i.MX RT1170 Processor Reference Manual

Document Number: IMXRT1170RM
Rev. 5, 01/2026

Contents

Section number **Title** **Page**

Chapter 1
About this Document

1.1 Audience 27

1.2 Organization 27

1.3 Suggested Reading 27

1.4 Conventions 28

1.5 Register Access 30

1.6 Acronyms and Abbreviations 32

Chapter 2
Introduction

2.1 Introduction 35

2.2 Features 37

2.3 Target Applications 40

2.4 Endianness Support 41

Chapter 3
Memory Maps

3.1 Memory system overview 43

3.2 System memory map (CM7) 43

3.3 System memory map (CM4) 45

3.4 AIPS-1 Memory Map 46

3.5 AIPS-2 Memory Map 50

3.6 AIPS-3 Memory Map 52

3.7 AIPS-4 Memory Map 52

3.8 AIPS M7 Memory Map 54

3.9 PPB M7 Memory Map 54

3.10 PPB M4 Memory Map 55

Chapter 4
Interrupts, DMA Events, and XBAR Assignments

4.1 Overview....57
4.2 CM7 interrupts....57
4.3 CM4 interrupts....72
4.4 DMA Mux....86
4.5 PIT Channel Assignments For Periodic DMA Triggering....100
4.6 XBAR Resource Assignments....100

Chapter 5
Direct Memory Access Multiplexer (DMAMUX)

5.1 Chip-specific DMAMUX information....117
5.2 Overview....117
5.3 Functional description....119
5.4 External signals....124
5.5 Application information....124
5.6 Initialization....127
5.7 Memory map/register definition....127

Chapter 6
Enhanced Direct Memory Access (eDMA)

6.1 Chip-specific eDMA information....131
6.2 Overview....131
6.3 Functional description....135
6.4 Initialization/application information....141
6.5 Memory map/register definition....156

Chapter 7
System Security

7.1 Chapter overview....219
7.2 Feature summary....219
7.3 Resource Management....222
7.4 Secure Key Manager (KEYMGR)....222
7.5 High-Assurance Boot (HAB)....223
7.6 Secure Non-Volatile Storage (SNVS) module....226

Section number	Title	Page
7.7	Cryptographic Acceleration and Assurance Module (CAAM)	228
7.8	On-Chip OTP Controller (OCOTP_CTRL)	229
7.9	Debug	230
7.10	Inline Encryption Engine (IEE)	232
7.11	On-the-Fly AES Decryption (OTFAD)	232
7.12	Memory-Mapped Cryptographic Acceleration Unit (MMCAU)	233
7.13	Code Watchdog Timer (CDOG)	233

Chapter 8
System Debug

8.1	Overview	235
8.2	Chip and Arm Platform Debug Architecture	235
8.3	Miscellaneous	243

Chapter 9
JTAG Controller (JTAGC)

9.1	Chip-specific JTAG information	245
9.2	Overview	245
9.3	Functional description	246
9.4	External signal description	258
9.5	Initialization/application information	259
9.6	Register description	260

Chapter 10
System Boot

10.1	Chip-specific Boot Information	263
10.2	Overview	271
10.3	Boot modes	273
10.4	Device configuration	277
10.5	Device initialization	279
10.6	Boot devices	282
10.7	Program image	328
10.8	External Memory Configuration Data (XMCD)	336

10.9 Serial Boot (Serial Downloader)....347
10.10 Recovery devices....360
10.11 SD/MMC manufacture mode....361
10.12 High-Assurance Boot (HAB)....361
10.13 ROM APIs....363

Chapter 11
External Signals and Pin Multiplexing

11.1 Overview....375

Chapter 12
IOMUX Controller (IOMUXC)

12.1 Chip-specific IOMUXC information....453
12.2 Overview....453
12.3 Functional description....455
12.4 Memory Map and register definition....458

Chapter 13
General Purpose Input/Output (GPIO)

13.1 Chip-specific GPIO information....1377
13.2 Overview....1378
13.3 Functional Description....1379
13.4 External Signals....1383
13.5 Application Information....1383
13.6 Memory Map/Register Definition....1384

Chapter 14
Clock and Power Management

14.1 Introduction....1401
14.2 Components of Clock and Power Management....1401
14.3 Power Management....1402
14.4 Clock Generation....1412

Chapter 15
Clock Controller Module (CCM)

15.1 Chip-specific CCM information.... 1421
15.2 Overview.... 1421
15.3 System Clocks.... 1423
15.4 Clock Tree.... 1439
15.5 Functional description.... 1445
15.6 External Signals.... 1480
15.7 Analog IP (AI) Interface.... 1480
15.8 Programming Guidelines.... 1482
15.9 Memory Map and register definition.... 1485

Chapter 16
Crystal Oscillator (XTALOSC)

16.1 Chip-specific XTALOSC information.... 1649
16.2 Overview.... 1649
16.3 Functional Description.... 1650
16.4 External Signals.... 1653
16.5 Memory Map and register definition.... 1654

Chapter 17
Power Management Unit (PMU)

17.1 Chip-specific PMU information.... 1675
17.2 Overview.... 1675
17.3 Functional Description.... 1676
17.4 External Signals.... 1682
17.5 Memory Map and register definition.... 1682

Chapter 18
PHY LDO (PHY_LDO)

18.1 Chip-specific PHY LDO information.... 1763
18.2 Overview.... 1763
18.3 Memory Map and register definition.... 1764

Chapter 19
General Power Controller (GPC)

19.1 Chip-specific General Power Controller (GPC) information.... 1769
19.2 Overview.... 1769
19.3 Functional description.... 1771
19.4 External Signals.... 1779
19.5 Initialization.... 1779
19.6 Memory Map and register definition.... 1780

Chapter 20
Power Gating and Memory Controller (PGMC)

20.1 Chip-specific Power Gating and Memory Controller (PGMC) information.... 1901
20.2 Overview.... 1901
20.3 Functional description.... 1903
20.4 External Signals.... 1908
20.5 Initialization.... 1908
20.6 Memory Map and register definition.... 1909

Chapter 21
DCDC Converter (DCDC)

21.1 Chip-specific DCDC information.... 1951
21.2 Overview.... 1951
21.3 Functional description.... 1953
21.4 External Signals.... 1957
21.5 Initialization.... 1957
21.6 Application Information.... 1958
21.7 Memory Map and register definition.... 1960

Chapter 22
Temperature Sensor (TMPSNS)

22.1 Chip-specific TMPSNS information.... 1999
22.2 Overview.... 1999
22.3 Functional description.... 2000
22.4 External Signals.... 2002
22.5 Initialization.... 2002

22.6 Application Information....2002
22.7 Memory Map and register definition....2003

Chapter 23
State Save and Restore Controller (SSARC)

23.1 Chip-specific State Save and Restore Controller (SSARC) information....2017
23.2 Overview....2017
23.3 Functional description....2018
23.4 External Signals....2021
23.5 Initialization....2021
23.6 Memory Map and register definition....2021

Chapter 24
Secure Non-Volatile Storage (SNVS)

24.1 Chip-specific SNVS information....2039
24.2 Overview....2039
24.3 SNVS functional description....2041
24.4 External Signals....2046
24.5 Initialization of SNVS....2047
24.6 Memory Map and register definition....2048

Chapter 25
System Reset Controller (SRC)

25.1 Chip-specific SRC information....2075
25.2 Overview....2075
25.3 Functional Description....2076
25.4 External Signals....2085
25.5 Initialization....2085
25.6 Memory Map and register definition....2086

Chapter 26
Fusemap

26.1 Overview....2109
26.2 Boot Fusemap....2111

26.3 Fusemap Descriptions Table....2120
26.4 FlexRAM Partition Table....2124

Chapter 27
On-Chip OTP Controller (OCOTP_CTRL)

27.1 Chip-specific OCOTP_CTRL information....2127
27.2 Overview....2127
27.3 Functional Description....2129
27.4 External Signals....2135
27.5 Fuse Map....2135
27.6 Memory Map/Register Definition....2135

Chapter 28
External Memory Controllers

28.1 Overview....2159
28.2 eMMC/eSD/SDIO....2159
28.3 Flexible Serial Peripheral Interface....2159

Chapter 29
Smart External Memory Controller (SEMC)

29.1 Chip-specific SEMC information....2161
29.2 Overview....2161
29.3 Functional Description....2164
29.4 External Signals....2212
29.5 Initialization....2217
29.6 Application Information....2217
29.7 Memory Map and Register Definition....2219

Chapter 30
FlexSPI Controller (FLEXSPI)

30.1 Chip-specific FlexSPI information....2289
30.2 Overview....2292
30.3 Functional description....2294
30.4 External signals....2353

30.5 Initialization..... 2354
30.6 Application information..... 2355
30.7 Memory map and register definition..... 2373
30.8 AHB memory map definition..... 2436

Chapter 31
External ECC Controller (XECC)

31.1 Chip-specific XECC information..... 2439
31.2 Overview..... 2439
31.3 Functional description..... 2441
31.4 External Signals..... 2445
31.5 Initialization..... 2445
31.6 Memory Map and register definition..... 2445

