to a new packet being accepted for transmission), the Transmitter exits LPI state but does not clear LPIEN bit. This enables the re-entry into LPI state when it is IDLE again. When LPIATE is 0, the LPI Auto timer is disabled and MAC Transmitter enters LPI state based on the settings of LPITXA and LPIEN bit descriptions.

Table continues on the next page...

Field	Function
	0b - LPI Timer is disabled 1b - LPI Timer is enabled
19 LPITXA	LPI Tx Automate This bit controls the behavior of the MAC when it is entering or coming out of the LPI mode on the Transmit side. LPI Tx Automate This bit controls the behavior of the MAC when it is entering or coming out of the LPI mode on the Transmit side. This bit is not functional in the EQOS-CORE configurations in which the Tx clock gating is done during the LPI mode. If the LPITXA and LPIEN bits are set to 1, the MAC enters the LPI mode only after all outstanding packets (in the core) and pending packets (in the application interface) have been transmitted. The MAC comes out of the LPI mode when the application sends any packet for transmission or the application issues a Tx FIFO Flush command. In addition, the MAC automatically clears the LPIEN bit when it exits the LPI state. If Tx FIFO Flush is set in the FTQ bit of MAC_TXQ0_OPERATION_MODE register, when the MAC is in the LPI mode, it exits the LPI mode. When this bit is 0, the LPIEN bit directly controls behavior of the MAC when it is entering or coming out of the LPI mode. 0b - LPI Tx Automate is disabled 1b - LPI Tx Automate is enabled
18 PLSEN	PHY Link Status Enable This bit enables the link status received on the RGMII, SGMII, or SMII Receive paths to be used for activating the LPI LS TIMER. PHY Link Status Enable This bit enables the link status received on the RGMII, SGMII, or SMII Receive paths to be used for activating the LPI LS TIMER. When this bit is set, the MAC uses the link-status bits of the MAC_PHYIF_CONTROL_STATUS register and the PLS bit for the LPI LS Timer trigger. When this bit is reset, the MAC ignores the link-status bits of the MAC_PHYIF_CONTROL_STATUS register and takes only the PLS bit. 0b - PHY Link Status is disabled 1b - PHY Link Status is enabled
17 PLS	PHY Link Status This bit indicates the link status of the PHY. PHY Link Status This bit indicates the link status of the PHY. The MAC Transmitter asserts the LPI pattern only when the link status is up (OKAY) at least for the time indicated by the LPI LS TIMER. When this bit is set, the link is considered to be okay (UP) and when this bit is reset, the link is considered to be down. 0b - link is down 1b - link is okay (UP)
16 LPIEN	LPI Enable When this bit is set, it instructs the MAC Transmitter to enter the LPI state. LPI Enable When this bit is set, it instructs the MAC Transmitter to enter the LPI state. When this bit is reset, it instructs the MAC to exit the LPI state and resume normal transmission. This bit is cleared when the LPITXA bit is set and the MAC exits the LPI state because of the arrival of a new packet for transmission. 0b - LPI state is disabled 1b - LPI state is enabled
15-10 —	Reserved

Table continues on the next page...

Field	Function
9 RLPIST	Receive LPI State When this bit is set, it indicates that the MAC is receiving the LPI pattern on the GMII or MII interface. 0b - Receive LPI state not detected 1b - Receive LPI state detected
8 TLPIST	Transmit LPI State When this bit is set, it indicates that the MAC is transmitting the LPI pattern on the GMII or MII interface. 0b - Transmit LPI state not detected 1b - Transmit LPI state detected
7-4 —	Reserved
3 RLPIEX	Receive LPI Exit When this bit is set, it indicates that the MAC Receiver has stopped receiving the LPI pattern on the GMII or MII interface, exited the LPI state, and resumed the normal reception. Receive LPI Exit When this bit is set, it indicates that the MAC Receiver has stopped receiving the LPI pattern on the GMII or MII interface, exited the LPI state, and resumed the normal reception. This bit is cleared by a read into this register (or this bit is written to 1 when RCWE bit in CSR_SW_CTRL register is set). Note: This bit may not be set if the MAC stops receiving the LPI pattern for a very short duration, such as, less than three clock cycles of CSR clock. 0b - Receive LPI exit not detected 1b - Receive LPI exit detected
2 RLPIEN	Receive LPI Entry When this bit is set, it indicates that the MAC Receiver has received an LPI pattern and entered the LPI state. Receive LPI Entry When this bit is set, it indicates that the MAC Receiver has received an LPI pattern and entered the LPI state. This bit is cleared by a read into this register (or this bit is written to 1 when RCWE bit in CSR_SW_CTRL register is set). Note: This bit may not be set if the MAC stops receiving the LPI pattern for a very short duration, such as, less than three clock cycles of CSR clock. 0b - Receive LPI entry not detected 1b - Receive LPI entry detected
1 TLPIEX	Transmit LPI Exit When this bit is set, it indicates that the MAC transmitter exited the LPI state after the application cleared the LPIEN bit and the LPI TW Timer has expired. Transmit LPI Exit When this bit is set, it indicates that the MAC transmitter exited the LPI state after the application cleared the LPIEN bit and the LPI TW Timer has expired. This bit is cleared by a read into this register (or this bit is written to 1 when RCWE bit in CSR_SW_CTRL register is set). 0b - Transmit LPI exit not detected 1b - Transmit LPI exit detected
0 TLPIEN	Transmit LPI Entry When this bit is set, it indicates that the MAC Transmitter has entered the LPI state because of the setting of the LPIEN bit. Transmit LPI Entry When this bit is set, it indicates that the MAC Transmitter has entered the LPI state because of the setting of the LPIEN bit. This bit is cleared by a read into this register (or this bit is written to 1 when RCWE bit in CSR_SW_CTRL register is set). 0b - Transmit LPI entry not detected 1b - Transmit LPI entry detected

61.7.1.32 LPI Timers Control (MAC_LPI_TIMERS_CONTROL)

61.7.1.32.1 Offset

Register	Offset
MAC_LPI_TIMERS_CONTROL	D4h

61.7.1.32.2 Function

The LPI Timers Control register controls the timeout values in the LPI states.

The LPI Timers Control register controls the timeout values in the LPI states. It specifies the time for which the MAC transmits the LPI pattern and also the time for which the MAC waits before resuming the normal transmission.

61.7.1.37 MAC Debug (MAC_DEBUG)

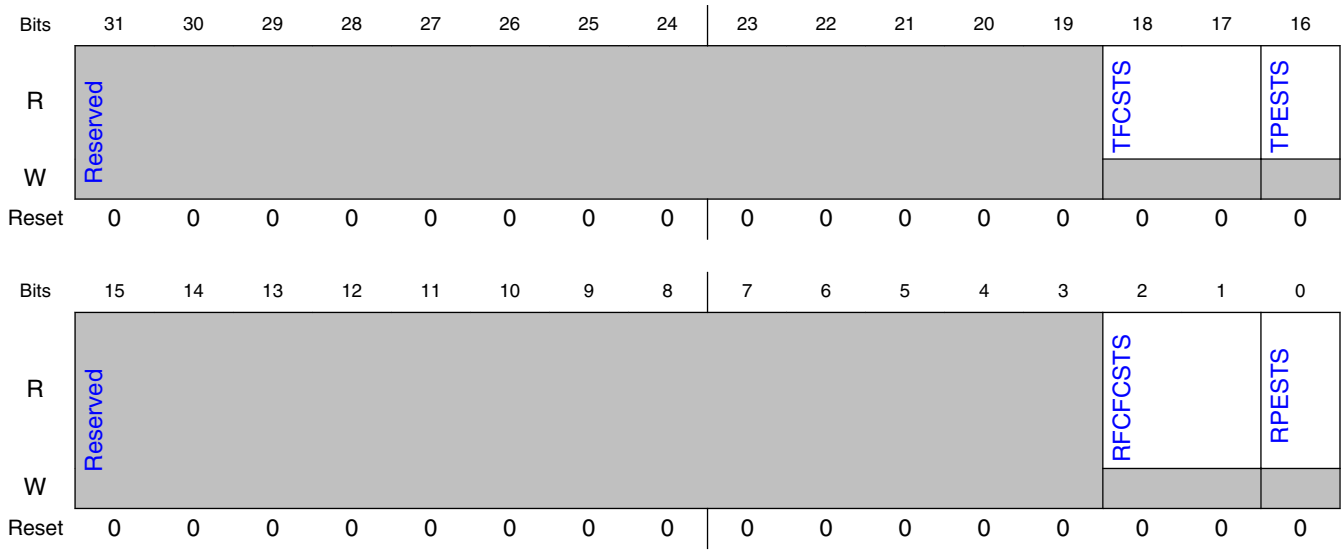
61.7.1.37.1 Offset

Register	Offset
MAC_DEBUG	114h

61.7.1.37.2 Function

The Debug register provides the debug status of various MAC blocks.

61.7.1.37.3 Diagram



61.7.1.37.4 Fields

Field	Function
31-19 —	Reserved
18-17 TFCSTS	MAC Transmit Packet Controller Status This field indicates the state of the MAC Transmit Packet Controller module. 00b - Idle state 01b - Waiting for one of the following: Status of the previous packet OR IPG or back off period to be over 10b - Generating and transmitting a Pause control packet (in full-duplex mode) 11b - Transferring input packet for transmission
16 TPESTS	MAC GMII or MII Transmit Protocol Engine Status When this bit is set, it indicates that the MAC GMII or MII transmit protocol engine is actively transmitting data, and it is not in the Idle state. 0b - MAC GMII or MII Transmit Protocol Engine Status not detected 1b - MAC GMII or MII Transmit Protocol Engine Status detected
15-3 —	Reserved
2-1 RFCFCSTS	MAC Receive Packet Controller FIFO Status When this bit is set, this field indicates the active state of the small FIFO Read and Write controllers of the MAC Receive Packet Controller module.
0 RPESTS	MAC GMII or MII Receive Protocol Engine Status When this bit is set, it indicates that the MAC GMII or MII receive protocol engine is actively receiving data, and it is not in the Idle state. 0b - MAC GMII or MII Receive Protocol Engine Status not detected 1b - MAC GMII or MII Receive Protocol Engine Status detected

61.7.1.38 Optional Features or Functions 0 (MAC_HW_FEATURE0)

61.7.1.38.1 Offset

Register	Offset
MAC_HW_FEATURE0	11Ch

61.7.1.38.2 Function

This register indicates the presence of first set of the optional features or functions of the DWC_ether_qos. The software driver can use this register to dynamically enable or disable the programs related to the optional blocks.

61.7.1.42 MDIO Address (MAC_MDIO_ADDRESS)

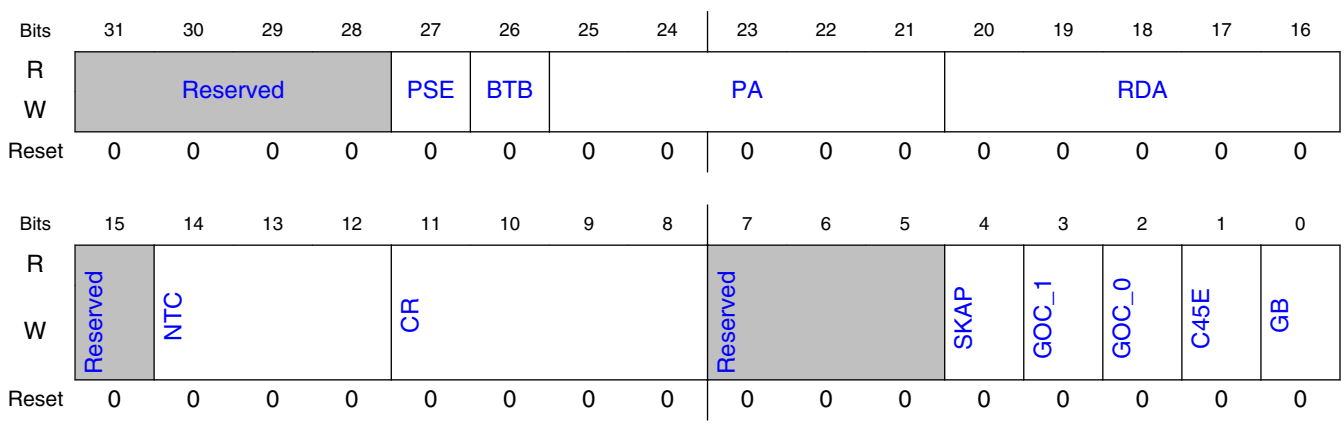
61.7.1.42.1 Offset

Register	Offset
MAC_MDIO_ADDRESS	200h

61.7.1.42.2 Function

The MDIO Address register controls the management cycles to external PHY through a management interface.

61.7.1.42.3 Diagram



61.7.1.42.4 Fields

Field	Function
31-28 —	Reserved
27 PSE	Preamble Suppression Enable When this bit is set, the SMA suppresses the 32-bit preamble and transmits MDIO frames with only 1 preamble bit. Preamble Suppression Enable When this bit is set, the SMA suppresses the 32-bit preamble and transmits MDIO frames with only 1 preamble bit. When this bit is 0, the MDIO frame always has 32 bits of preamble as defined in the IEEE specifications. 0b - Preamble Suppression disabled 1b - Preamble Suppression enabled
26 BTB	Back to Back transactions When this bit is set and the NTC has value greater than 0, then the MAC informs the completion of a read or write command at the end of frame transfer (before the trailing clocks are transmitted). Back to Back transactions When this bit is set and the NTC has value greater than 0, then the MAC informs the completion of a read or write command at the end of frame transfer (before the trailing clocks are transmitted). The software can thus initiate the next command which is executed immediately irrespective of the number trailing clocks generated for the previous frame. When this bit is reset, then the read/write command completion (GB is cleared) only after the trailing clocks are generated. In this mode, it is ensured that the NTC is always generated after each frame. This bit must not be set when NTC=0. 0b - Back to Back transactions disabled 1b - Back to Back transactions enabled
25-21 PA	Physical Layer Address This field indicates which Clause 22 PHY devices (out of 32 devices) the MAC is accessing. Physical Layer Address This field indicates which Clause 22 PHY devices (out of 32 devices) the MAC is accessing. This field indicates which Clause 45 capable PHYs (out of 32 PHYs) the MAC is accessing.
20-16 RDA	Register/Device Address These bits select the PHY register in selected Clause 22 PHY device. Register/Device Address These bits select the PHY register in selected Clause 22 PHY device. These bits select the Device (MMD) in selected Clause 45 capable PHY.
15 —	Reserved
14-12 NTC	Number of Trailing Clocks This field controls the number of trailing clock cycles generated on gmii_mdc_o (MDC) after the end of transmission of MDIO frame. Number of Trailing Clocks

Table continues on the next page...

Field	Function
	This field controls the number of trailing clock cycles generated on gmii_mdc_o (MDC) after the end of transmission of MDIO frame. The valid values can be from 0 to 7. Programming the value to 3'h3 indicates that there are additional three clock cycles on the MDC line after the end of MDIO frame transfer.
11-8 CR	CSR Clock Range The CSR Clock Range selection determines the frequency of the MDC clock according to the CSR clock frequency used in your design: - 0000: CSR clock = 60-100 MHz; MDC clock = CSR clock/42 - 0001: CSR clock = 100-150 MHz; MDC clock = CSR clock/62 - 0010: CSR clock = 20-35 MHz; MDC clock = CSR clock/16 - 0011: CSR clock = 35-60 MHz; MDC clock = CSR clock/26 - 0100: CSR clock = 150-250 MHz; MDC clock = CSR clock/102 - 0101: CSR clock = 250-300 MHz; MDC clock = CSR clock/124 - 0110: CSR clock = 300-500 MHz; MDC clock = CSR clock/204 - 0111: CSR clock = 500-800 MHz; MDC clock = CSR clock/324 The suggested range of CSR clock frequency applicable for each value (when Bit 11 = 0) ensures that the MDC clock is approximately between 1. CSR Clock Range The CSR Clock Range selection determines the frequency of the MDC clock according to the CSR clock frequency used in your design: - 0000: CSR clock = 60-100 MHz; MDC clock = CSR clock/42 - 0001: CSR clock = 100-150 MHz; MDC clock = CSR clock/62 - 0010: CSR clock = 20-35 MHz; MDC clock = CSR clock/16 - 0011: CSR clock = 35-60 MHz; MDC clock = CSR clock/26 - 0100: CSR clock = 150-250 MHz; MDC clock = CSR clock/102 - 0101: CSR clock = 250-300 MHz; MDC clock = CSR clock/124 - 0110: CSR clock = 300-500 MHz; MDC clock = CSR clock/204 - 0111: CSR clock = 500-800 MHz; MDC clock = CSR clock/324 The suggested range of CSR clock frequency applicable for each value (when Bit 11 = 0) ensures that the MDC clock is approximately between 1.0 MHz to 2.5 MHz freqency range. When Bit 11 is set, you can achieve a higher frequency of the MDC clock than the frequency limit of 2.5 MHz (specified in the IEEE 802.3) and program a clock divider of lower value. For example, when CSR clock is of 100 MHz frequency and you program these bits as 1010, the resultant MDC clock is of 12.5 MHz which is above the range specified in IEEE 802.3. Program the following values only if the interfacing chips support faster MDC clocks: - 1000: CSR clock/4 - 1001: CSR clock/6 - 1010: CSR clock/8 - 1011: CSR clock/10 - 1100: CSR clock/12 - 1101: CSR clock/14 - 1110: CSR clock/16 - 1111: CSR clock/18 These bits are not used for accessing RevMII. These bits are read-only if the RevMII interface is selected as single PHY interface.
7-5 —	Reserved
4 SKAP	Skip Address Packet When this bit is set, the SMA does not send the address packets before read, write, or post-read increment address packets. Skip Address Packet

Table continues on the next page...

Field	Function
	When this bit is set, the SMA does not send the address packets before read, write, or post-read increment address packets. This bit is valid only when C45E is set. 0b - Skip Address Packet is disabled 1b - Skip Address Packet is enabled
3 GOC_1	GMII Operation Command 1 This bit is higher bit of the operation command to the PHY or RevMII, GOC_1 and GOC_O is encoded as follows: - 00: Reserved - 01: Write - 10: Post Read Increment Address for Clause 45 PHY - 11: Read When Clause 22 PHY or RevMII is enabled, only Write and Read commands are valid. 0b - GMII Operation Command 1 is disabled 1b - GMII Operation Command 1 is enabled
2 GOC_0	GMII Operation Command 0 This is the lower bit of the operation command to the PHY or RevMII. GMII Operation Command 0 This is the lower bit of the operation command to the PHY or RevMII. When in SMA mode (MDIO master) this bit along with GOC_1 determines the operation to be performed to the PHY. When only RevMII is selected in configuration this bit is read-only and tied to 1. 0b - GMII Operation Command 0 is disabled 1b - GMII Operation Command 0 is enabled
1 C45E	Clause 45 PHY Enable When this bit is set, Clause 45 capable PHY is connected to MDIO. Clause 45 PHY Enable When this bit is set, Clause 45 capable PHY is connected to MDIO. When this bit is reset, Clause 22 capable PHY is connected to MDIO. 0b - Clause 45 PHY is disabled 1b - Clause 45 PHY is enabled
0 GB	GMII Busy The application sets this bit to instruct the SMA to initiate a Read or Write access to the MDIO slave. GMII Busy The application sets this bit to instruct the SMA to initiate a Read or Write access to the MDIO slave. The MAC clears this bit after the MDIO frame transfer is completed. Hence the software must not write or change any of the fields in MAC_MDIO_ADDRESS and MAC_MDIO_DATA registers as long as this bit is set. For write transfers, the application must first write 16-bit data in the GDI field (and also RA field when C45E is set) in MAC_MDIO_DATA register before setting this bit. When C45E is set, it should also write into the RA field of MAC_MDIO_DATA register before initiating a read transfer. When a read transfer is completed (GB=0), the data read from the PHY register is valid in the GD field of the MAC_MDIO_DATA register. Note: Even if the addressed PHY is not present, there is no change in the functionality of this bit. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0b - GMII Busy is disabled 1b - GMII Busy is enabled

61.7.1.43 MAC MDIO Data (MAC_MDIO_DATA)

61.7.1.43.1 Offset

Register	Offset
MAC_MDIO_DATA	204h

61.7.1.43.2 Function

The MAC_MDIO_DATA register stores the Write data to be written to the PHY register located at the address specified in MAC_MDIO_ADDRESS. This register also stores the Read data from the PHY register located at the address specified by MAC_MDIO_ADDRESS register.

61.7.1.43.3 Diagram

61.7.1.43.4 Fields

Field	Function
31-16 RA	Register Address This field is valid only when C45E is set. Register Address This field is valid only when C45E is set. It contains the Register Address in the PHY to which the MDIO frame is intended for.
15-0 GD	GMII Data This field contains the 16-bit data value read from the PHY or RevMII after a Management Read operation or the 16-bit data value to be written to the PHY or RevMII before a Management Write operation.

61.7.1.44 CSR Software Control (MAC_CSR_SW_CTRL)

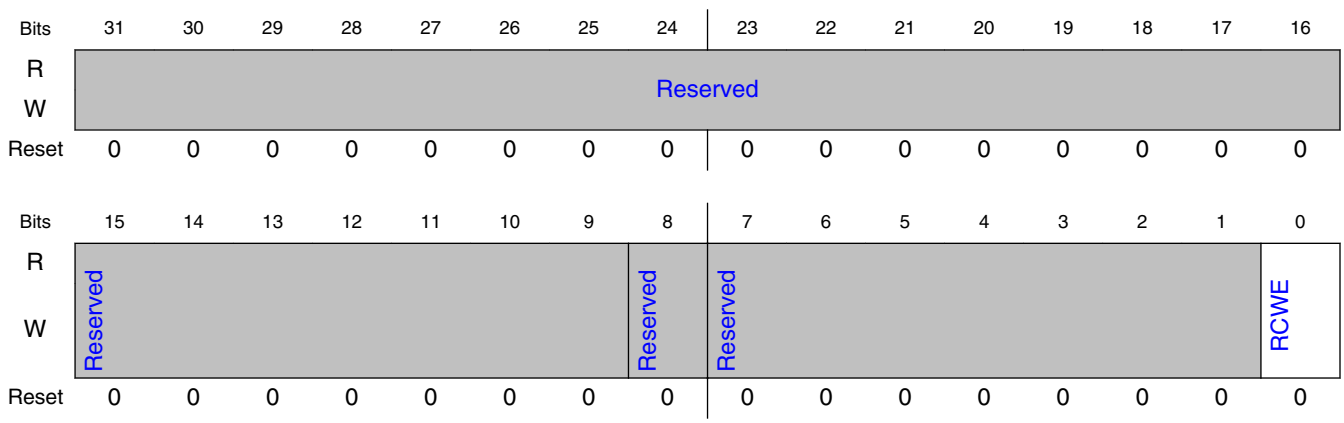
61.7.1.44.1 Offset

Register	Offset
MAC_CSR_SW_CTRL	230h

61.7.1.44.2 Function

This register contains SW programmable controls for changing the CSR access response and status bits clearing.

61.7.1.44.3 Diagram



61.7.1.44.4 Fields

Field	Function
31-9 —	Reserved
8 —	Reserved
7-1 —	Reserved
0 RCWE	Register Clear on Write 1 Enable When this bit is set, the access mode of some register fields changes to Clear on Write 1, the application needs to set that respective bit to 1 to clear it. Register Clear on Write 1 Enable When this bit is set, the access mode of some register fields changes to Clear on Write 1, the application needs to set that respective bit to 1 to clear it.

Field	Function
	When this bit is reset, the access mode of these register fields remain as Clear on Read. 0b - Register Clear on Write 1 is disabled 1b - Register Clear on Write 1 is enabled

61.7.1.45 Frame Preemption Control (MAC_FPE_CTRL_STS)

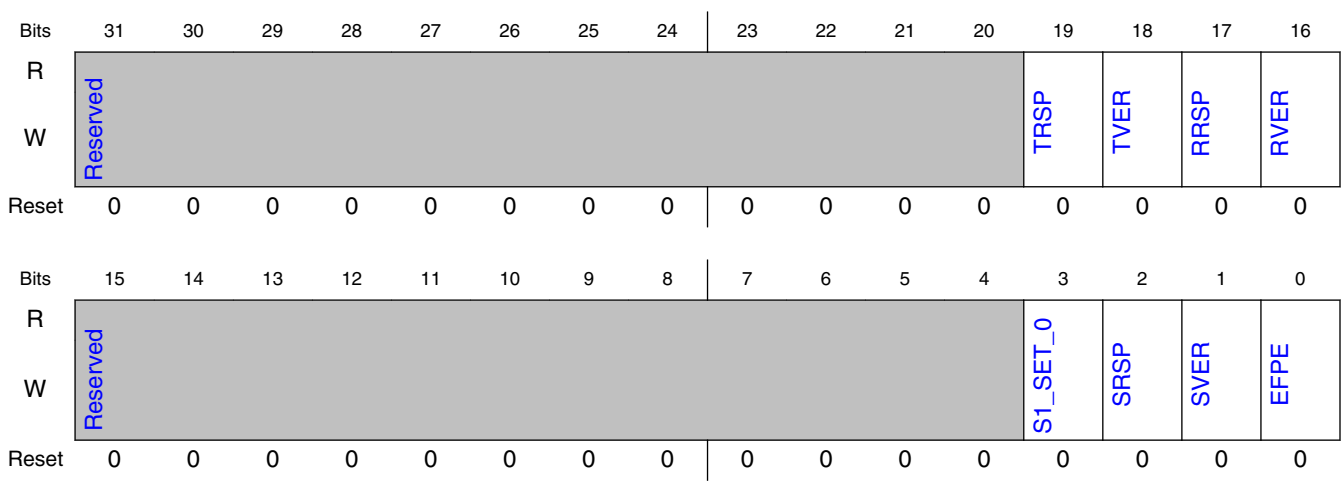
61.7.1.45.1 Offset

Register	Offset
MAC_FPE_CTRL_STS	234h

61.7.1.45.2 Function

This register controls the operation of Frame Preemption.

61.7.1.45.3 Diagram



61.7.1.45.4 Fields

Field	Function
31-20 —	Reserved
19	Transmitted Respond Frame Set when a Respond mPacket is transmitted (triggered by setting SRSP field).

Table continues on the next page...

Field	Function
TRSP	Transmitted Respond Frame Set when a Respond mPacket is transmitted (triggered by setting SRSP field). An interrupt can be generated for this event if FPEIE bit of MAC_INTERRUPT_ENABLE is set. Access restriction applies. Clears on read (or write of 1 when RCWE bit in CSR_SW_CTRL register is set). Self-set to 1 on internal event. 0b - Not transmitted Respond Frame 1b - transmitted Respond Frame
18 TVER	Transmitted Verify Frame Set when a Verify mPacket is transmitted (triggered by setting SVER field). Transmitted Verify Frame Set when a Verify mPacket is transmitted (triggered by setting SVER field). An interrupt can be generated for this event if FPEIE bit of MAC_INTERRUPT_ENABLE is set. Access restriction applies. Clears on read (or write of 1 when RCWE bit in CSR_SW_CTRL register is set). Self-set to 1 on internal event. 0b - Not transmitted Verify Frame 1b - transmitted Verify Frame
17 RRSP	Received Respond Frame Set when a Respond mPacket is received. Received Respond Frame Set when a Respond mPacket is received. An interrupt can be generated for this event if FPEIE bit of MAC_INTERRUPT_ENABLE is set. Access restriction applies. Clears on read (or write of 1 when RCWE bit in CSR_SW_CTRL register is set). Self-set to 1 on internal event. 0b - Not received Respond Frame 1b - Received Respond Frame
16 RVER	Received Verify Frame Set when a Verify mPacket is received. Received Verify Frame Set when a Verify mPacket is received. An interrupt can be generated for this event if FPEIE bit of MAC_INTERRUPT_ENABLE is set. Access restriction applies. Clears on read (or write of 1 when RCWE bit in CSR_SW_CTRL register is set). Self-set to 1 on internal event. 0b - Not received Verify Frame 1b - Received Verify Frame
15-4 —	Reserved
3 S1_SET_0	Reserved, Must be set to "0". Reserved, Must be set to "0". This field is reserved for Synopsys internal use, and must always be set to "0" unless instructed by Synopsys. Setting to "1" might cause unexpected behavior in the IP.
2 SRSP	Send Respond mPacket When set indicates hardware to send a Respond mPacket. Send Respond mPacket When set indicates hardware to send a Respond mPacket. Reset by hardware after sending the Respond mPacket. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.

Table continues on the next page...

Field	Function
	0b - Send Respond mPacket is disabled 1b - Send Respond mPacket is enabled
1 SVER	Send Verify mPacket When set indicates hardware to send a verify mPacket. Send Verify mPacket When set indicates hardware to send a verify mPacket. Reset by hardware after sending the Verify mPacket. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0b - Send Verify mPacket is disabled 1b - Send Verify mPacket is enabled
0 EFPE	Enable Tx Frame Preemption When set Frame Preemption Tx functionality is enabled. 0b - Tx Frame Preemption is disabled 1b - Tx Frame Preemption is enabled

61.7.1.46 32-bit Binary Rollover Equivalent Time (MAC_PRESN_TIME_NS)

61.7.1.46.1 Offset

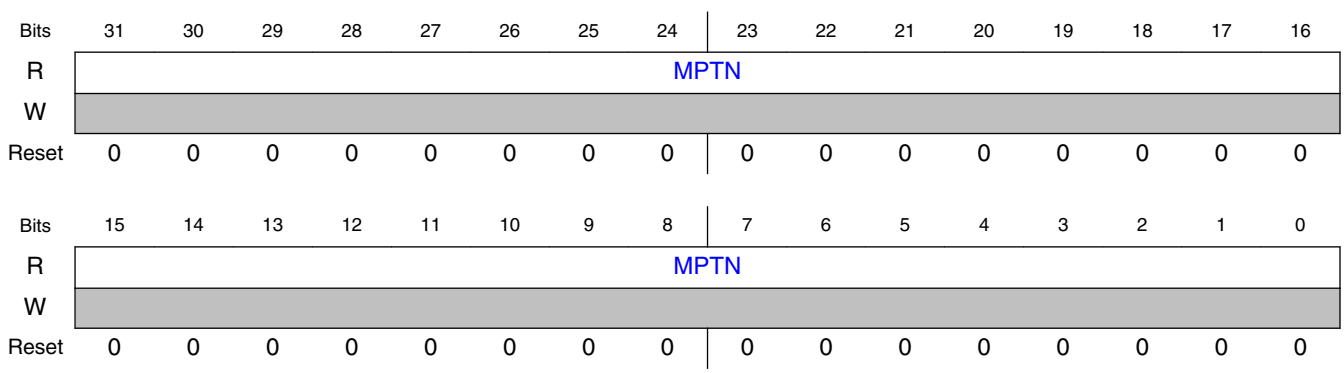
Register	Offset
MAC_PRESN_TIME_NS	240h

61.7.1.46.2 Function

This register contains the 32-bit binary rollover equivalent time of the PTP System Time in ns

Exists when DWC_EQOS_FLEXI_PPS_OUT_EN is configured

61.7.1.46.3 Diagram



61.7.1.46.4 Fields

Field	Function
31-0 MPTN	MAC 1722 Presentation Time in ns These bits indicate the value of the 32-bit binary rollover equivalent time of the PTP System Time in ns

61.7.1.47 MAC 1722 Presentation Time (MAC_PRESN_TIME_UPDT)

61.7.1.47.1 Offset

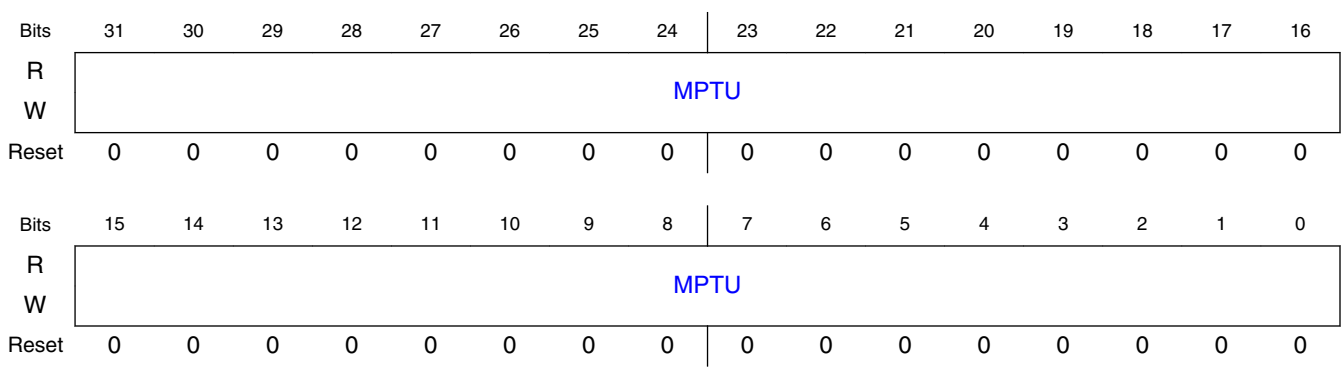
Register	Offset
MAC_PRESN_TIME_UPDT	244h

61.7.1.47.2 Function

This field holds the 32-bit value of MAC 1722 Presentation Time in ns, that should be added to the Current Presentation Time Counter value. Init happens when TSINIT is set, and update happens when the TSUPDT bit is set (TSINIT and TSINIT defined in TIMESTAMP_CONTROL register).

Exists when DWC_EQOS_FLEXI_PPS_OUT_EN is configured

61.7.1.47.3 Diagram



61.7.1.47.4 Fields

Field	Function
31-0 MPTU	MAC 1722 Presentation Time Update This field holds the init value or the update value for the presentation time. MAC 1722 Presentation Time Update This field holds the init value or the update value for the presentation time. When used for update, this field holds the 32-bit value in ns, that should be added to the Current Presentation Time Counter value. Init happens when TSINIT is set, and update happens when the TSUPDT bit is set (TSINIT and TSINIT defined in MAC_TIMESTAMP_CONTROL register). When ADDSUB field of MAC_SYSTEM_TIME_NANOSECONDS_UPDATE is set, this value is directly used for subtraction

61.7.1.48 MAC Address0 High (MAC_ADDRESS0_HIGH)

61.7.1.48.1 Offset

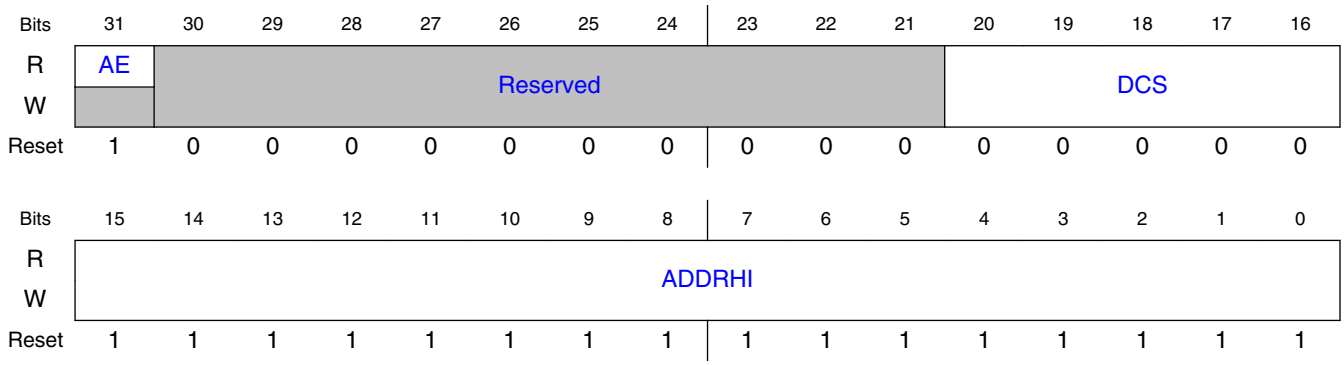
Register	Offset
MAC_ADDRESS0_HIGH	300h

61.7.1.48.2 Function

The MAC Address0 High register holds the upper 16 bits of the first 6-byte MAC address of the station. The first DA byte that is received on the (G)MII interface corresponds to the LS byte (Bits [7:0]) of the MAC Address Low register. For example, if 0x112233445566 is received (0x11 in lane 0 of the first column) on the (G)MII as the destination address, then the MacAddress0 Register [47:0] is compared with 0x665544332211.

If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address0 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain.

61.7.1.48.3 Diagram



61.7.1.48.4 Fields

Field	Function
31 AE	Address Enable This bit is always set to 1. 0b - INVALID : This bit must be always set to 1 1b - This bit is always set to 1
30-21 —	Reserved
20-16 DCS	DMA Channel Select If the PDC bit of MAC_EXT_CONFIGURATION register is not set: This field contains the binary representation of the DMA Channel number to which an Rx packet whose DA matches the MAC Address0 content is routed. DMA Channel Select If the PDC bit of MAC_EXT_CONFIGURATION register is not set: This field contains the binary representation of the DMA Channel number to which an Rx packet whose DA matches the MAC Address0 content is routed. If the PDC bit of MAC_EXT_CONFIGURATION register is set: This field contains the one-hot representation of one or more DMA Channel numbers to which an Rx packet whose DA matches the MAC Address0 content is routed.
15-0 ADDRHI	MAC Address0[47:32] This field contains the upper 16 bits [47:32] of the first 6-byte MAC address. MAC Address0[47:32] This field contains the upper 16 bits [47:32] of the first 6-byte MAC address. The MAC uses this field for filtering the received packets and inserting the MAC address in the Transmit Flow Control (Pause) Packets.

61.7.1.49 MAC Address0 Low (MAC_ADDRESS0_LOW)

61.7.1.49.1 Offset

Register	Offset
MAC_ADDRESS0_LOW	304h

61.7.1.49.2 Function

The MAC Address0 Low register holds the lower 32 bits of the 6-byte first MAC address of the station.

61.7.1.49.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

61.7.1.95.4 Fields

Field	Function
31-0 ADDRLO	MAC ADDRESS23 [31:0] This field contains the lower 32 bits of 24th 6-byte MAC address. MAC ADDRESS23 [31:0] This field contains the lower 32 bits of 24th 6-byte MAC address. The content of this field is undefined until loaded by the application after the initialization process.

61.7.1.96 MAC Address24 High (MAC_ADDRESS24_HIGH)

61.7.1.96.1 Offset

Register	Offset
MAC_ADDRESS24_HIGH	3C0h

61.7.1.96.2 Function

The MAC ADDRESS24 High register holds the upper 16 bits of the 25th 6-byte MAC address of the station.

The MAC ADDRESS24 High register holds the upper 16 bits of the 25th 6-byte MAC address of the station.

If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC ADDRESS24 Low Register are

written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain.

DMA Channel Select If the PDC bit of MAC_EXT_CONFIGURATION register is not set: This field contains the binary representation of the DMA Channel number to which an Rx packet whose DA matches the MAC Address(#i) content is routed. If the PDC bit of MAC_EXT_CONFIGURATION register is set: This field contains the one-hot representation of one or more DMA Channel numbers to which an Rx packet whose DA matches the MAC Address(#i) content is routed.
15-0 ADDRHI	MAC ADDRESS29 [47:32] This field contains the upper 16 bits[47:32] of the 30th 6-byte MAC address.

61.7.1.107 MAC Address29 Low (MAC_ADDRESS29_LOW)

61.7.1.107.1 Offset

Register	Offset
MAC_ADDRESS29_LOW	3ECh

61.7.1.107.2 Function

The MAC ADDRESS29 Low register holds the lower 32 bits of the 30th 6-byte MAC address of the station.

61.7.1.107.3 Diagram

61.7.1.107.4 Fields

Field	Function
31-0 ADDRLO	MAC ADDRESS29 [31:0] This field contains the lower 32 bits of 30th 6-byte MAC address. MAC ADDRESS29 [31:0] This field contains the lower 32 bits of 30th 6-byte MAC address. The content of this field is undefined until loaded by the application after the initialization process.

61.7.1.108 MAC Address30 High (MAC_ADDRESS30_HIGH)

61.7.1.108.1 Offset

Register	Offset
MAC_ADDRESS30_HIGH	3F0h

61.7.1.108.2 Function

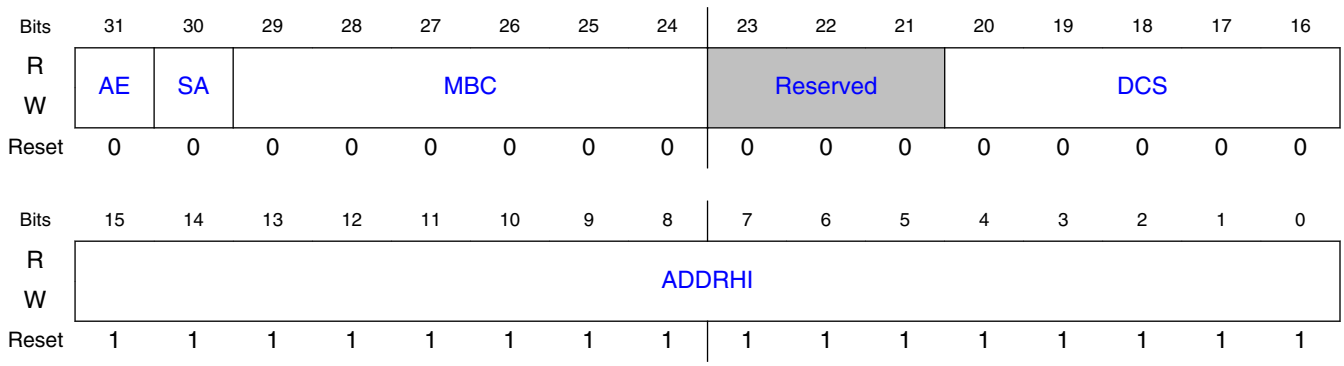
The MAC ADDRESS30 High register holds the upper 16 bits of the 31st 6-byte MAC address of the station.

The MAC ADDRESS30 High register holds the upper 16 bits of the 31st 6-byte MAC address of the station.

If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC ADDRESS30 Low Register are

written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain.

61.7.1.108.3 Diagram



61.7.1.108.4 Fields

Field	Function
31 AE	Address Enable When this bit is set, the address filter module uses the 31st MAC address for perfect filtering. Address Enable When this bit is set, the address filter module uses the 31st MAC address for perfect filtering. When this bit is reset, the address filter module ignores the address for filtering. 0b - Address is ignored 1b - Address is enabled
30 SA	Source Address When this bit is set, the MAC ADDRESS30[47:0] is used to compare with the SA fields of the received packet. Source Address When this bit is set, the MAC ADDRESS30[47:0] is used to compare with the SA fields of the received packet. When this bit is reset, the MAC ADDRESS30[47:0] is used to compare with the DA fields of the received packet. 0b - Compare with Destination Address 1b - Compare with Source Address
29-24 MBC	Mask Byte Control These bits are mask control bits for comparing each of the MAC Address bytes. Mask Byte Control These bits are mask control bits for comparing each of the MAC Address bytes. When set high, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC ADDRESS30 registers. Each bit controls the masking of the bytes as follows: - Bit 29: ADDRESS30_High[15:8] - Bit 28: ADDRESS30_High[7:0] - Bit 27: ADDRESS30_Low[31:24]

Table continues on the next page...

Field	Function
	- .. - Bit 24: ADDRESS30_Low[7:0] You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address.
23-21 —	Reserved
20-16 DCS	DMA Channel Select If the PDC bit of MAC_EXT_CONFIGURATION register is not set: This field contains the binary representation of the DMA Channel number to which an Rx packet whose DA matches the MAC Address(#i) content is routed. DMA Channel Select If the PDC bit of MAC_EXT_CONFIGURATION register is not set: This field contains the binary representation of the DMA Channel number to which an Rx packet whose DA matches the MAC Address(#i) content is routed. If the PDC bit of MAC_EXT_CONFIGURATION register is set: This field contains the one-hot representation of one or more DMA Channel numbers to which an Rx packet whose DA matches the MAC Address(#i) content is routed.
15-0 ADDRHI	MAC ADDRESS30 [47:32] This field contains the upper 16 bits[47:32] of the 31st 6-byte MAC address.