Chapter 32
Ultra Secured Digital Host Controller (uSDHC)

32.1 Chip-specific uSDHC information..... 2471
32.2 Overview..... 2471
32.3 Functional description..... 2474
32.4 External signals..... 2507
32.5 Application of uSDHC..... 2508
32.6 Software restrictions..... 2534
32.7 uSDHC memory map/register definition..... 2536

Chapter 33
ARM Cortex M7 Platform (M7)

33.1 Chip-specific Arm Cortex M7 information..... 2611
33.2 Overview..... 2613
33.3 Functional Description..... 2614
33.4 External Signals..... 2615
33.5 Memory Map and register definition..... 2615

Chapter 34
ARM Cortex M4 Platform (M4)

34.1 Chip-specific Arm Cortex M4 information.... 2619
34.2 Overview.... 2620
34.3 Configuration.... 2622
34.4 Performance.... 2622
34.5 Platform sub-blocks.... 2623
34.6 Debug.... 2625
34.7 Local Memory Controller (LMEM).... 2627
34.8 Miscellaneous Control Module (MCM).... 2652
34.9 MCM Memory Map/Register Definition.... 2653

Chapter 35
Messaging Unit (MU)

35.1 Chip-specific MU information.... 2677
35.2 Overview.... 2677
35.3 Functional Description.... 2679
35.4 External Signals.... 2691
35.5 Initialization.... 2691
35.6 Application Information.... 2692
35.7 MU Processor A-side Memory Map/Register Definition.... 2694
35.8 MU Processor B-side Memory Map/Register Definition.... 2708

Chapter 36
Network Interconnect Bus System (NIC-301)

36.1 Chip-specific NIC-301 information.... 2723
36.2 Overview.... 2723
36.3 External Signals.... 2724
36.4 Memory Map and Register Definition.... 2724

Chapter 37
On-Chip RAM Memory Controller (OCRAM)

37.1 Chip-specific OCRAM information.... 2731
37.2 Overview.... 2731
37.3 Functional Description.... 2733

Chapter 38
MECC64

38.1 Chip-specific MECC information....2735
38.2 Overview....2735
38.3 Functional description....2737
38.4 Signals....2739
38.5 Initialization....2740
38.6 Application information....2740
38.7 Memory Map and register definition....2740

Chapter 39
FlexRAM

39.1 Chip-specific FlexRAM information....2765
39.2 Overview....2766
39.3 Functional description....2768
39.4 Memory Map and Register Definition....2774

Chapter 40
AHB to IP Bridge (AIPS Lite)

40.1 Chip-specific AIPS Lite information....2833
40.2 Overview....2833
40.3 Functional Description....2833
40.4 Memory Map/Register Definition....2834

Chapter 41
Semaphores (SEMA4)

41.1 Chip-specific SEMA4 information....2835
41.2 Overview....2835
41.3 Functional Description....2837
41.4 External Signal Description....2842
41.5 Initialization Information....2842
41.6 Application Information....2842
41.7 Memory map and register definition....2844

Chapter 42
Resource Domain Controller (RDC)

42.1 Chip-specific RDC information....2855
42.2 Overview....2856
42.3 Functional Description....2857
42.4 External Signals....2864
42.5 Programming Interface....2864
42.6 RDC Memory Map/Register Definition....2871
42.7 RDC SEMA42 Memory Map/Register Definition....2890

Chapter 43
Extended Resource Domain Controller 2 (XRDC2)

43.1 Chip-specific XRDC2 information....2899
43.2 Overview....2909
43.3 Functional description....2911
43.4 External Signals....2918
43.5 Initialization....2918
43.6 Application information....2918
43.7 Memory Map and register definition....2919

Chapter 44
Display And Camera Overview

44.1 Overview....2943

Chapter 45
CMOS Sensor Interface (CSI)

45.1 Chip-specific CSI information....2947
45.2 Overview....2947
45.3 Functional Description....2949
45.4 External Signals....2969
45.5 Initialization....2969
45.6 CSI Memory Map/Register Definition....2969

Chapter 46

MIPI CSI2 (MIPI_CSI2)

46.1 Chip-specific MIPI CSI-2 information....3007
46.2 Overview....3007
46.3 Functional description....3010
46.4 External Signals....3022
46.5 Initialization....3022
46.6 Memory Map and register definition....3023

Chapter 47
Enhanced LCD Interface (eLCDIF)

47.1 Chip-specific eLCDIF information....3039
47.2 Overview....3039
47.3 Functional Description....3041
47.4 External Signals....3058
47.5 Initialization....3058
47.6 eLCDIF Memory Map/Register Definition....3059

Chapter 48
LCDIF Interface v2 (LCDIF v2)

48.1 Chip-specific LCDIFv2 information....3089
48.2 Overview....3089
48.3 Functional description....3092
48.4 External Signals....3099
48.5 Application information....3099
48.6 Memory Map and register definition....3100

Chapter 49
MIPI DSI Host Controller (MIPI_DSI)

49.1 Chip-specific MIPI DSI information....3131
49.2 Overview....3131
49.3 Functional description....3134
49.4 External Signals....3155
49.5 Application Information....3155

49.6 Initialization.....3156
49.7 Memory Map and register definition.....3156

Chapter 50
Video Mux Controller (VIDEO_MUX)

50.1 Chip-specific VIDEO MUX information.....3227
50.2 Overview.....3227
50.3 Functional description.....3229
50.4 External Signals.....3230
50.5 Initialization.....3231
50.6 Memory Map and register definition.....3231

Chapter 51
Display Content Integrity Checker (DCIC)

51.1 Chip-specific DCIC information.....3239
51.2 Overview.....3239
51.3 Functional Description.....3240
51.4 External Signals.....3244
51.5 System Considerations.....3244
51.6 DCIC Memory Map/Register Definition.....3245

Chapter 52
Pixel Pipeline (PXP)

52.1 Chip-specific PXP information.....3257
52.2 Overview.....3257
52.3 Functional Description.....3258
52.4 External Signals.....3293
52.5 Initialization.....3293
52.6 PXP Memory Map/Register Definition.....3293

Chapter 53
Graphics Processing Unit (GPU2D)

53.1 Chip-specific GPU information.....3331
53.2 Overview.....3331

53.3 Functional description....3333
53.4 Software Application Programming Interface (API)....3334

Chapter 54
Audio Overview

54.1 Audio Overview....3337

Chapter 55
Asynchronous Sample Rate Converter (ASRC)

55.1 Chip-specific Asynchronous Sample Rate Converter (ASRC) information....3345
55.2 Overview....3346
55.3 Functional Description....3349
55.4 External Signals....3358
55.5 Application Information....3359
55.6 ASRC Memory Map/Register Definition....3360

Chapter 56
PDM Microphone Interface (PDM)

56.1 Chip-specific PDM Microphone Interface (PDM) information....3413
56.2 Overview....3413
56.3 Functional Description....3415
56.4 External Signals....3432
56.5 Initialization....3433
56.6 Application Information....3437
56.7 PDM register descriptions....3437

Chapter 57
Medium Quality Sound (MQS)

57.1 Chip-specific MQS information....3463
57.2 Overview....3463
57.3 Functional Description....3464
57.4 External Signals....3465
57.5 Application Information....3466

Chapter 58

Synchronous Audio Interface (SAI)

58.1 Chip-specific SAI information....3467
58.2 Overview....3468
58.3 Functional description....3470
58.4 External signals....3481
58.5 Memory map and register definition....3481

Chapter 59
Sony/Philips Digital Interface (SPDIF)

59.1 Chip-specific SPDIF information....3519
59.2 Overview....3519
59.3 Functional Description....3521
59.4 External Signals....3531
59.5 Application Information....3532
59.6 SPDIF Memory Map/Register Definition....3533

Chapter 60
10/100 /1000 -Mbps Ethernet MAC (ENET/ENET1G)

60.1 Chip-specific ENET information....3559
60.2 Overview....3559
60.3 Functional description....3564
60.4 External signals....3630
60.5 Memory map/register definition....3632

Chapter 61
Ethernet Quality Of Service (ENET_QOS)

61.1 Chip-specific ENET QOS information....3765
61.2 Overview....3765
61.3 Functional description....3767
61.4 External signals....3924
61.5 Initialization....3926
61.6 Application Information....3929
61.7 Memory Map and register definition....3950

Chapter 62
Universal Serial Bus Controller (USB)

62.1 Chip-specific USB information.... 4837
62.2 Overview.... 4837
62.3 Functional Description.... 4839
62.4 External Signals.... 4844
62.5 USB Operation Model.... 4844
62.6 USB Non-Core Memory Map/Register Definition.... 5011
62.7 USB Core Memory Map/Register Definition.... 5017

Chapter 63
Universal Serial Bus 2.0 Integrated PHY (USB-PHY)

63.1 Chip-specific USB-PHY information.... 5107
63.2 Overview.... 5107
63.3 Functional Description.... 5108
63.4 External Signals.... 5115
63.5 Initialization and Application Information.... 5115
63.6 Recommended Register Configuration for USB Certification.... 5115
63.7 Register Macro Usage.... 5116
63.8 USB PHY Memory Map/Register Definition.... 5117

Chapter 64
USB Device Charger Detection Module (USBDCD)

64.1 Chip-specific USBDCD information.... 5157
64.2 Overview.... 5157
64.3 Functional description.... 5159
64.4 External Signals.... 5176
64.5 Initialization information.... 5177
64.6 Application information.... 5177
64.7 Memory map/Register definition.... 5178

Chapter 65
Euro, MasterCard, Visa Subscriber Identification Module (EMVSIM)

65.1 Chip-specific EMVSIM information....5191
65.2 Overview....5191
65.3 Functional Description....5193
65.4 External Signals....5209
65.5 Initialization....5209
65.6 Application Information....5212
65.7 Memory Map and Registers....5217

Chapter 66
Flexible Controller Area Network (FLEXCAN)

66.1 Chip-specific FLEXCAN information....5249
66.2 Overview....5250
66.3 Functional description....5253
66.4 FlexCAN signal descriptions....5309
66.5 Initialization/application information....5309
66.6 Memory map/register definition....5311

Chapter 67
Flexible I/O (FlexIO)

67.1 Chip-specific FlexIO information....5391
67.2 Overview....5391
67.3 Functional description....5393
67.4 Application Information....5409
67.5 FlexIO Signal Descriptions....5429
67.6 Memory Map and Registers....5429

Chapter 68
Keypad Port (KPP)

68.1 Chip-specific KPP information....5465
68.2 Overview....5465
68.3 Functional Description....5467
68.4 External Signals....5475
68.5 Initialization/Application Information....5477

68.6 Memory Map and Register Definition....5478

Chapter 69
Low Power Inter-Integrated Circuit (LPI2C)

69.1 Chip-specific LPI2C information.... 5485
69.2 Overview....5485
69.3 Functional description....5488
69.4 Signal descriptions....5500
69.5 Memory Map and Registers....5501

Chapter 70
Low Power Serial Peripheral Interface (LPSPI)

70.1 Chip-specific LPSPI information....5545
70.2 Overview....5545
70.3 Functional description....5547
70.4 Signals....5558
70.5 Memory map and registers....5559

Chapter 71
Low Power Universal Asynchronous Receiver/ Transmitter (LPUART)

71.1 Chip-specific LPUART information....5585
71.2 Overview....5585
71.3 Functional description....5588
71.4 External signals....5606
71.5 Register definition....5606

Chapter 72
Timers Overview

72.1 Overview....5635

Chapter 73
Enhanced Flex Pulse Width Modulator (eFlexPWM)

73.1 Chip-specific FlexPWM information.... 5639
73.2 Overview....5639
73.3 Functional description....5641

73.4 External signals 5682
73.5 eFlexPWM register descriptions..... 5684

Chapter 74
General Purpose Timer (GPT)

74.1 Chip-specific GPT information..... 5817
74.2 Overview..... 5817
74.3 External Signals..... 5819
74.4 Clocks..... 5820
74.5 Functional Description..... 5822
74.6 Initialization/ Application Information 5826
74.7 Memory map/register definition..... 5827

Chapter 75
Periodic Interrupt Timer (PIT)

75.1 Chip-specific PIT information..... 5839
75.2 Introduction..... 5839
75.3 Modes of operation..... 5841
75.4 Functional description..... 5841
75.5 Initialization and application information..... 5845
75.6 Memory Map and Registers..... 5846

Chapter 76
Quad Timer (TMR)

76.1 Chip-specific TMR information..... 5855
76.2 Overview..... 5855
76.3 Modes of Operation..... 5857
76.4 Functional Description..... 5857
76.5 Resets..... 5874
76.6 Clocks..... 5874
76.7 Interrupts..... 5875
76.8 DMA..... 5877
76.9 Memory map/register definition..... 5877

Chapter 77
Quadrature Decoder (QDC)

77.1 Chip-specific QDC information....5897
77.2 Overview....5897
77.3 Functional description....5902

Chapter 1
About this Document

1.1 Audience

The reference manual is intended for the board-level product designers and product software developers. This manual assumes that the reader has a background in computer engineering and/or software engineering and understands the concepts of the digital system design, microprocessor architecture, input/output (I/O) devices, industry standard communication, and device interface protocols.

1.2 Organization

The reference manual describes the chip at a system level and provides an architectural overview. It also describes the system memory map, system-level interrupt events, external pins and pin multiplexing, external memory, system debug, system boot, multimedia subsystem, power management, and system security.

1.3 Suggested Reading

This section lists additional resources that provide background for the information in the reference manual, as well as general information about the architecture.

Table 1-1. Suggested Reading

Type	Description	Resource
Fact Sheet	The Fact Sheet is an overview of the product key features and its uses.	i.MX RT Series Crossover Processor Fact Sheet
Reference Manual	The Reference Manual contains a comprehensive description of the structure and function (operation) of a device.	
Data Sheet	The Data Sheet includes electrical characteristics and signal connections.

	Product documentation page on nxp.com with a list of all documentation related to the device.	
Community Forum	i.MX RT Community support forum for questions, support, and information about the device.	i.MX RT Community

1.4 Conventions

The reference manual uses the following notational conventions:

cleared / set

When a bit has a value of zero, it is said to be cleared; when it has a value of one, it is said to be set.

mnemonics

Instruction mnemonics are shown in lowercase bold.

italics

Italics indicate variable command parameters, for example, **bcctr***x*.

The book titles in the text are set in italics.

15

An integer in decimal.

0x

the prefix to denote a hexadecimal number.

0b

The prefix to denote a binary number. Binary values of 0 and 1 are written without a prefix.

n'H4000CA00

The n-bit hexadecimal number.

BLK_REG_NAME

The register names are all uppercase. The block mnemonic is prepended with an underscore delimiter (_).

BLK_REG[FIELD]

The fields within registers appear in brackets. For example, ESR[RLS] refers to the Receive Last Slot field of the ESAI Status Register.

BLK_REG[*n*]

The bit number *n* within the BLK.REG register.

BLK_REG[*l:r*]

The register bit ranges. The ranges are indicated by the left-most bit number *l* and the right-most bit number *r*, separated by a colon (:). For example, ESR[15:0] refers to the lower half word in the ESAI Status Register.

x, U

In some contexts, such as signal encodings, an unitalicized x indicates a "don't care" or "uninitialized". The binary value can be 1 or 0.

x

An italicized *x* indicates an alphanumeric variable.

n, m

Italicized *n or m* represent integer variables.

!

Binary logic operator NOT.

&&

Binary logic operator AND.

||

Binary logic operator OR.

^ or <O+>

Binary logic operator XOR. For example, A <O+> B.

|

Bit-wise OR. For example, 0b0001 | 0b1000 yields the value of 0b1001.

&

Bit-wise AND. For example, 0b0001 & 0b1000 yields the value of 0b0000.

{A,B}

Concatenation, where the *n*-bit value A is prepended to the *m*-bit value B to form an (*n* +*m*)-bit value. For example, {0, REG*m* [14:0]} yeilds a 16-bit value with 0 in the most significant bit.

- or grey fill

Indicates a reserved bit field in a register. Although these bits can be written to with ones or zeros, they always read zeros.

>>

Shift right logical one position.

<<

Shift left logical one position.

<=
    Assignment.
==
    Compare equal.
!=
    Compare not equal.
>
    Greater than.
<
    Less than.

1.5 Register Access

1.5.1 Register Diagram Field Access Type Legend

This figure provides the interpretation of the notation used in the register diagrams for a number of common field access types:

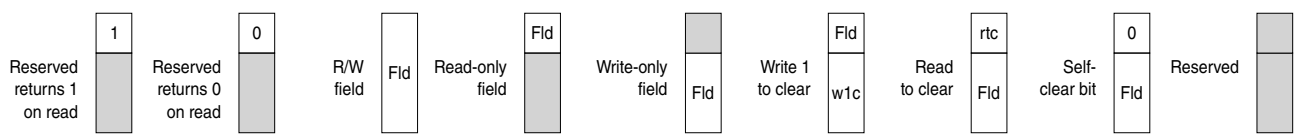

Figure 1-1. Register Field Conventions

NOTE

For reserved register fields, the software should mask off the data in the field after a read (the software can't rely on the contents of data read from a reserved field) and always write all zeros.

1.5.2 Register Macro Usage

A common operation is to update one field without disturbing the contents of the remaining fields in the register. Normally, this requires a read-modify-write (RMW) operation, where the CPU reads the register, modifies the target field, then writes the results back to the register. This is an expensive operation in terms of CPU cycles, because of the initial register read.

To address this issue, some hardware registers are implemented as a group, including registers that can be used to either set, clear, or toggle (SCT) individual bits of the primary register. When writing to an SCT register, all the bits set to 1 perform the associated operation on the primary register, while the bits set to 0 are not affected. The SCT registers always read back 0, and should be considered write-only. The SCT registers are not implemented if the primary register is read-only.