61.7.1.109 MAC Address30 Low (MAC_ADDRESS30_LOW)

61.7.1.109.1 Offset

Register	Offset
MAC_ADDRESS30_LOW	3F4h

61.7.1.109.2 Function

The MAC ADDRESS30 Low register holds the lower 32 bits of the 31st 6-byte MAC address of the station.

61.7.1.109.3 Diagram

61.7.1.123.4 Fields

Field	Function
31-0 ADDRLO	MAC ADDRESS37 [31:0] This field contains the lower 32 bits of the 38th 6-byte MAC address. MAC ADDRESS37 [31:0] This field contains the lower 32 bits of the 38th 6-byte MAC address. The content of this field is undefined until loaded by the Application after the initialization process.

61.7.1.124 MAC Address38 High (MAC_ADDRESS38_HIGH)

61.7.1.124.1 Offset

Register	Offset
MAC_ADDRESS38_HIGH	430h

61.7.1.124.2 Function

The MAC ADDRESS38 High register holds the upper 16 bits of the 39th 6-byte MAC address of the station.

The MAC ADDRESS38 High register holds the upper 16 bits of the 39th 6-byte MAC address of the station.

If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address Low Register are written. For proper synchronization updates, you should perform the consecutive writes to the MAC Address Low Register after at least four clock cycles of the destination clock.

The MAC ADDRESS46 High register holds the upper 16 bits of the 47th 6-byte MAC address of the station.

The MAC ADDRESS46 High register holds the upper 16 bits of the 47th 6-byte MAC address of the station.

If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address Low Register are written. For proper synchronization updates, you should perform the consecutive writes to the MAC Address Low Register after at least four clock cycles of the destination clock.

The MAC ADDRESS63 High register holds the upper 16 bits of the 64th 6-byte MAC address of the station.

The MAC ADDRESS63 High register holds the upper 16 bits of the 64th 6-byte MAC address of the station.

If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address Low Register are written. For proper synchronization updates, you should perform the consecutive writes to the MAC Address Low Register after at least four clock cycles of the destination clock.

61.7.1.176.4 Fields

Field	Function
31-9 —	Reserved
8 UCDBC	Update MMC Counters for Dropped Broadcast Packets Note: The CNTRST bit has a higher priority than the CNTPRST bit. Update MMC Counters for Dropped Broadcast Packets Note: The CNTRST bit has a higher priority than the CNTPRST bit. Therefore, when the software tries to set both bits in the same write cycle, all counters are cleared and the CNTPRST bit is not set. When set, the MAC updates all related MMC Counters for Broadcast packets that are dropped because of the setting of the DBF bit of MAC_Packet_Filter register. When reset, the MMC Counters are not updated for dropped Broadcast packets. 0b - Update MMC Counters for Dropped Broadcast Packets is disabled 1b - Update MMC Counters for Dropped Broadcast Packets is enabled
7-6 —	Reserved
5 CNTPRSTLVL	Full-Half Preset When this bit is low and the CNTPRST bit is set, all MMC counters get preset to almost-half value. Full-Half Preset When this bit is low and the CNTPRST bit is set, all MMC counters get preset to almost-half value. All octet counters get preset to 0x7FFF_F800 (Half 2KBytes) and all packet-counters gets preset to 0x7FFF_FFF0 (Half 16). When this bit is high and the CNTPRST bit is set, all MMC counters get preset to almost-full value. All octet counters get preset to 0xFFFF_F800 (Full 2KBytes) and all packet-counters gets preset to 0xFFFF_FFF0 (Full 16). For 16-bit counters, the almost-half preset values are 0x7800 and 0x7FF0 for the respective octet and packet counters. Similarly, the almost-full preset values for the 16-bit counters are 0xF800 and 0xFFF0. 0b - Full-Half Preset is disabled

Table continues on the next page...

Field	Function
	1b - Full-Half Preset is enabled
4 CNTPRST	Counters Preset When this bit is set, all counters are initialized or preset to almost full or almost half according to the CNTPRSTLVL bit. Counters Preset When this bit is set, all counters are initialized or preset to almost full or almost half according to the CNTPRSTLVL bit. This bit is cleared automatically after 1 clock cycle. This bit, along with the CNTPRSTLVL bit, is useful for debugging and testing the assertion of interrupts because of MMC counter becoming half-full or full. Access restriction applies. Self-cleared. Setting 0 clears. Setting 1 sets. 0b - Counters Preset is disabled 1b - Counters Preset is enabled
3 CNTFREEZ	MMC Counter Freeze When this bit is set, it freezes all MMC counters to their current value. MMC Counter Freeze When this bit is set, it freezes all MMC counters to their current value. Until this bit is reset to 0, no MMC counter is updated because of any transmitted or received packet. If any MMC counter is read with the Reset on Read bit set, then that counter is also cleared in this mode. 0b - MMC Counter Freeze is disabled 1b - MMC Counter Freeze is enabled
2 RSTONRD	Reset on Read When this bit is set, the MMC counters are reset to zero after Read (self-clearing after reset). Reset on Read When this bit is set, the MMC counters are reset to zero after Read (self-clearing after reset). The counters are cleared when the least significant byte lane (Bits[7:0]) is read. 0b - Reset on Read is disabled 1b - Reset on Read is enabled
1 CNTSTOPRO	Counter Stop Rollover When this bit is set, the counter does not roll over to zero after reaching the maximum value. 0b - Counter Stop Rollover is disabled 1b - Counter Stop Rollover is enabled
0 CNTRST	Counters Reset When this bit is set, all counters are reset. Counters Reset When this bit is set, all counters are reset. This bit is cleared automatically after 1 clock cycle. Access restriction applies. Self-cleared. Setting 0 clears. Setting 1 sets. 0b - Counters are not reset 1b - All counters are reset

61.7.1.177 MMC Rx Interrupt (MAC_MMC_RX_INTERRUPT)

61.7.1.177.1 Offset

Register	Offset
MAC_MMC_RX_INTERRUPT	704h

61.7.1.177.2 Function

This register maintains the interrupts generated from all Receive statistics counters.

This register maintains the interrupts generated from all Receive statistics counters.

The MMC Receive Interrupt register maintains the interrupts that are generated when the following occur:

- Receive statistic counters reach half of their maximum values (0x8000_0000 for 32 bit counter and 0x8000 for 16 bit counter).

- Receive statistic counters cross their maximum values (0xFFFF_FFFF for 32 bit counter and 0xFFFF for 16 bit counter).

When the Counter Stop Rollover is set, interrupts are set but the counter remains at all-ones. The MMC Receive Interrupt register

is a 32 bit register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (Bits[7:0]) of the respective counter must be read to clear the interrupt bit.

Note: R_SS_RC means that this register bit is set internally, and it is cleared when the Counter register is read.

61.7.1.178 MMC Tx Interrupt (MAC_MMC_TX_INTERRUPT)

61.7.1.178.1 Offset

Register	Offset
MAC_MMC_TX_INTERRUPT	708h

61.7.1.178.2 Function

This register maintains the interrupts generated from all Transmit statistics counters.

This register maintains the interrupts generated from all Transmit statistics counters.

The MMC Transmit Interrupt register maintains the interrupts generated when transmit statistic counters reach half their maximum values

(0x8000_0000 for 32 bit counter and 0x8000 for 16 bit counter), and when they cross their maximum values (0xFFFF_FFFF for 32-bit counter and 0xFFFF for 16-bit counter).

When Counter Stop Rollover is set, the interrupts are set but the counter remains at all-ones.

The MMC Transmit Interrupt register is a 32 bit register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read.

The least significant byte lane (Bits[7:0]) of the respective counter must be read to clear the interrupt bit.

61.7.1.224.4 Fields

Field	Function
31-0 RXUCASTG	Rx Unicast Packets Good This field indicates the number of good unicast packets received.

61.7.1.225 Length Error Packets Received (MAC_RX_LENGTH_ERROR_PACKETS)

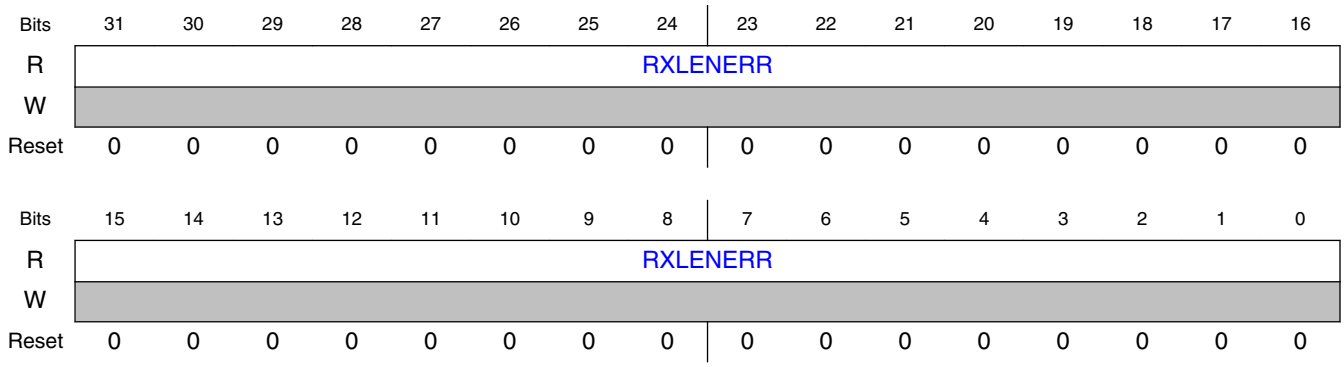
61.7.1.225.1 Offset

Register	Offset
MAC_RX_LENGTH_ERROR_PACKETS	7C8h

61.7.1.225.2 Function

This register provides the number of packets received by DWC_ether_qos with length error (Length Type field not equal to packet size), for all packets with valid length field.

61.7.1.225.3 Diagram



61.7.1.225.4 Fields

Field	Function
31-0 RXLENERR	Rx Length Error Packets This field indicates the number of packets received with length error (Length Type field not equal to packet size), for all packets with valid length field.

61.7.1.226 Out-of-range Type Packets Received (MAC_RX_OUT_OF_RANGE_TYPE_PACKETS)

61.7.1.226.1 Offset

Register	Offset
MAC_RX_OUT_OF_RANGE_TYPE_PACKETS	7CCh

61.7.1.226.2 Function

This register provides the number of packets received by DWC_ether_qos with length field not equal to the valid packet size (greater than 1,500 but less than 1,536).

61.7.1.226.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

61.7.1.237 MMC IPC Receive Interrupt Mask (MAC_MMC_IPC_RX_INTERRUPT_MASK)

61.7.1.237.1 Offset

Register	Offset
MAC_MMC_IPC_RX_INTERRUPT_MASK	800h

61.7.1.237.2 Function

This register maintains the mask for the interrupt generated from the receive IPC statistic counters.

The MMC Receive Checksum Off load Interrupt Mask register maintains the masks for the interrupts generated when the receive IPC (Checksum Off load) statistic counters reach half their maximum value, and when they reach their maximum values. This register is 32 bits wide.

61.7.1.238 MMC IPC Receive Interrupt (MAC_MMC_IPC_RX_INTERRUPT)

61.7.1.238.1 Offset

Register	Offset
MAC_MMC_IPC_RX_INTERRUPT	808h

61.7.1.238.2 Function

This register maintains the interrupt that the receive IPC statistic counters generate.

The MMC Receive Checksum Offload Interrupt register maintains the interrupts generated when receive IPC statistic counters reach half their maximum values (0x8000_0000 for 32 bit counter and 0x8000 for 16 bit counter), and when they cross their maximum values (0xFFFF_FFFF for 32 bit counter and 0xFFFF for 16 bit counter). When Counter Stop Rollover is set, the interrupts are set but the counter remains at all-ones.

The MMC Receive Checksum Offload Interrupt register is 32 bit wide. When the MMC IPC counter that caused the interrupt is read, its corresponding interrupt bit is cleared. The counter's least-significant byte lane (Bits[7:0]) must be read to clear the interrupt bit.

61.7.1.245.4 Fields

Field	Function
31-0 RXIPV6HDRERRPKT	RxIPv6 Header Error Packets This field indicates the number of IPv6 datagrams received with header (length or version mismatch) errors.

61.7.1.246 IPv6 Datagrams Received with No Payload (MAC_RXIPV6_NO_PAYLOAD_PACKETS)

61.7.1.246.1 Offset

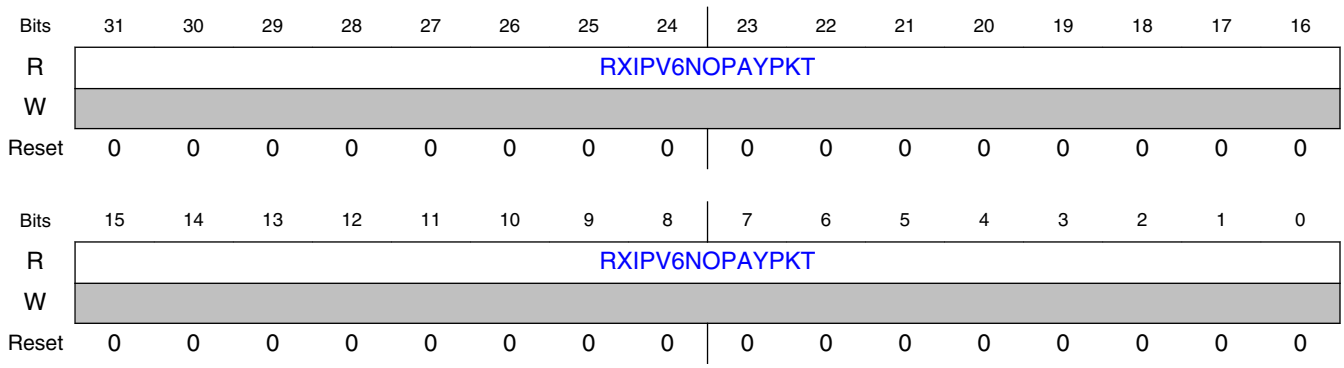
Register	Offset
MAC_RXIPV6_NO_PAYLOAD_PACKETS	82Ch

61.7.1.246.2 Function

This register provides the number of IPv6 datagram packets received by DWC_ether_qos that did not have a TCP, UDP, or ICMP payload.

This register provides the number of IPv6 datagram packets received by DWC_ether_qos that did not have a TCP, UDP, or ICMP payload. This includes all IPv6 datagrams with fragmentation or security extension headers.

61.7.1.246.3 Diagram



61.7.1.246.4 Fields

Field	Function
31-0 RXIPV6NOPAYPKT	RxIPv6 Payload Packets This field indicates the number of IPv6 datagram packets received that did not have a TCP, UDP, or ICMP payload. RxIPv6 Payload Packets This field indicates the number of IPv6 datagram packets received that did not have a TCP, UDP, or ICMP payload. This includes all IPv6 datagrams with fragmentation or security extension headers.

61.7.1.247 IPv6 Datagrams Received with Good UDP (MAC_RXUDP_GOOD_PACKETS)

61.7.1.247.1 Offset

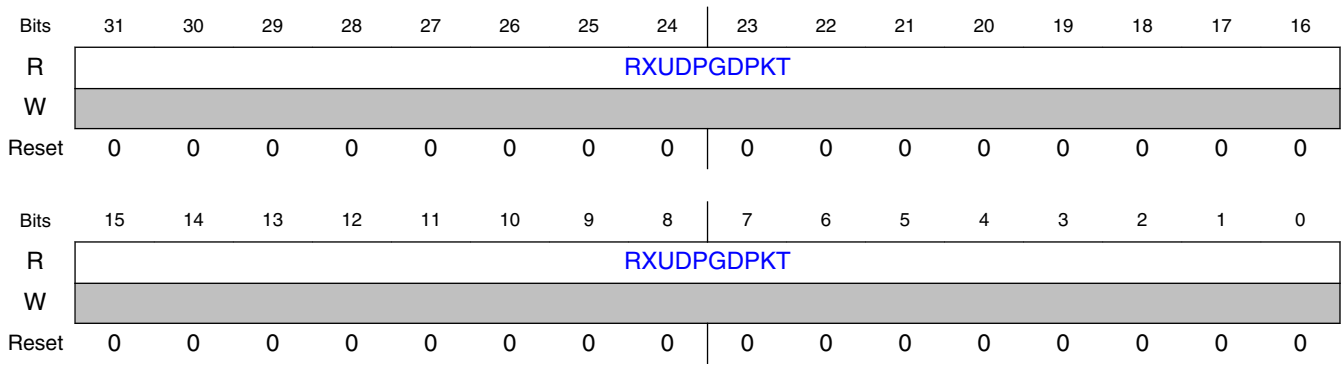
Register	Offset
MAC_RXUDP_GOOD_PACKETS	830h

61.7.1.247.2 Function

This register provides the number of good IP datagrams received by DWC_ether_qos with a good UDP payload.

This register provides the number of good IP datagrams received by DWC_ether_qos with a good UDP payload. This counter is not updated when the RxIPv4_UDP_Checksum_Disabled_Packets counter is incremented.

61.7.1.247.3 Diagram



61.7.1.247.4 Fields

Field	Function
31-0 RXUDPGDPKT	RxUDP Good Packets This field indicates the number of good IP datagrams received with a good UDP payload. RxUDP Good Packets This field indicates the number of good IP datagrams received with a good UDP payload. This counter is not updated when the RxIPv4_UDP_Checksum_Disabled_Packets counter is incremented.

61.7.1.248 IPv6 Datagrams Received with UDP Checksum Error (MAC_RXUDP_ERROR_PACKETS)

61.7.1.248.1 Offset

Register	Offset
MAC_RXUDP_ERROR_PACKETS	834h

61.7.1.248.2 Function

This register provides the number of good IP datagrams received by DWC_ether_qos whose UDP payload has a checksum error.

61.7.1.248.3 Diagram

61.7.1.251.4 Fields

Field	Function
31-0 RXICMPGDPKT	RxICMP Good Packets This field indicates the number of good IP datagrams received with a good ICMP payload.

61.7.1.252 IPv6 Datagrams Received with ICMP Checksum Error (MAC_RXICMP_ERROR_PACKETS)

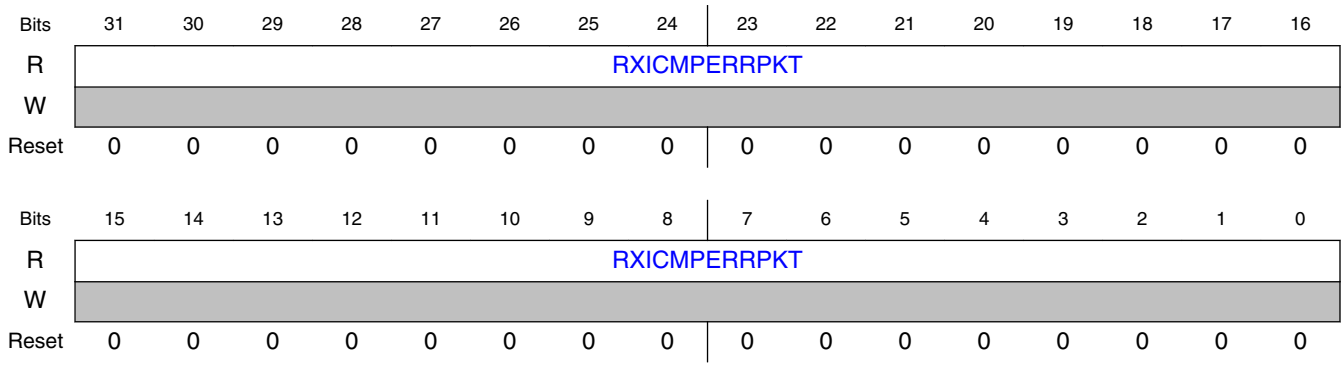
61.7.1.252.1 Offset

Register	Offset
MAC_RXICMP_ERROR_PACKETS	844h

61.7.1.252.2 Function

This register provides the number of good IP datagrams received by DWC_ether_qos whose ICMP payload has a checksum error.

61.7.1.252.3 Diagram



61.7.1.252.4 Fields

Field	Function
31-0 RXICMPERRPKT	RxICMP Error Packets This field indicates the number of good IP datagrams received whose ICMP payload has a checksum error.

61.7.1.253 Good Bytes Received in IPv4 Datagrams (MAC_RXIPV4_GOOD_OCTETS)

61.7.1.253.1 Offset

Register	Offset
MAC_RXIPV4_GOOD_OCTETS	850h

61.7.1.253.2 Function

This register provides the number of bytes received by DWC_ether_qos in good IPv4 datagrams encapsulating TCP, UDP, or ICMP data. (Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

61.7.1.253.3 Diagram

Field	Function
31-0 RXIPV4FRAGOCT	RxIPv4 Fragmented Octets This field indicates the number of bytes received in fragmented IPv4 datagrams. RxIPv4 Fragmented Octets This field indicates the number of bytes received in fragmented IPv4 datagrams. The value in the Length field of IPv4 header is used to update this counter. (Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

61.7.1.257 Bytes Received with UDP Checksum Disabled (MAC_RXIPV4_UDP_CHECKSUM_DISABLE_OCTETS)

61.7.1.257.1 Offset

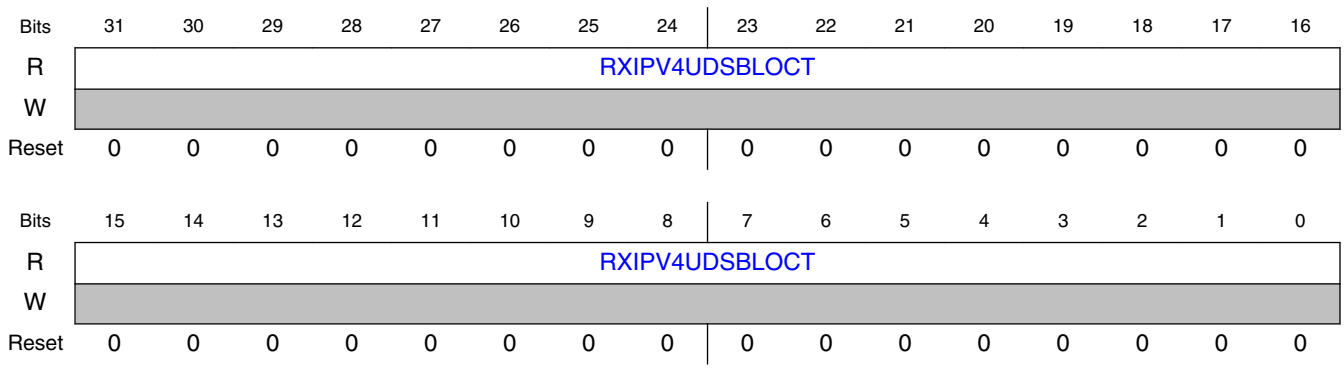
Register	Offset
MAC_RXIPV4_UDP_CHECKSUM_DISABLE_OCTETS	860h

61.7.1.257.2 Function

This register provides the number of bytes received by DWC_ether_qos in a UDP segment that had the UDP checksum disabled.

This register provides the number of bytes received by DWC_ether_qos in a UDP segment that had the UDP checksum disabled. This counter does not count IP Header bytes. (Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

61.7.1.257.3 Diagram



61.7.1.257.4 Fields

Field	Function
31-0 RXIPV4UDSBLOCT	RxIPv4 UDP Checksum Disable Octets This field indicates the number of bytes received in a UDP segment that had the UDP checksum disabled. RxIPv4 UDP Checksum Disable Octets This field indicates the number of bytes received in a UDP segment that had the UDP checksum disabled. This counter does not count IP Header bytes. (Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

61.7.1.258 Bytes Received in Good IPv6 Datagrams (MAC_RXIPV6_GOOD_OCTETS)

61.7.1.258.1 Offset

Register	Offset
MAC_RXIPV6_GOOD_OCTETS	864h

61.7.1.258.2 Function

This register provides the number of bytes received by DWC_ether_qos in good IPv6 datagrams encapsulating TCP, UDP, or ICMP data.

This register provides the number of bytes received by DWC_ether_qos in good IPv6 datagrams encapsulating TCP, UDP, or ICMP data. (Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

31-0 RXICMPERROCT	RxICMP Error Octets This field indicates the number of bytes received in a ICMP segment that had checksum errors. RxICMP Error Octets This field indicates the number of bytes received in a ICMP segment that had checksum errors. This counter does not count IP header bytes.

61.7.1.267 MMC FPE Transmit Interrupt (MAC_MMC_FPE_TX_INTERRUPT)

61.7.1.267.1 Offset

Register	Offset
MAC_MMC_FPE_TX_INTERRUPT	8A0h

61.7.1.267.2 Function

This register maintains the interrupts generated from all FPE related Transmit statistics counters.

This register maintains the interrupts generated from all FPE related Transmit statistics counters. The MMC FPE Transmit Interrupt register maintains the interrupts generated when transmit statistic counters reach half their maximum values (0x8000_0000 for 32 bit counter and 0x8000 for 16 bit counter), and when they cross their maximum values (0xFFFF_FFFF for 32-bit counter and 0xFFFF for 16-bit counter). When Counter Stop Rollover is set, the interrupts are set but the counter remains at all-ones. The MMC FPE Transmit Interrupt register is a 32 bit register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (Bits[7:0]) of the respective counter must be read to clear the interrupt bit.

61.7.1.267.3 Diagram

MMC Rx Packet SMD Error Counter Interrupt Status This bit is set when the Rx_Packet_SMD_Err_Cntr counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event. Exists when any one of the RX/TX MMC counters are enabled during FPE Enabled configuration. 0b - MMC Rx Packet SMD Error Counter Interrupt Status not detected 1b - MMC Rx Packet SMD Error Counter Interrupt Status detected
0 PAECIS	MMC Rx Packet Assembly Error Counter Interrupt Status This bit is set when the Rx_Packet_Assemble_Err_Cntr counter reaches half of the maximum value or the maximum value. MMC Rx Packet Assembly Error Counter Interrupt Status This bit is set when the Rx_Packet_Assemble_Err_Cntr counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event. Exists when any one of the RX/TX MMC counters are enabled during FPE Enabled configuration. 0b - MMC Rx Packet Assembly Error Counter Interrupt Status not detected 1b - MMC Rx Packet Assembly Error Counter Interrupt Status detected

61.7.1.272 MMC FPE Receive Interrupt Mask (MAC_MMC_FPE_RX_INTERRUPT_MASK)

61.7.1.272.1 Offset

Register	Offset
MAC_MMC_FPE_RX_INTERRUPT_MASK	8C4h

61.7.1.272.2 Function

This register maintains the masks for interrupts generated from all FPE related Receive statistics counters.

This register maintains the masks for interrupts generated from all FPE related Receive statistics counters. The MMC Receive Interrupt Mask register maintains the masks for the interrupts generated when FPE related receive statistic counters reach half of their maximum value or the maximum values. This register is 32 bit wide.

0 L3PEN0	Layer 3 Protocol Enable When this bit is set, the Layer 3 IP Source or Destination Address matching is enabled for IPv6 packets. Layer 3 Protocol Enable When this bit is set, the Layer 3 IP Source or Destination Address matching is enabled for IPv6 packets. When this bit is reset, the Layer 3 IP Source or Destination Address matching is enabled for IPv4 packets. The Layer 3 matching is done only when the L3SAM0 or L3DAM0 bit is set. 0b - Layer 3 Protocol is disabled 1b - Layer 3 Protocol is enabled

61.7.1.278 Layer 4 Address 0 (MAC_LAYER4_ADDRESS0)

61.7.1.278.1 Offset

Register	Offset
MAC_LAYER4_ADDRESS0	904h

61.7.1.278.2 Function

The MAC_LAYER4_ADDRESS0, MAC_L3_L4_CONTROL0, MAC_LAYER3_ADDR0_Reg0, MAC_LAYER3_ADDR1_Reg0, MAC_LAYER3_ADDR2_Reg0 and MAC_LAYER3_ADDR3_Reg0 registers are reserved (RO with default value) if Enable Layer 3 and Layer 4 Packet Filter option is not selected while configuring the core.

You can configure the Layer 3 and Layer 4 Address Registers to be double-synchronized by selecting the Synchronize Layer 3 and Layer 4 Address Registers to Rx Clock Domain option while configuring the core. When you select this option, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Layer 3 and Layer 4 Address Registers are written. For proper synchronization updates, you should perform consecutive writes to same Layer 3 and Layer 4 Address Registers after at least four clock cycles delay of the destination clock.

61.7.1.278.3 Diagram

When this bit is reset, the Layer 3 IP Source or Destination Address matching is enabled for IPv4 packets. The Layer 3 matching is done only when the L3SAM0 or L3DAM0 bit is set. 0b - Layer 3 Protocol is disabled 1b - Layer 3 Protocol is enabled

61.7.1.284 Layer 4 Address 0 (MAC_LAYER4_ADDRESS1)

61.7.1.284.1 Offset

Register	Offset
MAC_LAYER4_ADDRESS1	934h

61.7.1.284.2 Function

The MAC_LAYER4_ADDRESS1, MAC_L3_L4_CONTROL1, MAC_LAYER3_ADDR0_Reg1, MAC_LAYER3_ADDR1_Reg1, MAC_LAYER3_ADDR2_Reg1 and MAC_LAYER3_ADDR3_Reg1 registers are reserved (RO with default value) if Enable Layer 3 and Layer 4 Packet Filter option is not selected while configuring the core.

You can configure the Layer 3 and Layer 4 Address Registers to be double-synchronized by selecting the Synchronize Layer 3 and Layer 4 Address Registers to Rx Clock Domain option while configuring the core. When you select this option, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Layer 3 and Layer 4 Address Registers are written. For proper synchronization updates, you should perform consecutive writes to same Layer 3 and Layer 4 Address Registers after at least four clock cycles delay of the destination clock.

31-29 —	Reserved
28 DMCHEN4	DMA Channel Select Enable When set, this bit enables the selection of the DMA channel number for the packet that is passed by this L3_L4 filter. DMA Channel Select Enable

Table continues on the next page...

Field	Function
	When set, this bit enables the selection of the DMA channel number for the packet that is passed by this L3_L4 filter. The DMA channel is indicated by the DMCHN bits. When this bit is reset, the DMA channel is not decided by this filter. 0b - DMA Channel Select is disabled 1b - DMA Channel Select is enabled
27 —	Reserved
26-24 DMCHN4	DMA Channel Number When DMCHEN is set high, this field selects the DMA Channel number to which the packet passed by this filter is routed. DMA Channel Number When DMCHEN is set high, this field selects the DMA Channel number to which the packet passed by this filter is routed. The width of this field depends on the number of the DMA channels present in your configuration.
23-22 —	Reserved
21 L4DPIM4	Layer 4 Destination Port Inverse Match Enable When this bit is set, the Layer 4 Destination Port number field is enabled for inverse matching. Layer 4 Destination Port Inverse Match Enable When this bit is set, the Layer 4 Destination Port number field is enabled for inverse matching. When this bit is reset, the Layer 4 Destination Port number field is enabled for perfect matching. This bit is valid and applicable only when the L4DPM4 bit is set high. 0b - Layer 4 Destination Port Inverse Match is disabled 1b - Layer 4 Destination Port Inverse Match is enabled
20 L4DPM4	Layer 4 Destination Port Match Enable When this bit is set, the Layer 4 Destination Port number field is enabled for matching. Layer 4 Destination Port Match Enable When this bit is set, the Layer 4 Destination Port number field is enabled for matching. When this bit is reset, the MAC ignores the Layer 4 Destination Port number field for matching. 0b - Layer 4 Destination Port Match is disabled 1b - Layer 4 Destination Port Match is enabled
19 L4SPIM4	Layer 4 Source Port Inverse Match Enable When this bit is set, the Layer 4 Source Port number field is enabled for inverse matching. Layer 4 Source Port Inverse Match Enable When this bit is set, the Layer 4 Source Port number field is enabled for inverse matching. When this bit is reset, the Layer 4 Source Port number field is enabled for perfect matching. This bit is valid and applicable only when the L4SPM0 bit is set high. 0b - Layer 4 Source Port Inverse Match is disabled 1b - Layer 4 Source Port Inverse Match is enabled
18 L4SPM4	Layer 4 Source Port Match Enable When this bit is set, the Layer 4 Source Port number field is enabled for matching. Layer 4 Source Port Match Enable When this bit is set, the Layer 4 Source Port number field is enabled for matching. When this bit is reset, the MAC ignores the Layer 4 Source Port number field for matching. 0b - Layer 4 Source Port Match is disabled 1b - Layer 4 Source Port Match is enabled

Table continues on the next page...

Field	Function
17 —	Reserved
16 L4PEN4	Layer 4 Protocol Enable When this bit is set, the Source and Destination Port number fields of UDP packets are used for matching. Layer 4 Protocol Enable When this bit is set, the Source and Destination Port number fields of UDP packets are used for matching. When this bit is reset, the Source and Destination Port number fields of TCP packets are used for matching. The Layer 4 matching is done only when the L4SPM0 or L4DPM4bit is set. 0b - Layer 4 Protocol is disabled 1b - Layer 4 Protocol is enabled
15-11 L3HDBM4	Layer 3 IP DA Higher Bits Match IPv4 Packets: This field contains the number of higher bits of IP Destination Address that are matched in the IPv4 packets. Layer 3 IP DA Higher Bits Match IPv4 Packets: This field contains the number of higher bits of IP Destination Address that are matched in the IPv4 packets. The following list describes the values of this field: - 0: No bits are masked. - 1: LSb[0] is masked - 2: Two LSbs [1:0] are masked - .. - 31: All bits except MSb are masked. IPv6 Packets: Bits[12:11] of this field correspond to Bits[6:5] of L3HSBM0 which indicate the number of lower bits of IP Source or Destination Address that are masked in the IPv6 packets. The following list describes the concatenated values of the L3HDBM0[1:0] and L3HSBM0 bits: - 0: No bits are masked. - 1: LSb[0] is masked. - 2: Two LSbs [1:0] are masked - .. - 127: All bits except MSb are masked. This field is valid and applicable only when the L3DAM0 or L3SAM0 bit is set.
10-6 L3HSBM4	Layer 3 IP SA Higher Bits Match IPv4 Packets: This field contains the number of lower bits of IP Source Address that are masked for matching in the IPv4 packets. Layer 3 IP SA Higher Bits Match IPv4 Packets: This field contains the number of lower bits of IP Source Address that are masked for matching in the IPv4 packets. The following list describes the values of this field: - 0: No bits are masked. - 1: LSb[0] is masked - 2: Two LSbs [1:0] are masked - ..

Table continues on the next page...

Field	Function
	- 31: All bits except MSb are masked. IPv6 Packets: This field contains Bits[4:0] of L3HSBM0. These bits indicate the number of higher bits of IP Source or Destination Address matched in the IPv6 packets. This field is valid and applicable only when the L3DAM0 or L3SAM0 bit is set high.
5 L3DAIM4	Layer 3 IP DA Inverse Match Enable When this bit is set, the Layer 3 IP Destination Address field is enabled for inverse matching. Layer 3 IP DA Inverse Match Enable When this bit is set, the Layer 3 IP Destination Address field is enabled for inverse matching. When this bit is reset, the Layer 3 IP Destination Address field is enabled for perfect matching. This bit is valid and applicable only when the L3DAM0 bit is set high. 0b - Layer 3 IP DA Inverse Match is disabled 1b - Layer 3 IP DA Inverse Match is enabled
4 L3DAM4	Layer 3 IP DA Match Enable When this bit is set, the Layer 3 IP Destination Address field is enabled for matching. Layer 3 IP DA Match Enable When this bit is set, the Layer 3 IP Destination Address field is enabled for matching. When this bit is reset, the MAC ignores the Layer 3 IP Destination Address field for matching. Note: When the L3PEN0 bit is set, you should set either this bit or the L3SAM0 bit because either IPv6 DA or SA can be checked for filtering. 0b - Layer 3 IP DA Match is disabled 1b - Layer 3 IP DA Match is enabled
3 L3SAIM4	Layer 3 IP SA Inverse Match Enable When this bit is set, the Layer 3 IP Source Address field is enabled for inverse matching. Layer 3 IP SA Inverse Match Enable When this bit is set, the Layer 3 IP Source Address field is enabled for inverse matching. When this bit reset, the Layer 3 IP Source Address field is enabled for perfect matching. This bit is valid and applicable only when the L3SAM0 bit is set. 0b - Layer 3 IP SA Inverse Match is disabled 1b - Layer 3 IP SA Inverse Match is enabled
2 L3SAM4	Layer 3 IP SA Match Enable When this bit is set, the Layer 3 IP Source Address field is enabled for matching. Layer 3 IP SA Match Enable When this bit is set, the Layer 3 IP Source Address field is enabled for matching. When this bit is reset, the MAC ignores the Layer 3 IP Source Address field for matching. Note: When the L3PEN0 bit is set, you should set either this bit or the L3DAM0 bit because either IPv6 SA or DA can be checked for filtering. 0b - Layer 3 IP SA Match is disabled 1b - Layer 3 IP SA Match is enabled

	When this bit is set, the Layer 3 IP Source or Destination Address matching is enabled for IPv6 packets. When this bit is reset, the Layer 3 IP Source or Destination Address matching is enabled for IPv4 packets. The Layer 3 matching is done only when the L3SAM0 or L3DAM0 bit is set. 0b - Layer 3 Protocol is disabled 1b - Layer 3 Protocol is enabled

61.7.1.302 Layer 4 Address 4 (MAC_LAYER4_ADDRESS4)

61.7.1.302.1 Offset

Register	Offset
MAC_LAYER4_ADDRESS4	9C4h

61.7.1.302.2 Function

The MAC_LAYER4_ADDRESS4, MAC_L3_L4_CONTROL4, MAC_LAYER3_ADDR0_Reg4, MAC_LAYER3_ADDR1_Reg4, MAC_LAYER3_ADDR2_Reg4 and MAC_LAYER3_ADDR3_Reg4) registers are reserved (RO with default value) if Enable Layer 3 and Layer 4 Packet Filter option is not selected while configuring the core.

You can configure the Layer 3 and Layer 4 Address Registers to be double-synchronized by selecting the Synchronize Layer 3 and Layer 4 Address Registers to Rx Clock Domain option while configuring the core. When you select this option, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Layer 3 and Layer 4 Address Registers are written. For proper synchronization updates, you should perform consecutive writes to same Layer 3 and Layer 4 Address Registers after at least four clock cycles delay of the destination clock.

61.7.1.319.4 Fields

Field	Function
31-29 —	Reserved
28 DMCHEN7	DMA Channel Select Enable When set, this bit enables the selection of the DMA channel number for the packet that is passed by this L3_L4 filter. DMA Channel Select Enable

Table continues on the next page...

Field	Function
	When set, this bit enables the selection of the DMA channel number for the packet that is passed by this L3_L4 filter. The DMA channel is indicated by the DMCHN bits. When this bit is reset, the DMA channel is not decided by this filter. 0b - DMA Channel Select is disabled 1b - DMA Channel Select is enabled
27 —	Reserved
26-24 DMCHN7	DMA Channel Number When DMCHEN is set high, this field selects the DMA Channel number to which the packet passed by this filter is routed. DMA Channel Number When DMCHEN is set high, this field selects the DMA Channel number to which the packet passed by this filter is routed. The width of this field depends on the number of the DMA channels present in your configuration.
23-22 —	Reserved
21 L4DPIM7	Layer 4 Destination Port Inverse Match Enable When this bit is set, the Layer 4 Destination Port number field is enabled for inverse matching. Layer 4 Destination Port Inverse Match Enable When this bit is set, the Layer 4 Destination Port number field is enabled for inverse matching. When this bit is reset, the Layer 4 Destination Port number field is enabled for perfect matching. This bit is valid and applicable only when the L4DPM7 bit is set high. 0b - Layer 4 Destination Port Inverse Match is disabled 1b - Layer 4 Destination Port Inverse Match is enabled
20 L4DPM7	Layer 4 Destination Port Match Enable When this bit is set, the Layer 4 Destination Port number field is enabled for matching. Layer 4 Destination Port Match Enable When this bit is set, the Layer 4 Destination Port number field is enabled for matching. When this bit is reset, the MAC ignores the Layer 4 Destination Port number field for matching. 0b - Layer 4 Destination Port Match is disabled 1b - Layer 4 Destination Port Match is enabled
19 L4SPIM7	Layer 4 Source Port Inverse Match Enable When this bit is set, the Layer 4 Source Port number field is enabled for inverse matching. Layer 4 Source Port Inverse Match Enable When this bit is set, the Layer 4 Source Port number field is enabled for inverse matching. When this bit is reset, the Layer 4 Source Port number field is enabled for perfect matching. This bit is valid and applicable only when the L4SPM0 bit is set high. 0b - Layer 4 Source Port Inverse Match is disabled 1b - Layer 4 Source Port Inverse Match is enabled
18 L4SPM7	Layer 4 Source Port Match Enable When this bit is set, the Layer 4 Source Port number field is enabled for matching. Layer 4 Source Port Match Enable When this bit is set, the Layer 4 Source Port number field is enabled for matching. When this bit is reset, the MAC ignores the Layer 4 Source Port number field for matching. 0b - Layer 4 Source Port Match is disabled 1b - Layer 4 Source Port Match is enabled

Table continues on the next page...

Field	Function
17 —	Reserved
16 L4PEN7	Layer 4 Protocol Enable When this bit is set, the Source and Destination Port number fields of UDP packets are used for matching. Layer 4 Protocol Enable When this bit is set, the Source and Destination Port number fields of UDP packets are used for matching. When this bit is reset, the Source and Destination Port number fields of TCP packets are used for matching. The Layer 4 matching is done only when the L4SPM0 or L4DPM7 bit is set. 0b - Layer 4 Protocol is disabled 1b - Layer 4 Protocol is enabled
15-11 L3HDBM7	Layer 3 IP DA Higher Bits Match IPv4 Packets: This field contains the number of higher bits of IP Destination Address that are matched in the IPv4 packets. Layer 3 IP DA Higher Bits Match IPv4 Packets: This field contains the number of higher bits of IP Destination Address that are matched in the IPv4 packets. The following list describes the values of this field: - 0: No bits are masked. - 1: LSb[0] is masked - 2: Two LSbs [1:0] are masked - .. - 31: All bits except MSb are masked. IPv6 Packets: Bits[12:11] of this field correspond to Bits[6:5] of L3HSBM0 which indicate the number of lower bits of IP Source or Destination Address that are masked in the IPv6 packets. The following list describes the concatenated values of the L3HDBM0[1:0] and L3HSBM0 bits: - 0: No bits are masked. - 1: LSb[0] is masked. - 2: Two LSbs [1:0] are masked - .. - 127: All bits except MSb are masked. This field is valid and applicable only when the L3DAM0 or L3SAM0 bit is set.
10-6 L3HSBM7	Layer 3 IP SA Higher Bits Match IPv4 Packets: This field contains the number of lower bits of IP Source Address that are masked for matching in the IPv4 packets. Layer 3 IP SA Higher Bits Match IPv4 Packets: This field contains the number of lower bits of IP Source Address that are masked for matching in the IPv4 packets. The following list describes the values of this field: - 0: No bits are masked. - 1: LSb[0] is masked - 2: Two LSbs [1:0] are masked - ..

Table continues on the next page...

Field	Function
	- 31: All bits except MSb are masked. IPv6 Packets: This field contains Bits[4:0] of L3HSBM0. These bits indicate the number of higher bits of IP Source or Destination Address matched in the IPv6 packets. This field is valid and applicable only when the L3DAM0 or L3SAM0 bit is set high.
5 L3DAIM7	Layer 3 IP DA Inverse Match Enable When this bit is set, the Layer 3 IP Destination Address field is enabled for inverse matching. Layer 3 IP DA Inverse Match Enable When this bit is set, the Layer 3 IP Destination Address field is enabled for inverse matching. When this bit is reset, the Layer 3 IP Destination Address field is enabled for perfect matching. This bit is valid and applicable only when the L3DAM0 bit is set high. 0b - Layer 3 IP DA Inverse Match is disabled 1b - Layer 3 IP DA Inverse Match is enabled
4 L3DAM7	Layer 3 IP DA Match Enable When this bit is set, the Layer 3 IP Destination Address field is enabled for matching. Layer 3 IP DA Match Enable When this bit is set, the Layer 3 IP Destination Address field is enabled for matching. When this bit is reset, the MAC ignores the Layer 3 IP Destination Address field for matching. Note: When the L3PEN0 bit is set, you should set either this bit or the L3SAM0 bit because either IPv6 DA or SA can be checked for filtering. 0b - Layer 3 IP DA Match is disabled 1b - Layer 3 IP DA Match is enabled
3 L3SAIM7	Layer 3 IP SA Inverse Match Enable When this bit is set, the Layer 3 IP Source Address field is enabled for inverse matching. Layer 3 IP SA Inverse Match Enable When this bit is set, the Layer 3 IP Source Address field is enabled for inverse matching. When this bit reset, the Layer 3 IP Source Address field is enabled for perfect matching. This bit is valid and applicable only when the L3SAM0 bit is set. 0b - Layer 3 IP SA Inverse Match is disabled 1b - Layer 3 IP SA Inverse Match is enabled
2 L3SAM7	Layer 3 IP SA Match Enable When this bit is set, the Layer 3 IP Source Address field is enabled for matching. Layer 3 IP SA Match Enable When this bit is set, the Layer 3 IP Source Address field is enabled for matching. When this bit is reset, the MAC ignores the Layer 3 IP Source Address field for matching. Note: When the L3PEN0 bit is set, you should set either this bit or the L3DAM0 bit because either IPv6 SA or DA can be checked for filtering. 0b - Layer 3 IP SA Match is disabled 1b - Layer 3 IP SA Match is enabled

Field	Function
	When this bit is set, the Layer 3 IP Source or Destination Address matching is enabled for IPv6 packets. When this bit is reset, the Layer 3 IP Source or Destination Address matching is enabled for IPv4 packets. The Layer 3 matching is done only when the L3SAM0 or L3DAM0 bit is set. 0b - Layer 3 Protocol is disabled 1b - Layer 3 Protocol is enabled

61.7.1.320 Layer 4 Address 7 (MAC_LAYER4_ADDRESS7)

61.7.1.320.1 Offset

Register	Offset
MAC_LAYER4_ADDRESS7	A54h

61.7.1.320.2 Function

The MAC_LAYER4_ADDRESS7, MAC_L3_L4_CONTROL7, MAC_LAYER3_ADDR0_Reg7, MAC_LAYER3_ADDR1_Reg7, MAC_LAYER3_ADDR2_Reg7 and MAC_LAYER3_ADDR3_Reg7 registers are reserved (RO with default value) if Enable Layer 3 and Layer 4 Packet Filter option is not selected while configuring the core.

You can configure the Layer 3 and Layer 4 Address Registers to be double-synchronized by selecting the Synchronize Layer 3 and Layer 4 Address Registers to Rx Clock Domain option while configuring the core. When you select this option, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Layer 3 and Layer 4 Address Registers are written. For proper synchronization updates, you should perform consecutive writes to same Layer 3 and Layer 4 Address Registers after at least four clock cycles delay of the destination clock.

When the L3PEN0 bit is reset in the MAC_L3_L4_CONTROL0 register, this field is not used.

61.7.1.324 Layer 3 Address 3 Register 7 (MAC_LAYER3_ADDR3_REG7)

61.7.1.324.1 Offset

Register	Offset
MAC_LAYER3_ADDR3_REG7	A6Ch

61.7.1.324.2 Function

The Layer 3 Address 3 Register 7 register is reserved for IPv4 packets. For IPv6 packets, it contains Bits[127:96] of 128-bit IP Source Address or Destination Address field.

61.7.1.324.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	L3A37															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	L3A37															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

61.7.1.324.4 Fields

Field	Function
31-0 L3A37	Layer 3 Address 3 Field When the L3PEN0 and L3SAM0 bits are set in the MAC_L3_L4_CONTROL0 register, this field contains the value to be matched with Bits[127:96] of the IP Source Address field in the IPv6 packets. Layer 3 Address 3 Field When the L3PEN0 and L3SAM0 bits are set in the MAC_L3_L4_CONTROL0 register, this field contains the value to be matched with Bits[127:96] of the IP Source Address field in the IPv6 packets. When the L3PEN0 and L3DAM0 bits are set in the MAC_L3_L4_CONTROL0 register, this field contains the value to be matched with Bits[127:96] of the IP Destination Address field in the IPv6 packets. When the L3PEN0 bit is reset in the MAC_L3_L4_CONTROL0 register, this field is not used.

61.7.1.325 MAC_INDIR_ACCESS_CTRL (MAC_INDIR_ACCESS_CTRL)

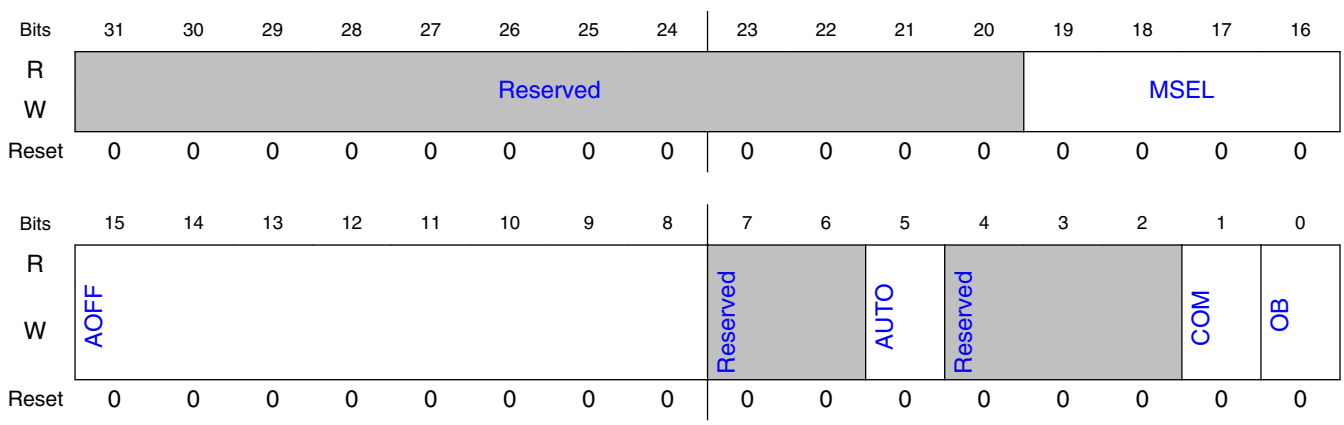
61.7.1.325.1 Offset

Register	Offset
MAC_INDIR_ACCESS_CTRL	A70h

61.7.1.325.2 Function

This register provides the Indirect Access control and status for MAC_<MSEl>_<AOFF> registers.

61.7.1.325.3 Diagram



61.7.1.325.4 Fields

Field	Function
31-20 —	Reserved
19-16 MSEL	Mode Select This field is used in indirect access of MAC_<MSEL>_<AOFF>. This field must be set along with initiation of read/write to MAC_<MSEL>_<AOFF> and should not be changed until the OB is reset. Values: 0000: ESTTyp_RXQ_ (Type based RXQ mappping) 0001-1111: Reserved for future use.

Table continues on the next page...

Field	Function
15-8 AOFF	Address Offset This field is used in indirect access of MAC_<MSEL>_<AOFF>. This field must be set along with initiation of read/write to MAC_<MSEL>_<AOFF> and should not be changed until the OB is reset. Values: 00000000: IndReg0(Indirect register 0) 00000001: IndReg1(Indirect register 1) ... 00000111: IndReg7(Indirect register 7) 00001000-11111111: Reserved for future use.
7-6 —	Reserved
5 AUTO	Auto increment enable 0b - AOFF is not incremented automatically. Software should program the correct Address Offset for each access. 1b - AOFF is incremented by 1. Software should ensure not to cause a wrap condition. Byte wise read/write is not supported when auto increment is enabled.
4-2 —	Reserved
1 COM	Command type. Indicates the register access type. 0b - Indicates a write operation 1b - Indicates a read operation
0 OB	Operation Busy This bit is set along with a read or write command for initiating the indirect access to MAC_<MSEL>_<AOFF> register. This bit is reset when the read or write command to MAC_<MSEL>_<AOFF> register is complete. The next indirect register access can be initiated only after this bit is reset. During a write operation, the bit is reset only after the data has been written into MAC_<MSEL>_<AOFF> register. During a read operation, the data should be read from MAC_INDIR_ACCESS_DATA register only after this bit is reset.

61.7.1.326 MAC_INDIR_ACCESS_DATA (MAC_INDIR_ACCESS_DATA)

61.7.1.326.1 Offset

Register	Offset
MAC_INDIR_ACCESS_DATA	A74h

61.7.1.326.2 Function

This register holds the read/write data for Indirect Access of MAC_<MSEL_<AOFF> registers.

61.7.1.326.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	DATA

R W	DATA															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

61.7.1.326.4 Fields

Field	Function
31-0 DATA	This field contains data to read/write for Indirect address access associated with MAC_INDIR_ACCESS_CTRL register.

61.7.1.327 Timestamp Control (MAC_TIMESTAMP_CONTROL)

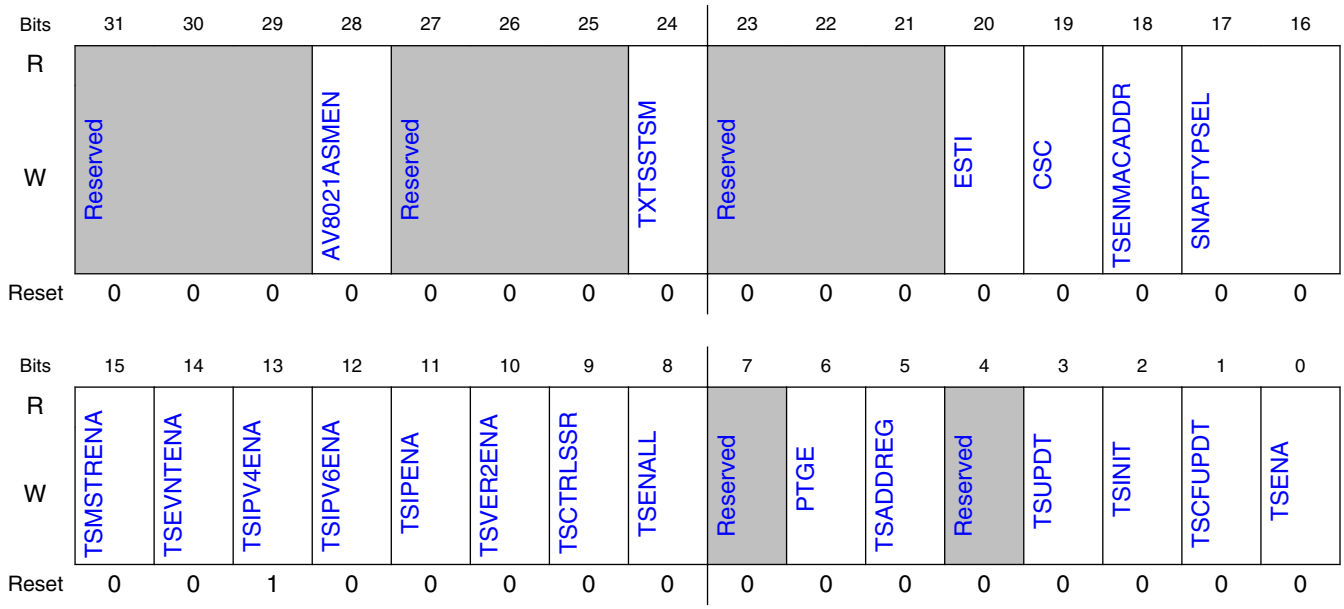
61.7.1.327.1 Offset

Register	Offset
MAC_TIMESTAMP_CONTROL	B00h

61.7.1.327.2 Function

This register controls the operation of the System Time generator and processing of PTP packets for timestamping in the Receiver.

61.7.1.327.3 Diagram



61.7.1.327.4 Fields

Field	Function
31-29 —	Reserved
28 AV8021ASMEN	AV 802. AV 802.1AS Mode Enable When this bit is set, the MAC processes only untagged PTP over Ethernet packets for providing PTP status and capturing timestamp snapshots, that is, IEEE 802.1AS mode of operation. When PTP offload feature is enabled, for the purpose of PTP offload, the transport specific field in the PTP header is generated and checked based on the value of this bit. 0b - AV 802.1AS Mode is disabled 1b - AV 802.1AS Mode is enabled
27-25 —	Reserved
24 TXTSSTSM	Transmit Timestamp Status Mode When this bit is set, the MAC overwrites the earlier transmit timestamp status even if it is not read by the software. Transmit Timestamp Status Mode When this bit is set, the MAC overwrites the earlier transmit timestamp status even if it is not read by the software. The MAC indicates this by setting the TXTSSMIS bit of the MAC_TX_TIMESTAMP_STATUS_NANOSECONDS register. When this bit is reset, the MAC ignores the timestamp status of current packet if the timestamp status of previous packet is not read by the software. The MAC indicates this by setting the TXTSSMIS bit of the MAC_TX_TIMESTAMP_STATUS_NANOSECONDS register. 0b - Transmit Timestamp Status Mode is disabled

Table continues on the next page...

Field	Function
	1b - Transmit Timestamp Status Mode is enabled
23-21 —	Reserved
20 ESTI	External System Time Input When this bit is set, the MAC uses the external 64-bit reference System Time input for the following: - To take the timestamp provided as status - To insert the timestamp in transmit PTP packets when One-step Timestamp or Timestamp Offload feature is enabled. External System Time Input When this bit is set, the MAC uses the external 64-bit reference System Time input for the following: - To take the timestamp provided as status - To insert the timestamp in transmit PTP packets when One-step Timestamp or Timestamp Offload feature is enabled. When this bit is reset, the MAC uses the internal reference System Time. 0b - External System Time Input is disabled 1b - External System Time Input is enabled
19 CSC	Enable checksum correction during OST for PTP over UDP/IPv4 packets When this bit is set, the last two bytes of PTP message sent over UDP/IPv4 is updated to keep the UDP checksum correct, for changes made to origin timestamp and/or correction field as part of one step timestamp operation. Enable checksum correction during OST for PTP over UDP/IPv4 packets When this bit is set, the last two bytes of PTP message sent over UDP/IPv4 is updated to keep the UDP checksum correct, for changes made to origin timestamp and/or correction field as part of one step timestamp operation. The application shall form the packet with these two dummy bytes. When reset, no updates are done to keep the UDP checksum correct. The application shall form the packet with UDP checksum set to 0. 0b - checksum correction during OST for PTP over UDP/IPv4 packets is disabled 1b - checksum correction during OST for PTP over UDP/IPv4 packets is enabled
18 TSENMACADDR	Enable MAC Address for PTP Packet Filtering When this bit is set, the DA MAC address (that matches any MAC Address register) is used to filter the PTP packets when PTP is directly sent over Ethernet. Enable MAC Address for PTP Packet Filtering When this bit is set, the DA MAC address (that matches any MAC Address register) is used to filter the PTP packets when PTP is directly sent over Ethernet. When this bit is set, received PTP packets with DA containing a special multicast or unicast address that matches the one programmed in MAC address registers are considered for processing as indicated below, when PTP is directly sent over Ethernet. For normal time stamping operation, MAC address registers 0 to 31 is considered for unicast destination address matching. For PTP offload, only MAC address register 0 is considered for unicast destination address matching. 0b - MAC Address for PTP Packet Filtering is disabled 1b - MAC Address for PTP Packet Filtering is enabled
17-16 SNAPTYPSEL	Select PTP packets for Taking Snapshots These bits, along with Bits 15 and 14, decide the set of PTP packet types for which snapshot needs to be taken. Select PTP packets for Taking Snapshots These bits, along with Bits 15 and 14, decide the set of PTP packet types for which snapshot needs to be taken. The encoding is given in Timestamp Snapshot Dependency on Register Bits Table.
15 TSMSTRENA	Enable Snapshot for Messages Relevant to Master When this bit is set, the snapshot is taken only for the messages that are relevant to the master node.

Table continues on the next page...

Field	Function
	Enable Snapshot for Messages Relevant to Master When this bit is set, the snapshot is taken only for the messages that are relevant to the master node. Otherwise, the snapshot is taken for the messages relevant to the slave node. 0b - Snapshot for Messages Relevant to Master is disabled 1b - Snapshot for Messages Relevant to Master is enabled
14 TSEVNTENA	Enable Timestamp Snapshot for Event Messages When this bit is set, the timestamp snapshot is taken only for event messages (SYNC, Delay_Req, Pdelay_Req, or Pdelay_Resp). Enable Timestamp Snapshot for Event Messages When this bit is set, the timestamp snapshot is taken only for event messages (SYNC, Delay_Req, Pdelay_Req, or Pdelay_Resp). When this bit is reset, the snapshot is taken for all messages except Announce, Management, and Signaling. For more information about the timestamp snapshots, see Timestamp Snapshot Dependency on Register Bits Table. 0b - Timestamp Snapshot for Event Messages is disabled 1b - Timestamp Snapshot for Event Messages is enabled
13 TSIPV4ENA	Enable Processing of PTP Packets Sent over IPv4-UDP When this bit is set, the MAC receiver processes the PTP packets encapsulated in IPv4-UDP packets. Enable Processing of PTP Packets Sent over IPv4-UDP When this bit is set, the MAC receiver processes the PTP packets encapsulated in IPv4-UDP packets. When this bit is reset, the MAC ignores the PTP transported over IPv4-UDP packets. This bit is set by default. 0b - Processing of PTP Packets Sent over IPv4-UDP is disabled 1b - Processing of PTP Packets Sent over IPv4-UDP is enabled
12 TSIPV6ENA	Enable Processing of PTP Packets Sent over IPv6-UDP When this bit is set, the MAC receiver processes the PTP packets encapsulated in IPv6-UDP packets. Enable Processing of PTP Packets Sent over IPv6-UDP When this bit is set, the MAC receiver processes the PTP packets encapsulated in IPv6-UDP packets. When this bit is clear, the MAC ignores the PTP transported over IPv6-UDP packets. 0b - Processing of PTP Packets Sent over IPv6-UDP is disabled 1b - Processing of PTP Packets Sent over IPv6-UDP is enabled
11 TSIPENA	Enable Processing of PTP over Ethernet Packets When this bit is set, the MAC receiver processes the PTP packets encapsulated directly in the Ethernet packets. Enable Processing of PTP over Ethernet Packets When this bit is set, the MAC receiver processes the PTP packets encapsulated directly in the Ethernet packets. When this bit is reset, the MAC ignores the PTP over Ethernet packets. 0b - Processing of PTP over Ethernet Packets is disabled 1b - Processing of PTP over Ethernet Packets is enabled
10 TSVER2ENA	Enable PTP Packet Processing for Version 2 Format When this bit is set, the IEEE 1588 version 2 format is used to process the PTP packets. Enable PTP Packet Processing for Version 2 Format When this bit is set, the IEEE 1588 version 2 format is used to process the PTP packets. When this bit is reset, the IEEE 1588 version 1 format is used to process the PTP packets. The IEEE 1588 formats are described in 'PTP Processing and Control'. 0b - PTP Packet Processing for Version 2 Format is disabled 1b - PTP Packet Processing for Version 2 Format is enabled

Table continues on the next page...

Field	Function
9 TSCTRLSSR	Timestamp Digital or Binary Rollover Control When this bit is set, the Timestamp Low register rolls over after 0x3B9A_C9FF value (that is, 1 nanosecond accuracy) and increments the timestamp (High) seconds. Timestamp Digital or Binary Rollover Control When this bit is set, the Timestamp Low register rolls over after 0x3B9A_C9FF value (that is, 1 nanosecond accuracy) and increments the timestamp (High) seconds. When this bit is reset, the rollover value of sub-second register is 0x7FFF_FFFF. The sub-second increment must be programmed correctly depending on the PTP reference clock frequency and the value of this bit. 0b - Timestamp Digital or Binary Rollover Control is disabled 1b - Timestamp Digital or Binary Rollover Control is enabled
8 TSENALL	Enable Timestamp for All Packets When this bit is set, the timestamp snapshot is enabled for all packets received by the MAC. 0b - Timestamp for All Packets disabled 1b - Timestamp for All Packets enabled
7 —	Reserved
6 PTGE	Presentation Time Generation Enable When this bit is set the Presentation Time generation will be enabled. 0b - Presentation Time Generation is disabled 1b - Presentation Time Generation is enabled
5 TSADDREG	Update Addend Register When this bit is set, the content of the Timestamp Addend register is updated in the PTP block for fine correction. Update Addend Register When this bit is set, the content of the Timestamp Addend register is updated in the PTP block for fine correction. This bit is cleared when the update is complete. This bit should be zero before it is set. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0b - Addend Register is not updated 1b - Addend Register is updated
4 —	Reserved
3 TSUPDT	Update Timestamp When this bit is set, the system time is updated (added or subtracted) with the value specified in MAC_System_Time_Seconds_Update and MAC_System_Time_Nanoseconds_Update registers. Update Timestamp When this bit is set, the system time is updated (added or subtracted) with the value specified in MAC_System_Time_Seconds_Update and MAC_System_Time_Nanoseconds_Update registers. This bit should be zero before updating it. This bit is reset when the update is complete in hardware. The Timestamp Higher Word register (if enabled during core configuration) is not updated. When Media Clock Generation and Recovery is configured (DWC_EQOS_FLEXI_PPS_OUT_EN) and enabled MAC_Presn_Time_Updt should also be updated before setting this field. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0b - Timestamp is not updated 1b - Timestamp is updated
2 TSINIT	Initialize Timestamp When this bit is set, the system time is initialized (overwritten) with the value specified in the MAC_System_Time_Seconds_Update and MAC_System_Time_Nanoseconds_Update registers.

Table continues on the next page...

Field	Function
	Initialize Timestamp When this bit is set, the system time is initialized (overwritten) with the value specified in the MAC_System_Time_Seconds_Update and MAC_System_Time_Nanoseconds_Update registers. This bit should be zero before it is updated. This bit is reset when the initialization is complete. The Timestamp Higher Word register (if enabled during core configuration) can only be initialized. When Media Clock Generation and Recovery is configured (DWC_EQOS_FLEXI_PPS_OUT_EN) and enabled MAC_Presn_Time_Updt should also be updated before setting this field. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0b - Timestamp is not initialized 1b - Timestamp is initialized
1 TSCFUPDT	Fine or Coarse Timestamp Update When this bit is set, the Fine method is used to update system timestamp. Fine or Coarse Timestamp Update When this bit is set, the Fine method is used to update system timestamp. When this bit is reset, Coarse method is used to update the system timestamp. 0b - Coarse method is used to update system timestamp 1b - Fine method is used to update system timestamp
0 TSENA	Enable Timestamp When this bit is set, the timestamp is added for Transmit and Receive packets. Enable Timestamp When this bit is set, the timestamp is added for Transmit and Receive packets. When disabled, timestamp is not added for transmit and receive packets and the Timestamp Generator is also suspended. You need to initialize the Timestamp (system time) after enabling this mode. On the Receive side, the MAC processes the 1588 packets only if this bit is set. 0b - Timestamp is disabled 1b - Timestamp is enabled

61.7.1.328 Subsecond Increment (MAC_SUB_SECOND_INCREMENT)

61.7.1.328.1 Offset

Register	Offset
MAC_SUB_SECOND_INCREMENT	B04h

61.7.1.328.2 Function

This register specifies the value to be added to the internal system time register every cycle of clk_ptp_ref_i clock.

61.7.1.328.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	Reserved								SSINC							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	SNSINC								Reserved							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

61.7.1.328.4 Fields

Field	Function
31-24 —	Reserved
23-16 SSINC	Sub-second Increment Value The value programmed in this field is accumulated every clock cycle (of clk_ptp_i) with the contents of the sub-second register. Sub-second Increment Value The value programmed in this field is accumulated every clock cycle (of clk_ptp_i) with the contents of the sub-second register. For example, when the PTP clock is 50 MHz (period is 20 ns), you should program 20 (0x14) when the System Time Nanoseconds register has an accuracy of 1 ns [Bit 9 (TSCTRLSSR) is set in TIMESTAMP_CONTROL]. When TSCTRLSSR is clear, the Nanoseconds register has a resolution of ~0.465 ns. In this case, you should program a value of 43 (0x2B) which is derived by 20 ns/0.465.
15-8 SNSINC	Sub-nanosecond Increment Value This field contains the sub-nanosecond increment value, represented in nanoseconds multiplied by 2^8. Sub-nanosecond Increment Value This field contains the sub-nanosecond increment value, represented in nanoseconds multiplied by 2^8. This value is accumulated with the sub-nanoseconds field of the subsecond register. For example, when TSCTRLSSR field in the TIMESTAMP_CONTROL register is set. and if the required increment is 5.3ns, then SSINC should be 0x05 and SNSINC should be 0x4C.
7-0 —	Reserved

61.7.1.329 System Time Seconds (MAC_SYSTEM_TIME_SECONDS)

61.7.1.329.1 Offset

Register	Offset
MAC_SYSTEM_TIME_SECONDS	B08h

61.7.1.329.2 Function

The System Time Seconds register, along with System Time Nanoseconds register, indicates the current value of the system time maintained by the MAC. Though it is updated on a continuous basis, there is some delay from the actual time because of clock domain transfer latencies (from clk_ptp_ref_i to CSR clock).

61.7.1.329.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

61.7.1.329.4 Fields

Field	Function
31-0 TSS	Timestamp Second The value in this field indicates the current value in seconds of the System Time maintained by the MAC.

61.7.1.330 System Time Nanoseconds (MAC_SYSTEM_TIME_NANOSECONDS)

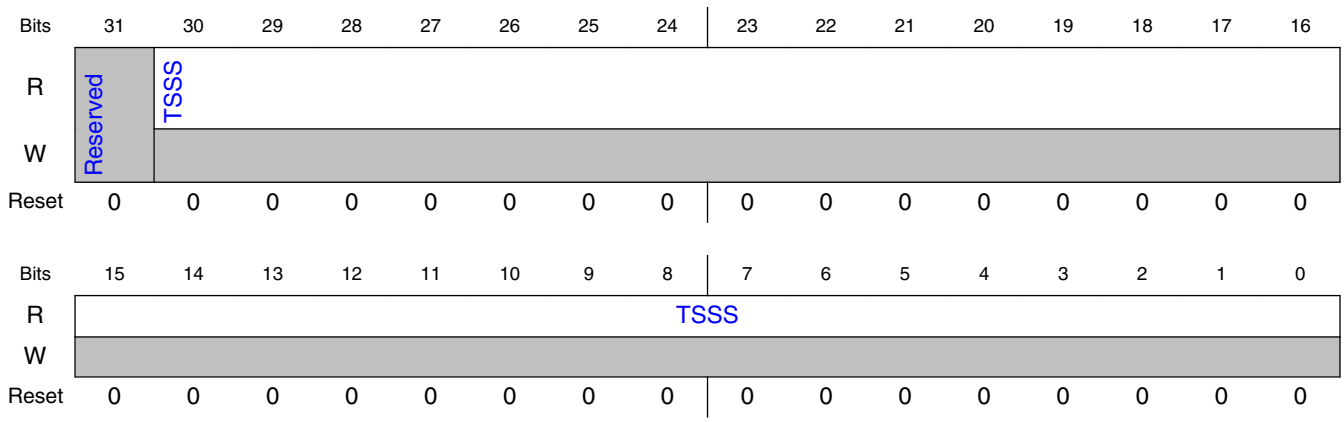
61.7.1.330.1 Offset

Register	Offset
MAC_SYSTEM_TIME_NANOSECONDS	B0Ch

61.7.1.330.2 Function

The System Time Nanoseconds register, along with System Time Seconds register, indicates the current value of the system time maintained by the MAC.

61.7.1.330.3 Diagram



61.7.1.330.4 Fields

Field	Function
31 —	Reserved
30-0 TSSS	Timestamp Sub Seconds The value in this field has the sub-second representation of time, with an accuracy of 0. Timestamp Sub Seconds The value in this field has the sub-second representation of time, with an accuracy of 0.46 ns. When Bit 9 is set in TIMESTAMP_CONTROL, each bit represents 1 ns. The maximum value is 0x3B9A_C9FF after which it rolls-over to zero.

61.7.1.331 System Time Seconds Update (MAC_SYSTEM_TIME_SECONDS_UPDATE)

61.7.1.331.1 Offset

Register	Offset
MAC_SYSTEM_TIME_SECONDS_UPDATE	B10h

61.7.1.331.2 Function

The System Time Seconds Update register, along with the System Time Nanoseconds Update register, initializes or updates the system time maintained by the MAC. You must write both registers before setting the TSINIT or TSUPDT bits in DWC_eqos_top_map/EQOS_MAC/MAC_TIMESTAMP_CONTROL.

61.7.1.331.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R W	TSS															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

61.7.1.331.4 Fields

Field	Function
31-0 TSS	Timestamp Seconds The value in this field is the seconds part of the update. Timestamp Seconds The value in this field is the seconds part of the update. When ADDSUB is reset, this field must be programmed with the seconds part of the update value. When ADDSUB is set, this field must be programmed with the complement of the seconds part of the update value. For example, if 2.000000001 seconds need to be subtracted from the system time, the TSS field in the MAC_Timestamp_Seconds_Update register must be 0xFFFF_FFFE (that is, 2^32 - 2).

61.7.1.332 System Time Nanoseconds Update (MAC_SYSTEM_TIME_NANOSECONDS_UPDATE)

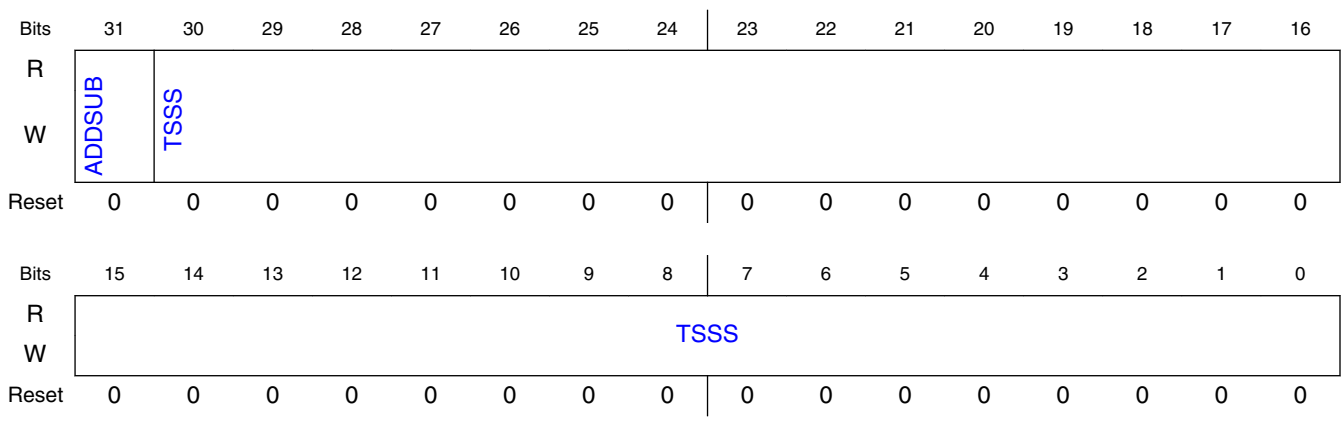
61.7.1.332.1 Offset

Register	Offset
MAC_SYSTEM_TIME_NANOSECONDS_UPDATE	B14h

61.7.1.332.2 Function

MAC System Time Nanoseconds Update register.

61.7.1.332.3 Diagram



61.7.1.332.4 Fields

Field	Function
31 ADDSUB	Add or Subtract Time When this bit is set, the time value is subtracted with the contents of the update register. Add or Subtract Time When this bit is set, the time value is subtracted with the contents of the update register. When this bit is reset, the time value is added with the contents of the update register. 0b - Add time 1b - Subtract time
30-0	Timestamp Sub Seconds The value in this field is the sub-seconds part of the update.

Field	Function
TSSS	Timestamp Sub Seconds The value in this field is the sub-seconds part of the update. When ADDSUB is reset, this field must be programmed with the sub-seconds part of the update value, with an accuracy based on the TSCTRLSSR bit of the TIMESTAMP_CONTROL register. When ADDSUB is set, this field must be programmed with the complement of the sub-seconds part of the update value as described below. When TSCTRLSSR bit in MAC_TIMESTAMP_CONTROL is set, the programmed value must be 10^9 - <sub-second value>. When TSCTRLSSR bit in MAC_TIMESTAMP_CONTROL is reset, the programmed value must be 2^31 - <sub-second_value>. When the TSCTRLSSR bit is reset in the TMAC_IMESTAMP_CONTROL register, each bit represents an accuracy of 0.46 ns. When the TSCTRLSSR bit is set in the MAC_TIMESTAMP_CONTROL register, each bit represents 1 ns and the programmed value should not exceed 0x3B9A_C9FF. For example, if 2.000000001 seconds need to be subtracted from the system time, then the TSSS field in the MAC_Timestamp_Nanoseconds_Update register must be 0x7FFF_FFFF (that is, 2^31 - 1), when TSCTRLSSR bit in MAC_TIMESTAMP_CONTROL is reset and 0x3B9A_C9FF (that is, 10^9 - 1), when TSCTRLSSR bit in MAC_TIMESTAMP_CONTROL is set.

61.7.1.333 Timestamp Addend (MAC_TIMESTAMP_ADDEND)

61.7.1.333.1 Offset

Register	Offset
MAC_TIMESTAMP_ADDEND	B18h

61.7.1.333.2 Function

Timestamp Addend register. This register value is used only when the system time is configured for Fine Update mode (TSCFUPDT bit in the MAC_TIMESTAMP_CONTROL register). The content of this register is added to a 32-bit accumulator in every clock cycle (of clk_ptp_ref_i) and the system time is updated whenever the accumulator overflows.

61.7.1.333.3 Diagram

61.7.1.334.4 Fields

Field	Function
31-16 —	Reserved
15-0 TSHWR	Timestamp Higher Word Register This field contains the most-significant 16-bits of timestamp seconds value. Timestamp Higher Word Register This field contains the most-significant 16-bits of timestamp seconds value. This register is optional. You can add this register by selecting the Add IEEE 1588 Higher Word Register option. This register is directly written to initialize the value and it is incremented when there is an overflow from 32-bits of the System Time Seconds register. Access restriction applies. Updated based on the event. Setting 1 sets. Setting 0 clears.

61.7.1.335 Timestamp Status (MAC_TIMESTAMP_STATUS)

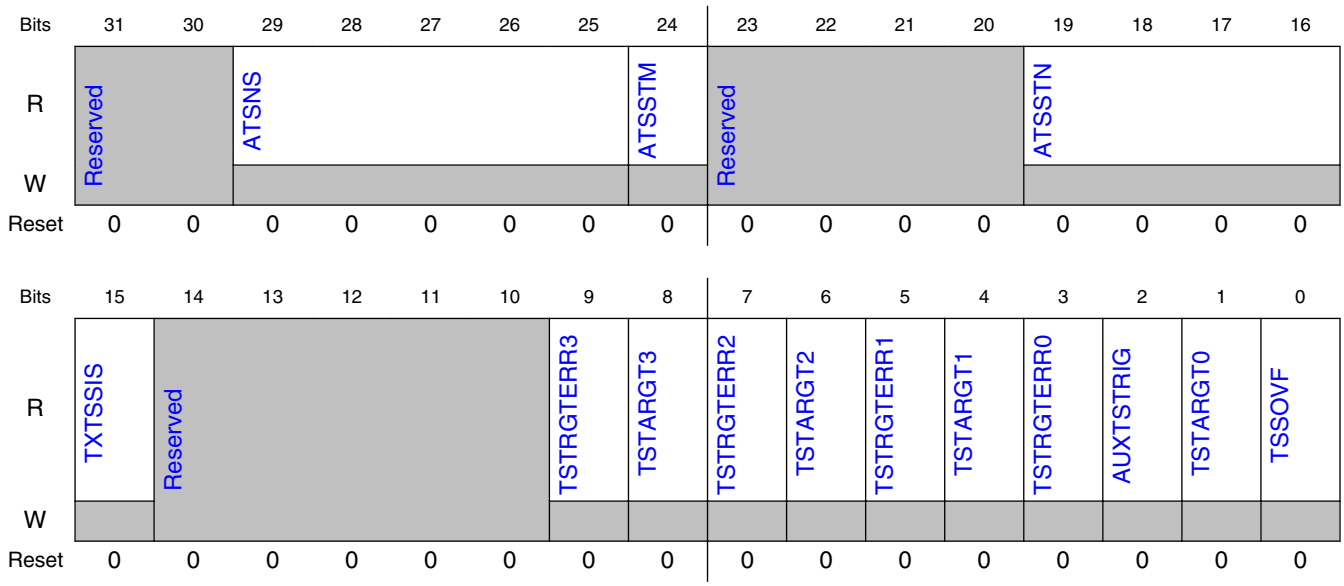
61.7.1.335.1 Offset

Register	Offset
MAC_TIMESTAMP_STATUS	B20h

61.7.1.335.2 Function

Timestamp Status register. All bits except Bits[27:25] gets cleared when the application reads this register.

61.7.1.335.3 Diagram



61.7.1.335.4 Fields

Field	Function
31-30 —	Reserved
29-25 ATSNS	Number of Auxiliary Timestamp Snapshots This field indicates the number of Snapshots available in the FIFO. Number of Auxiliary Timestamp Snapshots This field indicates the number of Snapshots available in the FIFO. A value equal to the selected depth of FIFO (4, 8, or 16) indicates that the Auxiliary Snapshot FIFO is full. These bits are cleared (to 00000) when the Auxiliary snapshot FIFO clear bit is set. This bit is valid only if the Add IEEE 1588 Auxiliary Snapshot option is selected.
24 ATSSTM	Auxiliary Timestamp Snapshot Trigger Missed This bit is set when the Auxiliary timestamp snapshot FIFO is full and external trigger was set. Auxiliary Timestamp Snapshot Trigger Missed This bit is set when the Auxiliary timestamp snapshot FIFO is full and external trigger was set. This indicates that the latest snapshot is not stored in the FIFO. This bit is valid only if the Add IEEE 1588 Auxiliary Snapshot option is selected. 0b - Auxiliary Timestamp Snapshot Trigger Missed status not detected 1b - Auxiliary Timestamp Snapshot Trigger Missed status detected
23-20 —	Reserved
19-16 ATSSTN	Auxiliary Timestamp Snapshot Trigger Identifier These bits identify the Auxiliary trigger inputs for which the timestamp available in the Auxiliary Snapshot Register is applicable. Auxiliary Timestamp Snapshot Trigger Identifier

Table continues on the next page...

Field	Function
	These bits identify the Auxiliary trigger inputs for which the timestamp available in the Auxiliary Snapshot Register is applicable. When more than one bit is set at the same time, it means that corresponding auxiliary triggers were sampled at the same clock. These bits are applicable only if the number of Auxiliary snapshots is more than one. One bit is assigned for each trigger as shown in the following list: - Bit 16: Auxiliary trigger 0 - Bit 17: Auxiliary trigger 1 - Bit 18: Auxiliary trigger 2 - Bit 19: Auxiliary trigger 3 The software can read this register to find the triggers that are set when the timestamp is taken. Access restriction applies. Clears on read. Self-set to 1 on internal event.
15 TXTSSIS	Tx Timestamp Status Interrupt Status In non-EQOS_CORE configurations when drop transmit status is enabled in MTL, this bit is set when the captured transmit timestamp is updated in the MAC_TX_TIMESTAMP_STATUS_NANOSECONDS and MAC_TX_TIMESTAMP_STATUS_SECONDS registers. Tx Timestamp Status Interrupt Status In non-EQOS_CORE configurations when drop transmit status is enabled in MTL, this bit is set when the captured transmit timestamp is updated in the MAC_TX_TIMESTAMP_STATUS_NANOSECONDS and TMAC_X_TIMESTAMP_STATUS_SECONDS registers. When PTP offload feature is enabled, this bit is set when the captured transmit timestamp is updated in the MAC_TX_TIMESTAMP_STATUS_NANOSECONDS and MAC_TX_TIMESTAMP_STATUS_SECONDS registers, for PTO generated Delay Request and Pdelay request packets. This bit is cleared when the MAC_TX_TIMESTAMP_STATUS_SECONDS register is read (or write to MAC_TX_TIMESTAMP_STATUS_SECONDS register when RCWE bit of CSR_SW_CTRL register is set). 0b - Tx Timestamp Status Interrupt status not detected 1b - Tx Timestamp Status Interrupt status detected
14-10 —	Reserved
9 TSTRGTERR3	Timestamp Target Time Error This bit is set when the latest target time programmed in the MAC_PPS3_TARGET_TIME_SECONDS and MAC_PPS3_TARGET_TIME_NANOSECONDS registers elapses. Timestamp Target Time Error This bit is set when the latest target time programmed in the MAC_PPS3_TARGET_TIME_SECONDS and MAC_PPS3_TARGET_TIME_NANOSECONDS registers elapses. This bit is cleared when the application reads this bit. Access restriction applies. Clears on read (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_CTRL register is set). Self-set to 1 on internal event. 0b - Timestamp Target Time Error status not detected 1b - Timestamp Target Time Error status detected
8 TSTARGT3	Timestamp Target Time Reached for Target Time PPS3 When this bit is set, it indicates that the value of system time is greater than or equal to the value specified in the MAC_PPS3_TARGET_TIME_SECONDS and MAC_PPS3_TARGET_TIME_NANOSECONDS registers. Timestamp Target Time Reached for Target Time PPS3 When this bit is set, it indicates that the value of system time is greater than or equal to the value specified in the MAC_PPS3_TARGET_TIME_SECONDS and MAC_PPS3_TARGET_TIME_NANOSECONDS registers.

Table continues on the next page...