With this architecture, it is possible to update one or more fields using only register writes. First, all bits of the target fields are cleared by a write to the associated clear register, then the desired value of the target fields is written to the set register. This sequence of two writes is referred to as a clear-set (CS) operation.

A CS operation does have one potential drawback. Whenever a field is modified, the hardware sees a value of 0 before the final value is written. For most fields, passing through the 0 state is not a problem. Nonetheless, this behavior is something to consider when using a CS operation.

Also, a CS operation is not required for fields that are one-bit wide. While the CS operation works in this case, it is more efficient to simply set or clear the target bit (that is, one write instead of two). A simple set or clear operation is also atomic, while a CS operation is not.

Note that not all macros for set, clear, or toggle (SCT) are atomic. For registers that do not provide hardware support for this functionality, these macros are implemented as a sequence of read-modify-write operations. When an atomic operation is required, the developer should pay attention to this detail, because unexpected behavior might result if an interrupt occurs in the middle of the critical section comprising the update sequence.

A set of SCT registers is offered for registers in many modules on this device, as described in this manual. In a module memory map table, the suffix _SET, _CLR, or _TOG is added to the base name of the register. For example, the CCM_ANALOG_PLL_ARM register has three other registers called CCM_ANALOG_PLL_ARM_SET, CCM_ANALOG_PLL_ARM_CLR, and CCM_ANALOG_PLL_ARM_TOG.

In the sub-section that describes one of these sets of registers, a short-hand convention is used to denote that a register has the SCT register set. There is an italicized *n* appended to the end of the short register name. Using the above example, the name used for this register is CCM_ANALOG_PLL_ARM*n*. When you see this designation, there is a SCT register set associated with the register, and you can verify this by checking it in the memory map table. The address offset for each of these registers is given in the form of the following example:

Address: 20C_8000h base + 0h offset + (4d × i), where i=0d to 3d

In this example, the address for each of the base registers and their three SCT registers can be calculated as:

Register	Address
CCM_ANALOG_PLL_ARM	20C_8000h
CCM_ANALOG_PLL_ARM_SET	20C_8004h
CCM_ANALOG_PLL_ARM_CLR	20C_8008h
CCM_ANALOG_PLL_ARM_TOG	20C_800Ch

1.6 Acronyms and Abbreviations

The table below contains acronyms and abbreviations used in this document.

Acronyms and Abbreviated Terms

Term	Meaning
ACMP	Analog Comparator
ADC	Analog-to-Digital Converter
AHB	Advanced High-performance Bus
AIPS	Arm IP Bus
ALU	Arithmetic Logic Unit
AMBA	Advanced Microcontroller Bus Architecture
APB	Advanced Peripheral Bus
ASRC	Asynchronous Sample Rate Converter
AXI	Advanced eXtensible Interface
CA/CM	Arm Cortex-A/Cortex-M
CAAM	Cryptographic Acceleration and Assurance Module
CAN	Controller Area Network
CCM	Clock Controller Module
CM7	Arm Cortex M7 Core
CPU	Central Processing Unit
CSI	CMOS Sensor Interface
CSU	Central Security Unit
CTI	Cross Trigger Interface
D-cache	Data cache
DAP	Debug Access Port
DDR	Double data rate
DMA	Direct memory access
DPLL	Digital phase-locked loop
DRAM	Dynamic random access memory

Table continues on the next page...

Term	Meaning
ECC	Error correcting codes
LPSPI	Low-power SPI
EDMA	Enhanced Direct Memory Access
EIM	External Interface Module
ENET	Ethernet
EPIT	Enhanced Periodic Interrupt Timer
EPROM	Erasable Programmable Read-Only Memory
ETF	Embedded Trace FIFO
ETM	Embedded Trace Macrocell
FIFO	First-In-First-Out
GIC	General Interrupt Controller
GPC	General Power Controller
GPIO	General-Purpose I/O
GPR	General-Purpose Register
GPS	Global Positioning System
GPT	General-Purpose Timer
GPU	Graphics Processing Unit
GPV	Global Programmers View
HAB	High-Assurance Boot
I-cache	Instruction cache
I2C or I^2C	Inter-Integrated Circuit
IC	Integrated Circuit
IEEE	Institute of Electrical and Electronics Engineers
IOMUX	Input-Output Multiplexer
IP	Intellectual Property
IrDA	Infrared Data Association
JTAG	Joint Test Action Group (a serial bus protocol usually used for test purposes)
ELCDIF	Liquid Crystal Display Interface
LDO	Low-Dropout
LIFO	Last-In-First-Out
LRU	Least-Recently Used
LPSR	Low-Power State Retention
LSB	Least-Significant Byte
LUT	Look-Up Table
LVDS	Low Voltage Differential Signaling
MAC	Medium Access Control
MCM	Miscellaneous Control Module
MMC	Multimedia Card
MSB	Most-Significant Byte
MT/s	Mega Transfers per second
OCRAM	On-Chip Random-Access Memory

Table continues on the next page...

Term	Meaning
OCOTP	On-Chip One-Time Programmable Controller
PCI	Peripheral Component Interconnect
PCIe	PCI express
BPC	Basic Power Controller
PIC	Programmable Interrupt Controller
PMU	Power Management Unit
POR	Power-On Reset
PSRAM	Pseudo-Static Random Access Memory
PWM	Pulse Width Modulation
PXP	Pixel Pipeline
QoS	Quality of Service
R2D	Radians to Degrees
RISC	Reduced Instruction Set Computing
ROM	Read-Only Memory
RTOS	Real-Time Operating System
Rx	Receive
SAI	Synchronous Audio Interface
SD	Secure Digital
SDIO	Secure Digital Input/Output
SDLC	Synchronous Data Link Control
SDMA	Smart DMA
SIM	Subscriber Identification Module
SNVS	Secure Non-Volatile Storage
SoC	System-on-Chip
SPBA	Shared Peripheral Bus Arbiter
SPDIF	Sony Philips Digital Interface
SPI	Serial Peripheral Interface
SRAM	Static Random-Access Memory
SRC	System Reset Controller
TFT	Thin-Film Transistor
TPIU	Trace Port Interface Unit
TSGEN	Time Stamp Generator
Tx	Transmit
TZASC	TrustZone Address Space Controller
UART	Universal Asynchronous Receiver/Transmitter
USB	Universal Serial Bus
USDHC	Ultra Secured Digital Host Controller
WDOG	Watchdog
WLAN	Wireless Local Area Network
WXGA	Wide Extended Graphics Array

Chapter 2
Introduction

2.1 Introduction

The i.MX RT1170 is a new processor family featuring NXP's advanced implementation of the high performance Arm Cortex®-M7 Core and a power efficient Arm Cortex®-M4 Core. It offers high-performance processing optimized for lowest power consumption and best real-time response.

The i.MX RT1170 has 2MB on-chip RAM in total, including a 512KB RAM which can be flexibly configured as TCM or general-purpose on-chip RAM. The i.MX RT1170 integrates advanced power management module with DCDC and LDO that reduces complexity of external power supply and simplifies power sequencing. The i.MX RT1170 also provides various memory interfaces, including SDRAM, Raw NAND FLASH, NOR FLASH, SD/eMMC, Quad SPI, HyperRAM/HyperFlash and a wide range of other interfaces for connecting peripherals, such as WLAN, Bluetooth®, GPS, displays, and camera sensors. Same as other i.MX processors, i.MX RT1170 also has rich audio and video features, including MIPI CSI/DSI, LCD display, graphics accelerator, camera interface, SPDIF and I2S audio interface.

2.1.1 Block Diagram

The functional block diagram is shown in the figure below. This diagram provides a view of the chip's major functional components and core complexes.