Field	Function
	Access restriction applies. Clears on read (or this bit is written to 1 when RCWE bit in CSR_SW_CTRL register is set). Self-set to 1 on internal event. 0b - Timestamp Target Time Reached for Target Time PPS3 status not detected 1b - Timestamp Target Time Reached for Target Time PPS3 status detected
7 TSTRGTERR2	Timestamp Target Time Error This bit is set when the latest target time programmed in the MAC_PPS2_TARGET_TIME_SECONDS and MAC_PPS2_TARGET_TIME_NANOSECONDS registers elapses. Timestamp Target Time Error This bit is set when the latest target time programmed in the MAC_PPS2_TARGET_TIME_SECONDS and MAC_PPS2_TARGET_TIME_NANOSECONDS registers elapses. This bit is cleared when the application reads this bit. Access restriction applies. Clears on read (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_CTRL register is set). Self-set to 1 on internal event. 0b - Timestamp Target Time Error status not detected 1b - Timestamp Target Time Error status detected
6 TSTARGT2	Timestamp Target Time Reached for Target Time PPS2 When set, this bit indicates that the value of system time is greater than or equal to the value specified in the MAC_PPS2_TARGET_TIME_SECONDS and MAC_PPS2_TARGET_TIME_NANOSECONDS registers. Timestamp Target Time Reached for Target Time PPS2 When set, this bit indicates that the value of system time is greater than or equal to the value specified in the MAC_PPS2_TARGET_TIME_SECONDS and MAC_PPS2_TARGET_TIME_NANOSECONDS registers. Access restriction applies. Clears on read (or this bit is written to 1 when RCWE bit in CSR_SW_CTRL register is set). Self-set to 1 on internal event. 0b - Timestamp Target Time Reached for Target Time PPS2 status not detected 1b - Timestamp Target Time Reached for Target Time PPS2 status detected
5 TSTRGTERR1	Timestamp Target Time Error This bit is set when the latest target time programmed in the MAC_PPS1_TARGET_TIME_SECONDS and MAC_PPS1_TARGET_TIME_NANOSECONDS registers elapses. Timestamp Target Time Error This bit is set when the latest target time programmed in the MAC_PPS1_TARGET_TIME_SECONDS and MAC_PPS1_TARGET_TIME_NANOSECONDS registers elapses. This bit is cleared when the application reads this bit. Access restriction applies. Clears on read (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_CTRL register is set). Self-set to 1 on internal event. 0b - Timestamp Target Time Error status not detected 1b - Timestamp Target Time Error status detected
4 TSTARGT1	Timestamp Target Time Reached for Target Time PPS1 When set, this bit indicates that the value of system time is greater than or equal to the value specified in the MAC_PPS1_TARGET_TIME_SECONDS and MAC_PPS1_TARGET_TIME_NANOSECONDS registers. Timestamp Target Time Reached for Target Time PPS1 When set, this bit indicates that the value of system time is greater than or equal to the value specified in the MAC_PPS1_TARGET_TIME_SECONDS and MAC_PPS1_TARGET_TIME_NANOSECONDS registers. Access restriction applies. Clears on read (or this bit is written to 1 when RCWE bit in CSR_SW_CTRL register is set). Self-set to 1 on internal event. 0b - Timestamp Target Time Reached for Target Time PPS1 status not detected

Table continues on the next page...

Field	Function
	1b - Timestamp Target Time Reached for Target Time PPS1 status detected
3 TSTRGTERR0	Timestamp Target Time Error This bit is set when the latest target time programmed in the MAC_PPS0_Target_Time_Seconds and MAC_PPS0_Target_Time_Nanoseconds registers elapses. Timestamp Target Time Error This bit is set when the latest target time programmed in the MAC_PPS0_Target_Time_Seconds and MAC_PPS0_TARGET_TIME_NANOSECONDS registers elapses. This bit is cleared when the application reads this bit. Access restriction applies. Clears on read (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_CTRL register is set). Self-set to 1 on internal event. 0b - Timestamp Target Time Error status not detected 1b - Timestamp Target Time Error status detected
2 AUXTSTRIG	Auxiliary Timestamp Trigger Snapshot This bit is set high when the auxiliary snapshot is written to the FIFO. Auxiliary Timestamp Trigger Snapshot This bit is set high when the auxiliary snapshot is written to the FIFO. This bit is valid only if the Add IEEE 1588 Auxiliary Snapshot option is selected. Access restriction applies. Clears on read (or this bit is written to 1 when RCWE bit in CSR_SW_CTRL register is set). Self-set to 1 on internal event. 0b - Auxiliary Timestamp Trigger Snapshot status not detected 1b - Auxiliary Timestamp Trigger Snapshot status detected
1 TSTARGT0	Timestamp Target Time Reached When set, this bit indicates that the value of system time is greater than or equal to the value specified in the MAC_PPS0_Target_Time_Seconds and MAC_PPS0_Target_Time_Nanoseconds registers. Timestamp Target Time Reached When set, this bit indicates that the value of system time is greater than or equal to the value specified in the MAC_PPS0_TARGET_TIME_SECONDS and MAC_PPS0_TARGET_TIME_NANOSECONDS registers. Access restriction applies. Clears on read (or this bit is written to 1 when RCWE bit in CSR_SW_CTRL register is set). Self-set to 1 on internal event. 0b - Timestamp Target Time Reached status not detected 1b - Timestamp Target Time Reached status detected
0 TSSOVF	Timestamp Seconds Overflow When this bit is set, it indicates that the seconds value of the timestamp (when supporting version 2 format) has overflowed beyond 32'hFFFF_FFFF. Timestamp Seconds Overflow When this bit is set, it indicates that the seconds value of the timestamp (when supporting version 2 format) has overflowed beyond 32'hFFFF_FFFF. Access restriction applies. Clears on read (or this bit is written to 1 when RCWE bit in CSR_SW_CTRL register is set). Self-set to 1 on internal event. 0b - Timestamp Seconds Overflow status not detected 1b - Timestamp Seconds Overflow status detected

61.7.1.336 Transmit Timestamp Status Nanoseconds (MAC_TX_TIMESTAMP_STATUS_NANOSECONDS)

61.7.1.336.1 Offset

Register	Offset
MAC_TX_TIMESTAMP_STATUS_NANOSECONDS	B30h

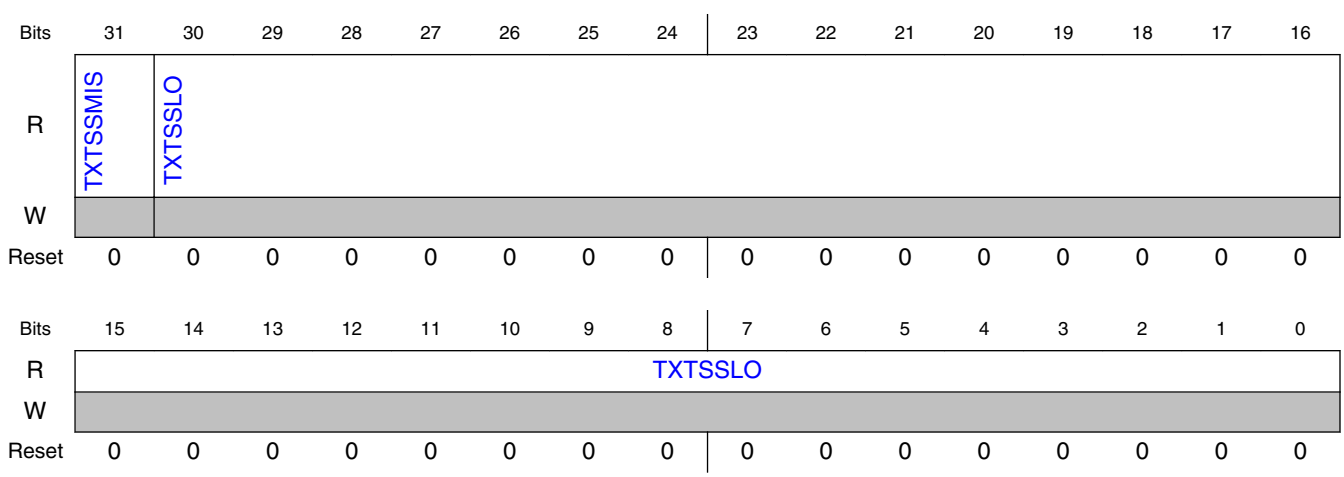
61.7.1.336.2 Function

This register contains the nanosecond part of timestamp captured for Transmit packets when Tx status is disabled.

The MAC_TX_TIMESTAMP_STATUS_NANOSECONDS register, along with MAC_TX_TIMESTAMP_STATUS_SECONDS, gives the 64-bit timestamp captured for the PTP packet successfully transmitted by the MAC. This value is considered to be read by the application when the last byte of MAC_TX_TIMESTAMP_STATUS_NANOSECONDS is read. In the little-endian mode, this means when bits[31:24] are read; in big-endian mode, bits[7:0] are read.

If the application does not read these registers and timestamp of another packet is captured, then either the current timestamp is lost (overwritten) or the new timestamp is lost (dropped), depending on the setting of the TXTSSTSM bit of the MAC_TIMESTAMP_CONTROL register. The status bit TXTSC bit [15] in MAC_TIMESTAMP_STATUS register is set whenever the MAC transmitter captures the timestamp.

61.7.1.336.3 Diagram



61.7.1.336.4 Fields

Field	Function
31 TXTSSMIS	Transmit Timestamp Status Missed When this bit is set, it indicates one of the following: - The timestamp of the current packet is ignored if TXTSSTSM bit of the TIMESTAMP_CONTROL register is reset - The timestamp of the previous packet is overwritten with timestamp of the current packet if TXTSSTSM bit of the MAC_TIMESTAMP_CONTROL register is set. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0b - Transmit Timestamp Status Missed status not detected 1b - Transmit Timestamp Status Missed status detected
30-0 TXTSSLO	Transmit Timestamp Status Low This field contains the 31 bits of the Nanoseconds field of the Transmit packet's captured timestamp.

61.7.1.337 Transmit Timestamp Status Seconds (MAC_TX_TIMESTAMP_STATUS_SECONDS)

61.7.1.337.1 Offset

Register	Offset
MAC_TX_TIMESTAMP_STATUS_SECONDS	B34h

61.7.1.337.2 Function

The register contains the higher 32 bits of the timestamp (in seconds) captured when a PTP packet is transmitted.

61.7.1.337.3 Diagram

61.7.1.337.4 Fields

Field	Function
31-0 TXTSSHI	Transmit Timestamp Status High This field contains the lower 32 bits of the Seconds field of Transmit packet's captured timestamp.

61.7.1.338 Auxiliary Timestamp Control (MAC_AUXILIARY_CONTROL)

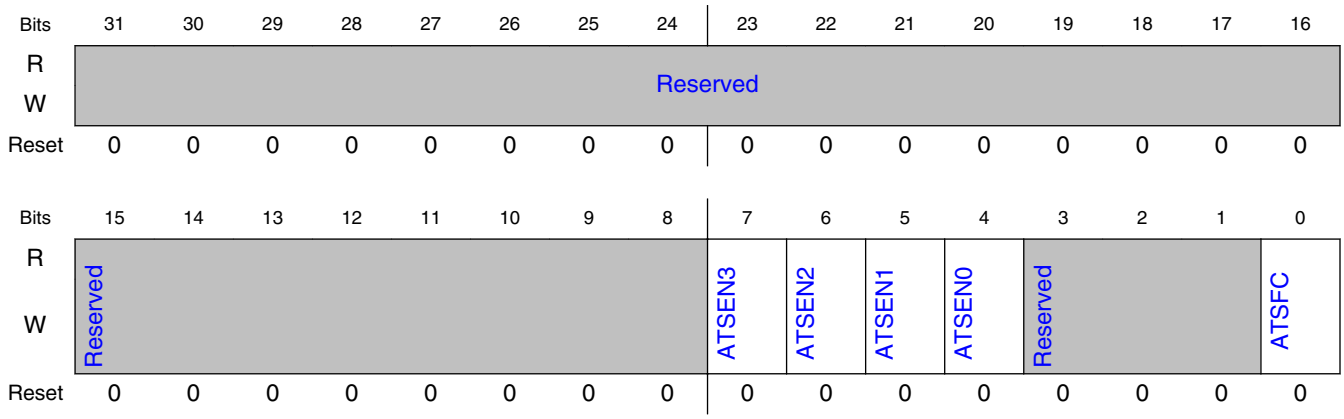
61.7.1.338.1 Offset

Register	Offset
MAC_AUXILIARY_CONTROL	B40h

61.7.1.338.2 Function

The Auxiliary Timestamp Control register controls the Auxiliary Timestamp snapshot.

61.7.1.338.3 Diagram



61.7.1.338.4 Fields

Field	Function
31-8 —	Reserved
7 ATSEN3	Auxiliary Snapshot 3 Enable This bit controls the capturing of Auxiliary Snapshot Trigger 3. When this bit is set, the auxiliary snapshot of the event on ptp_aux_trig_i[3] input is enabled. When this bit is reset, the events on this input are ignored. 0b - Auxiliary Snapshot $i is disabled 1b - Auxiliary Snapshot $i is enabled
6 ATSEN2	Auxiliary Snapshot 2 Enable This bit controls the capturing of Auxiliary Snapshot Trigger 2. When this bit is set, the auxiliary snapshot of the event on ptp_aux_trig_i[2] input is enabled. When this bit is reset, the events on this input are ignored. 0b - Auxiliary Snapshot $i is disabled 1b - Auxiliary Snapshot $i is enabled
5 ATSEN1	Auxiliary Snapshot 1 Enable This bit controls the capturing of Auxiliary Snapshot Trigger 1. When this bit is set, the auxiliary snapshot of the event on ptp_aux_trig_i[1] input is enabled. When this bit is reset, the events on this input are ignored. 0b - Auxiliary Snapshot $i is disabled 1b - Auxiliary Snapshot $i is enabled
4 ATSEN0	Auxiliary Snapshot 0 Enable This bit controls the capturing of Auxiliary Snapshot Trigger 0. When this bit is set, the auxiliary snapshot of the event on ptp_aux_trig_i[0] input is enabled. When this bit is reset, the events on this input are ignored. 0b - Auxiliary Snapshot $i is disabled 1b - Auxiliary Snapshot $i is enabled
3-1 —	Reserved

Table continues on the next page...

Field	Function
0 ATSFC	Auxiliary Snapshot FIFO Clear When set, this bit resets the pointers of the Auxiliary Snapshot FIFO. This bit is cleared when the pointers are reset and the FIFO is empty. When this bit is high, the auxiliary snapshots are stored in the FIFO. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0b - Auxiliary Snapshot FIFO Clear is disabled 1b - Auxiliary Snapshot FIFO Clear is enabled

61.7.1.339 Auxiliary Timestamp Nanoseconds (MAC_AUXILIARY_TIMESTAMP_NANOSECONDS)

61.7.1.339.1 Offset

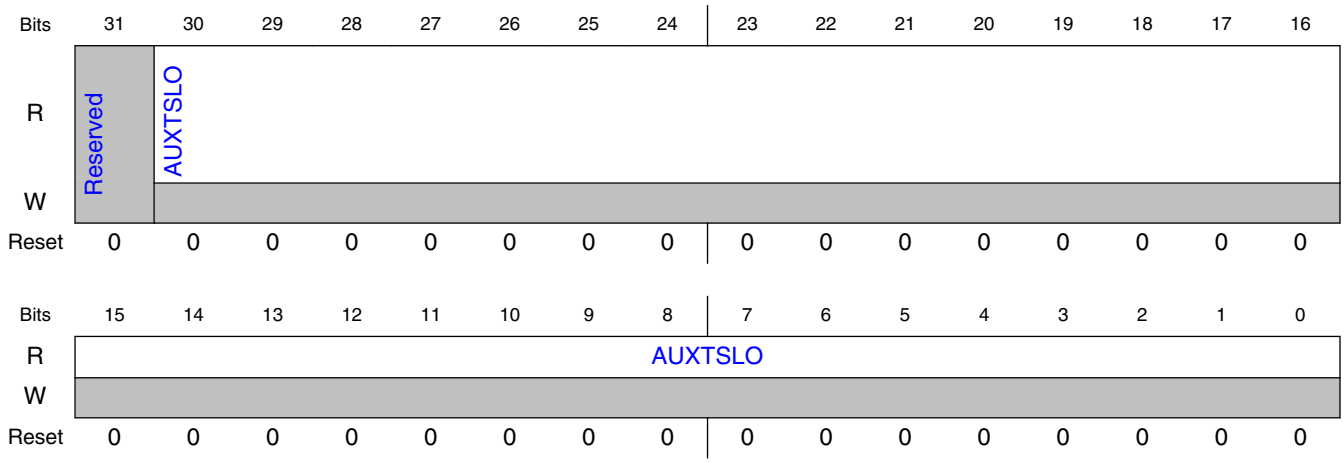
Register	Offset
MAC_AUXILIARY_TIMESTAMP_NANOSECONDS	B48h

61.7.1.339.2 Function

The Auxiliary Timestamp Nanoseconds register, along with MAC_Auxiliary_Timestamp_Seconds, gives the 64-bit timestamp stored as auxiliary snapshot. These two registers form the read port of a 64-bit wide FIFO with a depth of 4, 8, or 16 as selected while configuring the core.

You can store multiple snapshots in this FIFO. Bits[29:25] in MAC_TIMESTAMP_STATUS indicate the fill-level of the FIFO. The top of the FIFO is removed only when the last byte of MAC_AUXILIARY_TIMESTAMP_SECONDS register is read. In the little-endian mode, this means when Bits[31:24] are read and in big-endian mode, Bits[7:0] are read.

61.7.1.339.3 Diagram



61.7.1.339.4 Fields

Field	Function
31 —	Reserved
30-0 AUXTSLO	Auxiliary Timestamp Contains the lower 31 bits (nanoseconds field) of the auxiliary timestamp.

61.7.1.340 Auxiliary Timestamp Seconds (MAC_AUXILIARY_TIMESTAMP_SECONDS)

61.7.1.340.1 Offset

Register	Offset
MAC_AUXILIARY_TIMESTAMP_SECONDS	B4Ch

61.7.1.340.2 Function

The Auxiliary Timestamp - Seconds register contains the lower 32 bits of the Seconds field of the auxiliary timestamp register.

61.7.1.340.3 Diagram

R W	OSTIAC															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

61.7.1.341.4 Fields

Field	Function
31-0 OSTIAC	One-Step Timestamp Ingress Asymmetry Correction This field contains the ingress path asymmetry value to be added to correctionField of Pdelay_Resp PTP packet. The programmed value should be in units of nanoseconds and multiplied by 2^16. For example, 2.5 ns is represented as 0x00028000. The value can also be negative, which is represented in 2's complement form with bit 31 representing the sign bit.

61.7.1.342 Timestamp Egress Asymmetry Correction (MAC_TIMESTAMP_EGRESS_ASYM_CORR)

61.7.1.342.1 Offset

Register	Offset
MAC_TIMESTAMP_EGRESS_ASYM_CORR	B54h

61.7.1.342.2 Function

The MAC Timestamp Egress Asymmetry Correction register contains the Egress Asymmetry Correction value to be used while updating the correction field in PDelay_Req PTP messages.

61.7.1.342.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R W	OSTEAC															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

61.7.1.342.4 Fields

Field	Function
31-0 OSTEAC	One-Step Timestamp Egress Asymmetry Correction This field contains the egress path asymmetry value to be subtracted from correctionField of Pdelay_Resp PTP packet. The programmed value must be the negated value in units of nanoseconds multiplied by 2^16. For example, if the required correction is +2.5 ns, the programmed value must be 0xFFFD_8000, which is the 2's complement of 0x0002_8000(2.5 * 216). Similarly, if the required correction is -3.3 ns, the programmed value is 0x0003_4CCC (3.3 * 216).

61.7.1.343 Timestamp Ingress Correction Nanosecond (MAC_TIMESTAMP_INGRESS_CORR_NANOSECOND)

61.7.1.343.1 Offset

Register	Offset
MAC_TIMESTAMP_INGRESS_CORR_NANOSECOND	B58h

61.7.1.343.2 Function

This register contains the correction value in nanoseconds to be used with the captured timestamp value in the ingress path.

61.7.1.343.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Function
28 —	Reserved
27-24 PPSCMD3	Flexible PPS3 Output Control This field controls the flexible PPS3 output (ptp_pps_o[3]) signal. Flexible PPS3 Output Control This field controls the flexible PPS3 output (ptp_pps_o[3]) signal. This field is similar to the PPSCMD0[2:0] field. If MCGREN3 is set, then PPSCMD3 indicated by these 4 bits [27:24] are taken as Presentation Time Control bits for media clock generation and recovery for comparator instance 3. This field is similar to the PPSCMD0 Presentation Time Control bits. If MCGREN3 is not set then only 3 bits from [26:24] is used as PPSCMD3 and the 4th bit is to be set as 0. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.
23 MCGREN2	MCGR Mode Enable for PPS2 Output This field enables the 2nd PPS instance to operate in PPS or MCGR mode. MCGR Mode Enable for PPS2 Output This field enables the 2nd PPS instance to operate in PPS or MCGR mode. When set it operates in MCGR mode and on reset it operates in PPS mode. 0b - 2nd PPS instance is disabled to operate in PPS or MCGR mode 1b - 2nd PPS instance is enabled to operate in PPS or MCGR mode
22-21 TRGTMODSEL2	Target Time Register Mode for PPS2 Output This field indicates the Target Time registers (MAC_PPS2_TARGET_TIME_SECONDS and MAC_PPS2_TARGET_TIME_NANOSECONDS) mode for PPS2 output signal. 00b - Target Time registers are programmed only for generating the interrupt event. The Flexible PPS function must not be enabled in this mode, otherwise spurious transitions may be observed on the corresponding ptp_pps_o output port 01b - Reserved 10b - Target Time registers are programmed for generating the interrupt event and starting or stopping the PPS0 output signal generation 11b - Target Time registers are programmed only for starting or stopping the PPS0 output signal generation. No interrupt is asserted
20 —	Reserved
19-16 PPSCMD2	Flexible PPS2 Output Control This field controls the flexible PPS2 output (ptp_pps_o[2]) signal. Flexible PPS2 Output Control This field controls the flexible PPS2 output (ptp_pps_o[2]) signal. This field is similar to the PPSCMD0 field. If MCGREN2 is set, then PPSCMD2 indicated by these 4 bits [19:16] are taken as Presentation Time Control bits for media clock generation and recovery for comparator instance 2. This field is similar to the PPSCMD0 Presentation Time Control bits. If MCGREN2 is not set then only 3 bits from [18:16] is used as PPSCMD2 and the 4th bit is to be set as 0. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.
15 MCGREN1	MCGR Mode Enable for PPS1 Output This field enables the 1st PPS instance to operate in PPS or MCGR mode. MCGR Mode Enable for PPS1 Output This field enables the 1st PPS instance to operate in PPS or MCGR mode. When set it operates in MCGR mode and on reset it operates in PPS mode. 0b - 1st PPS instance is disabled to operate in PPS or MCGR mode 1b - 1st PPS instance is enabled to operate in PPS or MCGR mode

Table continues on the next page...

Field	Function
14-13 TRGTMODSEL1	Target Time Register Mode for PPS1 Output This field indicates the Target Time registers (MAC_PPS1_TARGET_TIME_SECONDS and MAC_PPS1_TARGET_TIME_NANOSECONDS) mode for PPS1 output signal. 00b - Target Time registers are programmed only for generating the interrupt event. The Flexible PPS function must not be enabled in this mode, otherwise spurious transitions may be observed on the corresponding ptp_pps_o output port 01b - Reserved 10b - Target Time registers are programmed for generating the interrupt event and starting or stopping the PPS0 output signal generation 11b - Target Time registers are programmed only for starting or stopping the PPS0 output signal generation. No interrupt is asserted
12 —	Reserved
11-8 PPSCMD1	Flexible PPS1 Output Control This field controls the flexible PPS1 output (ptp_pps_o[1]) signal. Flexible PPS1 Output Control This field controls the flexible PPS1 output (ptp_pps_o[1]) signal. This field is similar to the PPSCMD0 field. If MCGREN1 is set, then PPSCMD1 indicated by these 4 bits [11:8] are taken as Presentation Time Control bits for media clock generation and recovery for comparator instance 1. This field is similar to the PPSCMD0 Presentation Time Control bits. If MCGREN1 is not set then only 3 bits from [10:8] is used as PPSCMD1 and the 4th bit is to be set as 0. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.
7 MCGREN0	MCGR Mode Enable for PPS0 Output This field enables the 0th PPS instance to operate in PPS or MCGR mode. MCGR Mode Enable for PPS0 Output This field enables the 0th PPS instance to operate in PPS or MCGR mode. When set it operates in MCGR mode and on reset it operates in PPS mode. 0b - 0th PPS instance is enabled to operate in PPS mode 1b - 0th PPS instance is enabled to operate in MCGR mode
6-5 TRGTMODSEL0	Target Time Register Mode for PPS0 Output This field indicates the Target Time registers (MAC_PPS0_TARGET_TIME_SECONDS and MAC_PPS0_TARGET_TIME_NANOSECONDS) mode for PPS0 output signal: 00b - Target Time registers are programmed only for generating the interrupt event. The Flexible PPS function must not be enabled in this mode, otherwise spurious transitions may be observed on the corresponding ptp_pps_o output port 01b - Reserved 10b - Target Time registers are programmed for generating the interrupt event and starting or stopping the PPS0 output signal generation 11b - Target Time registers are programmed only for starting or stopping the PPS0 output signal generation. No interrupt is asserted
4 PPSEN0	Flexible PPS Output Mode Enable When this bit is set, Bits[3:0] function as PPSCMD. Flexible PPS Output Mode Enable When this bit is set, Bits[3:0] function as PPSCMD. When this bit is reset, Bits[3:0] function as PPSCTRL (Fixed PPS mode). 0b - Flexible PPS Output Mode is disabled 1b - Flexible PPS Output Mode is enabled
3-0 PPSCTRL_PPSCMD	PPS Output Frequency Control This field controls the frequency of the PPS0 output (ptp_pps_o[0]) signal. PPS Output Frequency Control

Field	Function
	This field controls the frequency of the PPS0 output (ptp_pps_o[0]) signal. The default value of PPSCTRL is 0000, and the PPS output is 1 pulse (of width clk_ptp_i) every second. For other values of PPSCTRL, the PPS output becomes a generated clock of following frequencies: - 0001: The binary rollover is 2 Hz, and the digital rollover is 1 Hz. - 0010: The binary rollover is 4 Hz, and the digital rollover is 2 Hz. - 0011: The binary rollover is 8 Hz, and the digital rollover is 4 Hz. - 0100: The binary rollover is 16 Hz, and the digital rollover is 8 Hz. - .. - 1111: The binary rollover is 32.768 KHz and the digital rollover is 16.384 KHz. Note: In the binary rollover mode, the PPS output (ptp_pps_o) has a duty cycle of 50 percent with these frequencies. In the digital rollover mode, the PPS output frequency is an average number. The actual clock is of different frequency that gets synchronized every second. For example: - When PPSCTRL = 0001, the PPS (1 Hz) has a low period of 537 ms and a high period of 463 ms - When PPSCTRL = 0010, the PPS (2 Hz) is a sequence of One clock of 50 percent duty cycle and 537 ms period Second clock of 463 ms period (268 ms low and 195 ms high) - When PPSCTRL = 0011, the PPS (4 Hz) is a sequence of Three clocks of 50 percent duty cycle and 268 ms period Fourth clock of 195 ms period (134 ms low and 61 ms high) This behavior is because of the non-linear toggling of bits in the digital rollover mode in the MAC_System_Time_Nanoseconds register. or Flexible PPS Output (ptp_pps_o[0]) Control Programming these bits with a non-zero value instructs the MAC to initiate an event. When the command is transferred or synchronized to the PTP clock domain, these bits get cleared automatically. The software should ensure that these bits are programmed only when they are 'all-zero'. The following list describes the values of PPSCMD0: - 0000: No Command - 0001: START Single Pulse This command generates single pulse rising at the start point defined in MAC_PPS0_Target_Time_Seconds and MAC_PPS0_Target_Time_Nanoseconds register and of a duration defined in the PPS0 Width Register. - 0010: START Pulse Train This command generates the train of pulses rising at the start point defined in the Target Time Registers and of a duration defined in the PPS0 Width Register and repeated at interval defined in the PPS Interval Register. By default, the PPS pulse train is free-running unless stopped by the 'Stop Pulse train at time' or 'Stop Pulse Train immediately' commands. - 0011: Cancel START This command cancels the START Single Pulse and START Pulse Train commands if the system time has not crossed the programmed start time. - 0100: STOP Pulse train at time

Field	Function
	This command stops the train of pulses initiated by the START Pulse Train command (PPSCMD = 0010) after the time programmed in the Target Time registers elapses. - 0101: STOP Pulse Train immediately This command immediately stops the train of pulses initiated by the START Pulse Train command (PPSCMD = 0010). - 110: Cancel STOP Pulse train This command cancels the STOP pulse train at time command if the programmed stop time has not elapsed. The PPS pulse train becomes free-running on the successful execution of this command. - 0111-1111: Reserved or Presentation Time Control If MCGREN0 is set then these bits are treated as Presentation time control bits. The following list describes the values of PPSCMD0: - 0000: No Operation related to MCGR will be carried out. If set to this value in the mid of clock recovery or generation all the processing inputs will be flushed. - 0001: Capture the Presentation time at rising edge of mcg_pst_trig_i[0] into the MAC_PPS0_Target_Time_Seconds register - 0010: Capture the Presentation time at falling edge of mcg_pst_trig_i[0] into the MAC_PPS0_Target_Time_Seconds register - 0011: Capture the Presentation time at both edges of mcg_pst_trig_i[0] into the MAC_PPS0_Target_Time_Seconds register - 0100-1000: Reserved - 1001: Toggle output on compare - 1010: Pulse output low on compare for one PTP-clock cycle - 1011: Pulse output high on compare for one PTP-clock cycle - 1100-1111: Reserved

61.7.1.350 PPS0 Target Time Seconds (MAC_PPS0_TARGET_TIME_SECONDS)

61.7.1.350.1 Offset

Register	Offset
MAC_PPS0_TARGET_TIME_SECONDS	B80h

61.7.1.350.2 Function

The PPS0 Target Time Seconds register, along with PPS0 Target Time Nanoseconds register, is used to schedule an interrupt event [Bit 1 of MAC_TIMESTAMP_STATUS] when the system time exceeds the value programmed in these registers.

61.7.1.350.3 Diagram

61.7.1.350.4 Fields

Field	Function
31-0 TSTRH0	PPS Target Time Seconds Register This field stores the time in seconds. PPS Target Time Seconds Register This field stores the time in seconds. When the timestamp value matches or exceeds both Target Timestamp registers, the MAC starts or stops the PPS signal output and generates an interrupt (if enabled) based on Target Time mode selected for the corresponding PPS output in the MAC_PPS_CONTROL register.

61.7.1.351 PPS0 Target Time Nanoseconds (MAC_PPS0_TARGET_TIME_NANOSECONDS)

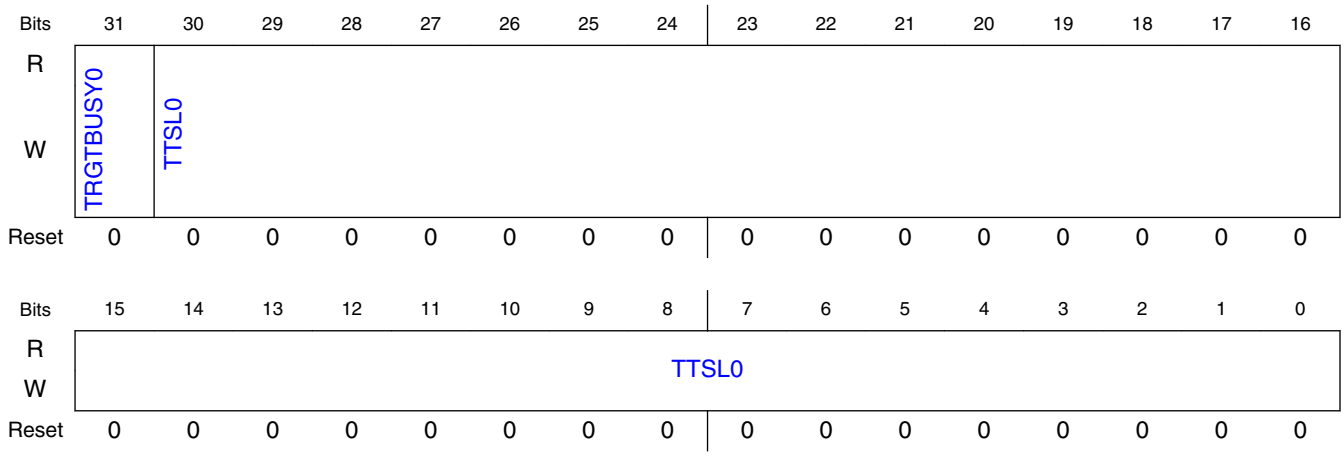
61.7.1.351.1 Offset

Register	Offset
MAC_PPS0_TARGET_TIME_NANOSECONDS	B84h

61.7.1.351.2 Function

PPS0 Target Time Nanoseconds register.

61.7.1.351.3 Diagram



61.7.1.351.4 Fields

Field	Function
31 TRGTBUSY0	PPS Target Time Register Busy The MAC sets this bit when the PPSCMD0 field in the PPS_CONTROL register is programmed to 010 or 011. PPS Target Time Register Busy The MAC sets this bit when the PPSCMD0 field in the MAC_PPS_CONTROL register is programmed to 010 or 011. Programming the PPSCMD0 field to 010 or 011 instructs the MAC to synchronize the Target Time Registers to the PTP clock domain. The MAC clears this bit after synchronizing the Target Time Registers to the PTP clock domain The application must not update the Target Time Registers when this bit is read as 1. Otherwise, the synchronization of the previous programmed time gets corrupted. 0b - PPS Target Time Register Busy status is not detected 1b - PPS Target Time Register Busy is detected
30-0 TTSL0	Target Time Low for PPS Register This register stores the time in (signed) nanoseconds. Target Time Low for PPS Register This register stores the time in (signed) nanoseconds. When the value of the timestamp matches the value in both Target Timestamp registers, the MAC starts or stops the PPS signal output and generates an interrupt (if enabled) based on the TRGTMODSEL0 field (Bits [6:5]) in PPS_CONTROL. When the TSCTRLSSR bit is reset in the MAC_TIMESTAMP_CONTROL register, this value should be (time in ns / 0.465). The actual start or stop time of the PPS signal output may have an error margin up to one unit of sub-second increment value. When the TSCTRLSSR bit is set in the MAC_TIMESTAMP_CONTROL register, this value should not exceed 0x3B9A_C9FF. The actual start or stop time of the PPS signal output may have an error margin up to one unit of sub-second increment value. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.

61.7.1.352 PPS0 Interval (MAC_PPS0_INTERVAL)

61.7.1.352.1 Offset

Register	Offset
MAC_PPS0_INTERVAL	B88h

61.7.1.352.2 Function

The PPS0 Interval register contains the number of units of sub-second increment value between the rising edges of PPS0 signal output (ptp_pps_o[0]).

61.7.1.352.3 Diagram

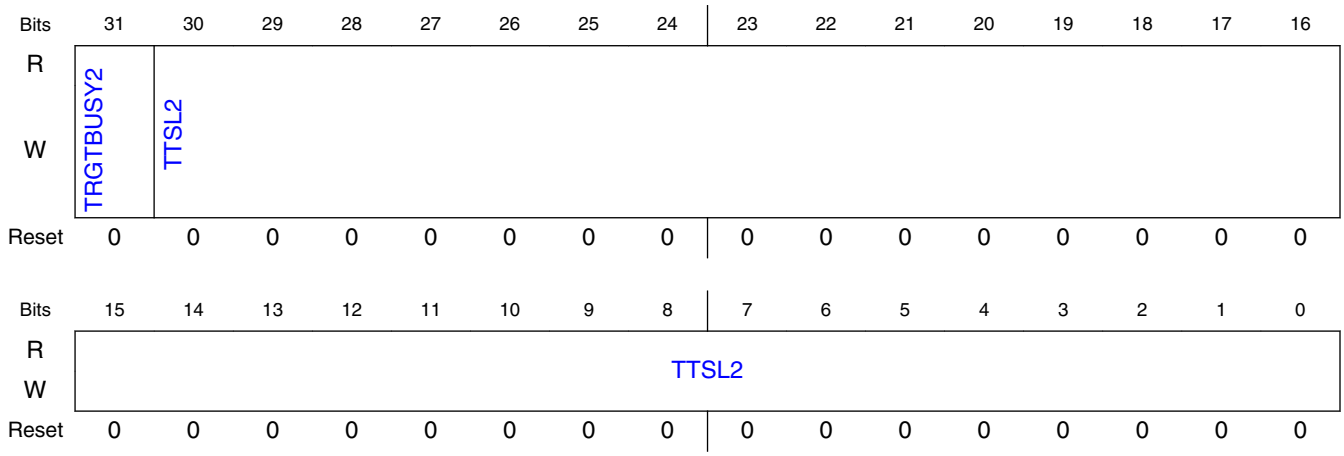
MAC_PPS2_TARGET_TIME_NANOSECONDS	BA4h

61.7.1.359.2 Function

PPS2 Target Time Nanoseconds register.

61.7.1.359.3 Diagram



61.7.1.359.4 Fields

Field	Function
31 TRGTBUSY2	PPS Target Time Register Busy The MAC sets this bit when the PPSCMD0 field in the PPS_CONTROL register is programmed to 010 or 011. PPS Target Time Register Busy The MAC sets this bit when the PPSCMD0 field in the PPS_CONTROL register is programmed to 010 or 011. Programming the PPSCMD0 field to 010 or 011 instructs the MAC to synchronize the Target Time Registers to the PTP clock domain. The MAC clears this bit after synchronizing the Target Time Registers to the PTP clock domain The application must not update the Target Time Registers when this bit is read as 1. Otherwise, the synchronization of the previous programmed time gets corrupted. 0b - PPS Target Time Register Busy status is not detected 1b - PPS Target Time Register Busy is detected
30-0 TTSL2	Target Time Low for PPS Register This register stores the time in (signed) nanoseconds. Target Time Low for PPS Register This register stores the time in (signed) nanoseconds. When the value of the timestamp matches the value in both Target Timestamp registers, the MAC starts or stops the PPS signal output and generates an interrupt (if enabled) based on the TRGTMODSEL0 field (Bits [6:5]) in PPS_CONTROL. When the TSCTRLSSR bit is reset in the TIMESTAMP_CONTROL register, this value should be (time in ns / 0.465). The actual start or stop time of the PPS signal output may have an error margin up to one unit of sub-second increment value. When the TSCTRLSSR bit is set in the TIMESTAMP_CONTROL register, this value should not exceed 0x3B9A_C9FF. The actual start or stop time of the PPS signal output may have an error margin up to one unit of sub-second increment value. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.

61.7.1.360 PPS2 Interval (MAC_PPS2_INTERVAL)

61.7.1.360.1 Offset

Register	Offset
MAC_PPS2_INTERVAL	BA8h

61.7.1.360.2 Function

The PPS2 Interval register contains the number of units of sub-second increment value between the rising edges of PPS2 signal output (ptp_pps_o[2]).

61.7.1.360.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

61.7.1.360.4 Fields

Field	Function
31-0 PPSINT2	PPS Output Signal Interval These bits store the interval between the rising edges of PPS2 signal output. PPS Output Signal Interval These bits store the interval between the rising edges of PPS2 signal output. The interval is stored in terms of number of units of sub-second increment value. You need to program one value less than the required interval. For example, if the PTP reference clock is 50 MHz (period of 20 ns), and desired interval between the rising edges of PPS2 signal output is 100 ns (that is, 5 units of sub-second increment value), you should program value 4 (5-1) in this register.

61.7.1.361 PPS2 Width (MAC_PPS2_WIDTH)

61.7.1.361.1 Offset

Register	Offset
MAC_PPS2_WIDTH	BACh

61.7.1.361.2 Function

The PPS2 Width register contains the number of units of sub-second increment value between the rising and corresponding falling edges of PPS2 signal output (ptp_pps_o[2]).

61.7.1.361.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

61.7.1.361.4 Fields

Field	Function
31-0 PPSWIDTH2	PPS Output Signal Width These bits store the width between the rising edge and corresponding falling edge of PPS0 signal output. PPS Output Signal Width These bits store the width between the rising edge and corresponding falling edge of PPS0 signal output. The width is stored in terms of number of units of sub-second increment value. You need to program one value less than the required interval. For example, if PTP reference clock is 50 MHz (period of 20 ns), and width between the rising and corresponding falling edges of PPS0 signal output is 80 ns (that is, four units of sub-second increment value), you should program value 3 (4-1) in this register. Note: The value programmed in this register must be lesser than the value programmed in MAC_PPS0_Interval.

61.7.1.362 PPS3 Target Time Seconds (MAC_PPS3_TARGET_TIME_SECONDS)

61.7.1.362.1 Offset

Register	Offset
MAC_PPS3_TARGET_TIME_SECONDS	BB0h

61.7.1.362.2 Function

The PPS3 Target Time Seconds register, along with PPS3 Target Time Nanoseconds register, is used to schedule an interrupt event [Bit 1 of TIMESTAMP_STATUS] when the system time exceeds the value programmed in these registers.

61.7.1.362.3 Diagram

61.7.1.365.4 Fields

Field	Function
31-0 PPSWIDTH3	PPS Output Signal Width These bits store the width between the rising edge and corresponding falling edge of PPS0 signal output. PPS Output Signal Width These bits store the width between the rising edge and corresponding falling edge of PPS0 signal output. The width is stored in terms of number of units of sub-second increment value. You need to program one value less than the required interval. For example, if PTP reference clock is 50 MHz (period of 20 ns), and width between the rising and corresponding falling edges of PPS0 signal output is 80 ns (that is, four units of sub-second increment value), you should program value 3 (4-1) in this register. Note: The value programmed in this register must be lesser than the value programmed in MAC_PPS0_Interval.

61.7.1.366 PTP Offload Engine Control (MAC_PTO_CONTROL)

61.7.1.366.1 Offset

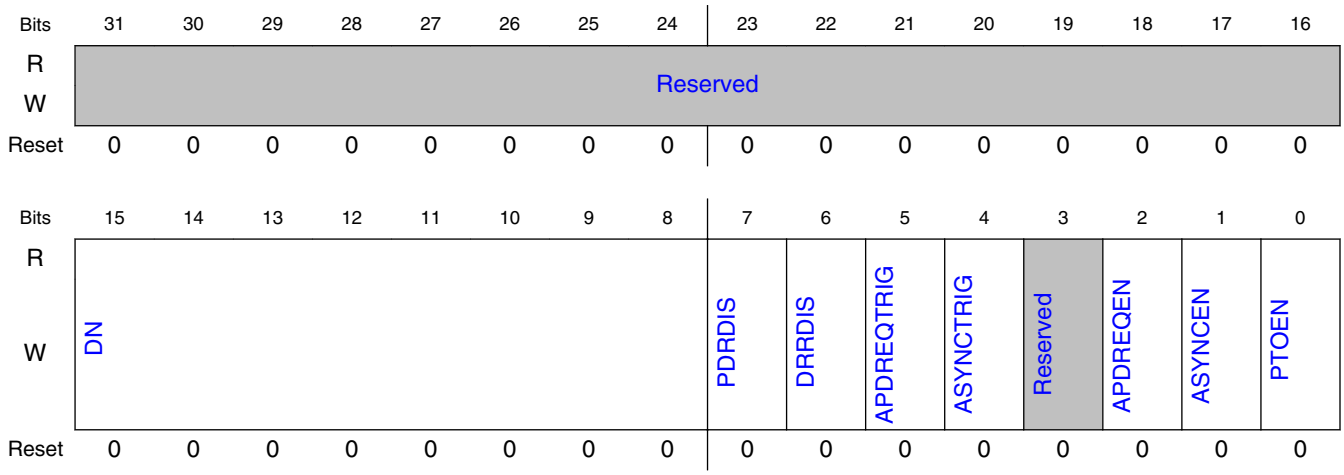
Register	Offset
MAC_PTO_CONTROL	BC0h

61.7.1.366.2 Function

This register controls the PTP Offload Engine operation.

This register controls the PTP Offload Engine operation. This register is available only when the Enable PTP Timestamp Offload feature is selected.

61.7.1.366.3 Diagram



61.7.1.366.4 Fields

Field	Function
31-16 —	Reserved
15-8 DN	Domain Number This field indicates the domain Number in which the PTP node is operating. Domain Number This field indicates the domain Number in which the PTP node is operating.
7 PDRDIS	Disable Peer Delay Response response generation When this bit is set, the Peer Delay Response (Pdelay_Resp) response is not be generated for received Peer Delay Request (Pdelay_Req) request packet, as required by the programmed mode. Disable Peer Delay Response response generation When this bit is set, the Peer Delay Response (Pdelay_Resp) response is not be generated for received Peer Delay Request (Pdelay_Req) request packet, as required by the programmed mode. Note: Setting this bit to 1 affects the normal PTP Offload operation and the time synchronization. So, this bit must be set only if there is problem with Pdelay_Resp generation in Hardware and/or Pdelay_Resp generation is handled by Software. 0b - Peer Delay Response response generation is enabled 1b - Peer Delay Response response generation is disabled
6 DRRDIS	Disable PTO Delay Request/Response response generation When this bit is set, the Delay Request and Delay response is not generated for received SYNC and Delay request packet respectively, as required by the programmed mode. Disable PTO Delay Request/Response response generation When this bit is set, the Delay Request and Delay response is not generated for received SYNC and Delay request packet respectively, as required by the programmed mode. 0b - PTO Delay Request/Response response generation is enabled 1b - PTO Delay Request/Response response generation is disabled
5 APDREQTRIG	Automatic PTP Pdelay_Req message Trigger When this bit is set, one PTP Pdelay_Req message is transmitted.

Table continues on the next page...

Field	Function
	Automatic PTP Pdelay_Req message Trigger When this bit is set, one PTP Pdelay_Req message is transmitted. This bit is automatically cleared after the PTP Pdelay_Req message is transmitted. The application should set the APDREQEN bit for this operation. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0b - Automatic PTP Pdelay_Req message Trigger is disabled 1b - Automatic PTP Pdelay_Req message Trigger is enabled
4 ASYNCTRIG	Automatic PTP SYNC message Trigger When this bit is set, one PTP SYNC message is transmitted. Automatic PTP SYNC message Trigger When this bit is set, one PTP SYNC message is transmitted. This bit is automatically cleared after the PTP SYNC message is transmitted. The application should set the ASYNCEN bit for this operation. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0b - Automatic PTP SYNC message Trigger is disabled 1b - Automatic PTP SYNC message Trigger is enabled
3 —	Reserved
2 APDREQEN	Automatic PTP Pdelay_Req message Enable When this bit is set, PTP Pdelay_Req message is generated periodically based on interval programmed or trigger from application, when the MAC is programmed to be in Peer-to-Peer Transparent mode. 0b - Automatic PTP Pdelay_Req message is disabled 1b - Automatic PTP Pdelay_Req message is enabled
1 ASYNCEN	Automatic PTP SYNC message Enable When this bit is set, PTP SYNC message is generated periodically based on interval programmed or trigger from application, when the MAC is programmed to be in Clock Master mode. 0b - Automatic PTP SYNC message is disabled 1b - Automatic PTP SYNC message is enabled
0 PTOEN	PTP Offload Enable When this bit is set, the PTP Offload feature is enabled. 0b - PTP Offload feature is disabled 1b - PTP Offload feature is enabled

61.7.1.367 Source Port Identity 0 (MAC_SOURCE_PORT_IDENTITY0)

61.7.1.367.1 Offset

Register	Offset
MAC_SOURCE_PORT_IDENTITY0	BC4h

61.7.1.367.2 Function

This register contains Bits[31:0] of the 80-bit Source Port Identity of the PTP node. This register is available only when the Enable PTP Timestamp Offload feature is selected.

61.7.1.367.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

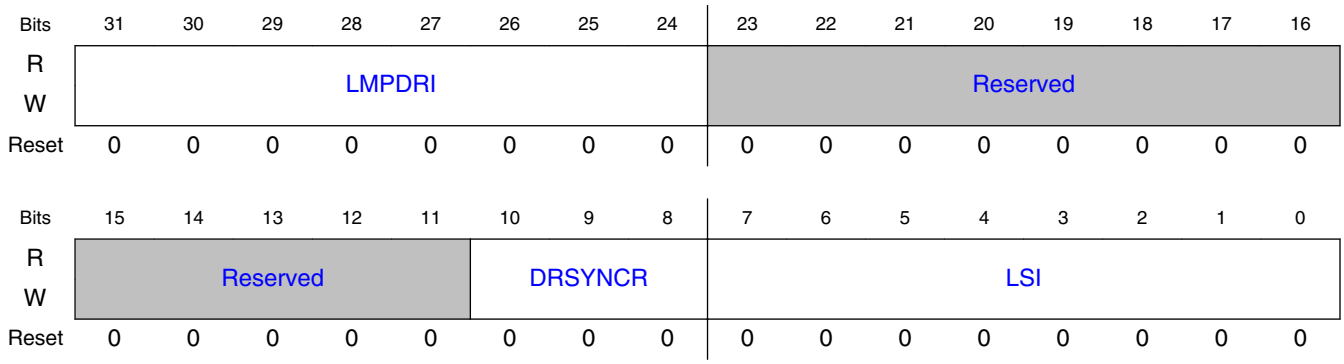
61.7.1.370.1 Offset

Register	Offset
MAC_LOG_MESSAGE_INTERVAL	BD0h

61.7.1.370.2 Function

This register contains the periodic intervals for automatic PTP packet generation. This register is available only when the Enable PTP Timestamp Offload feature is selected.

61.7.1.370.3 Diagram



61.7.1.370.4 Fields

Field	Function
31-24 LMPDRI	Log Min Pdelay_Req Interval This field indicates logMinPdelayReqInterval of PTP node. Log Min Pdelay_Req Interval This field indicates logMinPdelayReqInterval of PTP node. This is used to schedule the periodic Pdelay request packet transmission. Allowed values are -15 to 15.Negative value must be represented in 2's-complement form. For example, if the required value is -1, the value programmed must be 0xFF.
23-11 —	Reserved
10-8 DRSYNCR	Delay_Req to SYNC Ratio In Slave mode, it is used for controlling frequency of Delay_Req messages transmitted. Delay_Req to SYNC Ratio In Slave mode, it is used for controlling frequency of Delay_Req messages transmitted. - 0: DelayReq generated for every received SYNC - 1: DelayReq generated every alternate reception of SYNC - 2: for every 4 SYNC messages - 3: for every 8 SYNC messages - 4: for every 16 SYNC messages - 5: for every 32 SYNC messages - 6-7: Reserved The master sends this information (logMinDelayReqInterval) in the DelayResp PTP messages to the slave. The DWC_ether_qos Receiver processes this value from the received DelayResp messages and updates this field accordingly. In the Slave mode, the host must not write/update this register unless it has to override the received value. In Master mode, the sum of this field and logSyncInterval (LSI) field is provided in the logMinDelayReqInterval field of the generated multicast Delay_Resp PTP message. Access restriction applies. Updated based on the event. Setting 1 sets. Setting 0 clears. 000b - DelayReq generated for every received SYNC 001b - DelayReq generated every alternate reception of SYNC 010b - for every 4 SYNC messages 011b - for every 8 SYNC messages

Table continues on the next page...

Field	Function
	100b - for every 16 SYNC messages 101b - for every 32 SYNC messages 110b - Reserved
7-0 LSI	Log Sync Interval This field indicates the periodicity of the automatically generated SYNC message when the PTP node is Master. Log Sync Interval This field indicates the periodicity of the automatically generated SYNC message when the PTP node is Master. Allowed values are -15 to 15. Negative value must be represented in 2's-complement form. For example, if the required value is -1, the value programmed must be 0xFF.

61.7.1.371 MTL Operation Mode (MTL_OPERATION_MODE)

61.7.1.371.1 Offset

Register	Offset
MTL_OPERATION_MODE	C00h

61.7.1.371.2 Function

The Operation Mode register establishes the Transmit and Receive operating modes and commands.

This bit must not be written to 1 when FIFO Debug Access is not enabled, that is FDBGEN bit is 0. Access restriction applies. Self-cleared. Setting 0 clears. Setting 1 sets. 0b - Reset All Pointers is disabled 1b - Reset All Pointers is enabled
7 —	Reserved
6-5 PKTSTATE	Encoded Packet State This field is used to write the control information to the Tx FIFO or Rx FIFO. Encoded Packet State This field is used to write the control information to the Tx FIFO or Rx FIFO. Tx FIFO: - 00: Packet Data - 01: Control Word - 10: SOP Data - 11: EOP Data Rx FIFO: - 00: Packet Data - 01: Normal Status - 10: Last Status

Table continues on the next page...

Field	Function
	- 11: EOP 00b - Packet Data 01b - Control Word/Normal Status 10b - SOP Data/Last Status 11b - EOP Data/EOP
4 —	Reserved
3-2 BYTEEN	Byte Enables This field indicates the number of data bytes valid in the data register during Write operation. Byte Enables This field indicates the number of data bytes valid in the data register during Write operation. This is valid only when PKTSTATE is 2'b10 (EOP) and Tx FIFO or Rx FIFO is selected. 00b - Byte 0 valid 01b - Byte 0 and Byte 1 are valid 10b - Byte 0, Byte 1, and Byte 2 are valid 11b - All four bytes are valid
1 DBGMOD	Debug Mode Access to FIFO When this bit is set, it indicates that the current access to the FIFO is read, write, and debug access. Debug Mode Access to FIFO When this bit is set, it indicates that the current access to the FIFO is read, write, and debug access. In this mode, the following access types are allowed: - Read and Write access to Tx FIFO, TSO FIFO, and Rx FIFO - Read access is allowed to Tx Status FIFO. When this bit is reset, it indicates that the current access to the FIFO is slave access bypassing the DMA. In this mode, the following access are allowed: - Write access to the Tx FIFO - Read access to the Rx FIFO and Tx Status FIFO 0b - Debug Mode Access to FIFO is disabled 1b - Debug Mode Access to FIFO is enabled
0 FDBGEN	FIFO Debug Access Enable When this bit is set, it indicates that the debug mode access to the FIFO is enabled. FIFO Debug Access Enable When this bit is set, it indicates that the debug mode access to the FIFO is enabled. When this bit is reset, it indicates that the FIFO can be accessed only through a master interface. 0b - FIFO Debug Access is disabled 1b - FIFO Debug Access is enabled

61.7.1.373 FIFO Debug Status (MTL_DBG_STS)

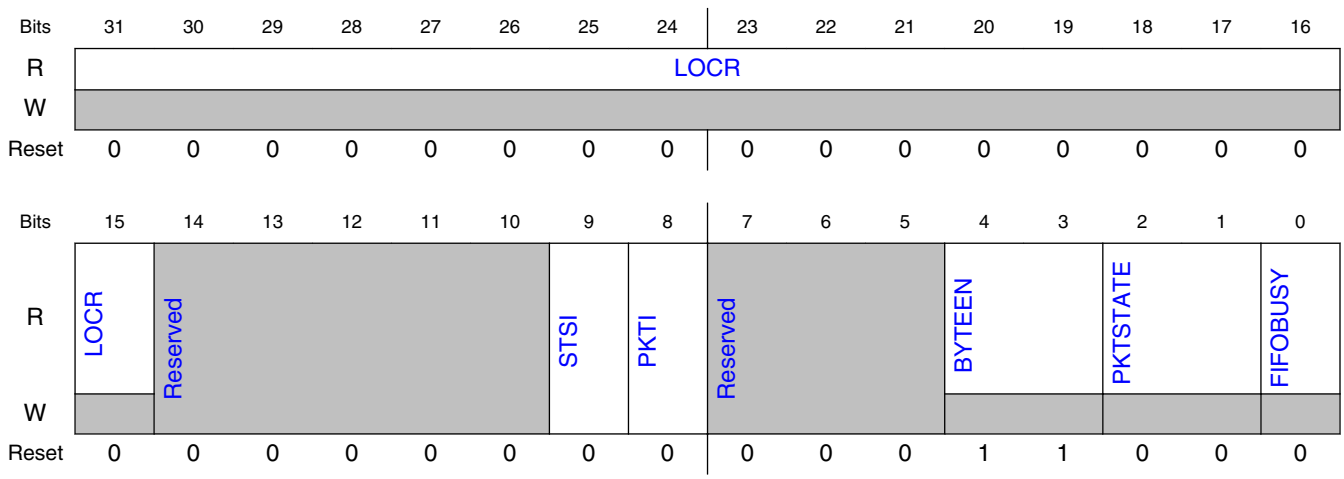
61.7.1.373.1 Offset

Register	Offset
MTL_DBG_STS	C0Ch

61.7.1.373.2 Function

The FIFO Debug Status register contains the status of FIFO debug access.

61.7.1.373.3 Diagram



61.7.1.373.4 Fields

Field	Function
31-15 LOCR	Remaining Locations in the FIFO Slave Access Mode: This field indicates the space available in selected FIFO. Remaining Locations in the FIFO Slave Access Mode: This field indicates the space available in selected FIFO. Debug Access Mode: This field contains the Write or Read pointer value of the selected FIFO during Write or Read operation, respectively. Reset: In single Tx Queue configurations, (DWC_EQOS_TXFIFO_SIZE/(DWC_EQOS_DATAWIDTH/8)), Otherwise 0000H
14-10 —	Reserved
9 STSI	Transmit Status Available Interrupt Status When set, this bit indicates that the Slave mode Tx packet is transmitted, and the status is available in Tx Status FIFO.

Table continues on the next page...

Field	Function
	Transmit Status Available Interrupt Status When set, this bit indicates that the Slave mode Tx packet is transmitted, and the status is available in Tx Status FIFO. This bit is reset when 1 is written to this bit. 0b - Transmit Status Available Interrupt Status not detected 1b - Transmit Status Available Interrupt Status detected
8 PKTI	Receive Packet Available Interrupt Status When set, this bit indicates that MAC layer has written the EOP of received packet to the Rx FIFO. Receive Packet Available Interrupt Status When set, this bit indicates that MAC layer has written the EOP of received packet to the Rx FIFO. This bit is reset when 1 is written to this bit. 0b - Receive Packet Available Interrupt Status not detected 1b - Receive Packet Available Interrupt Status detected
7-5 —	Reserved
4-3 BYTEEN	Byte Enables This field indicates the number of data bytes valid in the data register during Read operation. Byte Enables This field indicates the number of data bytes valid in the data register during Read operation. This is valid only when PKTSTATE is 2'b10 (EOP) and Tx FIFO or Rx FIFO is selected. 00b - Byte 0 valid 01b - Byte 0 and Byte 1 are valid 10b - Byte 0, Byte 1, and Byte 2 are valid 11b - All four bytes are valid
2-1 PKTSTATE	Encoded Packet State This field is used to get the control or status information of the selected FIFO. Encoded Packet State This field is used to get the control or status information of the selected FIFO. Tx FIFO: - 00: Packet Data - 01: Control Word - 10: SOP Data - 11: EOP Data Rx FIFO: - 00: Packet Data - 01: Normal Status - 10: Last Status - 11: EOP This field is applicable only for Tx FIFO and Rx FIFO during Read operation. 00b - Packet Data 01b - Control Word/Normal Status 10b - SOP Data/Last Status 11b - EOP Data/EOP
0 FIFOBUSY	FIFO Busy When set, this bit indicates that a FIFO operation is in progress in the MAC and content of the following fields is not valid: - All other fields of this register - All fields of the MTL_FIFO_DEBUG_DATA register

Field	Function
	0b - FIFO Busy not detected 1b - FIFO Busy detected

61.7.1.374 FIFO Debug Data (MTL_FIFO_DEBUG_DATA)

61.7.1.374.1 Offset

Register	Offset
MTL_FIFO_DEBUG_DATA	C10h

61.7.1.374.2 Function

The FIFO Debug Data register contains the data to be written to or read from the FIFOs.

61.7.1.374.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

61.7.1.374.4 Fields

Field	Function
31-0 FDBGDATA	FIFO Debug Data During debug or slave access write operation, this field contains the data to be written to the Tx FIFO, Rx FIFO, or TSO FIFO. FIFO Debug Data During debug or slave access write operation, this field contains the data to be written to the Tx FIFO, Rx FIFO, or TSO FIFO. During debug or slave access read operation, this field contains the data read from the Tx FIFO, Rx FIFO, TSO FIFO, or Tx Status FIFO.

61.7.1.375 MTL Interrupt Status (MTL_INTERRUPT_STATUS)

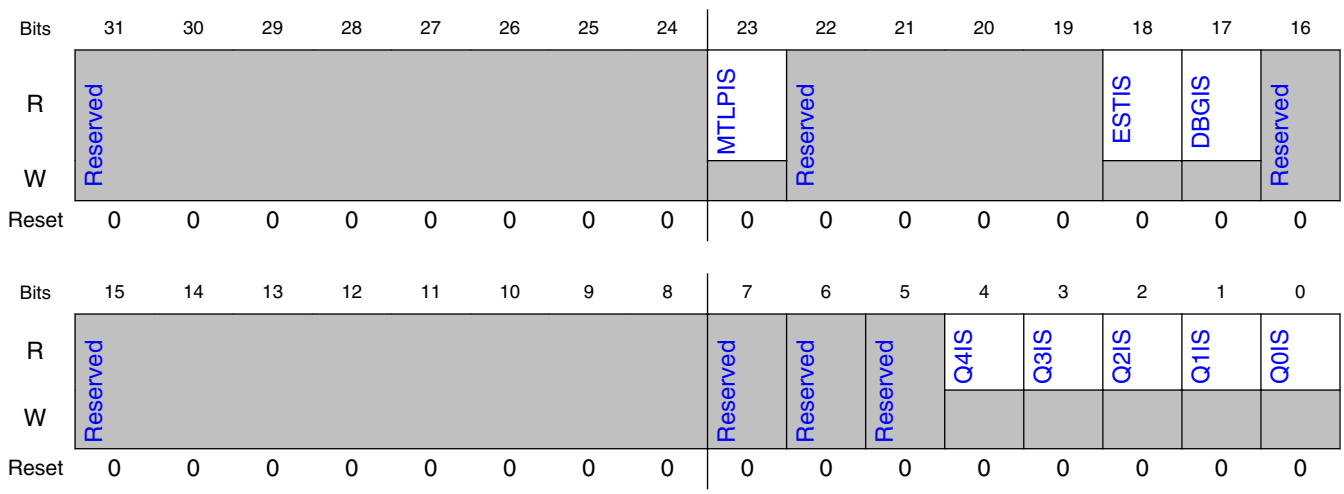
61.7.1.375.1 Offset

Register	Offset
MTL_INTERRUPT_STATUS	C20h

61.7.1.375.2 Function

The software driver (application) reads this register during interrupt service routine or polling to determine the interrupt status of MTL queues and the MAC.

61.7.1.375.3 Diagram



61.7.1.375.4 Fields

Field	Function
31-24 —	Reserved
23 MTLPIS	MTL Rx Parser Interrupt Status This bit indicates that there is an interrupt from Rx Parser Block. MTL Rx Parser Interrupt Status This bit indicates that there is an interrupt from Rx Parser Block. To reset this bit, the application must read the MTL_RXP_INTERRUPT_STATUS register to get the exact cause of the interrupt and clear its source.

Table continues on the next page...

Field	Function
	0b - MTL Rx Parser Interrupt status not detected 1b - MTL Rx Parser Interrupt status detected
22-19 —	Reserved
18 ESTIS	EST (TAS- 802. EST (TAS- 802.1Qbv) Interrupt Status This bit indicates an interrupt event during the operation of 802.1Qbv. To reset this bit, the application must clear the error/event that has caused the Interrupt. 0b - EST (TAS- 802.1Qbv) Interrupt status not detected 1b - EST (TAS- 802.1Qbv) Interrupt status detected
17 DBGIS	Debug Interrupt status This bit indicates an interrupt event during the slave access. Debug Interrupt status This bit indicates an interrupt event during the slave access. To reset this bit, the application must read the FIFO Debug Access Status register to get the exact cause of the interrupt and clear its source. 0b - Debug Interrupt status not detected 1b - Debug Interrupt status detected
16 —	Reserved
15-8 —	Reserved
7 —	Reserved
6 —	Reserved
5 —	Reserved
4 Q4IS	Queue 4 Interrupt status This bit indicates that there is an interrupt from Queue 4. Queue 4 Interrupt status This bit indicates that there is an interrupt from Queue 4. To reset this bit, the application must read the MTL_Q4_INTERRUPT_CONTROL_STATUS register to get the exact cause of the interrupt and clear its source. 0b - Queue 4 Interrupt status not detected 1b - Queue 4 Interrupt status detected
3 Q3IS	Queue 3 Interrupt status This bit indicates that there is an interrupt from Queue 3. Queue 3 Interrupt status This bit indicates that there is an interrupt from Queue 3. To reset this bit, the application must read the MTL_Q3_INTERRUPT_CONTROL_STATUS register to get the exact cause of the interrupt and clear its source. 0b - Queue 3 Interrupt status not detected 1b - Queue 3 Interrupt status detected
2 Q2IS	Queue 2 Interrupt status This bit indicates that there is an interrupt from Queue 2. Queue 2 Interrupt status

Table continues on the next page...

Field	Function
	This bit indicates that there is an interrupt from Queue 2. To reset this bit, the application must read the MTL_Q2_INTERRUPT_CONTROL_STATUS register to get the exact cause of the interrupt and clear its source. 0b - Queue 2 Interrupt status not detected 1b - Queue 2 Interrupt status detected
1 Q1IS	Queue 1 Interrupt status This bit indicates that there is an interrupt from Queue 1. Queue 1 Interrupt status This bit indicates that there is an interrupt from Queue 1. To reset this bit, the application must read the MTL_Q1_INTERRUPT_CONTROL_STATUS register to get the exact cause of the interrupt and clear its source. 0b - Queue 1 Interrupt status not detected 1b - Queue 1 Interrupt status detected
0 Q0IS	Queue 0 Interrupt status This bit indicates that there is an interrupt from Queue 0. Queue 0 Interrupt status This bit indicates that there is an interrupt from Queue 0. To reset this bit, the application must read Queue 0 Interrupt Control and Status register to get the exact cause of the interrupt and clear its source. 0b - Queue 0 Interrupt status not detected 1b - Queue 0 Interrupt status detected

61.7.1.376 Receive Queue and DMA Channel Mapping 0 (MTL_RXQ_DMA_MAP0)

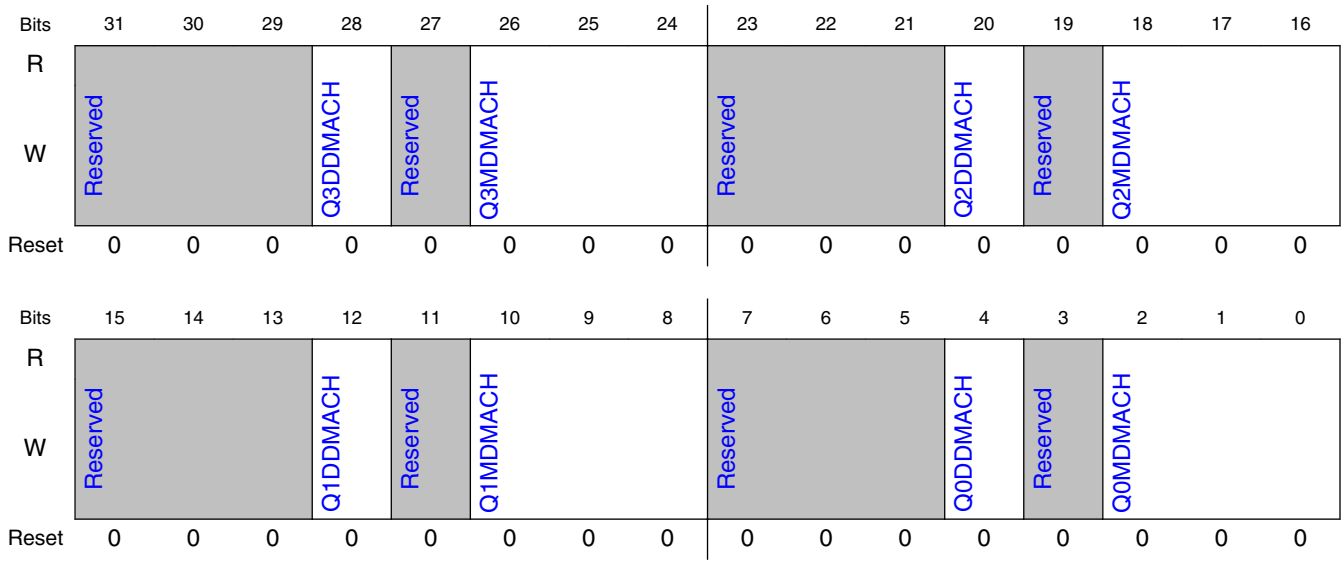
61.7.1.376.1 Offset

Register	Offset
MTL_RXQ_DMA_MAP0	C30h

61.7.1.376.2 Function

The Receive Queue and DMA Channel Mapping 0 register is reserved in EQOS-CORE and EQOS-MTL configurations.

61.7.1.376.3 Diagram



61.7.1.376.4 Fields

Field	Function
31-29 —	Reserved
28 Q3DDMACH	Queue 3 Enabled for Dynamic (per packet) DMA Channel Selection When set, this bit indicates that the packets received in Queue 3 are routed to a particular DMA channel as decided in the MAC Receiver based on the DMA channel number programmed in the L3-L4 filter registers, or the Ethernet DA address. Queue 3 Enabled for Dynamic (per packet) DMA Channel Selection When set, this bit indicates that the packets received in Queue 3 are routed to a particular DMA channel as decided in the MAC Receiver based on the DMA channel number programmed in the L3-L4 filter registers, or the Ethernet DA address. When reset, this bit indicates that the packets received in Queue 3 are routed to the DMA Channel programmed in the Q3MDMACH field (Bits[26:24]). 0b - Queue 3 disabled for DA-based DMA Channel Selection 1b - Queue 3 enabled for DA-based DMA Channel Selection
27 —	Reserved
26-24 Q3MDMACH	Queue 3 Mapped to DMA Channel This field controls the routing of the received packet in Queue 3 to the DMA channel: - 000: DMA Channel 0 - 001: DMA Channel 1 - 010: DMA Channel 2 - 011: DMA Channel 3 - 100: DMA Channel 4 - 101: Reserved - 110: Reserved - 111: Reserved This field is valid when the Q3DDMACH field is reset. Queue 3 Mapped to DMA Channel This field controls the routing of the received packet in Queue 3 to the DMA channel: - 000: DMA Channel 0 - 001: DMA Channel 1

Table continues on the next page...

Field	Function
	- 010: DMA Channel 2 - 011: DMA Channel 3 - 100: DMA Channel 4 - 101: Reserved - 110: Reserved - 111: Reserved This field is valid when the Q3DDMACH field is reset. Note: The width of this field depends on the number of RX DMA channels and not all the values may be valid in some configurations. For example, if the number of RX DMA channels selected is 2, only 000 and 001 are valid, the others are reserved
23-21 —	Reserved
20 Q2DDMACH	Queue 2 Enabled for DA-based DMA Channel Selection When set, this bit indicates that the packets received in Queue 2 are routed to a particular DMA channel as decided in the MAC Receiver based on the DMA channel number programmed in the L3-L4 filter registers, or the Ethernet DA address. Queue 2 Enabled for DA-based DMA Channel Selection When set, this bit indicates that the packets received in Queue 2 are routed to a particular DMA channel as decided in the MAC Receiver based on the DMA channel number programmed in the L3-L4 filter registers, or the Ethernet DA address. When reset, this bit indicates that the packets received in Queue 2 are routed to the DMA Channel programmed in the Q2MDMACH field (Bits[18:16]). 0b - Queue 2 disabled for DA-based DMA Channel Selection 1b - Queue 2 enabled for DA-based DMA Channel Selection
19 —	Reserved
18-16 Q2MDMACH	Queue 2 Mapped to DMA Channel This field controls the routing of the received packet in Queue 2 to the DMA channel: - 000: DMA Channel 0 - 001: DMA Channel 1 - 010: DMA Channel 2 - 011: DMA Channel 3 - 100: DMA Channel 4 - 101: Reserved - 110: Reserved - 111: Reserved This field is valid when the Q2DDMACH field is reset.
15-13 —	Reserved
12 Q1DDMACH	Queue 1 Enabled for DA-based DMA Channel Selection When set, this bit indicates that the packets received in Queue 1 are routed to a particular DMA channel as decided in the MAC Receiver based on the DMA channel number programmed in the L3-L4 filter registers, or the Ethernet DA address. Queue 1 Enabled for DA-based DMA Channel Selection When set, this bit indicates that the packets received in Queue 1 are routed to a particular DMA channel as decided in the MAC Receiver based on the DMA channel number programmed in the L3-L4 filter registers, or the Ethernet DA address. When reset, this bit indicates that the packets received in Queue 1 are routed to the DMA Channel programmed in the Q1MDMACH field (Bits[10:8]). 0b - Queue 1 disabled for DA-based DMA Channel Selection 1b - Queue 1 enabled for DA-based DMA Channel Selection
11 —	Reserved

Table continues on the next page...

Field	Function
10-8 Q1MDMACH	Queue 1 Mapped to DMA Channel This field controls the routing of the received packet in Queue 1 to the DMA channel: - 000: DMA Channel 0 - 001: DMA Channel 1 - 010: DMA Channel 2 - 011: DMA Channel 3 - 100: DMA Channel 4 - 101: Reserved - 110: Reserved - 111: Reserved This field is valid when the Q1DDMACH field is reset. Queue 1 Mapped to DMA Channel This field controls the routing of the received packet in Queue 1 to the DMA channel: - 000: DMA Channel 0 - 001: DMA Channel 1 - 010: DMA Channel 2 - 011: DMA Channel 3 - 100: DMA Channel 4 - 101: Reserved - 110: Reserved - 111: Reserved This field is valid when the Q1DDMACH field is reset. The width of this field depends on the number of RX DMA channels and not all the values may be valid in some configurations. For example, if the number of RX DMA channels selected is 2, only 000 and 001 are valid, the other bits are reserved.
7-5 —	Reserved
4 Q0DDMACH	Queue 0 Enabled for DA-based DMA Channel Selection When set, this bit indicates that the packets received in Queue 0 are routed to a particular DMA channel as decided in the MAC Receiver based on the DMA channel number programmed in the L3-L4 filter registers, or the Ethernet DA address. Queue 0 Enabled for DA-based DMA Channel Selection When set, this bit indicates that the packets received in Queue 0 are routed to a particular DMA channel as decided in the MAC Receiver based on the DMA channel number programmed in the L3-L4 filter registers, or the Ethernet DA address. When reset, this bit indicates that the packets received in Queue 0 are routed to the DMA Channel programmed in the Q0MDMACH field. 0b - Queue 0 disabled for DA-based DMA Channel Selection 1b - Queue 0 enabled for DA-based DMA Channel Selection
3 —	Reserved
2-0 Q0MDMACH	Queue 0 Mapped to DMA Channel This field controls the routing of the packet received in Queue 0 to the DMA channel: - 000: DMA Channel 0 - 001: DMA Channel 1 - 010: DMA Channel 2 - 011: DMA Channel 3 - 100: DMA Channel 4 - 101: Reserved - 110: Reserved - 111: Reserved This field is valid when the Q0DDMACH field is reset. Queue 0 Mapped to DMA Channel This field controls the routing of the packet received in Queue 0 to the DMA channel: - 000: DMA Channel 0 - 001: DMA Channel 1 - 010: DMA Channel 2 - 011: DMA Channel 3

Field	Function
	- 100: DMA Channel 4 - 101: Reserved - 110: Reserved - 111: Reserved This field is valid when the Q0DDMACH field is reset. The width of this field depends on the number of RX DMA channels and not all the values may be valid in some configurations. For example, if the number of RX DMA channels selected is 2, only 000 and 001 are valid, the other bits are reserved.

61.7.1.377 Receive Queue and DMA Channel Mapping 1 (MTL_RXQ_DMA_MAP1)

61.7.1.377.1 Offset

Register	Offset
MTL_RXQ_DMA_MAP1	C34h

61.7.1.377.2 Function

The Receive Queue and DMA Channel Mapping 1 register is reserved in EQOS-CORE and EQOS-MTL configurations.

61.7.1.378 Time Based Scheduling Control (MTL_TBS_CTRL)

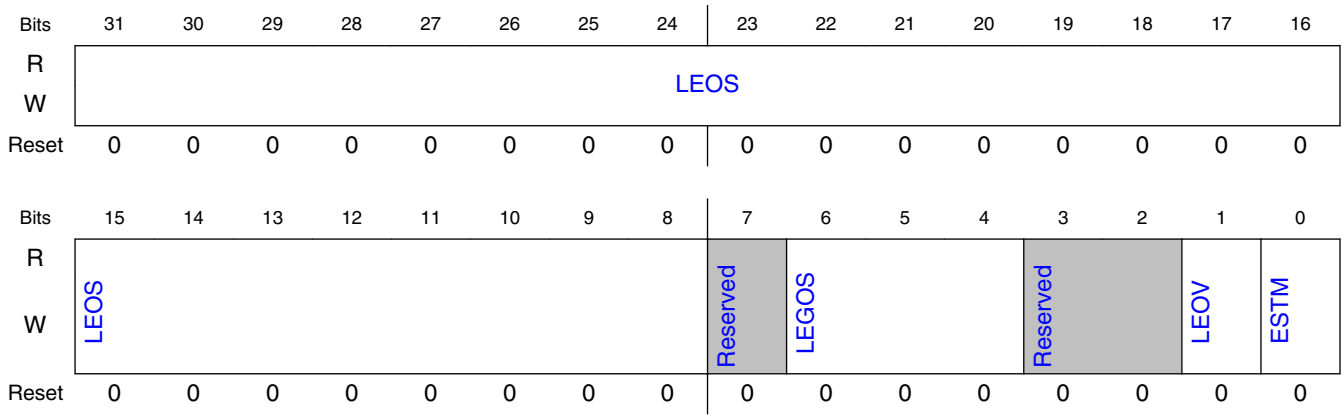
61.7.1.378.1 Offset

Register	Offset
MTL_TBS_CTRL	C40h

61.7.1.378.2 Function

This register controls the operation of Time Based Scheduling.

61.7.1.378.3 Diagram



61.7.1.378.4 Fields

Field	Function
31-8 LEOS	Launch Expiry Offset The value in units of 256 nanoseconds that has to be added to the Launch time to compute the Launch Expiry time. Launch Expiry Offset The value in units of 256 nanoseconds that has to be added to the Launch time to compute the Launch Expiry time. Value valid only when LEOV is set. Max value: 999,999,999 ns, additionally should be smaller than CTR-1 value when ESTM mode is set since this value is a modulo CTR value.
7 —	Reserved
6-4 LEGOS	Launch Expiry GSN Offset The number GSN slots that has to be added to the Launch GSN to compute the Launch Expiry time. Launch Expiry GSN Offset The number GSN slots that has to be added to the Launch GSN to compute the Launch Expiry time. Value valid only when LEOV is set.
3-2 —	Reserved
1 LEOV	Launch Expiry Offset Valid When set indicates the LEOS field is valid. Launch Expiry Offset Valid When set indicates the LEOS field is valid. When not set, indicates the Launch Expiry Offset is not valid and the MTL must not check for Launch expiry time. 0b - LEOS field is invalid 1b - LEOS field is valid
0 ESTM	EST offset Mode When this bit is set, the Launch Time value used in Time Based Scheduling is interpreted as an EST offset value and is added to the Base Time Register (BTR) of the current list. EST offset Mode When this bit is set, the Launch Time value used in Time Based Scheduling is interpreted as an EST offset value and is added to the Base Time Register (BTR) of the current list.

Field	Function
	When reset, the Launch Time value is used as an absolute value that should be compared with the System time [39:8]. 0b - EST offset Mode is disabled 1b - EST offset Mode is enabled

61.7.1.379 Enhancements to Scheduled Transmission Control (MTL_EST_CONTROL)

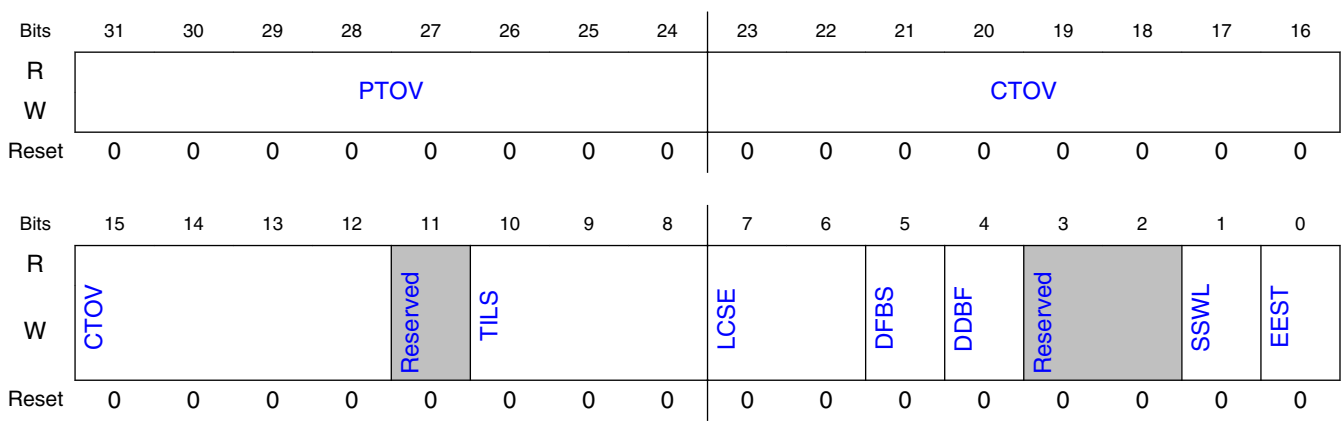
61.7.1.379.1 Offset

Register	Offset
MTL_EST_CONTROL	C50h

61.7.1.379.2 Function

This register controls the operation of Enhancements to Scheduled Transmission (IEEE802.1Qbv).

61.7.1.379.3 Diagram



61.7.1.379.4 Fields

Field	Function
31-24	PTP Time Offset Value The value of PTP Clock period multiplied by 6 in nanoseconds.
PTOV	PTP Time Offset Value

Table continues on the next page...

Field	Function
	The value of PTP Clock period multiplied by 6 in nanoseconds. This value is needed to avoid transmission overruns at the beginning of the installation of a new GCL.
23-12 CTOV	Current Time Offset Value Provides a 12 bit time offset value in nano second that is added to the current time to compensate for all the implementation pipeline delays such as the CDC sync delay, buffering delays, data path delays etc. Current Time Offset Value Provides a 12 bit time offset value in nano second that is added to the current time to compensate for all the implementation pipeline delays such as the CDC sync delay, buffering delays, data path delays etc. This offset helps to ensure that the impact of gate controls is visible on the line exactly at the pre-determined schedule (or as close to the schedule as possible).
11 —	Reserved
10-8 TILS	Time Interval Left Shift Amount This field provides the left shift amount for the programmed Time Interval values used in the Gate Control Lists. Time Interval Left Shift Amount This field provides the left shift amount for the programmed Time Interval values used in the Gate Control Lists. - 000: No left shift needed (equal to x1ns) - 001: Left shift TI by 1 bit (equal to x2ns) - 010: Left shift TI by 2 bits (equal to x4ns) - . - . - 100: Left shift TI by 7 bits (equal to x128ns) Based on the configuration one or more bits of this field should be treated as Reserved/Read-Only.
7-6 LCSE	Loop Count to report Scheduling Error Programmable number of GCL list iterations before reporting an HLBS error defined in EST_STATUS register. 00b - 4 iterations 01b - 8 iterations 10b - 16 iterations 11b - 32 iterations
5 DFBS	Drop Frames causing Scheduling Error When set frames reported to cause HOL Blocking due to not getting scheduled (HLBS field of EST_STATUS register) after 4,8,16,32 (based on LCSE field of this register) GCL iterations are dropped. 0b - Do not Drop Frames causing Scheduling Error 1b - Drop Frames causing Scheduling Error
4 DDBF	Do not Drop frames during Frame Size Error When set, frames are not be dropped during Head-of-Line blocking due to Frame Size Error (HLBF field of MTL_EST_STATUS register). 0b - Drop frames during Frame Size Error 1b - Do not Drop frames during Frame Size Error
3-2 —	Reserved
1 SSWL	Switch to S/W owned list When set indicates that the software has programmed that list that it currently owns (SWOL) and the hardware should switch to the new list based on the new BTR. Switch to S/W owned list

Table continues on the next page...

Field	Function
	When set indicates that the software has programmed that list that it currently owns (SWOL) and the hardware should switch to the new list based on the new BTR. Hardware clears this bit when the switch to the SWOL happens to indicate the completion of the switch or when an BTR error (BTRE in Status register) is set. When BTRE is set this bit is cleared but SWOL is not updated as the switch was not successful. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0b - Switch to S/W owned list is disabled 1b - Switch to S/W owned list is enabled
0 EEST	Enable EST When reset, the gate control list processing is halted and all gates are assumed to be in Open state. Enable EST When reset, the gate control list processing is halted and all gates are assumed to be in Open state. Should be set for the hardware to start processing the gate control lists. During the toggle from 0 to 1, the gate control list processing starts only after the SSWL bit it set. When DWC_EQOS_ASP_ECC is selected during the configuration, if any uncorrectable error is detected in the EST memory the hardware will reset this bit and disable the EST function. 0b - EST is disabled 1b - EST is enabled

61.7.1.380 MTL_EST_EXT_CONTROL (MTL_EST_EXT_CONTROL)

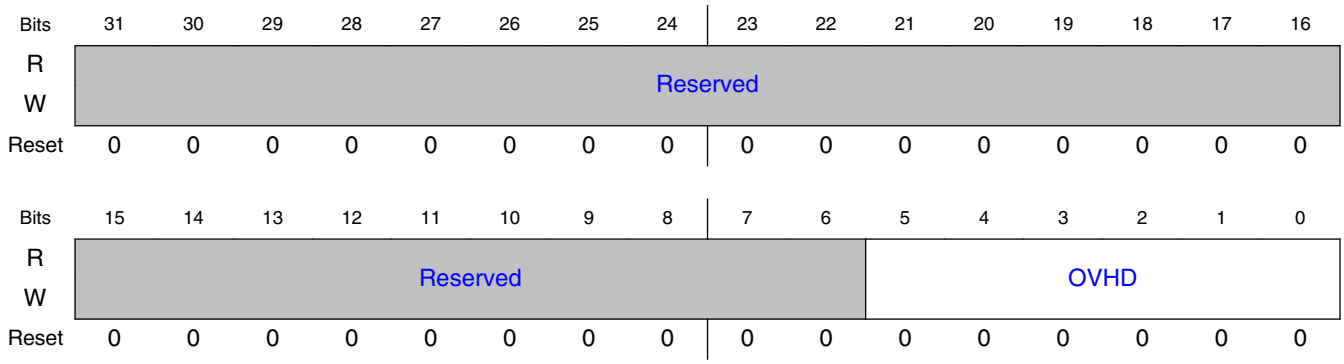
61.7.1.380.1 Offset

Register	Offset
MTL_EST_EXT_CONTROL	C54h

61.7.1.380.2 Function

This register indicates the number of overhead bytes for EST related scheduling.

61.7.1.380.3 Diagram



61.7.1.380.4 Fields

Field	Function
31-6 —	Reserved
5-0 OVHD	Overhead Bytes Value This field indicates the fixed overhead for every packet to account for EST Scheduler Delay, IPG or EIPG, and Preamble bytes.