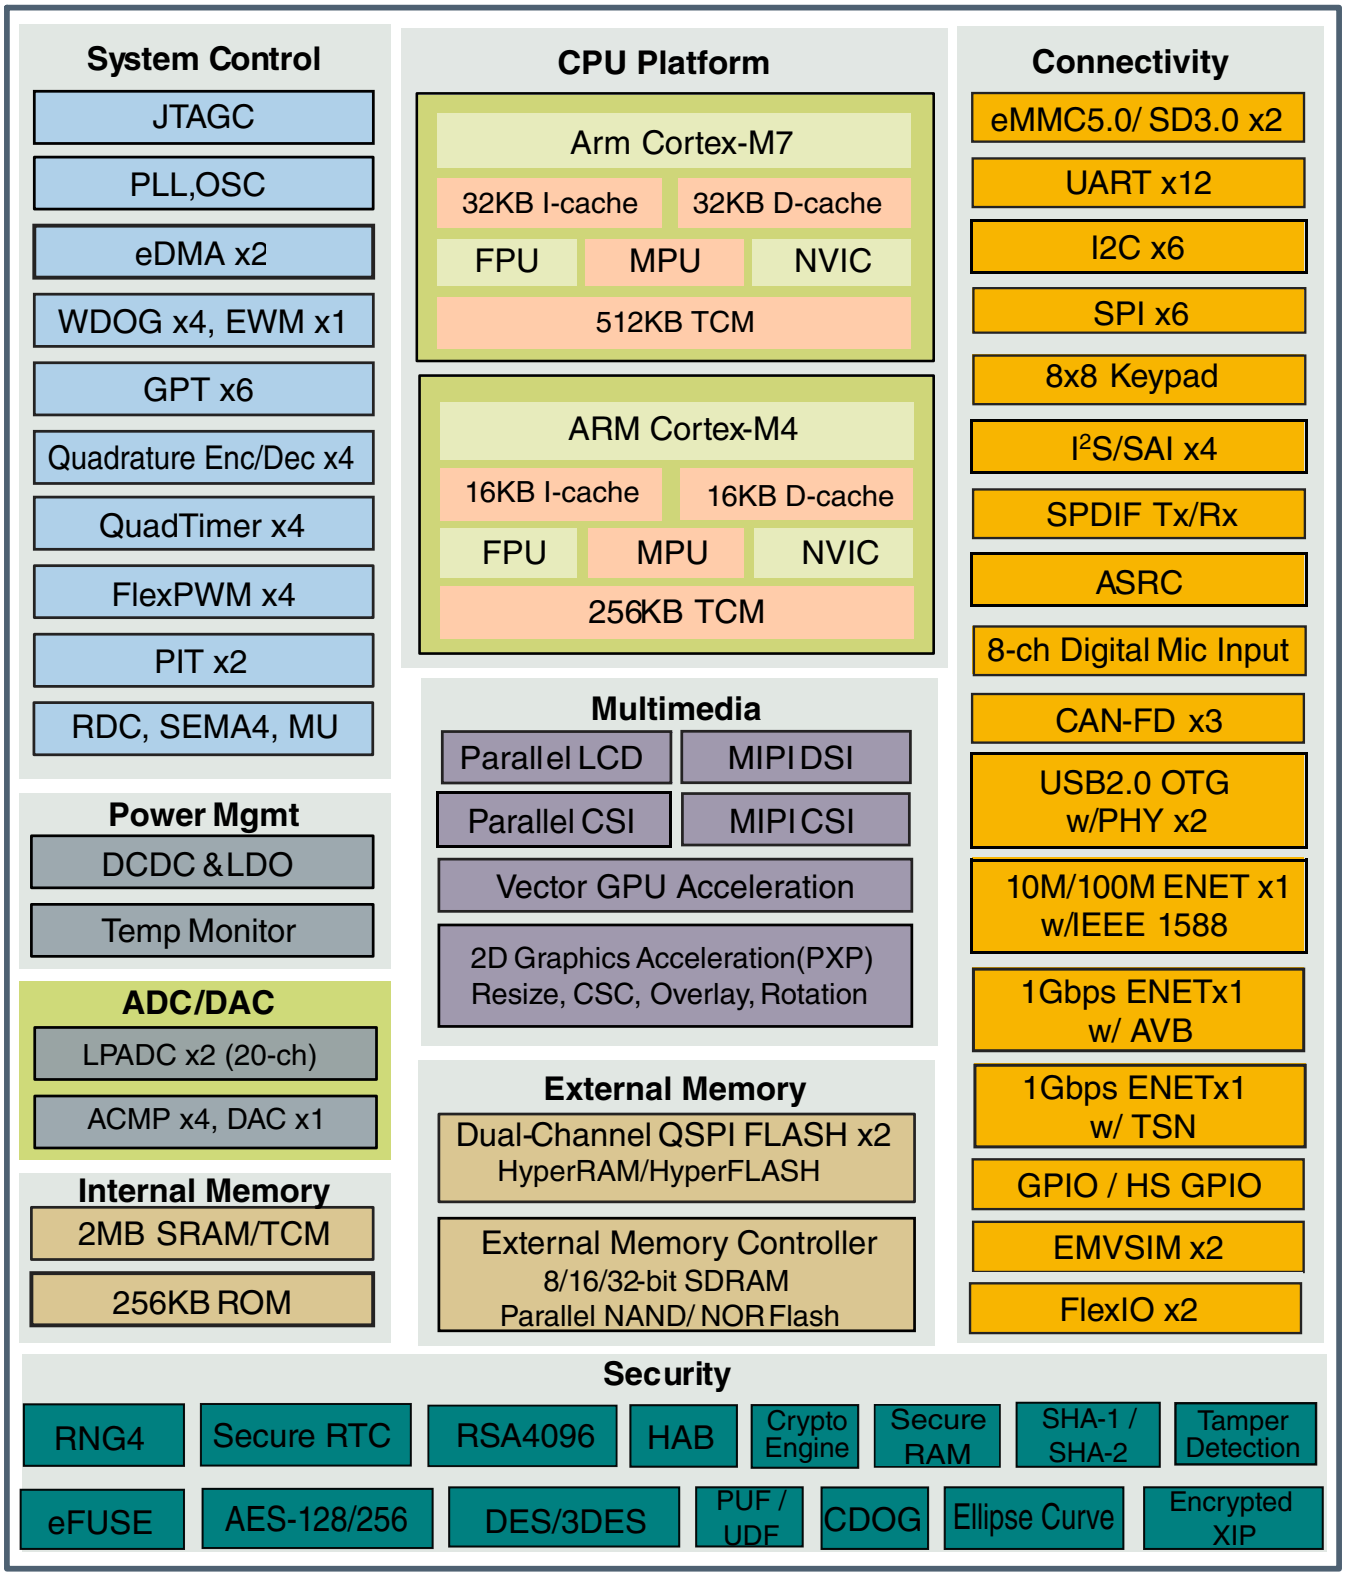

Figure 2-1. Simplified Block Diagram

2.1.2 System Bus Diagram

The system bus diagram is shown below.