61.7.1.381 Enhancements to Scheduled Transmission Status (MTL_EST_STATUS)

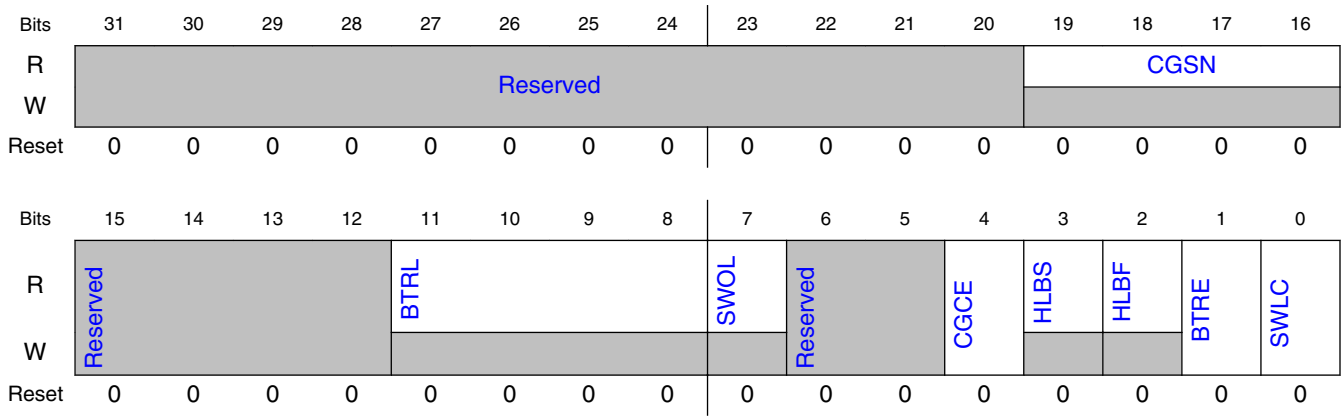
61.7.1.381.1 Offset

Register	Offset
MTL_EST_STATUS	C58h

61.7.1.381.2 Function

This register provides Status related to Enhancements to Scheduled Transmission (IEEE802.1Qbv).

61.7.1.381.3 Diagram



61.7.1.381.4 Fields

Field	Function
31-20 —	Reserved
19-16 CGSN	Current GCL Slot Number Indicates the slot number of the GCL list. Current GCL Slot Number Indicates the slot number of the GCL list. Slot number is a modulo 16 count of the GCL List loops executed so far. Even if a new GCL list is installed, the count is incremental.
15-12 —	Reserved
11-8 BTRL	BTR Error Loop Count Provides the minimum count (N) for which the equation Current Time =< New BTR + (N * New Cycle Time) becomes true. BTR Error Loop Count Provides the minimum count (N) for which the equation Current Time =< New BTR + (N * New Cycle Time) becomes true. N = "1111" indicates the iterations exceeded the value of 8 and the hardware was not able to update New BTR to be equal to or greater than Current Time. Software intervention is needed to update the New BTR. Value cleared when BTRE field of this register is cleared.
7 SWOL	S/W owned list When '0' indicates Gate control list number "0" is owned by software and when "1" indicates the Gate Control list "1" is owned by the software. S/W owned list When '0' indicates Gate control list number "0" is owned by software and when "1" indicates the Gate Control list "1" is owned by the software. Any reads/writes by the software (using indirect access via GCL_Control) is directed to the list indicated by this value by default. The inverse of this value is treated as HWOL. R/W operations performed by hardware are directed to the list pointed by HWOL by default. 0b - Gate control list number "0" is owned by software 1b - Gate control list number "1" is owned by software
6-5	Reserved

Table continues on the next page...

Field	Function
—	
4 CGCE	Constant Gate Control Error This error occurs when the list length (LLR) is 1 and the programmed Time Interval (TI) value after the optional Left Shifting is less than or equal to the Cycle Time (CTR). Constant Gate Control Error This error occurs when the list length (LLR) is 1 and the programmed Time Interval (TI) value after the optional Left Shifting is less than or equal to the Cycle Time (CTR). The above programming implies Gates are either always Closed or always Open based on the Gate Control values; the same effect can be achieved by other simpler (non TSN) programming mechanisms. Since the implementation does not support such a programming an error is reported. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Constant Gate Control Error not detected 1b - Constant Gate Control Error detected
3 HLBS	Head-Of-Line Blocking due to Scheduling Set when the frame is not able to win arbitration and get scheduled even after 4 iterations of the GCL. Head-Of-Line Blocking due to Scheduling Set when the frame is not able to win arbitration and get scheduled even after 4 iterations of the GCL. Indicates to software a potential programming error. The one hot encoded values of the Queue Numbers that are not able to make progress are indicated in the MTL_EST_SCH_ERROR register. Bit cleared when MTL_EST_SCH_ERROR register is all zeroes. 0b - Head-Of-Line Blocking due to Scheduling not detected 1b - Head-Of-Line Blocking due to Scheduling detected
2 HLBF	Head-Of-Line Blocking due to Frame Size Set when HOL Blocking is noticed on one or more Queues as a result of none of the Time Intervals of gate open in the GCL being greater than or equal to the duration needed for frame size (or frame fragment size when preemption is enabled) transmission. Head-Of-Line Blocking due to Frame Size Set when HOL Blocking is noticed on one or more Queues as a result of none of the Time Intervals of gate open in the GCL being greater than or equal to the duration needed for frame size (or frame fragment size when preemption is enabled) transmission. The one hot encoded Queue numbers that are experiencing HLBF are indicated in the MTL_EST_FRM_SIZE_ERROR register. Additionally, the first Queue number that experienced HLBF along with the frame size is captured in MTL_EST_FRM_SIZE_CAPTURE register. Bit cleared when MTL_EST_FRAME_SIZE_ ERROR register is all zeros. 0b - Head-Of-Line Blocking due to Frame Size not detected 1b - Head-Of-Line Blocking due to Frame Size detected
1 BTRE	BTR Error When "1" indicates a programming error in the BTR of SWOL where the programmed value is less than current time. BTR Error When "1" indicates a programming error in the BTR of SWOL where the programmed value is less than current time. If the BTRL = "1111", SWOL is not updated and Software should reprogram the BTR to a value greater than current time and then set SSWL to reinitiate the switch to SWOL. Else if the value of BTRL < "1111", SWOL is updated and this field indicates the number of iterations (of + CycleTime) taken by hardware to update the BTR to a value greater than Current Time. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - BTR Error not detected 1b - BTR Error detected
0 SWLC	Switch to S/W owned list Complete When "1" indicates the hardware has successfully switched to the SWOL, and the SWOL bit has been updated to that effect. Switch to S/W owned list Complete

Field	Function
	When "1" indicates the hardware has successfully switched to the SWOL, and the SWOL bit has been updated to that effect. Cleared when the SSWL of MTL_EST_CONTROL register transitions from 0 to 1, or on a software write. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Switch to S/W owned list Complete not detected 1b - Switch to S/W owned list Complete detected

61.7.1.382 EST Scheduling Error (MTL_EST_SCH_ERROR)

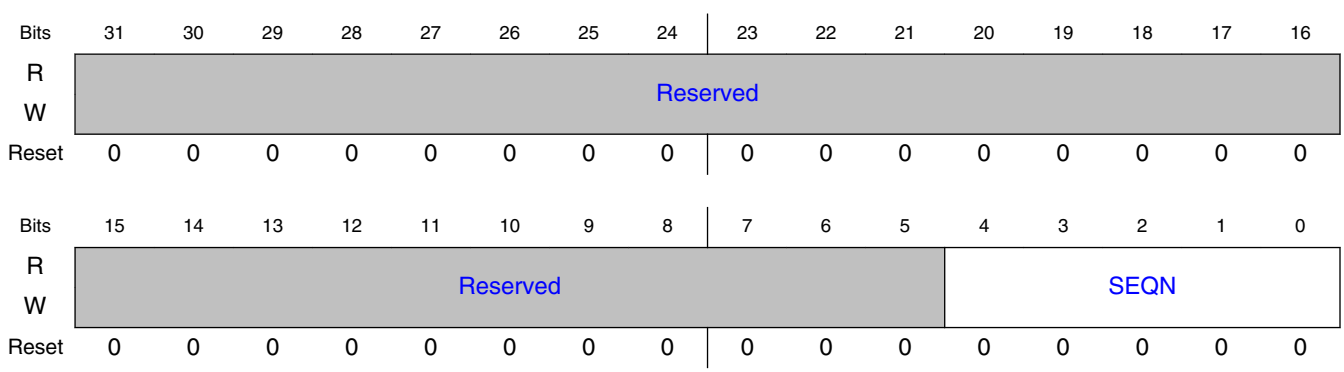
61.7.1.382.1 Offset

Register	Offset
MTL_EST_SCH_ERROR	C60h

61.7.1.382.2 Function

This register provides the One Hot encoded Queue Numbers that are having the Scheduling related error (timeout).

61.7.1.382.3 Diagram



61.7.1.382.4 Fields

Field	Function
31-5 —	Reserved

4-0 FEQN	Frame Size Error Queue Number The One Hot Encoded Queue Numbers that have experienced error described in HLBF field of status register. Frame Size Error Queue Number The One Hot Encoded Queue Numbers that have experienced error described in HLBF field of status register. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.

61.7.1.384 EST Frame Size Capture (MTL_EST_FRM_SIZE_CAPTURE)

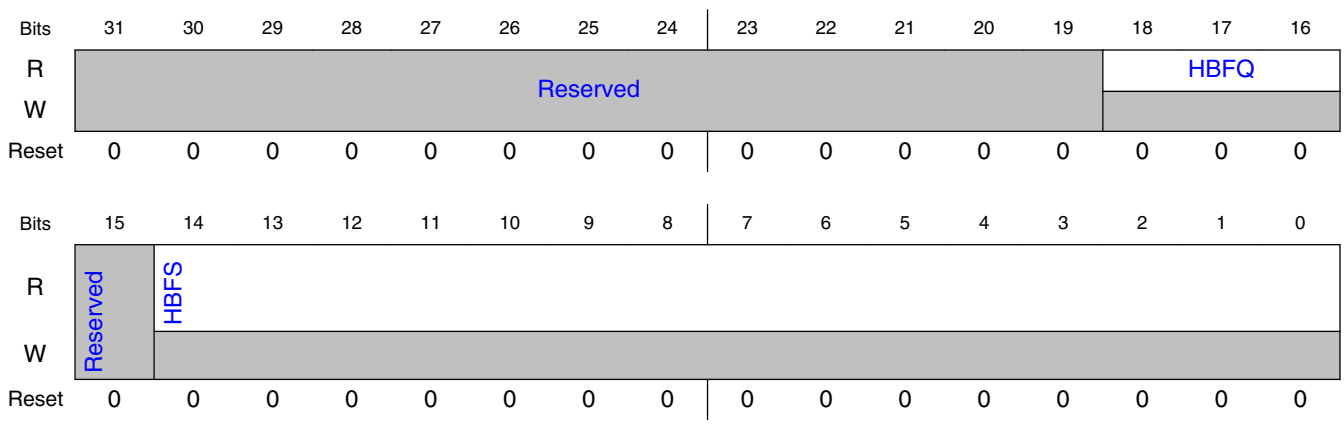
61.7.1.384.1 Offset

Register	Offset
MTL_EST_FRM_SIZE_CAPTURE	C68h

61.7.1.384.2 Function

This register captures the Frame Size and Queue Number of the first occurrence of the Frame Size related error. Up on clearing it captures the data of immediate next occurrence of a similar error.

61.7.1.384.3 Diagram



61.7.1.384.4 Fields

Field	Function
31-19 —	Reserved
18-16 HBFQ	Queue Number of HLBF Captures the binary value of the of the first Queue (number) experiencing HLBF error (see HLBF field of status register). Queue Number of HLBF Captures the binary value of the of the first Queue (number) experiencing HLBF error (see HLBF field of status register). Value once written is not altered by any subsequent queue errors of similar nature. Once cleared the queue number of the next occurring HLBF error is captured. Width is based on the number of Tx Queues configured; remaining bits are Read-Only. Cleared when MTL_EST_FRM_SIZE_ERROR register is all zeros.
15 —	Reserved
14-0 HBFS	Frame Size of HLBF Captures the Frame Size of the dropped frame related to queue number indicated in HBFQ field of this register. Frame Size of HLBF Captures the Frame Size of the dropped frame related to queue number indicated in HBFQ field of this register. Contents of this register should be considered invalid, if this field is zero. Cleared when MTL_EST_FRM_SIZE_ERROR register is all zeros.

61.7.1.385 EST Interrupt Enable (MTL_EST_INTR_ENABLE)

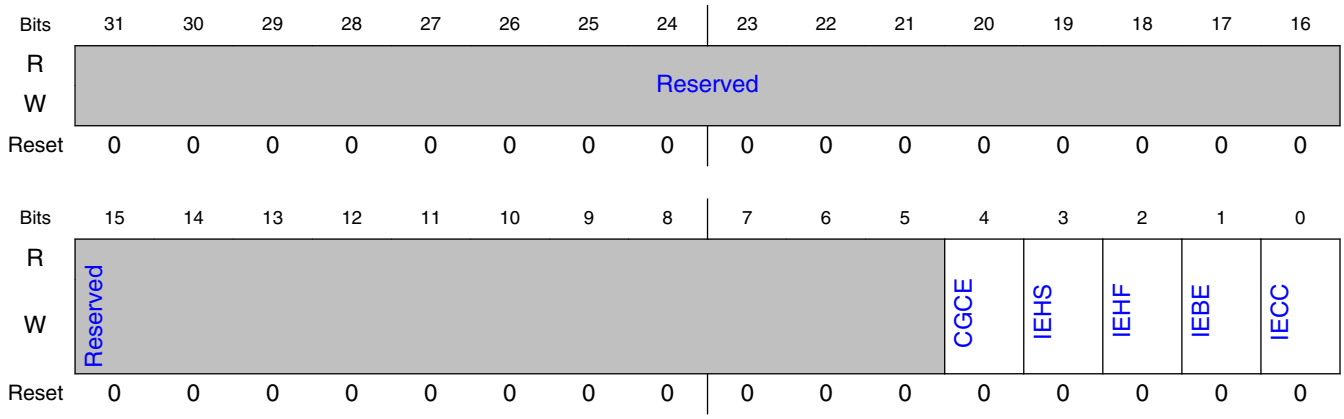
61.7.1.385.1 Offset

Register	Offset
MTL_EST_INTR_ENABLE	C70h

61.7.1.385.2 Function

This register implements the Interrupt Enable bits for the various events that generate an interrupt. Bit positions have a 1 to 1 correlation with the status bit positions in MTL_ETS_STATUS register.

61.7.1.385.3 Diagram



61.7.1.385.4 Fields

Field	Function
31-5 —	Reserved
4 CGCE	Interrupt Enable for CGCE When set, generates interrupt when the Constant Gate Control Error occurs and is indicated in the status. Interrupt Enable for CGCE When set, generates interrupt when the Constant Gate Control Error occurs and is indicated in the status. When reset this event does not generate an interrupt 0b - Interrupt for CGCE is disabled 1b - Interrupt for CGCE is enabled
3 IEHS	Interrupt Enable for HLBS When set, generates interrupt when the Head-of-Line Blocking due to Scheduling issue and is indicated in the status. Interrupt Enable for HLBS When set, generates interrupt when the Head-of-Line Blocking due to Scheduling issue and is indicated in the status. When reset this event does not generate an interrupt. 0b - Interrupt for HLBS is disabled 1b - Interrupt for HLBS is enabled
2 IEHF	Interrupt Enable for HLBF When set, generates interrupt when the Head-of-Line Blocking due to Frame Size error occurs and is indicated in the status. Interrupt Enable for HLBF When set, generates interrupt when the Head-of-Line Blocking due to Frame Size error occurs and is indicated in the status. When reset this event does not generate an interrupt. 0b - Interrupt for HLBF is disabled 1b - Interrupt for HLBF is enabled
1 IEBE	Interrupt Enable for BTR Error When set, generates interrupt when the BTR Error occurs and is indicated in the status. Interrupt Enable for BTR Error

Table continues on the next page...

61.7.1.386.4 Fields

Field	Function
31-24 —	Reserved
23-22 ESTEIEC	ECC Inject Error Control for EST Memory When EIEE bit of this register is set, following are the errors inserted based on the value encoded in this field. ECC Inject Error Control for EST Memory When EIEE bit of this register is set, following are the errors inserted based on the value encoded in this field. This filed will be valid only if DWC_EQOS_ASP_ECC feature is selected during the configuration, else it will be reserved. 00b - Insert 1 bit error 01b - Insert 2 bit errors 10b - Insert 3 bit errors 11b - Insert 1 bit error in address field
21 ESTEIEE	EST ECC Inject Error Enable When set along with EEST bit of MTL_EST_CONTROL register, enables the ECC error injection feature. EST ECC Inject Error Enable When set along with EEST bit of MTL_EST_CONTROL register, enables the ECC error injection feature. When reset, disables the ECC error injection feature. 0b - EST ECC Inject Error is disabled 1b - EST ECC Inject Error is enabled
20 ERR0	When set indicates the last write operation was aborted as software writes to GCL and GCL registers is prohibited when SSWL bit of MTL_EST_CONTROL Register is set. When set indicates the last write operation was aborted as software writes to GCL and GCL registers is prohibited when SSWL bit of MTL_EST_CONTROL Register is set. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - ERR0 is disabled 1b - ERR1 is enabled
19-17 —	Reserved
16-8 ADDR	Gate Control List Address: (GCLA when GCRR is "0"). Gate Control List Address: (GCLA when GCRR is "0"). Provides the address (row number) of the Gate Control List at which the R/W operation has to be performed. By default the Gate Control List pointed by SWOL of MTL_EST_STATUS is selected for R/W, however if the DBGM bit of this register is set, a debug mode access is given to R/W from DBGB. The width of this field is dependent on DWC_EQOS_EST_DEP; unused bits should be treated as read only. Gate Control list Related Registers Address: (GCRA when GCRR is "1"). By default the GCL related register set pointed by SWOL of MTL_EST_STATUS is selected for R/W, however if the DBGM bit of this register is set, a debug mode access is given to R/W from DBGB. Lower 3 bits are only used in this mode, higher order bits are treated as dont cares. - 000: BTR Low (31:0) - 001: BTR High (63:31)

Table continues on the next page...

Field	Function
	- 010: CTR Low (31:0) - 011: CTR High (39:32) - 100: TER (31:0) - 101: LLR (n:0) (where n is (log{DWC_EQOS_EST_DEP} / log2)) - Others: Reserved
7-6 —	Reserved
5 DBGB	Debug Mode Bank Select When set to "0" indicates R/W in debug mode should be directed to Bank 0 (GCL0 and corresponding Time related registers). Debug Mode Bank Select When set to "0" indicates R/W in debug mode should be directed to Bank 0 (GCL0 and corresponding Time related registers). When set to "1" indicates R/W in debug mode should be directed to Bank 1 (GCL1 and corresponding Time related registers). This value is used when DBGM is set and overrides by value of SWOL which is normally used. 0b - R/W in debug mode should be directed to Bank 0 1b - R/W in debug mode should be directed to Bank 1
4 DBGM	Debug Mode When set to "1" indicates R/W in debug mode where the memory bank (for GCL and Time related registers) is explicitly provided by DBGB value, when set to "0" SWOL bit is used to determine which bank to use. 0b - Debug Mode is disabled 1b - Debug Mode is enabled
3 —	Reserved
2 GCRR	Gate Control Related Registers When set to "1" indicates the R/W access is for the GCL related registers (BTR, CTR, TER, LLR) whose address is provided by GCRA. Gate Control Related Registers When set to "1" indicates the R/W access is for the GCL related registers (BTR, CTR, TER, LLR) whose address is provided by GCRA. When "0" indicates R/W should be directed to GCL from the address provided by GCLA. 0b - Gate Control Related Registers are disabled 1b - Gate Control Related Registers are enabled
1 R1W0	Read '1', Write '0': When set to '1': Read Operation When set to '0': Write Operation. 0b - Write Operation 1b - Read Operation
0 SRWO	Start Read/Write Op When set indicates a Read/Write Op has started and is in progress. Start Read/Write Op When set indicates a Read/Write Op has started and is in progress. When reset by hardware indicates the R/W Op has completed or an error has occurred (when bit 20 is set) Reads: Data can be read from MTL_EST_GCL_DATA register after this bit is reset Writes: MTL_EST_GCL_DATA should be programmed with write data before setting SRWO. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0b - Start Read/Write Op disabled 1b - Start Read/Write Op enabled

61.7.1.389.4 Fields

Field	Function
31-16 RADV	Release Advance The maximum time in nanoseconds that can elapse between issuing a RELEASE to the MAC and the MAC being ready to resume transmission of preemptable frames, in the absence of there being any express frames available for transmission.
15-0 HADV	Hold Advance The maximum time in nanoseconds that can elapse between issuing a HOLD to the MAC and the MAC ceasing to transmit any preemptable frame that is in the process of transmission or any preemptable frames that are queued for transmission.

61.7.1.390 RXP Control Status (MTL_RXP_CONTROL_STATUS)

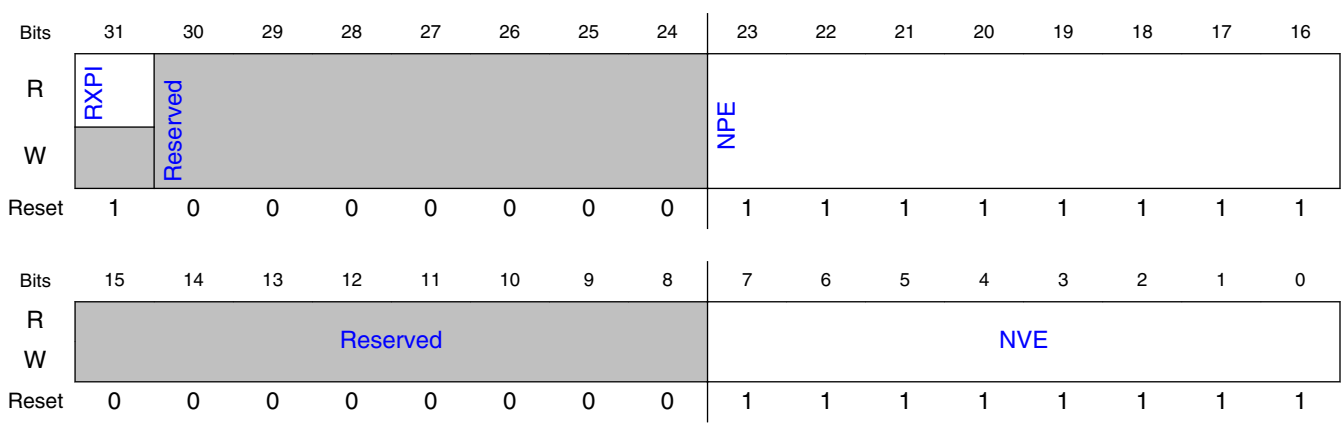
61.7.1.390.1 Offset

Register	Offset
MTL_RXP_CONTROL_STATUS	CA0h

61.7.1.390.2 Function

The RXP Control Status register establishes the operating mode of Rx Parser and provides some status.

61.7.1.390.3 Diagram



61.7.1.390.4 Fields

Field	Function
31 RXPI	RX Parser in Idle state This status bit is set to 1 when the Rx parser is in Idle State and waiting for a new packet for processing. RX Parser in Idle state This status bit is set to 1 when the Rx parser is in Idle State and waiting for a new packet for processing. This bit is used as a handshake with software when parser gets disables. After disabling, when bit is set then software can update the Rx parser instruction table. 0b - RX Parser not in Idle state 1b - RX Parser in Idle state
30-24 —	Reserved
23-16 NPE	Number of parsable entries in the Instruction table This control indicates the number of parsable entries in the Instruction Memory. Number of parsable entries in the Instruction table This control indicates the number of parsable entries in the Instruction Memory. This is used in Rx parser logic to detect programming Error. In case number of parsed entries for a packet is more than this entry then NPEOVIS bit in the MTL_RXP_INTERRUPT_CONTROL_STATUS register is set.
15-8 —	Reserved
7-0 NVE	Number of valid entries in the Instruction table This control indicates the number of valid entries in the Instruction Memory. Number of valid entries in the Instruction table This control indicates the number of valid entries in the Instruction Memory. This is used in Rx parser logic to detect any programming Error. In case while parsing Table address (memory address) found to be more than this entry then NVEOVIS bit in the MTL_RXP_INTERRUPT_CONTROL_STATUS register is set. Note: The minimum value of this should be 2.

61.7.1.391 RXP Interrupt Control Status (MTL_RXP_INTERRUPT_CONTROL_STATUS)

61.7.1.391.1 Offset

Register	Offset
MTL_RXP_INTERRUPT_CONTROL_STATUS	CA4h

61.7.1.391.2 Function

The RXP Interrupt Control Status register provides enable control for the interrupts and provides interrupt status.

61.7.1.391.3 Diagram

When this bit is reset, the NVEOVIS interrupt is disabled. 0b - Number of Valid Entries Overflow Interrupt is disabled 1b - Number of Valid Entries Overflow Interrupt is enabled
15-4 —	Reserved
3 PDRFIS	Packet Dropped due to RF Interrupt Status If the Rx Parser result says to drop the packet by setting RF=1 in the instruction memory, then this bit is set to 1. Packet Dropped due to RF Interrupt Status If the Rx Parser result says to drop the packet by setting RF=1 in the instruction memory, then this bit is set to 1. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Packet Dropped due to RF Interrupt Status not detected 1b - Packet Dropped due to RF Interrupt Status detected
2 FOOVIS	Frame Offset Overflow Interrupt Status While parsing if the Instruction table entry's 'Frame Offset' found to be more than EOF offset, then then this bit is set. Frame Offset Overflow Interrupt Status While parsing if the Instruction table entry's 'Frame Offset' found to be more than EOF offset, then then this bit is set. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Frame Offset Overflow Interrupt Status not detected 1b - Frame Offset Overflow Interrupt Status detected
1 NPEOVIS	Number of Parsable Entries Overflow Interrupt Status While parsing a packet if the number of parsed entries found to be more than NPE[] (Number of Parseable Entries in MTL_RXP_CONTROL register),then this bit is set to 1. Number of Parsable Entries Overflow Interrupt Status While parsing a packet if the number of parsed entries found to be more than NPE[] (Number of Parseable Entries in MTL_RXP_CONTROL register),then this bit is set to 1. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Number of Parsable Entries Overflow Interrupt Status not detected 1b - Number of Parsable Entries Overflow Interrupt Status detected
0 NVEOVIS	Number of Valid Entries Overflow Interrupt Status While parsing if the Instruction address found to be more than NVE (Number of Valid Entries in MTL_RXP_CONTROL register), then this bit is set to 1. Number of Valid Entries Overflow Interrupt Status While parsing if the Instruction address found to be more than NVE (Number of Valid Entries in MTL_RXP_CONTROL register), then this bit is set to 1. This bit is cleared when the application writes 1 to this bit.

Field	Function
	Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Number of Valid Entries Overflow Interrupt Status not detected 1b - Number of Valid Entries Overflow Interrupt Status detected

61.7.1.392 RXP Drop Count (MTL_RXP_DROP_CNT)

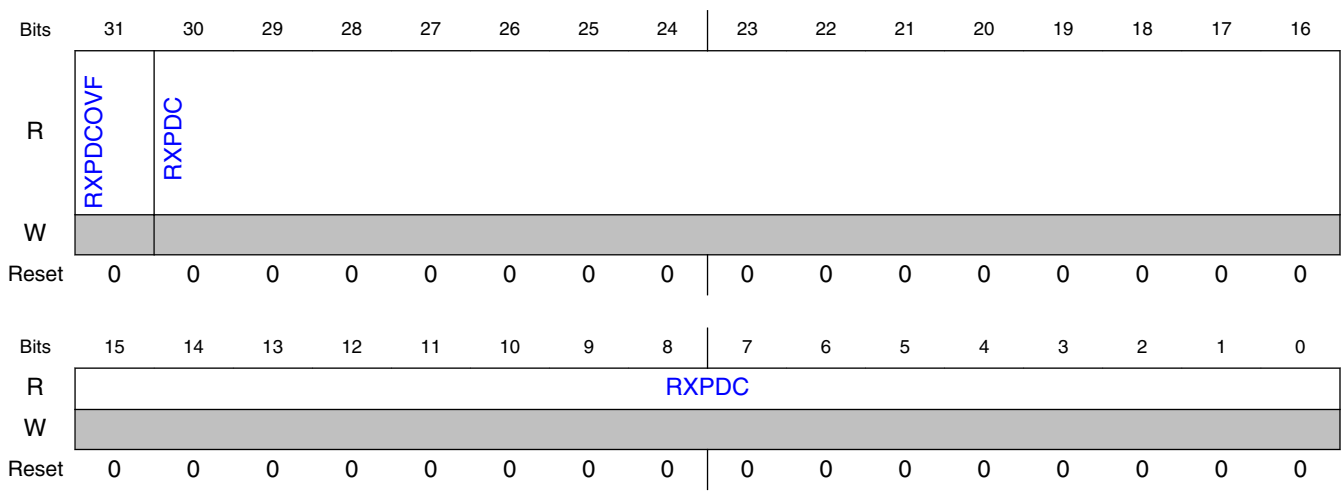
61.7.1.392.1 Offset

Register	Offset
MTL_RXP_DROP_CNT	CA8h

61.7.1.392.2 Function

The MTL_RXP_DROP_CNT register provides the drop count of Rx Parser initiated drops.

61.7.1.392.3 Diagram



61.7.1.392.4 Fields

Field	Function
31 RXPDCOVF	Rx Parser Drop Counter Overflow Bit When set, this bit indicates that the MTL_RXP_DROP_CNT (RXPDC) Counter field crossed the maximum limit. Rx Parser Drop Counter Overflow Bit

Table continues on the next page...

Field	Function
	When set, this bit indicates that the MTL_RXP_DROP_CNT (RXPDC) Counter field crossed the maximum limit. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0b - Rx Parser Drop count overflow not occurred 1b - Rx Parser Drop count overflow occurred
30-0 RXPDC	Rx Parser Drop count This 31-bit counter is implemented whenever a Rx Parser Drops a packet due to RF =1. Rx Parser Drop count This 31-bit counter is implemented whenever a Rx Parser Drops a packet due to RF =1. The counter is cleared when the register is read.

61.7.1.393 RXP Error Count (MTL_RXP_ERROR_CNT)

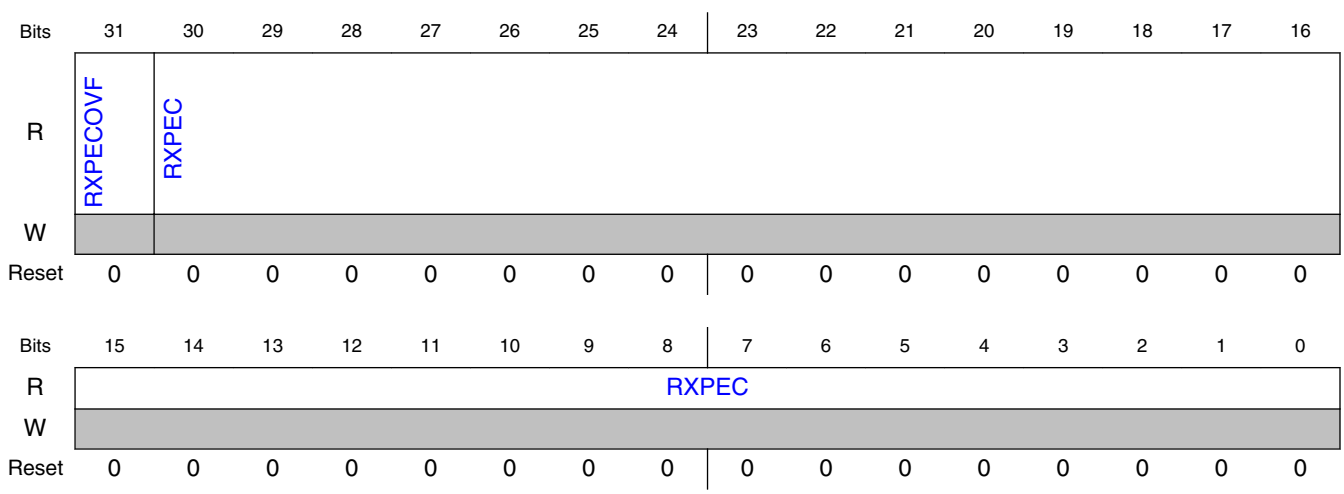
61.7.1.393.1 Offset

Register	Offset
MTL_RXP_ERROR_CNT	CACh

61.7.1.393.2 Function

The RXP_ERROR_CNT register provides the Rx Parser related error occurrence count.

61.7.1.393.3 Diagram



61.7.1.393.4 Fields

Field	Function
31 RXPECOVF	Rx Parser Error Counter Overflow Bit When set, this bit indicates that the MTL_RXP_ERROR_CNT (RXPEC) Counter field crossed the maximum limit. Rx Parser Error Counter Overflow Bit When set, this bit indicates that the MTL_RXP_ERROR_CNT (RXPEC) Counter field crossed the maximum limit. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0b - Rx Parser Error count overflow not occurred 1b - Rx Parser Error count overflow occurred
30-0 RXPEC	Rx Parser Error count This 31-bit counter is implemented whenever a Rx Parser encounters following Error scenarios - Entry address >= NVE[] - Number Parsed Entries >= NPE[] - Entry address > EOF data entry address The counter is cleared when the register is read.

61.7.1.394 RXP Indirect Access Control and Status (MTL_RXP_INDIRECT_ACC_CONTROL_STATUS)

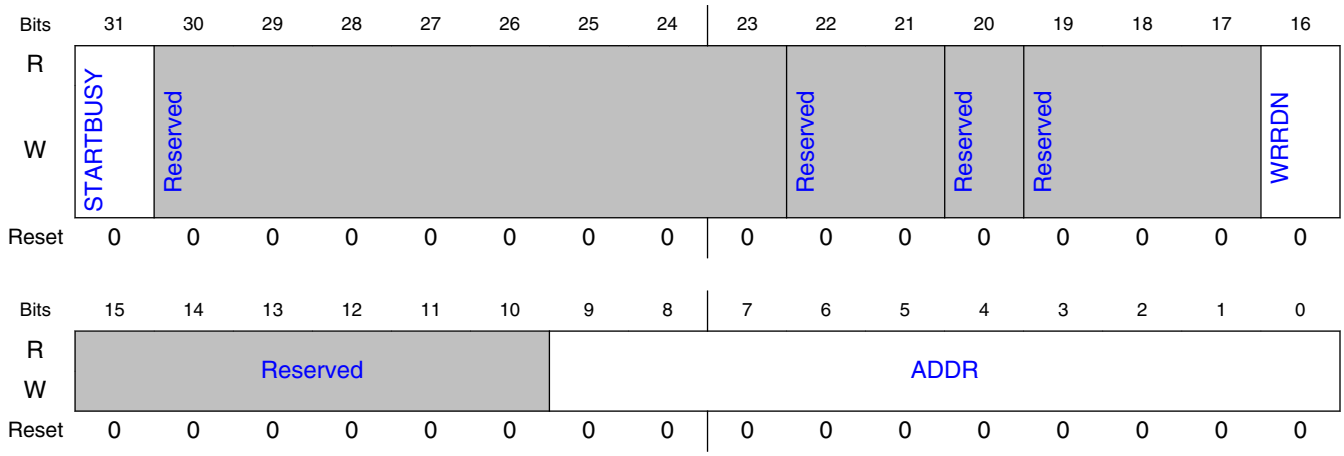
61.7.1.394.1 Offset

Register	Offset
MTL_RXP_INDIRECT_ACC_CONTROL_STATUS	CB0h

61.7.1.394.2 Function

The RXP_INDIRECT_ACC_CONTROL_STATUS register provides the Indirect Access control and status for Rx Parser memory.

61.7.1.394.3 Diagram



61.7.1.394.4 Fields

Field	Function
31 STARTBUSY	FRP Instruction Table Access Busy When this bit is set to 1 by the software then it indicates to start the Read/Write operation from/to the Rx Parser Memory. FRP Instruction Table Access Busy When this bit is set to 1 by the software then it indicates to start the Read/Write operation from/to the Rx Parser Memory. Software should read this bit as 0 before issuing read or write request to access the Parser Memory Instructions. This bit when set to 1 indicates that hardware is busy until its gets cleared by hardware and software should not issue any read or write operation. 0b - hardware not busy 1b - hardware is busy (Read/Write operation from/to the Rx Parser Memory)
30-23 —	Reserved
22-21 —	Reserved
20 —	Reserved
19-17 —	Reserved
16 WRRDN	Read Write Control When this bit is set to 1 indicates the write operation to the Rx Parser Memory. Read Write Control When this bit is set to 1 indicates the write operation to the Rx Parser Memory. When this bit is set to 0 indicates the read operation to the Rx Parser Memory. 0b - Read operation to the Rx Parser Memory 1b - Write operation to the Rx Parser Memory

Table continues on the next page...

Field	Function
15-10 —	Reserved
9-0 ADDR	FRP Instruction Table Offset Address This field indicates the ADDR of the 32-bit entry in Rx parser instruction table. FRP Instruction Table Offset Address This field indicates the ADDR of the 32-bit entry in Rx parser instruction table. Each entry has 128-bit (4x32-bit words). The X depends on the configurable DWC_EQOS_FRP_ENTRIES If DWC_EQOS_FRP_ENTRIES == 256 , then X = 9 If DWC_EQOS_FRP_ENTRIES = 128 , then X = 8 IF DWC_EQOS_FRP_ENTRIES = 64, then X = 7 This is can be written by the software before issuing any Read/Write command. The hardware auto-increments this field after the read-write operation gets completed.

61.7.1.395 RXP Indirect Access Data (MTL_RXP_INDIRECT_ACC_DATA)

61.7.1.395.1 Offset

Register	Offset
MTL_RXP_INDIRECT_ACC_DATA	CB4h

61.7.1.395.2 Function

The RXP_INDIRECT_ACC_DATA registers holds the data associated to Indirect Access to Rx Parser memory.

61.7.1.395.3 Diagram

61.7.1.396.4 Fields

Field	Function
31 RXPBCOF	Rx Parser bypass Counter Overflow Bit. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0b - Indicates that MTL_RXP_BYPASS_CNT[RXPBC] counter field has not crossed the maximum limit 1b - Indicates that MTL_RXP_BYPASS_CNT[RXPBC] counter field has crossed the maximum limit
30-0 RXPBC	Rx Parser Bypass Count This 31-bit counter is implemented when a Rx Parser bypass a packet due to AF=1 and RF=1. The counter is cleared when the register is read.

61.7.1.397 Queue 0 Transmit Operation Mode (MTL_TXQ0_OPERATION_MODE)

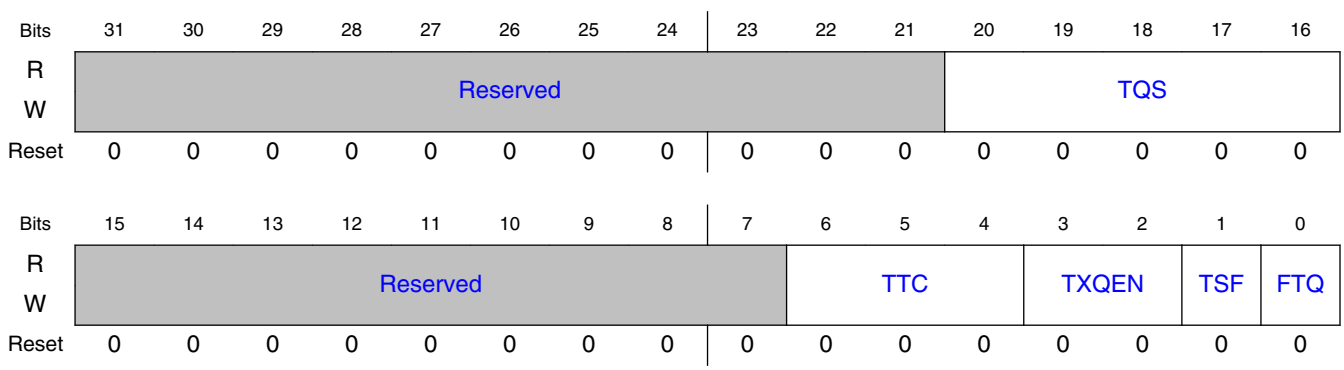
61.7.1.397.1 Offset

Register	Offset
MTL_TXQ0_OPERATION_MODE	D00h

61.7.1.397.2 Function

The Queue 0 Transmit Operation Mode register establishes the Transmit queue operating modes and commands.

61.7.1.397.3 Diagram



61.7.1.397.4 Fields

Field	Function
31-21 —	Reserved
20-16 TQS	Transmit Queue Size This field indicates the size of the allocated Transmit queues in blocks of 256 bytes. Transmit Queue Size This field indicates the size of the allocated Transmit queues in blocks of 256 bytes. The TQS field is read-write only if the number of Tx Queues more than one, the reset value is 0x0 and indicates size of 256 bytes. When the number of Tx Queues is one, the field is read-only and the configured TX FIFO size in blocks of 256 bytes is reflected in the reset value. The width of this field depends on the Tx memory size selected in your configuration. For example, if the memory size is 2048, the width of this field is 3 bits: LOG2(2048/256) = LOG2(8) = 3 bits
15-7 —	Reserved
6-4 TTC	Transmit Threshold Control These bits control the threshold level of the MTL Tx Queue. Transmit Threshold Control These bits control the threshold level of the MTL Tx Queue. The transmission starts when the packet size within the MTL Tx Queue is larger than the threshold. In addition, full packets with length less than the threshold are also transmitted. These bits are used only when the TSF bit is reset. 000b - 32 001b - 64 010b - 96 011b - 128 100b - 192 101b - 256 110b - 384 111b - 512
3-2 TXQEN	Transmit Queue Enable This field is used to enable/disable the transmit queue 0. Transmit Queue Enable This field is used to enable/disable the transmit queue 0. - 2'b00: Not enabled - 2'b01: Reserved - 2'b10: Enabled - 2'b11: Reserved This field is Read Only in Single Queue configurations and Read Write in Multiple Queue configurations. Note: In multiple Tx queues configuration, all the queues are disabled by default. Enable the Tx queue by programming this field. 00b - Not enabled 01b - Enable in AV mode (Reserved in non-AV) 10b - Enabled 11b - Reserved
1 TSF	Transmit Store and Forward When this bit is set, the transmission starts when a full packet resides in the MTL Tx queue.

Table continues on the next page...