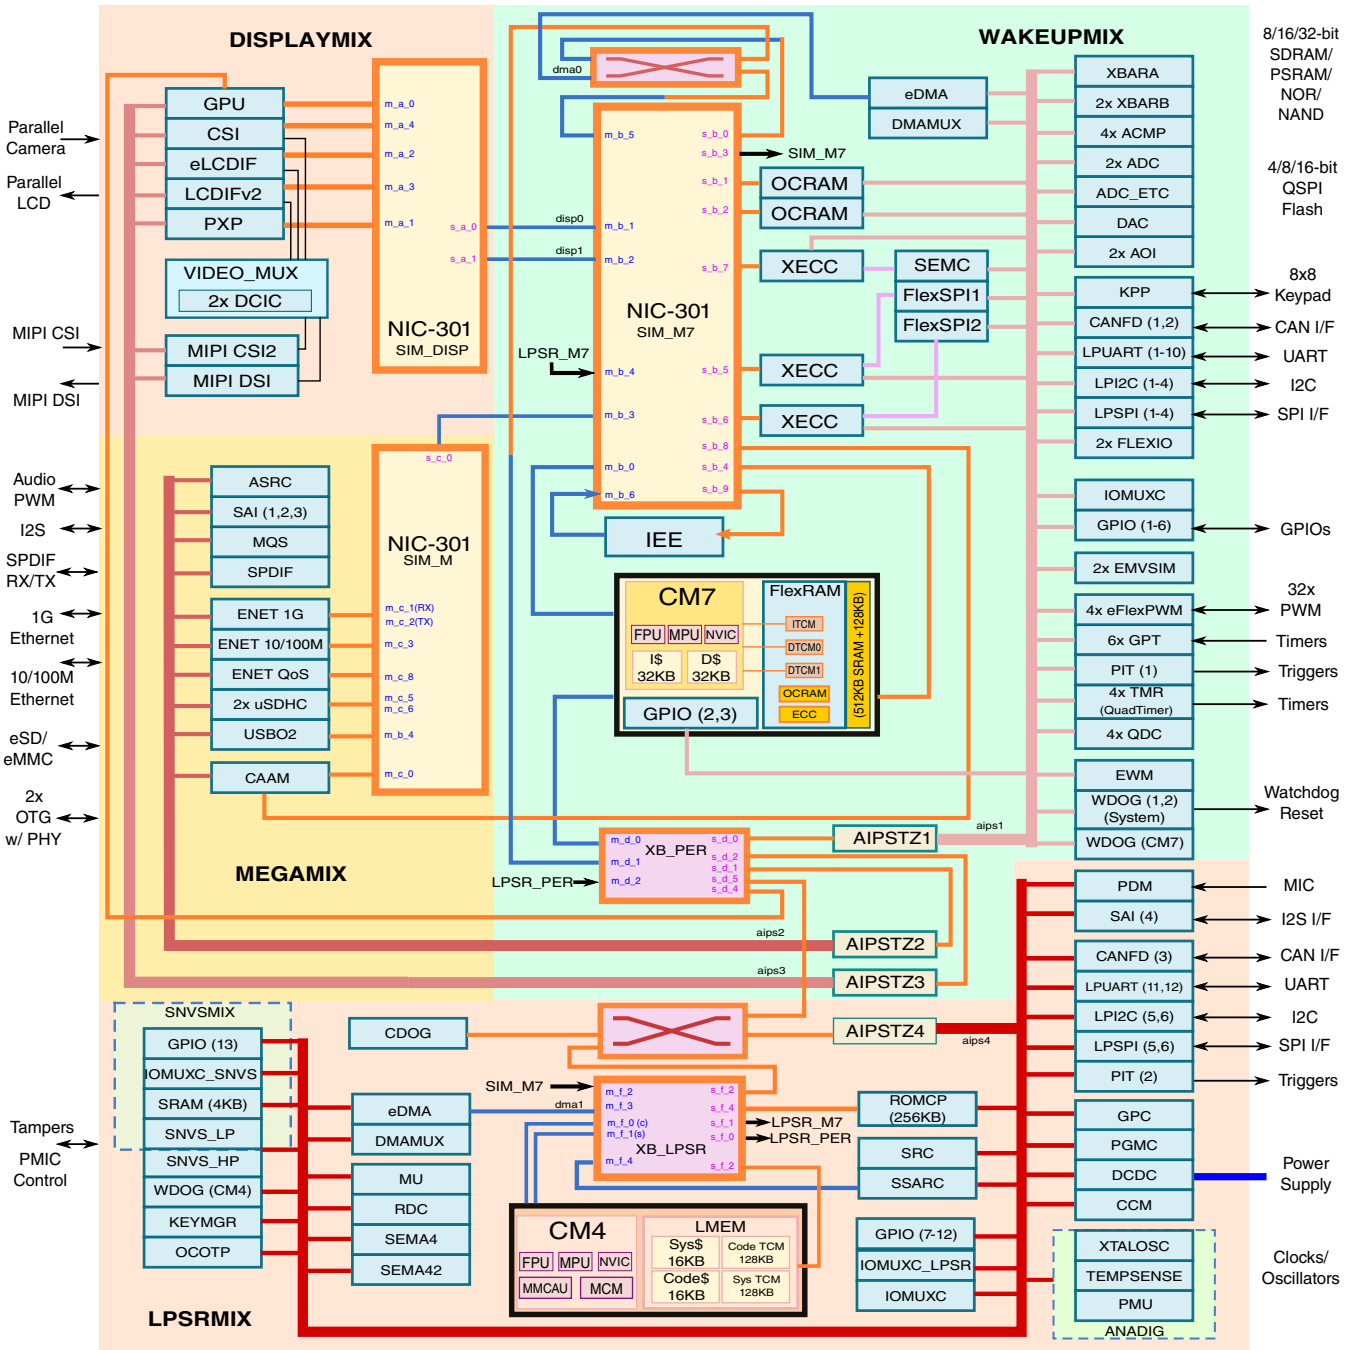

Figure 2-2. Bus Diagram

2.2 Features

The i.MX RT1170 processors are based on Arm®Cortex®-M7 Platform, and Arm®Cortex®-M4 which have the following features:

Single Arm Cortex-M7 with:
- 32KB L1 Instruction Cache
- 32KB L1 Data Cache
- Single-precision and double-precision FPU (Floating Point Unit)
- Integrated Memory Protection Unit (MPU), up to 16 individual protection regions
- Up to 512KB I-TCM and D-TCM in total
- ECC support for cache and TCM

Single Arm Cortex-M4 with:
- 16KB L1 Instruction Cache
- 16KB L1 Data Cache
- Single-precision FPU defined by ARMv7-M Architecture FPv4-SP
- ECC support for TCM
- Integrated MPU with 8 individual protection regions

On Chip Memory:
- Boot ROM (256KB)
- On-chip RAM (2MB in total)
  - FlexRAM - configurable 512KB RAM shared with M7 TCM and 256KB RAM shared with M4 TCM

NOTE

When using the M4 boot mode, FlexRAM will not be accessible until the M7 domain is released

  - OCRAM - dedicated 1.25MB RAM

External Memory Interfaces:
- 8/16/32-bit SDRAM, up to SDRAM-133/SDRAM-166/SDRAM-200
- 8/16-bit SLC NAND FLASH, with ECC handled in software
- SD/eMMC
- Single/Dual channel Quad SPI FLASH with XIP support
- Parallel NOR FLASH with XIP support
- SPI NOR/NAND FLASH
- HyperRAM/HyperFLASH
- Synchronization mode for all devices

Graphics:
- Generic 2D Graphics engine (PXP)
  - BitBlit

    - Flexible image composition options – alpha, chroma key
    - Image rotation (90, 180, 270 degree rotation)
    - Porter-Duff operation
    - Image resize
    - Color space conversion
    - Multiple pixel format support (RGB, YUV444, YUV422, YUV420, YUV400)
    - Standard 2D-DMA operation
- Vector Graphics Processing (GPU)
    - Real-time hardware curve tessellation of lines, quadratic and cubic Bezier curves
    - OpenVG 1.1 support
    - 16x Line Anti-aliasing
    - Vector Drawing

Display Interface:

- Parallel RGB LCD Interface (eLCDIF) that supports 8/16/24-bit I/F, up to WXGA with 60fps, and Index color with 256 entry x 24bit color LUT
- Parallel RGB LCD Interface Version 2 (LCDIFv2) that is enhanced based on the above version, supporting up to 8 layers of alpha blending
- MIPI Display Serial Interface (MIPI DSI) with 2-lane I/F and Smart LCD Display with 8080 interface through SEMC

Camera Sensor Interface:

- Parallel Camera - CMOS Sensor Interface (CSI) with 8/16/24-bit input
- MIPI Camera Sensor Interface (MIPI CSI2) with 2-lane I/F

Audio:

- SPDIF Input and Output
- 4x Synchronous Audio Interface (SAI) modules supporting I2S, AC97, TDM, and Codec/DSP interfaces
- MQS interface for medium quality audio via GPIO pads
- PDM microphone interface with 4 pairs inputs
- Asynchronous Sample Rate Converter (ASRC)

Connectivity:

- 2x USB 2.0 OTG controller with integrated PHY interfaces
- 2x Ultra Secure Digital Host Controller (uSDHC) interfaces
- 1x 10M/100M Ethernet controller with support for IEEE1588
- 1x Gigabit Ethernet controller with support for AVB
- 1x Gigabit Ethernet controller with Time Sensitive Networking (TSN) Capability
- 12x Universal asynchronous receiver/transmitter (UARTs) modules
- 6x I2C modules
- 6x SPI modules
- 3x CAN-FD modules

Timers:

- 6x General Programmable Timer (GPT)
- 2x Periodical Interrupt Timer (PIT)
- 4x Quad Timer (QTimer)
- 4x FlexPWM
- 4x Quadrature Encoder/Decoder
- 4x WatchDog modules (WDOG)

Analog:

- 2x Analog-Digital-Converters (ADC) (up to 20 channels)
- 4x Analog Comparators (ACMP)
- 1x 12-bit Digital-Analog-Converter (DAC)

Security:

- High Assurance Boot (HAB)
- Random Number Generator (RNG4)
- Secure Non-volatile Storage (SNVS)
  - Secure real-time clock (RTC)
  - Zero Master Key (ZMK)
  - Tamper Detection
- JTAG Controller (JTAGC)
- Cryptographic Acceleration and Assurance Module (CAAM)
- Inline Encryption Engine (IEE)
- On-the-Fly AES Decryption (OTFAD)
- Secure always-on RAM (4KB)
- Secure key management (KEYMGR) and protection
- Secure and trusted access control
- Code WatchDog Timer (CDOG)
- Manufacturing Protection

System Debug:

- Arm CoreSight debug and trace architecture
- Trace Port Interface Unit (TPIU) to support off-chip real-time trace
- Cross Triggering Interface (CTI)
- Support for 5-pin (JTAG) and SWD debug interfaces

Power Management:

- Full PMIC integration, including on-chip DCDC and LDO
- Temperature sensor with programmable trim points
- GPC hardware power management controller

2.3 Target Applications

This processor can be used in areas such as industrial HMI, IoT, high-end audio appliance, medium/low-end instrument cluster, Point-of-Sale(PoS), motor control and home appliances, etc.

2.4 Endianness Support

The chip supports only the Little Endian mode.

Chapter 3
Memory Maps

3.1 Memory system overview

This section introduces the memory architecture of the chip.

NOTE

Accessing the reserved memory regions can result in unpredictable behavior.

3.2 System memory map (CM7)

The table below shows the CM7 memory map:

Table 3-1. System memory map (CM7)

Start Address	End Address	Size	Description
E010_0000	FFFF_FFFF	511MB	Reserved
E000_0000	E00F_FFFF	1MB	PPB M7
C000_0000	DFFF_FFFF	512MB	SEMC3
A000_0000	BFFF_FFFF	512MB	SEMC2
9000_0000	9FFF_FFFF	256MB	SEMC1
8000_0000	8FFF_FFFF	256MB	SEMC0
7FC0_0000	7FFF_FFFF	4MB	FlexSPI2 RX FIFO
7F80_0000	7FBF_FFFF	4MB	FlexSPI2 TX FIFO
6000_0000	7F7F_FFFF	504MB	FlexSPI2/ FlexSPI2 ciphertext
4280_0000	5FFF_FFFF	472MB	Reserved
4210_0000	427F_FFFF	7MB	Reserved
4200_0000	420F_FFFF	1MB	AIPS M7 (Peripheral, Platform)
41A0_0000	41FF_FFFF	6MB	Reserved
4190_0000	419F_FFFF	1MB	CDOG (Peripheral, AHB)

Table continues on the next page...