Field	Function
	Transmit Store and Forward When this bit is set, the transmission starts when a full packet resides in the MTL Tx queue. When this bit is set, the TTC values specified in Bits[6:4] of this register are ignored. This bit should be changed only when the transmission is stopped. 0b - Transmit Store and Forward is disabled 1b - Transmit Store and Forward is enabled
0 FTQ	Flush Transmit Queue When this bit is set, the Tx queue controller logic is reset to its default values. Flush Transmit Queue When this bit is set, the Tx queue controller logic is reset to its default values. Therefore, all the data in the Tx queue is lost or flushed. This bit is internally reset when the flushing operation is complete. Until this bit is reset, you should not write to the MTL_TXQ0_OPERATION_MODE register. The data which is already accepted by the MAC transmitter is not flushed. It is scheduled for transmission and results in underflow and runt packet transmission. Note: The flush operation is complete only when the Tx queue is empty and the application has accepted the pending Tx Status of all transmitted packets. To complete this flush operation, the PHY Tx clock (clk_tx_i) should be active. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0b - Flush Transmit Queue is disabled 1b - Flush Transmit Queue is enabled

61.7.1.398 Queue 0 Underflow Counter (MTL_TXQ0_UNDERFLOW)

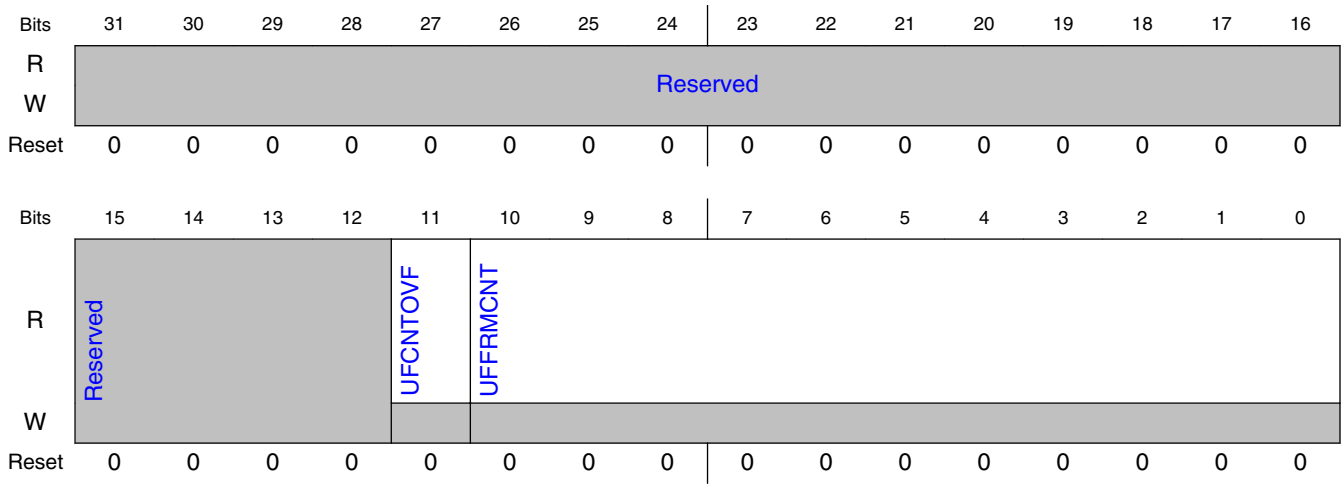
61.7.1.398.1 Offset

Register	Offset
MTL_TXQ0_UNDERFLOW	D04h

61.7.1.398.2 Function

The Queue 0 Underflow Counter register contains the counter for packets aborted because of Transmit queue underflow and packets missed because of Receive queue packet flush

61.7.1.398.3 Diagram



61.7.1.398.4 Fields

Field	Function
31-12 —	Reserved
11 UFCNTOVF	Overflow Bit for Underflow Packet Counter This bit is set every time the Tx queue Underflow Packet Counter field overflows, that is, it has crossed the maximum count. Overflow Bit for Underflow Packet Counter This bit is set every time the Tx queue Underflow Packet Counter field overflows, that is, it has crossed the maximum count. In such a scenario, the overflow packet counter is reset to all-zeros and this bit indicates that the rollover happened. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0b - Overflow not detected for Underflow Packet Counter 1b - Overflow detected for Underflow Packet Counter
10-0 UFFRMCNT	Underflow Packet Counter This field indicates the number of packets aborted by the controller because of Tx Queue Underflow. Underflow Packet Counter This field indicates the number of packets aborted by the controller because of Tx Queue Underflow. This counter is incremented each time the MAC aborts outgoing packet because of underflow. The counter is cleared when this register is read with mci_be_i[0] at 1'b1. Access restriction applies. Clears on read. Self-set to 1 on internal event.

61.7.1.399 Queue 0 Transmit Debug (MTL_TXQ0_DEBUG)

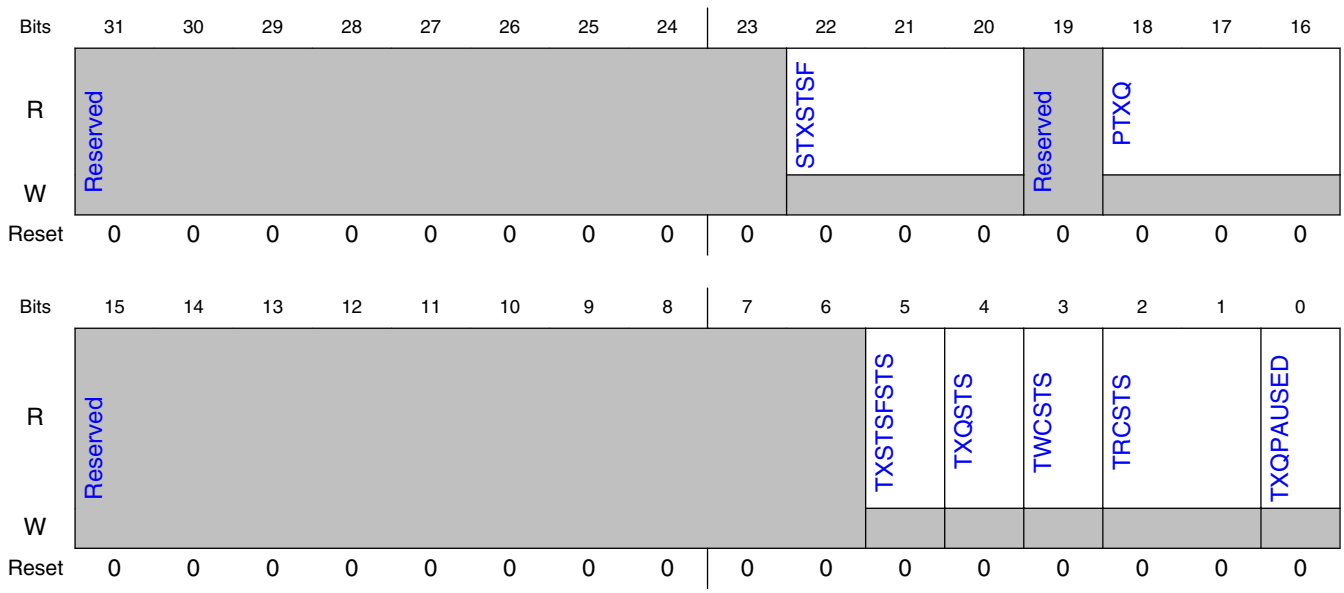
61.7.1.399.1 Offset

Register	Offset
MTL_TXQ0_DEBUG	D08h

61.7.1.399.2 Function

The Queue 0 Transmit Debug register gives the debug status of various blocks related to the Transmit queue.

61.7.1.399.3 Diagram



61.7.1.399.4 Fields

Field	Function
31-23 —	Reserved
22-20 STXSTSF	Number of Status Words in Tx Status FIFO of Queue This field indicates the current number of status in the Tx Status FIFO of this queue. Number of Status Words in Tx Status FIFO of Queue This field indicates the current number of status in the Tx Status FIFO of this queue. When the DTXSTS bit of MTL_OPERATION_MODE register is set to 1, this field does not reflect the number of status words in Tx Status FIFO.
19 —	Reserved

Table continues on the next page...

Field	Function
18-16 PTXQ	Number of Packets in the Transmit Queue This field indicates the current number of packets in the Tx Queue. Number of Packets in the Transmit Queue This field indicates the current number of packets in the Tx Queue. When the DTXSTS bit of MTL_OPERATION_MODE register is set to 1, this field does not reflect the number of packets in the Transmit queue.
15-6 —	Reserved
5 TXSTSFSTS	MTL Tx Status FIFO Full Status When high, this bit indicates that the MTL Tx Status FIFO is full. MTL Tx Status FIFO Full Status When high, this bit indicates that the MTL Tx Status FIFO is full. Therefore, the MTL cannot accept any more packets for transmission. 0b - MTL Tx Status FIFO Full status is not detected 1b - MTL Tx Status FIFO Full status is detected
4 TXQSTS	MTL Tx Queue Not Empty Status When this bit is high, it indicates that the MTL Tx Queue is not empty and some data is left for transmission. 0b - MTL Tx Queue Not Empty status is not detected 1b - MTL Tx Queue Not Empty status is detected
3 TWCSTS	MTL Tx Queue Write Controller Status When high, this bit indicates that the MTL Tx Queue Write Controller is active, and it is transferring the data to the Tx Queue. 0b - MTL Tx Queue Write Controller status is not detected 1b - MTL Tx Queue Write Controller status is detected
2-1 TRCSTS	MTL Tx Queue Read Controller Status This field indicates the state of the Tx Queue Read Controller: 00b - Idle state 01b - Read state (transferring data to the MAC transmitter) 10b - Waiting for pending Tx Status from the MAC transmitter 11b - Flushing the Tx queue because of the Packet Abort request from the MAC
0 TXQPAUSED	Transmit Queue in Pause When this bit is high and the Rx flow control is enabled, it indicates that the Tx Queue is in the Pause condition (in the full-duplex only mode) because of the following: - Reception of the PFC packet for the priorities assigned to the Tx Queue when PFC is enabled - Reception of 802. Transmit Queue in Pause When this bit is high and the Rx flow control is enabled, it indicates that the Tx Queue is in the Pause condition (in the full-duplex only mode) because of the following: - Reception of the PFC packet for the priorities assigned to the Tx Queue when PFC is enabled - Reception of 802.3x Pause packet when PFC is disabled 0b - Transmit Queue in Pause status is not detected 1b - Transmit Queue in Pause status is detected

61.7.1.400 Queue 0 ETS Status (MTL_TXQ0_ETS_STATUS)

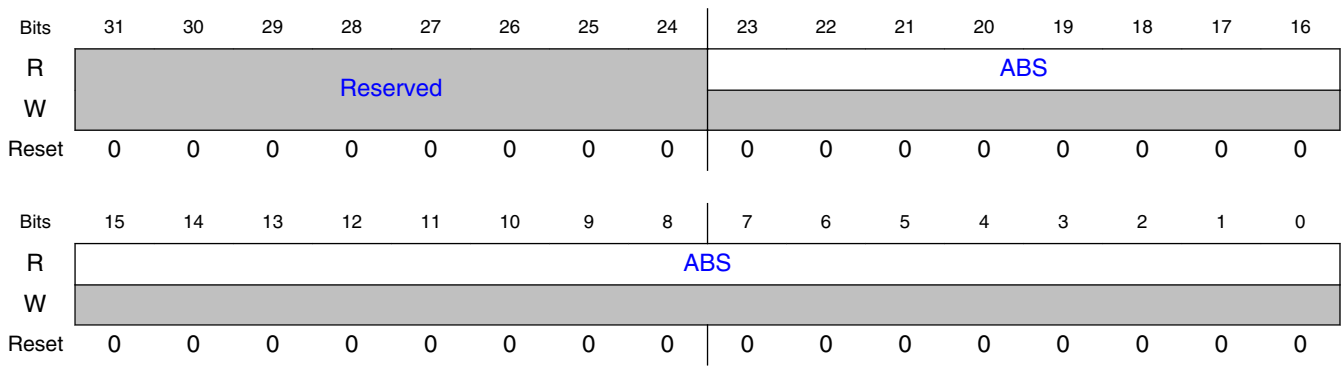
61.7.1.400.1 Offset

Register	Offset
MTL_TXQ0_ETS_STATUS	D14h

61.7.1.400.2 Function

The Queue 0 ETS Status register provides the average traffic transmitted in Queue 0.

61.7.1.400.3 Diagram



61.7.1.400.4 Fields

Field	Function
31-24 —	Reserved
23-0 ABS	Average Bits per Slot This field contains the average transmitted bits per slot. Average Bits per Slot This field contains the average transmitted bits per slot. When the DCB operation is enabled for Queue 0, this field is computed over every 10 million bit times slot (4 ms in 2500 Mbps; 10 ms in 1000 Mbps; 100 ms in 100 Mbps). The maximum value is 0x989680.

61.7.1.401 Queue 0 Quantum or Weights (MTL_TXQ0_QUANTUM_WEIGHT)

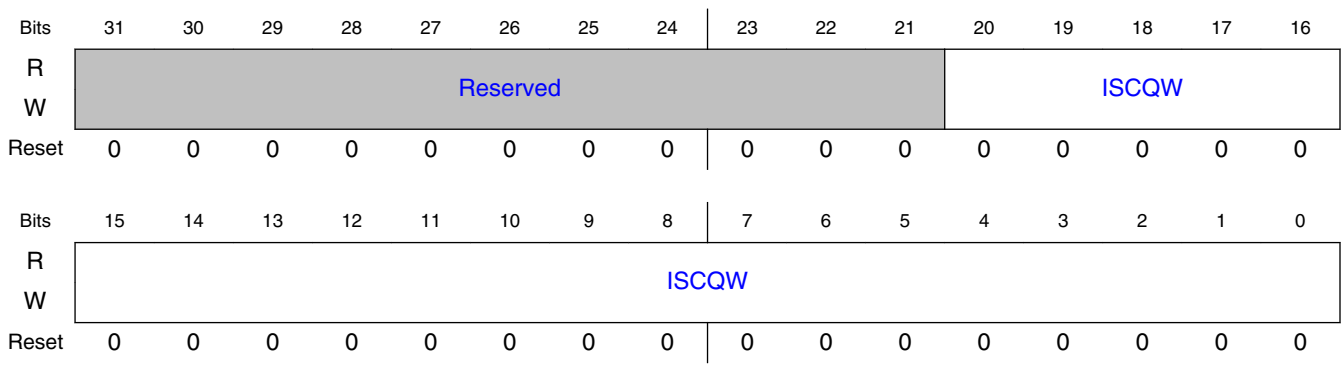
61.7.1.401.1 Offset

Register	Offset
MTL_TXQ0_QUANTUM_WEIGHT	D18h

61.7.1.401.2 Function

The Queue 0 Quantum or Weights register contains the quantum value for Deficit Weighted Round Robin (DWRR), weights for the Weighted Round Robin (WRR), and Weighted Fair Queuing (WFQ) for Queue 0.

61.7.1.401.3 Diagram



61.7.1.401.4 Fields

Field	Function
31-21 —	Reserved
20-0 ISCQW	Quantum or Weights When the DCB operation is enabled with DWRR algorithm for Queue 0 traffic, this field contains the quantum value in bytes to be added to credit during every queue scanning cycle. Quantum or Weights When the DCB operation is enabled with DWRR algorithm for Queue 0 traffic, this field contains the quantum value in bytes to be added to credit during every queue scanning cycle. The maximum value is 0x1312D0 bytes. When DCB operation is enabled with WFQ algorithm for Queue 0 traffic, this field contains the weight for this queue. The maximum value is 0x3FFF where weight of 0 indicates 100% bandwidth. Bits[20:14] must be written to zero. The higher the programmed weights lesser the bandwidth allocated for the particular Transmit Queue. This is because the weights are used to compute the packet finish time (weights*packet_size). Lesser the finish time, higher the probability of the packet getting scheduled first and using more bandwidth.

Field	Function
	When DCB operation or generic queuing operation is enabled with WRR algorithm for Queue 0 traffic, this field contains the weight for this queue. The maximum value is 0x64. Bits [20:7] must be written to zero.

61.7.1.402 Queue 0 Interrupt Control Status (MTL_Q0_INTERRUPT_CONTROL_STATUS)

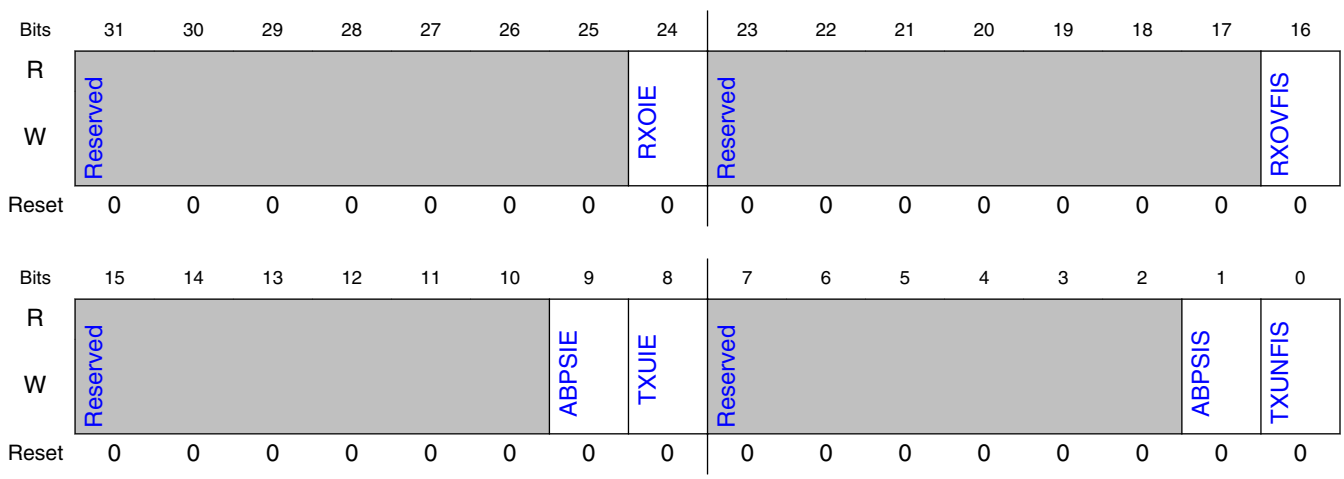
61.7.1.402.1 Offset

Register	Offset
MTL_Q0_INTERRUPT_CONTROL_STATUS	D2Ch

61.7.1.402.2 Function

This register contains the interrupt enable and status bits for the queue 0 interrupts.

61.7.1.402.3 Diagram



61.7.1.402.4 Fields

Field	Function
31-25 —	Reserved

Field	Function
24 RXOIE	Receive Queue Overflow Interrupt Enable When this bit is set, the Receive Queue Overflow interrupt is enabled. Receive Queue Overflow Interrupt Enable When this bit is set, the Receive Queue Overflow interrupt is enabled. When this bit is reset, the Receive Queue Overflow interrupt is disabled. 0b - Receive Queue Overflow Interrupt is disabled 1b - Receive Queue Overflow Interrupt is enabled
23-17 —	Reserved
16 RXOVFIS	Receive Queue Overflow Interrupt Status This bit indicates that the Receive Queue had an overflow while receiving the packet. Receive Queue Overflow Interrupt Status This bit indicates that the Receive Queue had an overflow while receiving the packet. If a partial packet is transferred to the application, the overflow status is set in RDES3[21]. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Receive Queue Overflow Interrupt Status not detected 1b - Receive Queue Overflow Interrupt Status detected
15-10 —	Reserved
9 ABPSIE	Average Bits Per Slot Interrupt Enable When this bit is set, the MAC asserts the sbd_intr_o or mci_intr_o interrupt when the average bits per slot status is updated. Average Bits Per Slot Interrupt Enable When this bit is set, the MAC asserts the sbd_intr_o or mci_intr_o interrupt when the average bits per slot status is updated. When this bit is cleared, the interrupt is not asserted for such an event. 0b - Average Bits Per Slot Interrupt is disabled 1b - Average Bits Per Slot Interrupt is enabled
8 TXUIE	Transmit Queue Underflow Interrupt Enable When this bit is set, the Transmit Queue Underflow interrupt is enabled. Transmit Queue Underflow Interrupt Enable When this bit is set, the Transmit Queue Underflow interrupt is enabled. When this bit is reset, the Transmit Queue Underflow interrupt is disabled. 0b - Transmit Queue Underflow Interrupt Status is disabled 1b - Transmit Queue Underflow Interrupt Status is enabled
7-2 —	Reserved
1 ABPSIS	Average Bits Per Slot Interrupt Status When set, this bit indicates that the MAC has updated the ABS value. Average Bits Per Slot Interrupt Status When set, this bit indicates that the MAC has updated the ABS value. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Average Bits Per Slot Interrupt Status not detected

Table continues on the next page...

Field	Function
	1b - Average Bits Per Slot Interrupt Status detected
0 TXUNFIS	Transmit Queue Underflow Interrupt Status This bit indicates that the Transmit Queue had an underflow while transmitting the packet. Transmit Queue Underflow Interrupt Status This bit indicates that the Transmit Queue had an underflow while transmitting the packet. Transmission is suspended and an Underflow Error TDES3[2] is set. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Transmit Queue Underflow Interrupt Status not detected 1b - Transmit Queue Underflow Interrupt Status detected

61.7.1.403 Queue 0 Receive Operation Mode (MTL_RXQ0_OPERATION_MODE)

61.7.1.403.1 Offset

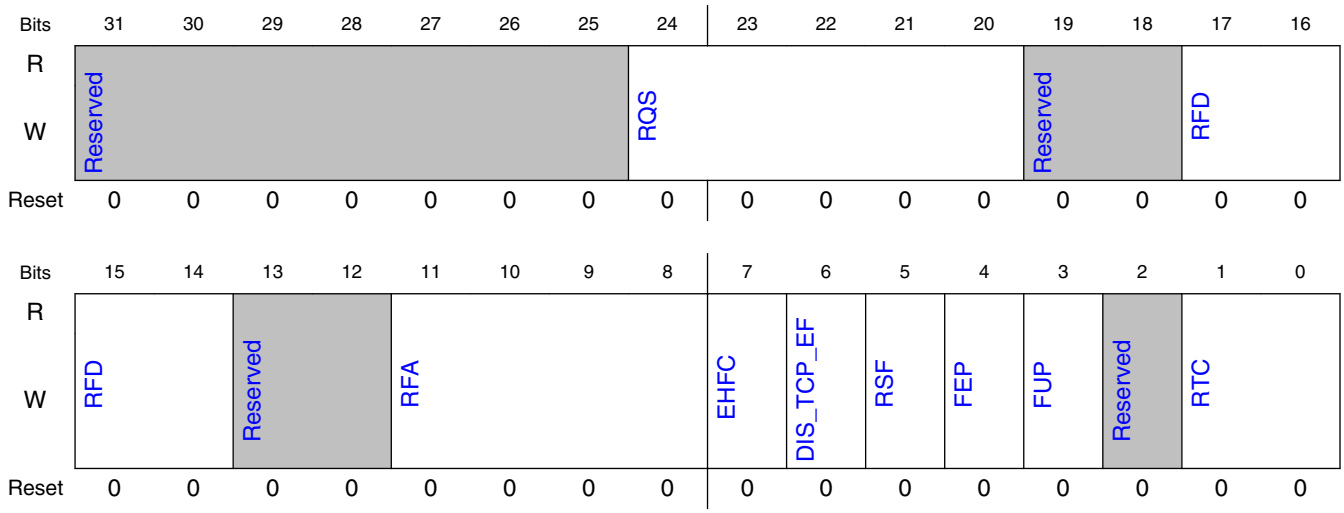
Register	Offset
MTL_RXQ0_OPERATION_MODE	D30h

61.7.1.403.2 Function

The Queue 0 Receive Operation Mode register establishes the Receive queue operating modes and command.

The RFA and RFD fields are not backward compatible with the RFA and RFD fields of 4.00a release

61.7.1.403.3 Diagram



61.7.1.403.4 Fields

Field	Function
31-25 —	Reserved
24-20 RQS	Receive Queue Size This field indicates the size of the allocated Receive queues in blocks of 256 bytes. Receive Queue Size This field indicates the size of the allocated Receive queues in blocks of 256 bytes. The RQS field is read-write only if the number of Rx Queues more than one, the reset value is 0x0 and indicates size of 256 bytes. When the number of Rx Queues is one, the field is read-only and the configured RX FIFO size in blocks of 256 bytes is reflected in the reset value. The width of this field depends on the Rx memory size selected in your configuration. For example, if the memory size is 2048, the width of this field is 3 bits: LOG2(2048/256) = LOG2(8) = 3 bits
19-18 —	Reserved
17-14 RFD	Threshold for Deactivating Flow Control (in half-duplex and full-duplex modes) These bits control the threshold (fill-level of Rx queue) at which the flow control is de-asserted after activation: - 0: Full minus 1 KB, that is, FULL 1 KB - 1: Full minus 1. Threshold for Deactivating Flow Control (in half-duplex and full-duplex modes) These bits control the threshold (fill-level of Rx queue) at which the flow control is de-asserted after activation: - 0: Full minus 1 KB, that is, FULL 1 KB - 1: Full minus 1.5 KB, that is, FULL 1.5 KB - 2: Full minus 2 KB, that is, FULL 2 KB - 3: Full minus 2.5 KB, that is, FULL 2.5 KB

Table continues on the next page...

Field	Function
	- ... - 14: Full minus 8 KB, that is, FULL 8 KB - 15: Full minus 8.5 KB, that is, FULL 8.5 KB The de-assertion is effective only after flow control is asserted. Note: The value must be programmed in such a way to make sure that the threshold is a positive number. When the EHFC is set high, these values are applicable only when the Rx queue size determined by the RQS field of this register, is equal to or greater than 4 KB. For a given queue size, the values ranges between 0 and the encoding for FULL minus (QSIZE - 0.5 KB) and all other values are illegal. Here the term FULL and QSIZE refers to the queue size determined by the RQS field of this register. The width of this field depends on RX FIFO size selected during the configuration. Remaining bits are reserved and read only.
13-12 —	Reserved
11-8 RFA	Threshold for Activating Flow Control (in half-duplex and full-duplex These bits control the threshold (fill-level of Rx queue) at which the flow control is activated: For more information on encoding for this field, see RFD.
7 EHFC	Enable Hardware Flow Control When this bit is set, the flow control signal operation, based on the fill-level of Rx queue, is enabled. Enable Hardware Flow Control When this bit is set, the flow control signal operation, based on the fill-level of Rx queue, is enabled. When reset, the flow control operation is disabled. 0b - Hardware Flow Control is disabled 1b - Hardware Flow Control is enabled
6 DIS_TCP_EF	Disable Dropping of TCP/IP Checksum Error Packets When this bit is set, the MAC does not drop the packets which only have the errors detected by the Receive Checksum Offload engine. Disable Dropping of TCP/IP Checksum Error Packets When this bit is set, the MAC does not drop the packets which only have the errors detected by the Receive Checksum Offload engine. Such packets have errors only in the encapsulated payload. There are no errors (including FCS error) in the Ethernet packet received by the MAC. When this bit is reset, all error packets are dropped if the FEP bit is reset. 0b - Dropping of TCP/IP Checksum Error Packets is enabled 1b - Dropping of TCP/IP Checksum Error Packets is disabled
5 RSF	Receive Queue Store and Forward When this bit is set, the DWC_ether_qos reads a packet from the Rx queue only after the complete packet has been written to it, ignoring the RTC field of this register. Receive Queue Store and Forward When this bit is set, the DWC_ether_qos reads a packet from the Rx queue only after the complete packet has been written to it, ignoring the RTC field of this register. When this bit is reset, the Rx queue operates in the Threshold (cut-through) mode, subject to the threshold specified by the RTC field of this register. 0b - Receive Queue Store and Forward is disabled 1b - Receive Queue Store and Forward is enabled
4 FEP	Forward Error Packets When this bit is reset, the Rx queue drops packets with error status (CRC error, GMII_ER, watchdog timeout, or overflow). Forward Error Packets

Table continues on the next page...

Field	Function
	When this bit is reset, the Rx queue drops packets with error status (CRC error, GMII_ER, watchdog timeout, or overflow). However, if the start byte (write) pointer of a packet is already transferred to the read controller side (in Threshold mode), the packet is not dropped. When this bit is set, all packets except the runt error packets are forwarded to the application or DMA. If the RSF bit is set and the Rx queue overflows when a partial packet is written, the packet is dropped irrespective of the setting of this bit. However, if the RSF bit is reset and the Rx queue overflows when a partial packet is written, a partial packet may be forwarded to the application or DMA. 0b - Forward Error Packets is disabled 1b - Forward Error Packets is enabled
3 FUP	Forward Undersized Good Packets When this bit is set, the Rx queue forwards the undersized good packets (packets with no error and length less than 64 bytes), including pad-bytes and CRC. Forward Undersized Good Packets When this bit is set, the Rx queue forwards the undersized good packets (packets with no error and length less than 64 bytes), including pad-bytes and CRC. When this bit is reset, the Rx queue drops all packets of less than 64 bytes, unless a packet is already transferred because of the lower value of Rx Threshold, for example, RTC = 01. 0b - Forward Undersized Good Packets is disabled 1b - Forward Undersized Good Packets is enabled
2 —	Reserved
1-0 RTC	Receive Queue Threshold Control These bits control the threshold level of the MTL Rx queue (in bytes): The received packet is transferred to the application or DMA when the packet size within the MTL Rx queue is larger than the threshold. Receive Queue Threshold Control These bits control the threshold level of the MTL Rx queue (in bytes): The received packet is transferred to the application or DMA when the packet size within the MTL Rx queue is larger than the threshold. In addition, full packets with length less than the threshold are automatically transferred. This field is valid only when the RSF bit is zero. This field is ignored when the RSF bit is set to 1. 00b - 64 01b - 32 10b - 96 11b - 128

61.7.1.404 Queue 0 Missed Packet and Overflow Counter (MTL_RXQ0_MISSED_PACKET_OVERFLOW_CNT)

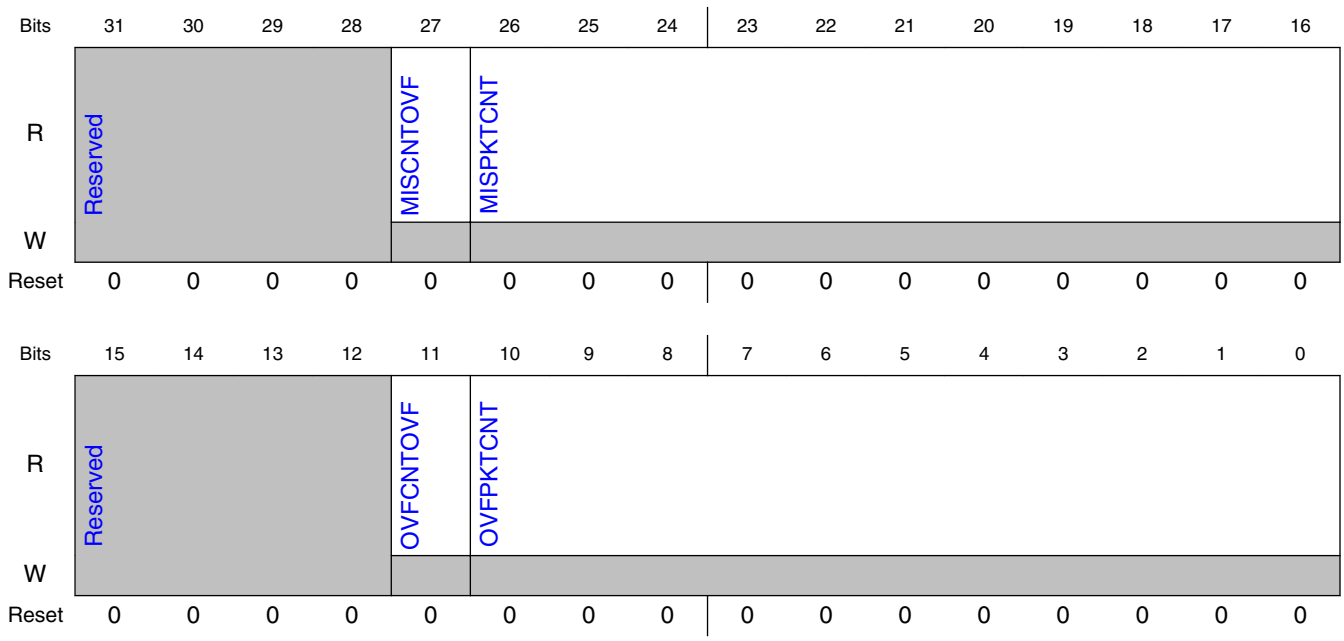
61.7.1.404.1 Offset

Register	Offset
MTL_RXQ0_MISSED_PACKET_OVERFLOW_CNT	D34h

61.7.1.404.2 Function

The Queue 0 Missed Packet and Overflow Counter register contains the counter for packets missed because of Receive queue packet flush and packets discarded because of Receive queue overflow.

61.7.1.404.3 Diagram



61.7.1.404.4 Fields

Field	Function
31-28 —	Reserved
27 MISCNTOVF	Missed Packet Counter Overflow Bit When set, this bit indicates that the Rx Queue Missed Packet Counter crossed the maximum limit. Missed Packet Counter Overflow Bit When set, this bit indicates that the Rx Queue Missed Packet Counter crossed the maximum limit. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0b - Missed Packet Counter overflow not detected 1b - Missed Packet Counter overflow detected
26-16 MISPKTCNT	Missed Packet Counter This field indicates the number of packets missed by the DWC_ether_qos because the application asserted ari_pkt_flush_i[] for this queue. Missed Packet Counter

Table continues on the next page...

Field	Function
	This field indicates the number of packets missed by the DWC_ether_qos because the application asserted ari_pkt_flush_i[] for this queue. This counter is reset when this register is read with mci_be_i[0] at 1b1. This counter is incremented by 1 when the DMA discards the packet because of buffer unavailability. Access restriction applies. Clears on read. Self-set to 1 on internal event.
15-12 —	Reserved
11 OVFCNTOVF	Overflow Counter Overflow Bit When set, this bit indicates that the Rx Queue Overflow Packet Counter field crossed the maximum limit. Overflow Counter Overflow Bit When set, this bit indicates that the Rx Queue Overflow Packet Counter field crossed the maximum limit. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0b - Overflow Counter overflow not detected 1b - Overflow Counter overflow detected
10-0 OVFPKTCNT	Overflow Packet Counter This field indicates the number of packets discarded by the DWC_ether_qos because of Receive queue overflow. Overflow Packet Counter This field indicates the number of packets discarded by the DWC_ether_qos because of Receive queue overflow. This counter is incremented each time the DWC_ether_qos discards an incoming packet because of overflow. This counter is reset when this register is read with mci_be_i[0] at 1'b1. Access restriction applies. Clears on read. Self-set to 1 on internal event.

61.7.1.405 Queue 0 Receive Debug (MTL_RXQ0_DEBUG)

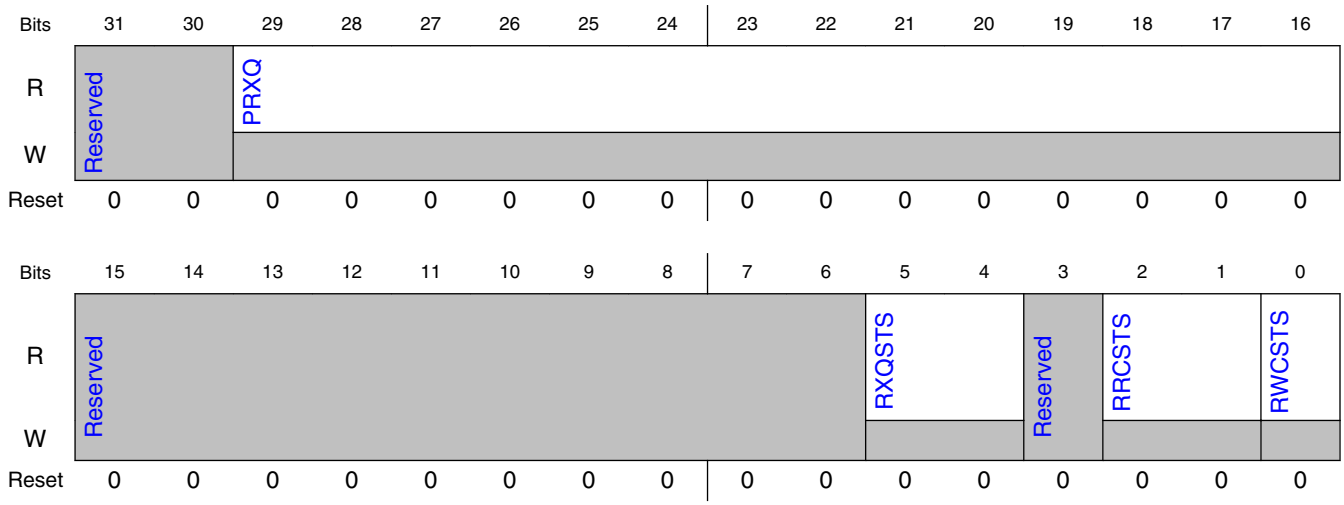
61.7.1.405.1 Offset

Register	Offset
MTL_RXQ0_DEBUG	D38h

61.7.1.405.2 Function

The Queue 0 Receive Debug register gives the debug status of various blocks related to the Receive queue.

61.7.1.405.3 Diagram



61.7.1.405.4 Fields

Field	Function
31-30 —	Reserved
29-16 PRXQ	Number of Packets in Receive Queue This field indicates the current number of packets in the Rx Queue. Number of Packets in Receive Queue This field indicates the current number of packets in the Rx Queue. The theoretical maximum value for this field is 256KB/16B = 16K Packets, that is, Max_Queue_Size/Min_Packet_Size.
15-6 —	Reserved
5-4 RXQSTS	MTL Rx Queue Fill-Level Status This field gives the status of the fill-level of the Rx Queue: 00b - Rx Queue empty 01b - Rx Queue fill-level below flow-control deactivate threshold 10b - Rx Queue fill-level above flow-control activate threshold 11b - Rx Queue full
3 —	Reserved
2-1 RRCSTS	MTL Rx Queue Read Controller State This field gives the state of the Rx queue Read controller: 00b - Idle state 01b - Reading packet data 10b - Reading packet status (or timestamp) 11b - Flushing the packet data and status
0 RWCSTS	MTL Rx Queue Write Controller Active Status When high, this bit indicates that the MTL Rx queue Write controller is active, and it is transferring a received packet to the Rx Queue. 0b - MTL Rx Queue Write Controller Active Status not detected 1b - MTL Rx Queue Write Controller Active Status detected

61.7.1.406 Queue 0 Receive Control (MTL_RXQ0_CONTROL)

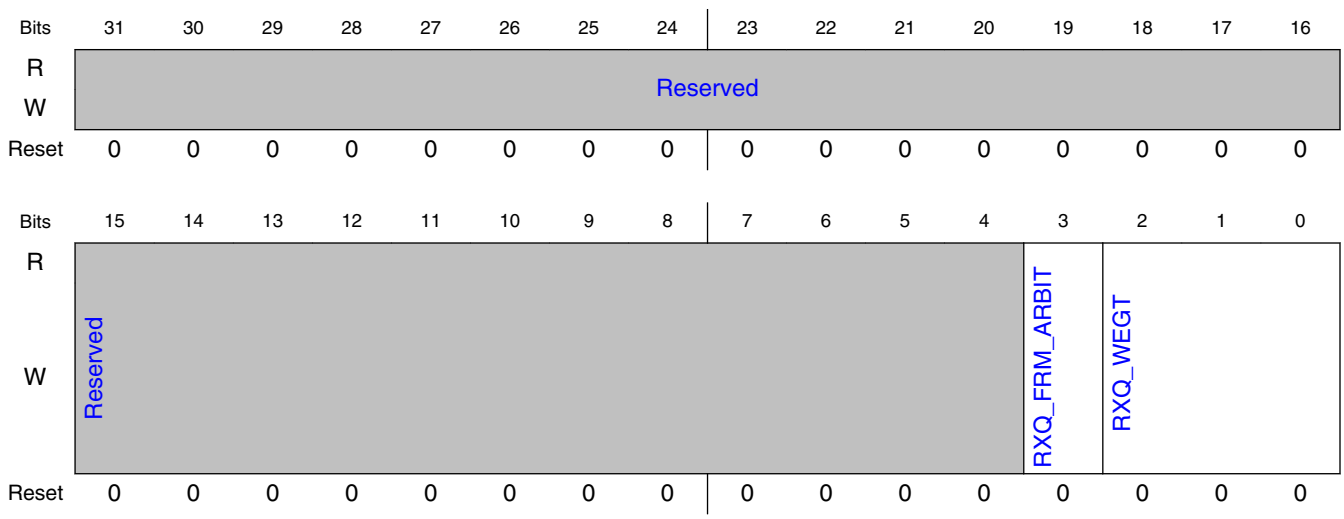
61.7.1.406.1 Offset

Register	Offset
MTL_RXQ0_CONTROL	D3Ch

61.7.1.406.2 Function

The Queue 0 Receive Control register controls the receive arbitration and passing of received packets to the application.

61.7.1.406.3 Diagram



61.7.1.406.4 Fields

Field	Function
31-4 —	Reserved
3 RXQ_FRM_ARBIT	Receive Queue Packet Arbitration When this bit is set, the DWC_ether_qos drives the packet data to the ARI interface such that the entire packet data of currently-selected queue is transmitted before switching to other queue. Receive Queue Packet Arbitration When this bit is set, the DWC_ether_qos drives the packet data to the ARI interface such that the entire packet data of currently-selected queue is transmitted before switching to other queue.

Table continues on the next page...

Field	Function
	When this bit is reset, the DWC_ether_qos drives the packet data to the ARI interface such that the following amount of data of currently-selected queue is transmitted before switching to other queue: - PBL amount of data (indicated by ari_qN_pbl_i[]) or - Complete data of a packet The status and the timestamp are not a part of the PBL data. Therefore, the DWC_ether_qos drives the complete status (including timestamp status) during first PBL request for the packet (in store-and-forward mode) or the last PBL request for the packet (in Threshold mode). 0b - Receive Queue Packet Arbitration is disabled 1b - Receive Queue Packet Arbitration is enabled
2-0 RXQ_WEGT	Receive Queue Weight This field indicates the weight assigned to the Rx Queue 0. Receive Queue Weight This field indicates the weight assigned to the Rx Queue 0. The weight is used as the number of continuous PBL or packets requests (depending on the RXQ_FRM_ARBIT) allocated to the queue in one arbitration cycle.

61.7.1.407 Queue 1 Transmit Operation Mode (MTL_TXQ1_OPERATION_MODE)

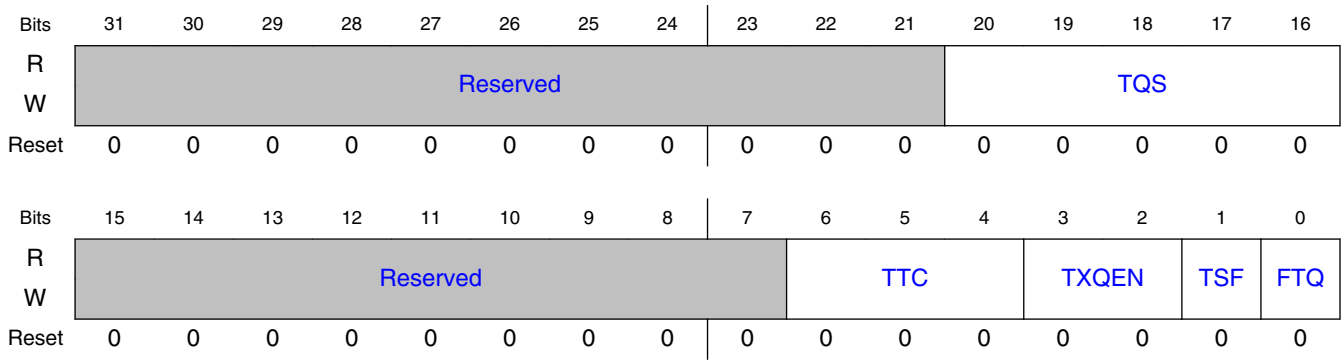
61.7.1.407.1 Offset

Register	Offset
MTL_TXQ1_OPERATION_MODE	D40h

61.7.1.407.2 Function

The Queue 1 Transmit Operation Mode register establishes the Transmit queue operating modes and commands.

61.7.1.407.3 Diagram



61.7.1.407.4 Fields

Field	Function
31-21 —	Reserved
20-16 TQS	Transmit Queue Size This field indicates the size of the allocated Transmit queues in blocks of 256 bytes. Transmit Queue Size This field indicates the size of the allocated Transmit queues in blocks of 256 bytes. The TQS field is read-write only if the number of Tx Queues more than one, the reset value is 0x0 and indicates size of 256 bytes. When the number of Tx Queues is one, the field is read-only and the configured TX FIFO size in blocks of 256 bytes is reflected in the reset value. The width of this field depends on the Tx memory size selected in your configuration. For example, if the memory size is 2048, the width of this field is 3 bits: LOG2(2048/256) = LOG2(8) = 3 bits
15-7 —	Reserved
6-4 TTC	Transmit Threshold Control These bits control the threshold level of the MTL Tx Queue. Transmit Threshold Control These bits control the threshold level of the MTL Tx Queue. The transmission starts when the packet size within the MTL Tx Queue is larger than the threshold. In addition, full packets with length less than the threshold are also transmitted. These bits are used only when the TSF bit is reset. 000b - 32 001b - 64 010b - 96 011b - 128 100b - 192 101b - 256 110b - 384 111b - 512
3-2 TXQEN	Transmit Queue Enable This field is used to enable/disable the transmit queue 0. Transmit Queue Enable

Table continues on the next page...