Table 3-1. System memory map (CM7) (continued)

Start Address	End Address	Size	Description
4180_0000	418F_FFFF	1MB	GPU2D (Peripheral, AHB)
4170_0000	417F_FFFF	1MB	Reserved
4160_0000	416F_FFFF	1MB	Reserved
4150_0000	415F_FFFF	1MB	Reserved
4140_0000	414F_FFFF	1MB	SIM_M7 configuration port
4130_0000	413F_FFFF	1MB	Reserved
4120_0000	412F_FFFF	1MB	Reserved
4110_0000	411F_FFFF	1MB	SIM_M configuration port
4100_0000	410F_FFFF	1MB	SIM_DISP configuration port
40C0_0000	40FF_FFFF	4MB	AIPS-4
4080_0000	40BF_FFFF	4MB	AIPS-3
4040_0000	407F_FFFF	4MB	AIPS-2
4000_0000	403F_FFFF	4MB	AIPS-1
3000_0000	3FFF_FFFF	256MB	FlexSPI1/ FlexSPI1 cipher text
2FC0_0000	2FFF_FFFF	4MB	FlexSPI1 RX FIFO
2F80_0000	2FBF_FFFF	4MB	FlexSPI1 TX FIFO
2040_0000	2F7F_FFFF	244MB	Reserved
2036_0000	203F_FFFF	640KB	OCRAM M7 [1]
2035_0000	2035_FFFF	64KB	OCRAM2 ECC
2034_0000	2034_FFFF	64KB	OCRAM1 ECC
202C_0000	2033_FFFF	512KB	OCRAM2
2024_0000	202B_FFFF	512KB	OCRAM1
2020_0000	2023_FFFF	256KB	OCRAM M4 (LMEM 128KB SRAM_L + 128KB SRAM_U backdoor) [2, 3]
2010_0000	201F_FFFF	1MB	Reserved
2008_0000	200F_FFFF	512KB	Reserved
2000_0000	2007_FFFF	512KB	DTCM (FlexRAM)
1000_0000	1FFF_FFFF	256MB	Reserved
0800_0000	0FFF_FFFF	128MB	Reserved
0040_0000	07FF_FFFF	124MB	Reserved
0029_0000	003F_FFFF	1472KB	Reserved
0028_0000	0028_FFFF	64KB	CAAM Secure RAM
0024_0000	0027_FFFF	256KB	Reserved
0020_0000	0023_FFFF	256KB	Reserved
0010_0000	001F_FFFF	1MB	Reserved
0008_0000	000F_FFFF	512KB	Reserved
0000_0000	0007_FFFF	512KB	ITCM (FlexRAM)

1. When ECC is not enabled, the size is OCRAM allocated from FLEXRAM + 128KB OCRAM. When ECC is enabled, the size is OCRAM allocated from FLEXRAM.
2. This is the remapping address for CM4 TCM. CM7 can access CM4 TCM through this aliased region.

3. For dual core part, this memory space cannot be accessed by CM7 or other masters while CM4 is powered down. The result is unpredictable in this condition.

NOTE

When the ECC feature is enabled, the users cannot utilise the ECC memory region in RAM.

3.3 System memory map (CM4)

The table below shows the CM4 memory map:

Table 3-2. System memory map (CM4)

Start address	End address	Size	Description
E010_0000	FFFF_FFFF	511MB	Reserved
E000_0000	E00F_FFFF	1MB	PPB M4
C000_0000	DFFF_FFFF	512MB	SEMC3
A000_0000	BFFF_FFFF	512MB	SEMC2
9000_0000	9FFF_FFFF	256MB	SEMC1
8000_0000	8FFF_FFFF	256MB	SEMC0
7FC0_0000	7FFF_FFFF	4MB	FlexSPI2 RX FIFO
7F80_0000	7FBF_FFFF	4MB	FlexSPI2 TX FIFO
6000_0000	7F7F_FFFF	504MB	FlexSPI2/FlexSPI2 ciphertext
4280_0000	5FFF_FFFF	472MB	Reserved

0008_0000	001F_FFFF	1536KB	Reserved
0004_0000	0007_FFFF	256KB	Reserved
0000_0000	0003_FFFF	256KB	Reserved

1. When ECC is not enabled, the size is OCRAM allocated from FLEXRAM + 128KB OCRAM. When ECC is enabled, the size is OCRAM allocated from FLEXRAM.
2. This is the remapping address for CM4 TCM. CM7 can access CM4 TCM through this aliased region.

NOTE

When the ECC feature is enabled, the users cannot utilize the ECC memory region in RAM.

3.4 AIPS-1 Memory Map

The table below shows the AIPS-1 memory map (This memory map applies to CM4 and CM7):

Chapter 4
Interrupts, DMA Events, and XBAR Assignments

4.1 Overview

This section describes the Interrupt assignments, DMA events, and XBAR resource assignments.

4.2 CM7 interrupts

The Nested Vectored Interrupt Controller (NVIC) collects interrupt request sources and provides an interface to the Cortex-M7 core.

The table below describes the Cortex-M7 interrupt sources:

Table 4-1. CM7 domain interrupt summary

IRQ	Interrupt Source	LOGIC	Description
0	EDMA	OR	eDMA Channel 0 Transfer Complete
0		OR	eDMA Channel 16 Transfer Complete
1		OR	eDMA Channel 1 Transfer Complete
1		OR	eDMA Channel 17 Transfer Complete
2		OR	eDMA Channel 2 Transfer Complete
2		OR	eDMA Channel 18 Transfer Complete
3		OR	eDMA Channel 3 Transfer Complete
3		OR	eDMA Channel 19 Transfer Complete

Table continues on the next page...

Table 4-1. CM7 domain interrupt summary (continued)

IRQ	Interrupt Source	LOGIC	Description
4		OR	eDMA Channel 4 Transfer Complete
4		OR	eDMA Channel 20 Transfer Complete
5		OR	eDMA Channel 5 Transfer Complete
5		OR	eDMA Channel 21 Transfer Complete
6		OR	eDMA Channel 6 Transfer Complete
6		OR	eDMA Channel 22 Transfer Complete
7		OR	eDMA Channel 7 Transfer Complete

48		OR	Interrupt from CAN line error
48		OR	ORed interrupts from ipi_int_MB

Table continues on the next page...

Table 4-1. CM7 domain interrupt summary (continued)

IRQ	Interrupt Source	LOGIC	Description
48		OR	Rx warning interrupt
48		OR	Tx warning interrupt
48		OR	Interrupt from wake up
48		OR	Bus off done interrupt
48		OR	FD error interrupt
49		OR	Correctable error interrupt
49		OR	Non correctable error int host
49		OR	Non correctable error int internal
50	FlexRAM	-	FlexRAM address out of range or access hit IRQ
51	KPP	-	Keypad Interrupt
52	Reserved	-	N/A
53	GPR_IRQ	-	SW interrupt IOMUXC_GPR_GPR7[GINT]
54	eLCDIF	-	eLCDIF Interrupt
55	LCDIFv2	-	LCDIFv2 Interrupt
56	CSI	-	CSI interrupt
57	PXP	-	PXP interrupt
58	MIPI_CSI	-	MIPI CSI interrupt
59	MIPI_DSI	-	MIPI DSI interrupt
60	GPU2D	-	GPU2D interrupt
61	GPIO6	-	Combined interrupt indication for GPIO6 signal 0 through 15
62	Reserved	-	-
63	DAC	OR	DAC interrupt
63		OR	DAC async interrupt
64	KEYMGR	-	PUF interrupt
65	WDOG2	-	Watchdog2 Timer reset
66	SNVS_HP	-	SRTC Consolidated Interrupt. Non TZ.
67		-	SRTC Security Interrupt. TZ.
68	SNVS_LP	OR	ON-OFF button press shorter than 5 secs (pulse event)
68	SNVS_HP	OR	ON-OFF button press shorter than 5 secs (pulse event)
69	CAAM	-	CAAM interrupt queue for JQ0
70		-	CAAM interrupt queue for JQ1
71		-	CAAM interrupt queue for JQ2
72		-	CAAM interrupt queue for JQ3
73		-	CAAM interrupt for recoverable error

Table continues on the next page...