Field	Function
	This field is used to enable/disable the transmit queue 0. - 2'b00: Not enabled - 2'b01: Enable in AV mode - 2'b10: Enabled - 2'b11: Reserved Note: In multiple Tx queues configuration, all the queues are disabled by default. Enable the Tx queue by programming this field. 00b - Not enabled 01b - Enable in AV mode (Reserved in non-AV) 10b - Enabled 11b - Reserved
1 TSF	Transmit Store and Forward When this bit is set, the transmission starts when a full packet resides in the MTL Tx queue. Transmit Store and Forward When this bit is set, the transmission starts when a full packet resides in the MTL Tx queue. When this bit is set, the TTC values specified in Bits[6:4] of this register are ignored. This bit should be changed only when the transmission is stopped. 0b - Transmit Store and Forward is disabled 1b - Transmit Store and Forward is enabled
0 FTQ	Flush Transmit Queue When this bit is set, the Tx queue controller logic is reset to its default values. Flush Transmit Queue When this bit is set, the Tx queue controller logic is reset to its default values. Therefore, all the data in the Tx queue is lost or flushed. This bit is internally reset when the flushing operation is complete. Until this bit is reset, you should not write to the MTL_TXQ1_OPERATION_MODE register. The data which is already accepted by the MAC transmitter is not flushed. It is scheduled for transmission and results in underflow and runt packet transmission. Note: The flush operation is complete only when the Tx queue is empty and the application has accepted the pending Tx Status of all transmitted packets. To complete this flush operation, the PHY Tx clock (clk_tx_i) should be active. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0b - Flush Transmit Queue is disabled 1b - Flush Transmit Queue is enabled

61.7.1.408 Queue 1 Underflow Counter (MTL_TXQ1_UNDERFLOW)

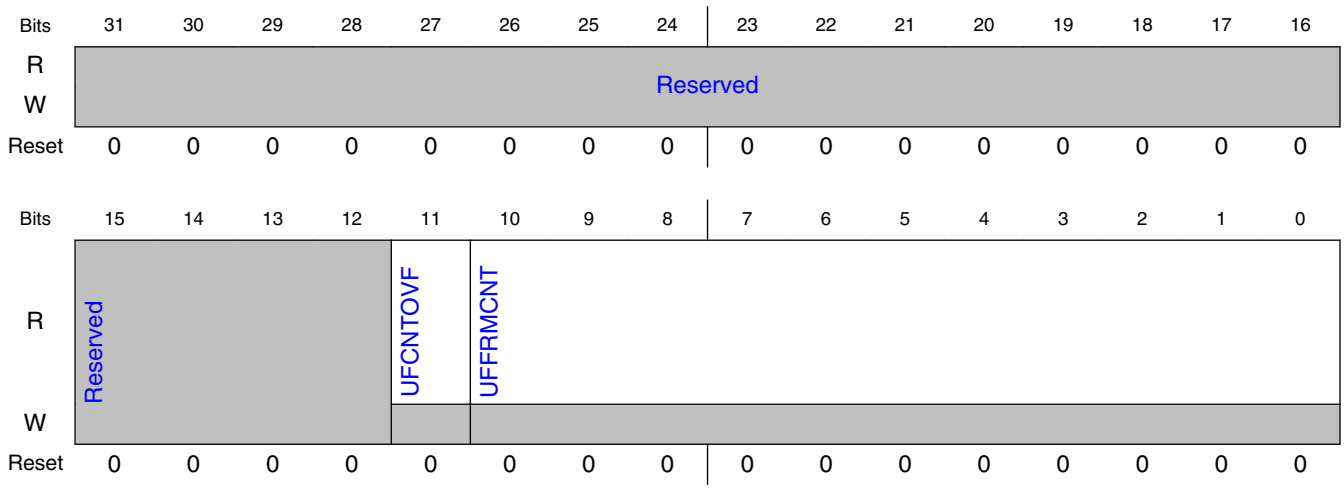
61.7.1.408.1 Offset

Register	Offset
MTL_TXQ1_UNDERFLOW	D44h

61.7.1.408.2 Function

The Queue 1 Underflow Counter register contains the counter for packets aborted because of Transmit queue underflow and packets missed because of Receive queue packet flush

61.7.1.408.3 Diagram



61.7.1.408.4 Fields

Field	Function
31-12 —	Reserved
11 UFCNTOVF	Overflow Bit for Underflow Packet Counter This bit is set every time the Tx queue Underflow Packet Counter field overflows, that is, it has crossed the maximum count. Overflow Bit for Underflow Packet Counter This bit is set every time the Tx queue Underflow Packet Counter field overflows, that is, it has crossed the maximum count. In such a scenario, the overflow packet counter is reset to all-zeros and this bit indicates that the rollover happened. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0b - Overflow not detected for Underflow Packet Counter 1b - Overflow detected for Underflow Packet Counter
10-0 UFFRMCNT	Underflow Packet Counter This field indicates the number of packets aborted by the controller because of Tx Queue Underflow. Underflow Packet Counter This field indicates the number of packets aborted by the controller because of Tx Queue Underflow. This counter is incremented each time the MAC aborts outgoing packet because of underflow. The counter is cleared when this register is read with mci_be_i[0] at 1'b1. Access restriction applies. Clears on read. Self-set to 1 on internal event.

61.7.1.409 Queue 1 Transmit Debug (MTL_TXQ1_DEBUG)

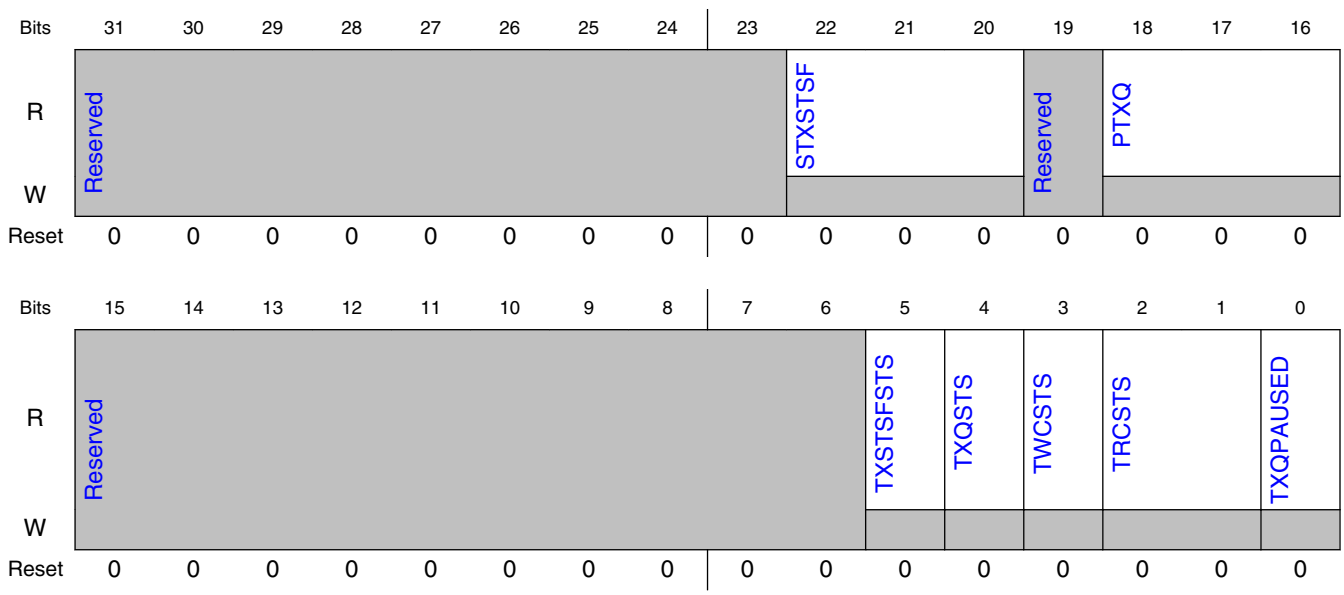
61.7.1.409.1 Offset

Register	Offset
MTL_TXQ1_DEBUG	D48h

61.7.1.409.2 Function

The Queue 1 Transmit Debug register gives the debug status of various blocks related to the Transmit queue.

61.7.1.409.3 Diagram



61.7.1.409.4 Fields

Field	Function
31-23 —	Reserved
22-20 STXSTSF	Number of Status Words in Tx Status FIFO of Queue This field indicates the current number of status in the Tx Status FIFO of this queue. Number of Status Words in Tx Status FIFO of Queue

Table continues on the next page...

Field	Function
	This field indicates the current number of status in the Tx Status FIFO of this queue. When the DTXSTS bit of OPERATION_MODE register is set to 1, this field does not reflect the number of status words in Tx Status FIFO.
19 —	Reserved
18-16 PTXQ	Number of Packets in the Transmit Queue This field indicates the current number of packets in the Tx Queue. Number of Packets in the Transmit Queue This field indicates the current number of packets in the Tx Queue. When the DTXSTS bit of MTL_OPERATION_MODE register is set to 1, this field does not reflect the number of packets in the Transmit queue.
15-6 —	Reserved
5 TXSTSFSTS	MTL Tx Status FIFO Full Status When high, this bit indicates that the MTL Tx Status FIFO is full. MTL Tx Status FIFO Full Status When high, this bit indicates that the MTL Tx Status FIFO is full. Therefore, the MTL cannot accept any more packets for transmission. 0b - MTL Tx Status FIFO Full status is not detected 1b - MTL Tx Status FIFO Full status is detected
4 TXQSTS	MTL Tx Queue Not Empty Status When this bit is high, it indicates that the MTL Tx Queue is not empty and some data is left for transmission. 0b - MTL Tx Queue Not Empty status is not detected 1b - MTL Tx Queue Not Empty status is detected
3 TWCSTS	MTL Tx Queue Write Controller Status When high, this bit indicates that the MTL Tx Queue Write Controller is active, and it is transferring the data to the Tx Queue. 0b - MTL Tx Queue Write Controller status is not detected 1b - MTL Tx Queue Write Controller status is detected
2-1 TRCSTS	MTL Tx Queue Read Controller Status This field indicates the state of the Tx Queue Read Controller: 00b - Idle state 01b - Read state (transferring data to the MAC transmitter) 10b - Waiting for pending Tx Status from the MAC transmitter 11b - Flushing the Tx queue because of the Packet Abort request from the MAC
0 TXQPAUSED	Transmit Queue in Pause When this bit is high and the Rx flow control is enabled, it indicates that the Tx Queue is in the Pause condition (in the full-duplex only mode) because of the following: - Reception of the PFC packet for the priorities assigned to the Tx Queue when PFC is enabled - Reception of 802. Transmit Queue in Pause When this bit is high and the Rx flow control is enabled, it indicates that the Tx Queue is in the Pause condition (in the full-duplex only mode) because of the following: - Reception of the PFC packet for the priorities assigned to the Tx Queue when PFC is enabled - Reception of 802.3x Pause packet when PFC is disabled 0b - Transmit Queue in Pause status is not detected 1b - Transmit Queue in Pause status is detected

61.7.1.410 Queue 1 ETS Control (MTL_TXQ1_ETS_CONTROL)

61.7.1.410.1 Offset

Register	Offset
MTL_TXQ1_ETS_CONTROL	D50h

61.7.1.410.2 Function

The Queue 1 ETS Control register controls the enhanced transmission selection operation.

61.7.1.412.4 Fields

Field	Function
31-21 —	Reserved
20-0 ISCQW	idleSlopeCredit, Quantum or Weights - idleSlopeCredit When AV feature is enabled, this field contains the idleSlopeCredit value required for the credit-based shaper algorithm for Queue 1. idleSlopeCredit, Quantum or Weights - idleSlopeCredit When AV feature is enabled, this field contains the idleSlopeCredit value required for the credit-based shaper algorithm for Queue 1. This is the rate of change of credit in bits per cycle (40 ns for 100 Mbps; 8 ns for 1000 Mbps; 3.2 ns for 2500 Mbps) when the credit is increasing. The software should program this field with computed credit in bits per cycle scaled by 1,024. The maximum value is portTransmitRate, that is, 0x2000 in 1000/2500 Mbps mode and 0x1000 in 100 Mbps mode. Bits[20:14] must be written to zero. - Quantum When the DCB operation is enabled with DWRR algorithm for Queue 1 traffic, this field contains the quantum value in bytes to be added to credit during every queue scanning cycle. The maximum value is 0x1312D0 bytes. - Weights When DCB operation is enabled with WFQ algorithm for Queue 1 traffic, this field contains the weight for this queue. The maximum value is 0x3FFF where weight of 0 indicates 100% bandwidth. Bits[20:14] must be written to zero. When DCB operation or generic queuing operation is enabled with WRR algorithm for Queue 1 traffic, this field contains the weight for this queue. The maximum value is 0x64. Bits [20:7] must be written to zero. - Note 1: In multiple Queue configuration this field in respective per queue register must be programmed to some non-zero value when multiple queues are enabled or single queue other than Q0 is enabled. This field need not be programmed when only Q0 is enabled. In general, when WRR algorithm is selected a non-zero value must be programmed on both Receive and Transmit. In Receive, the register is MTL_OPERATION_MODE register.

Field	Function
	- Note 2: For WFQ algorithm, higher the programmed weights lesser the bandwidth allocated for that Transmit Queue. The finish time is not a function of particular packet alone but it is as per the formula: (previous_finish_time of particular Transmit Queue + (weights*packet_size)) - Note 3: The weights programmed do not correspond to the number of packets but the fraction of bandwidth or time allocated for particular queue w.r.t. total BW or time.

61.7.1.413 Queue 1 sendSlopeCredit (MTL_TXQ1_SENDSLOPECREDIT)

61.7.1.413.1 Offset

Register	Offset
MTL_TXQ1_SENDSLOPECREDIT	D5Ch

61.7.1.413.2 Function

The sendSlopeCredit register contains the sendSlope credit value required for the credit-based shaper algorithm for the Queue.

Field	Function
31-25 —	Reserved
24-20 RQS	Receive Queue Size This field indicates the size of the allocated Receive queues in blocks of 256 bytes. Receive Queue Size This field indicates the size of the allocated Receive queues in blocks of 256 bytes. The RQS field is read-write only if the number of Rx Queues more than one, the reset value is 0x0 and indicates size of 256 bytes. When the number of Rx Queues is one, the field is read-only and the configured RX FIFO size in blocks of 256 bytes is reflected in the reset value. The width of this field depends on the Rx memory size selected in your configuration. For example, if the memory size is 2048, the width of this field is 3 bits: LOG2(2048/256) = LOG2(8) = 3 bits

Table continues on the next page...

Field	Function
19-18 —	Reserved
17-14 RFD	Threshold for Deactivating Flow Control (in half-duplex and full-duplex modes) These bits control the threshold (fill-level of Rx queue) at which the flow control is de-asserted after activation: - 0: Full minus 1 KB, that is, FULL 1 KB - 1: Full minus 1. Threshold for Deactivating Flow Control (in half-duplex and full-duplex modes) These bits control the threshold (fill-level of Rx queue) at which the flow control is de-asserted after activation: - 0: Full minus 1 KB, that is, FULL 1 KB - 1: Full minus 1.5 KB, that is, FULL 1.5 KB - 2: Full minus 2 KB, that is, FULL 2 KB - 3: Full minus 2.5 KB, that is, FULL 2.5 KB - ... - 14: Full minus 8 KB, that is, FULL 8 KB - 15: Full minus 8.5 KB, that is, FULL 8.5 KB The de-assertion is effective only after flow control is asserted. Note: The value must be programmed in such a way to make sure that the threshold is a positive number. When the EHFC is set high, these values are applicable only when the Rx queue size determined by the RQS field of this register, is equal to or greater than 4 KB. For a given queue size, the values ranges between 0 and the encoding for FULL minus (QSIZE - 0.5 KB) and all other values are illegal. Here the term FULL and QSIZE refers to the queue size determined by the RQS field of this register. The width of this field depends on RX FIFO size selected during the configuration. Remaining bits are reserved and read only.
13-12 —	Reserved
11-8 RFA	Threshold for Activating Flow Control (in half-duplex and full-duplex These bits control the threshold (fill-level of Rx queue) at which the flow control is activated: For more information on encoding for this field, see RFD.
7 EHFC	Enable Hardware Flow Control When this bit is set, the flow control signal operation, based on the fill-level of Rx queue, is enabled. Enable Hardware Flow Control When this bit is set, the flow control signal operation, based on the fill-level of Rx queue, is enabled. When reset, the flow control operation is disabled. 0b - Hardware Flow Control is disabled 1b - Hardware Flow Control is enabled
6 DIS_TCP_EF	Disable Dropping of TCP/IP Checksum Error Packets When this bit is set, the MAC does not drop the packets which only have the errors detected by the Receive Checksum Offload engine. Disable Dropping of TCP/IP Checksum Error Packets When this bit is set, the MAC does not drop the packets which only have the errors detected by the Receive Checksum Offload engine. Such packets have errors only in the encapsulated payload. There are no errors (including FCS error) in the Ethernet packet received by the MAC. When this bit is reset, all error packets are dropped if the FEP bit is reset. 0b - Dropping of TCP/IP Checksum Error Packets is enabled

Table continues on the next page...

Field	Function
	1b - Dropping of TCP/IP Checksum Error Packets is disabled
5 RSF	Receive Queue Store and Forward When this bit is set, the DWC_ether_qos reads a packet from the Rx queue only after the complete packet has been written to it, ignoring the RTC field of this register. Receive Queue Store and Forward When this bit is set, the DWC_ether_qos reads a packet from the Rx queue only after the complete packet has been written to it, ignoring the RTC field of this register. When this bit is reset, the Rx queue operates in the Threshold (cut-through) mode, subject to the threshold specified by the RTC field of this register. 0b - Receive Queue Store and Forward is disabled 1b - Receive Queue Store and Forward is enabled
4 FEP	Forward Error Packets When this bit is reset, the Rx queue drops packets with error status (CRC error, GMII_ER, watchdog timeout, or overflow). Forward Error Packets When this bit is reset, the Rx queue drops packets with error status (CRC error, GMII_ER, watchdog timeout, or overflow). However, if the start byte (write) pointer of a packet is already transferred to the read controller side (in Threshold mode), the packet is not dropped. When this bit is set, all packets except the runt error packets are forwarded to the application or DMA. If the RSF bit is set and the Rx queue overflows when a partial packet is written, the packet is dropped irrespective of the setting of this bit. However, if the RSF bit is reset and the Rx queue overflows when a partial packet is written, a partial packet may be forwarded to the application or DMA. 0b - Forward Error Packets is disabled 1b - Forward Error Packets is enabled
3 FUP	Forward Undersized Good Packets When this bit is set, the Rx queue forwards the undersized good packets (packets with no error and length less than 64 bytes), including pad-bytes and CRC. Forward Undersized Good Packets When this bit is set, the Rx queue forwards the undersized good packets (packets with no error and length less than 64 bytes), including pad-bytes and CRC. When this bit is reset, the Rx queue drops all packets of less than 64 bytes, unless a packet is already transferred because of the lower value of Rx Threshold, for example, RTC = 01. 0b - Forward Undersized Good Packets is disabled 1b - Forward Undersized Good Packets is enabled
2 —	Reserved
1-0 RTC	Receive Queue Threshold Control These bits control the threshold level of the MTL Rx queue (in bytes): The received packet is transferred to the application or DMA when the packet size within the MTL Rx queue is larger than the threshold. Receive Queue Threshold Control These bits control the threshold level of the MTL Rx queue (in bytes): The received packet is transferred to the application or DMA when the packet size within the MTL Rx queue is larger than the threshold. In addition, full packets with length less than the threshold are automatically transferred. This field is valid only when the RSF bit is zero. This field is ignored when the RSF bit is set to 1. 00b - 64 01b - 32 10b - 96 11b - 128

20-16 TQS	Transmit Queue Size This field indicates the size of the allocated Transmit queues in blocks of 256 bytes. Transmit Queue Size This field indicates the size of the allocated Transmit queues in blocks of 256 bytes. The TQS field is read-write only if the number of Tx Queues more than one, the reset value is 0x0 and indicates size of 256 bytes. When the number of Tx Queues is one, the field is read-only and the configured TX FIFO size in blocks of 256 bytes is reflected in the reset value. The width of this field depends on the Tx memory size selected in your configuration. For example, if the memory size is 2048, the width of this field is 3 bits: LOG2(2048/256) = LOG2(8) = 3 bits
15-7 —	Reserved
6-4 TTC	Transmit Threshold Control These bits control the threshold level of the MTL Tx Queue. Transmit Threshold Control These bits control the threshold level of the MTL Tx Queue. The transmission starts when the packet size within the MTL Tx Queue is larger than the threshold. In addition, full packets with length less than the threshold are also transmitted. These bits are used only when the TSF bit is reset. 000b - 32 001b - 64 010b - 96 011b - 128 100b - 192 101b - 256 110b - 384 111b - 512
3-2 TXQEN	Transmit Queue Enable This field is used to enable/disable the transmit queue 0. Transmit Queue Enable

Table continues on the next page...

Field	Function
	This field is used to enable/disable the transmit queue 0. - 2'b00: Not enabled - 2'b01: Enable in AV mode - 2'b10: Enabled - 2'b11: Reserved Note: In multiple Tx queues configuration, all the queues are disabled by default. Enable the Tx queue by programming this field. 00b - Not enabled 01b - Enable in AV mode (Reserved in non-AV) 10b - Enabled 11b - Reserved
1 TSF	Transmit Store and Forward When this bit is set, the transmission starts when a full packet resides in the MTL Tx queue. Transmit Store and Forward When this bit is set, the transmission starts when a full packet resides in the MTL Tx queue. When this bit is set, the TTC values specified in Bits[6:4] of this register are ignored. This bit should be changed only when the transmission is stopped. 0b - Transmit Store and Forward is disabled 1b - Transmit Store and Forward is enabled
0 FTQ	Flush Transmit Queue When this bit is set, the Tx queue controller logic is reset to its default values. Flush Transmit Queue When this bit is set, the Tx queue controller logic is reset to its default values. Therefore, all the data in the Tx queue is lost or flushed. This bit is internally reset when the flushing operation is complete. Until this bit is reset, you should not write to the MTL_TXQ2_OPERATION_MODE register. The data which is already accepted by the MAC transmitter is not flushed. It is scheduled for transmission and results in underflow and runt packet transmission. Note: The flush operation is complete only when the Tx queue is empty and the application has accepted the pending Tx Status of all transmitted packets. To complete this flush operation, the PHY Tx clock (clk_tx_i) should be active. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0b - Flush Transmit Queue is disabled 1b - Flush Transmit Queue is enabled

61.7.1.422 Queue 2 Underflow Counter (MTL_TXQ2_UNDERFLOW)

61.7.1.422.1 Offset

Register	Offset
MTL_TXQ2_UNDERFLOW	D84h

61.7.1.426.4 Fields

Field	Function
31-21 —	Reserved
20-0 ISCQW	idleSlopeCredit, Quantum or Weights - idleSlopeCredit When AV feature is enabled, this field contains the idleSlopeCredit value required for the credit-based shaper algorithm for Queue 2. idleSlopeCredit, Quantum or Weights - idleSlopeCredit When AV feature is enabled, this field contains the idleSlopeCredit value required for the credit-based shaper algorithm for Queue 2. This is the rate of change of credit in bits per cycle (40 ns for 100 Mbps; 8 ns for 1000 Mbps; 3.2 ns for 2500 Mbps) when the credit is increasing. The software should program this field with computed credit in bits per cycle scaled by 1,024. The maximum value is portTransmitRate, that is, 0x2000 in 1000/2500 Mbps mode and 0x1000 in 100 Mbps mode. Bits[20:14] must be written to zero. - Quantum When the DCB operation is enabled with DWRR algorithm for Queue 2 traffic, this field contains the quantum value in bytes to be added to credit during every queue scanning cycle. The maximum value is 0x1312D0 bytes. - Weights When DCB operation is enabled with WFQ algorithm for Queue 2 traffic, this field contains the weight for this queue. The maximum value is 0x3FFF where weight of 0 indicates 100% bandwidth. Bits[20:14] must be written to zero. When DCB operation or generic queuing operation is enabled with WRR algorithm for Queue 2 traffic, this field contains the weight for this queue. The maximum value is 0x64. Bits [20:7] must be written to zero. - Note 1: In multiple Queue configuration this field in respective per queue register must be programmed to some non-zero value when multiple queues are enabled or single queue other than Q0 is enabled. This field need not be programmed when only Q0 is enabled. In general, when WRR algorithm is selected a non-zero value must be programmed on both Receive and Transmit. In Receive, the register is MTL_OPERATION_MODE register.

Field	Function
	- Note 2: For WFQ algorithm, higher the programmed weights lesser the bandwidth allocated for that Transmit Queue. The finish time is not a function of particular packet alone but it is as per the formula: (previous_finish_time of particular Transmit Queue + (weights*packet_size)) - Note 3: The weights programmed do not correspond to the number of packets but the fraction of bandwidth or time allocated for particular queue w.r.t. total BW or time.

61.7.1.427 Queue 2 sendSlopeCredit (MTL_TXQ2_SENDSLOPECREDIT)

61.7.1.427.1 Offset

Register	Offset
MTL_TXQ2_SENDSLOPECREDIT	D9Ch

61.7.1.427.2 Function

The sendSlopeCredit register contains the sendSlope credit value required for the credit-based shaper algorithm for the Queue.

13-0 SSC	sendSlopeCredit Value When AV operation is enabled, this field contains the sendSlopeCredit value required for credit-based shaper algorithm for Queue 2. sendSlopeCredit Value When AV operation is enabled, this field contains the sendSlopeCredit value required for credit-based shaper algorithm for Queue 2. This is the rate of change of credit in bits per cycle (40 ns, 8 ns and 3.2 ns for 100 Mbps, 1000 Mbps and 2500 Mbps respectively) when the credit is decreasing. The software should program this field with computed credit in bits per cycle scaled by 1,024. The maximum value is portTransmitRate, that is, 0x2000 in 1000/2500 Mbps mode and 0x1000 in 100 Mbps mode. This field should be programmed with absolute sendSlopeCredit value. The credit-based shaper logic subtracts it from the accumulated credit when Channel 2 is selected for transmission.

61.7.1.428 Queue 2 hiCredit (MTL_TXQ2_HICREDIT)

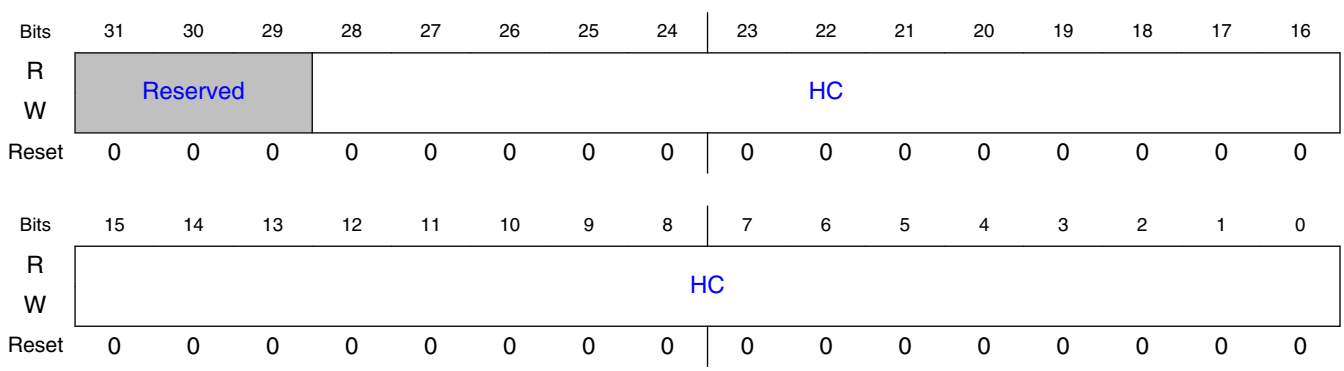
61.7.1.428.1 Offset

Register	Offset
MTL_TXQ2_HICREDIT	DA0h

61.7.1.428.2 Function

The hiCredit register contains the hiCredit value required for the credit-based shaper algorithm for the Queue.

61.7.1.428.3 Diagram



61.7.1.428.4 Fields

Field	Function
31-29 —	Reserved
28-0 HC	hiCredit Value When the AV feature is enabled, this field contains the hiCredit value required for the credit-based shaper algorithm. hiCredit Value When the AV feature is enabled, this field contains the hiCredit value required for the credit-based shaper algorithm. This is the maximum value that can be accumulated in the credit parameter. This is specified in bits scaled by 1,024. The maximum value is maxInterferenceSize, that is, best-effort maximum packet size (16,384 bytes or 131,072 bits). The value to be specified is 131,072 * 1,024 = 134,217,728 or 0x0800_0000.

61.7.1.429 Queue 2 loCredit (MTL_TXQ2_LOCREDIT)

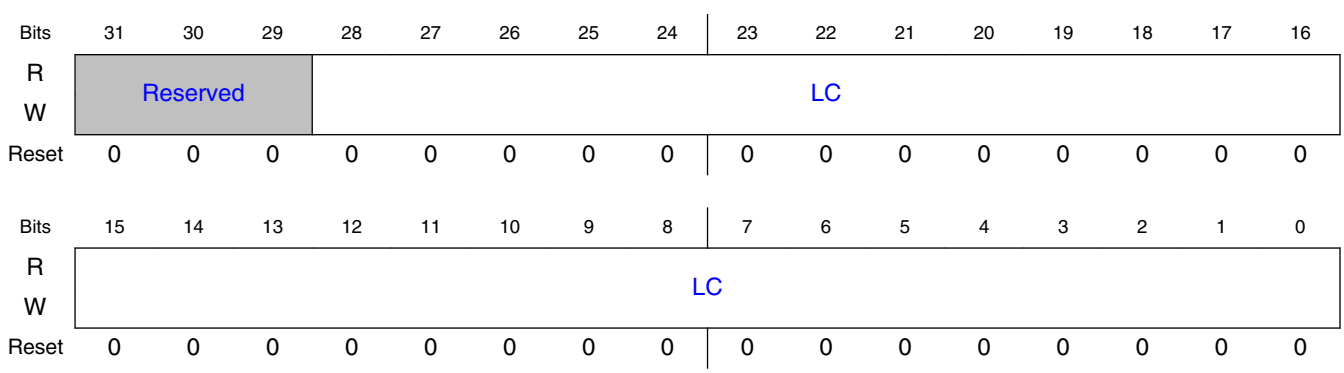
61.7.1.429.1 Offset

Register	Offset
MTL_TXQ2_LOCREDIT	DA4h

61.7.1.429.2 Function

The loCredit register contains the loCredit value required for the credit-based shaper algorithm for the Queue.

61.7.1.429.3 Diagram



61.7.1.429.4 Fields

Field	Function
31-29 —	Reserved
28-0 LC	loCredit Value When AV operation is enabled, this field contains the loCredit value required for the credit-based shaper algorithm. loCredit Value When AV operation is enabled, this field contains the loCredit value required for the credit-based shaper algorithm. This is the minimum value that can be accumulated in the credit parameter. This is specified in bits scaled by 1,024. The maximum value to be programmed is corresponds to twice the maxFrameSize transmitted from this queue. If the maxFrameSize is 8192 bytes, then (8192*2) * 8 * 1024 = 134,217,728 or 0x0800_0000. Because it is a negative value, the programmed value is 2's complement of the value, that is, 0x1800_0000.

61.7.1.430 Queue 2 Interrupt Control Status (MTL_Q2_INTERRUPT_CONTROL_STATUS)

61.7.1.430.1 Offset

Register	Offset
MTL_Q2_INTERRUPT_CONTROL_STATUS	DACh

61.7.1.430.2 Function

This register contains the interrupt enable and status bits for the queue 2 interrupts.

61.7.1.430.3 Diagram

31-25 —	Reserved
24 RXOIE	Receive Queue Overflow Interrupt Enable When this bit is set, the Receive Queue Overflow interrupt is enabled. Receive Queue Overflow Interrupt Enable When this bit is set, the Receive Queue Overflow interrupt is enabled. When this bit is reset, the Receive Queue Overflow interrupt is disabled. 0b - Receive Queue Overflow Interrupt is disabled 1b - Receive Queue Overflow Interrupt is enabled
23-17 —	Reserved
16 RXOVFIS	Receive Queue Overflow Interrupt Status This bit indicates that the Receive Queue had an overflow while receiving the packet. Receive Queue Overflow Interrupt Status This bit indicates that the Receive Queue had an overflow while receiving the packet. If a partial packet is transferred to the application, the overflow status is set in RDES3[21]. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Receive Queue Overflow Interrupt Status not detected 1b - Receive Queue Overflow Interrupt Status detected
15-10 —	Reserved
9 ABPSIE	Average Bits Per Slot Interrupt Enable When this bit is set, the MAC asserts the sbd_intr_o or mci_intr_o interrupt when the average bits per slot status is updated. Average Bits Per Slot Interrupt Enable

Table continues on the next page...

Field	Function
	When this bit is set, the MAC asserts the sbd_intr_o or mci_intr_o interrupt when the average bits per slot status is updated. When this bit is cleared, the interrupt is not asserted for such an event. 0b - Average Bits Per Slot Interrupt is disabled 1b - Average Bits Per Slot Interrupt is enabled
8 TXUIE	Transmit Queue Underflow Interrupt Enable When this bit is set, the Transmit Queue Underflow interrupt is enabled. Transmit Queue Underflow Interrupt Enable When this bit is set, the Transmit Queue Underflow interrupt is enabled. When this bit is reset, the Transmit Queue Underflow interrupt is disabled. 0b - Transmit Queue Underflow Interrupt Status is disabled 1b - Transmit Queue Underflow Interrupt Status is enabled
7-2 —	Reserved
1 ABPSIS	Average Bits Per Slot Interrupt Status When set, this bit indicates that the MAC has updated the ABS value. Average Bits Per Slot Interrupt Status When set, this bit indicates that the MAC has updated the ABS value. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Average Bits Per Slot Interrupt Status not detected 1b - Average Bits Per Slot Interrupt Status detected
0 TXUNFIS	Transmit Queue Underflow Interrupt Status This bit indicates that the Transmit Queue had an underflow while transmitting the packet. Transmit Queue Underflow Interrupt Status This bit indicates that the Transmit Queue had an underflow while transmitting the packet. Transmission is suspended and an Underflow Error TDES3[2] is set. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Transmit Queue Underflow Interrupt Status not detected 1b - Transmit Queue Underflow Interrupt Status detected

61.7.1.431 Queue 2 Receive Operation Mode (MTL_RXQ2_OPERATION_MODE)

61.7.1.431.1 Offset

Register	Offset
MTL_RXQ2_OPERATION_MODE	DB0h

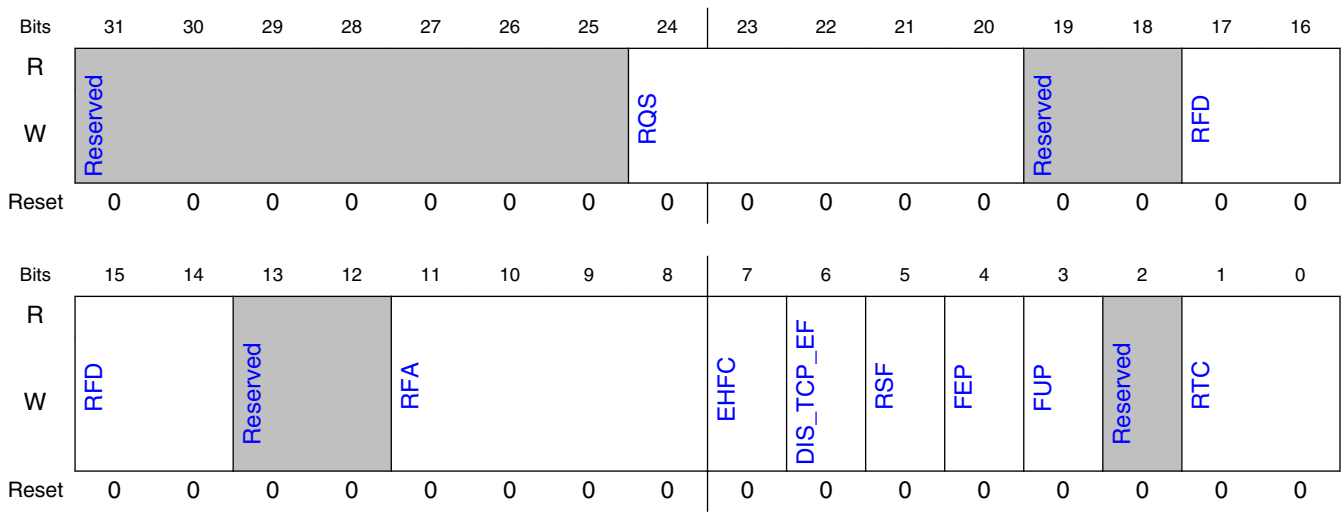
61.7.1.431.2 Function

The Queue 2 Receive Operation Mode register establishes the Receive queue operating modes and command.

The Queue 2 Receive Operation Mode register establishes the Receive queue operating modes and command.

The RFA and RFD fields are not backward compatible with the RFA and RFD fields of 4.00a release

61.7.1.431.3 Diagram



61.7.1.431.4 Fields

Field	Function
31-25 —	Reserved
24-20 RQS	Receive Queue Size This field indicates the size of the allocated Receive queues in blocks of 256 bytes. Receive Queue Size This field indicates the size of the allocated Receive queues in blocks of 256 bytes. The RQS field is read-write only if the number of Rx Queues more than one, the reset value is 0x0 and indicates size of 256 bytes. When the number of Rx Queues is one, the field is read-only and the configured RX FIFO size in blocks of 256 bytes is reflected in the reset value. The width of this field depends on the Rx memory size selected in your configuration. For example, if the memory size is 2048, the width of this field is 3 bits: LOG2(2048/256) = LOG2(8) = 3 bits

Table continues on the next page...

Field	Function
19-18 —	Reserved
17-14 RFD	Threshold for Deactivating Flow Control (in half-duplex and full-duplex modes) These bits control the threshold (fill-level of Rx queue) at which the flow control is de-asserted after activation: - 0: Full minus 1 KB, that is, FULL 1 KB - 1: Full minus 1. Threshold for Deactivating Flow Control (in half-duplex and full-duplex modes) These bits control the threshold (fill-level of Rx queue) at which the flow control is de-asserted after activation: - 0: Full minus 1 KB, that is, FULL 1 KB - 1: Full minus 1.5 KB, that is, FULL 1.5 KB - 2: Full minus 2 KB, that is, FULL 2 KB - 3: Full minus 2.5 KB, that is, FULL 2.5 KB - ... - 14: Full minus 8 KB, that is, FULL 8 KB - 15: Full minus 8.5 KB, that is, FULL 8.5 KB The de-assertion is effective only after flow control is asserted. Note: The value must be programmed in such a way to make sure that the threshold is a positive number. When the EHFC is set high, these values are applicable only when the Rx queue size determined by the RQS field of this register, is equal to or greater than 4 KB. For a given queue size, the values ranges between 0 and the encoding for FULL minus (QSIZE - 0.5 KB) and all other values are illegal. Here the term FULL and QSIZE refers to the queue size determined by the RQS field of this register. The width of this field depends on RX FIFO size selected during the configuration. Remaining bits are reserved and read only.
13-12 —	Reserved
11-8 RFA	Threshold for Activating Flow Control (in half-duplex and full-duplex These bits control the threshold (fill-level of Rx queue) at which the flow control is activated: For more information on encoding for this field, see RFD.
7 EHFC	Enable Hardware Flow Control When this bit is set, the flow control signal operation, based on the fill-level of Rx queue, is enabled. Enable Hardware Flow Control When this bit is set, the flow control signal operation, based on the fill-level of Rx queue, is enabled. When reset, the flow control operation is disabled. 0b - Hardware Flow Control is disabled 1b - Hardware Flow Control is enabled
6 DIS_TCP_EF	Disable Dropping of TCP/IP Checksum Error Packets When this bit is set, the MAC does not drop the packets which only have the errors detected by the Receive Checksum Offload engine. Disable Dropping of TCP/IP Checksum Error Packets When this bit is set, the MAC does not drop the packets which only have the errors detected by the Receive Checksum Offload engine. Such packets have errors only in the encapsulated payload. There are no errors (including FCS error) in the Ethernet packet received by the MAC. When this bit is reset, all error packets are dropped if the FEP bit is reset. 0b - Dropping of TCP/IP Checksum Error Packets is enabled

Table continues on the next page...

Field	Function
	1b - Dropping of TCP/IP Checksum Error Packets is disabled
5 RSF	Receive Queue Store and Forward When this bit is set, the DWC_ether_qos reads a packet from the Rx queue only after the complete packet has been written to it, ignoring the RTC field of this register. Receive Queue Store and Forward When this bit is set, the DWC_ether_qos reads a packet from the Rx queue only after the complete packet has been written to it, ignoring the RTC field of this register. When this bit is reset, the Rx queue operates in the Threshold (cut-through) mode, subject to the threshold specified by the RTC field of this register. 0b - Receive Queue Store and Forward is disabled 1b - Receive Queue Store and Forward is enabled
4 FEP	Forward Error Packets When this bit is reset, the Rx queue drops packets with error status (CRC error, GMII_ER, watchdog timeout, or overflow). Forward Error Packets When this bit is reset, the Rx queue drops packets with error status (CRC error, GMII_ER, watchdog timeout, or overflow). However, if the start byte (write) pointer of a packet is already transferred to the read controller side (in Threshold mode), the packet is not dropped. When this bit is set, all packets except the runt error packets are forwarded to the application or DMA. If the RSF bit is set and the Rx queue overflows when a partial packet is written, the packet is dropped irrespective of the setting of this bit. However, if the RSF bit is reset and the Rx queue overflows when a partial packet is written, a partial packet may be forwarded to the application or DMA. 0b - Forward Error Packets is disabled 1b - Forward Error Packets is enabled
3 FUP	Forward Undersized Good Packets When this bit is set, the Rx queue forwards the undersized good packets (packets with no error and length less than 64 bytes), including pad-bytes and CRC. Forward Undersized Good Packets When this bit is set, the Rx queue forwards the undersized good packets (packets with no error and length less than 64 bytes), including pad-bytes and CRC. When this bit is reset, the Rx queue drops all packets of less than 64 bytes, unless a packet is already transferred because of the lower value of Rx Threshold, for example, RTC = 01. 0b - Forward Undersized Good Packets is disabled 1b - Forward Undersized Good Packets is enabled
2 —	Reserved
1-0 RTC	Receive Queue Threshold Control These bits control the threshold level of the MTL Rx queue (in bytes): The received packet is transferred to the application or DMA when the packet size within the MTL Rx queue is larger than the threshold. Receive Queue Threshold Control These bits control the threshold level of the MTL Rx queue (in bytes): The received packet is transferred to the application or DMA when the packet size within the MTL Rx queue is larger than the threshold. In addition, full packets with length less than the threshold are automatically transferred. This field is valid only when the RSF bit is zero. This field is ignored when the RSF bit is set to 1. 00b - 64 01b - 32 10b - 96 11b - 128

61.7.1.432 Queue 2 Missed Packet and Overflow Counter (MTL_RXQ2_MISSED_PACKET_OVERFLOW_CNT)

61.7.1.432.1 Offset

Register	Offset
MTL_RXQ2_MISSED_PACKET_OVERFLOW_CNT	DB4h

61.7.1.432.2 Function

The Queue 2 Missed Packet and Overflow Counter register contains the counter for packets missed because of Receive queue packet flush and packets discarded because of Receive queue overflow.

61.7.1.432.3 Diagram