Table 4-1. CM7 domain interrupt summary (continued)

IRQ	Interrupt Source	LOGIC	Description
74		-	CAAM interrupt for RTIC
75	CDOG	-	CDOG interrupt
76	SAI1	OR	SAI RX interrupt
76		OR	SAI RX async interrupt
76		OR	SAI TX interrupt
76		OR	SAI TX async interrupt
77	SAI2	OR	SAI RX interrupt
77		OR	SAI RX async interrupt
77		OR	SAI TX interrupt
77		OR	SAI TX async interrupt
78	SAI3	-	SAI RX interrupt
79		-	SAI TX interrupt
80	SAI4	-	SAI RX interrupt
81		-	SAI TX interrupt
82	SPDIF	OR	SPDIF RX interrupt
82		OR	SPDIF TX interrupt
83	TMPSNS (Temperature Sensor)	-	Global Ored interrupt of all TMPSNS individual interrupts
84	TMPSNS (Temperature Sensor)	OR	TempSensor low
84		OR	TempSensor high
85		-	TempSensor panic
86	PMU	-	LPSR 1p8 brownout interrupt
87		-	Reserved
88	LPADC1	OR	ADC1 interrupt
88		OR	ADC1 async interrupt
89	LPADC2	OR	ADC2 interrupt
89		OR	ADC2 async interrupt
90	USBPHY1	-	USB1 wakeup interrupt when USB1 core is power down
91	USBPHY2	-	USB2 wakeup interrupt when USB2 core is power down
92	RDC	-	RDC reconfiguration complete interrupt
93	GPIO13	-	Combined interrupt indication for GPIO13 signal 0 through 31
94	Reserved	-	-
95	VIDEO_MUX	OR	DCIC1 Error Interrupt
95		OR	DCIC1 Function Interrupt
96		OR	DCIC2 Error Interrupt
96		OR	DCIC2 Function Interrupt

Table continues on the next page...

4.3 CM4 interrupts

The Nested Vectored Interrupt Controller (NVIC) collects up to 218 interrupt requests from all i.MX sources and provides an interface to the Cortex M4 core.

The table below describes the M4 interrupt sources:

Table 4-2. CM4 domain interrupt summary

IRQ	Interrupt Source	LOGIC	Interrupt Description
0	EDMA_LPSR	OR	eDMA_LPSR Channel 0 Transfer Complete
0		OR	eDMA_LPSR Channel 16 Transfer Complete
1		OR	eDMA_LPSR Channel 1 Transfer Complete

203-207	Reserved	-	Reserved

4.5 PIT Channel Assignments For Periodic DMA Triggering

This table shows the PIT channel to DMA channel correspondence.

Table 4-4. PIT Channel Assignments For Periodic DMA Triggering

DMA Channel Number	PIT Channel
eDMA Channel 0	PIT1 Channel 0
eDMA Channel 1	PIT1 Channel 1
eDMA Channel 2	PIT1 Channel 2
eDMA Channel 3	PIT1 Channel 3
eDMA_LPSR Channel 0	PIT2 Channel 0
eDMA_LPSR Channel 1	PIT2 Channel 1
eDMA_LPSR Channel 2	PIT2 Channel 2
eDMA_LPSR Channel 3	PIT2 Channel 3

4.6 XBAR Resource Assignments

This table shows the XBAR resource assignments in the chip.

NOTE

ADC_ETC0_COCO0 ... ADC_ETC1_COCO3 in the table are corresponding to coco0 ... coco7, also ADC_ETC0_TRIG0 ... ADC_ETC1_TRIG3 corresponding to trg0 ... trg7, see the figure "ADC_ETC block diagram" in the ADC_ETC chapter.

Table 4-5. XBAR1 Input Assignments

Assigned Input	XBAR1 Input	Gate
LOGIC LOW	XBAR1_IN00	-
LOGIC HIGH	XBAR1_IN01	-
GND	XBAR1_IN02	-
GND	XBAR1_IN03	-
IOMUX_XBAR_INOUT04	XBAR1_IN04	-
IOMUX_XBAR_INOUT05	XBAR1_IN05	-
IOMUX_XBAR_INOUT06	XBAR1_IN06	-
IOMUX_XBAR_INOUT07	XBAR1_IN07	-
IOMUX_XBAR_INOUT08	XBAR1_IN08	-
IOMUX_XBAR_INOUT09	XBAR1_IN09	-
IOMUX_XBAR_INOUT10	XBAR1_IN10	-
IOMUX_XBAR_INOUT11	XBAR1_IN11	-
IOMUX_XBAR_INOUT12	XBAR1_IN12	-
IOMUX_XBAR_INOUT13	XBAR1_IN13	-
IOMUX_XBAR_INOUT14	XBAR1_IN14	-
IOMUX_XBAR_INOUT15	XBAR1_IN15	-
IOMUX_XBAR_INOUT16	XBAR1_IN16	-
IOMUX_XBAR_INOUT17	XBAR1_IN17	-
IOMUX_XBAR_INOUT18	XBAR1_IN18	-
IOMUX_XBAR_INOUT19	XBAR1_IN19	-
IOMUX_XBAR_INOUT20	XBAR1_IN20	-
IOMUX_XBAR_INOUT21	XBAR1_IN21	-

Chapter 5
Direct Memory Access Multiplexer (DMAMUX)

5.1 Chip-specific DMAMUX information

The chip has two DMA controllers and correspondingly two DMAMUX. EDMA is in CM7 domain and co-works with CM7, EDMA_LPSR is in CM4 domain and co-works with CM4. DMA_CH_MUX serves EDMA and DMA_CH_MUX_LPSR serves EDMA_LPSR.

5.2 Overview

The Direct Memory Access Multiplexer (DMAMUX) routes DMA sources, called slots, to any of the 32 DMA channels.

5.2.1 Block diagram

The following figure illustrates the block diagram of DMAMUX.

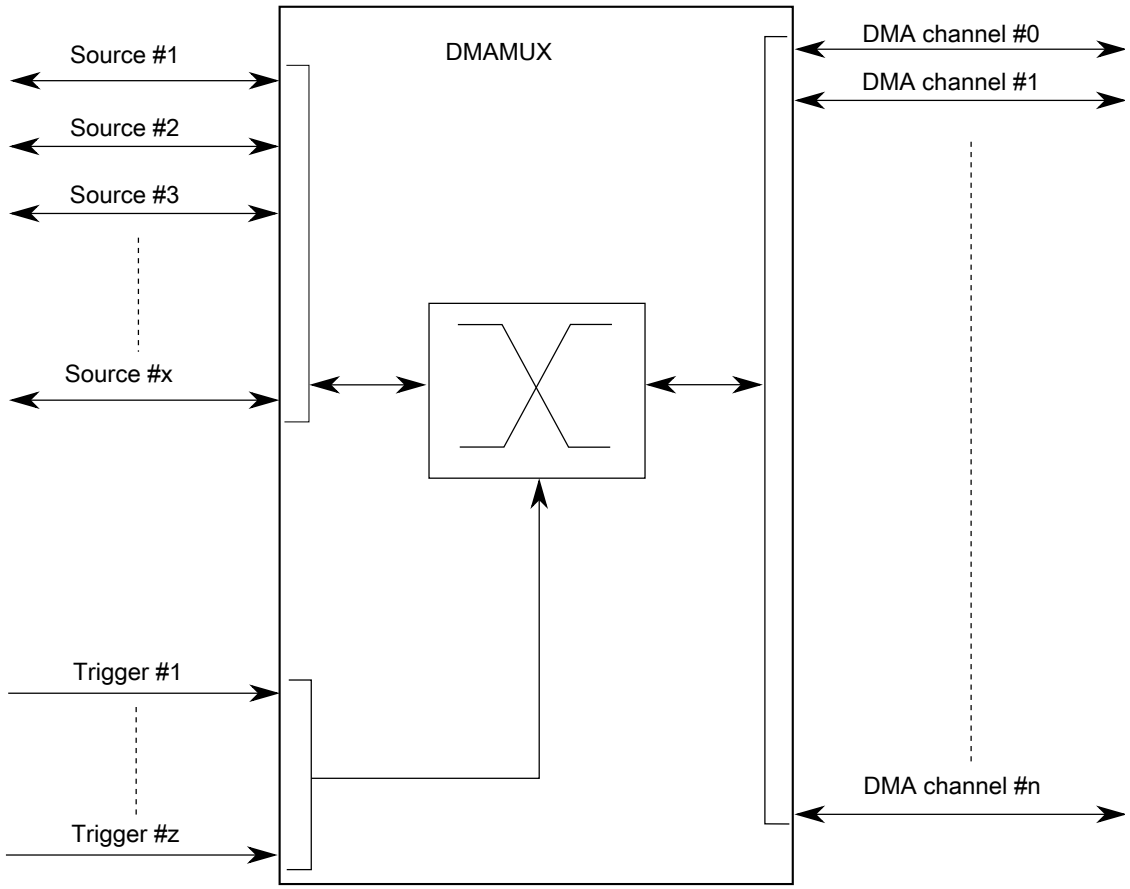

Figure 5-1. DMAMUX block diagram

5.2.2 Features

The DMAMUX module provides these features:

- Up to 208 peripheral slots can be routed to 32 channels.
- 32 independently selectable DMA channel routers.
  - Each channel output can be individually configured to be Always On and not depend on any of the peripheral slots.
  - The first 4 channels additionally provide a trigger functionality.
- Each channel router can be assigned to one of the possible peripheral DMA slots.
- On every memory map configuration change for a any channel, this module signals to the DMA Controller to reset the internal state machine for that channel and it can accept a new request based on the new configuration.

5.3 Functional description

The primary purpose of the DMAMUX is to provide flexibility in the system's use of the available DMA channels.

As such, configuration of the DMAMUX is intended to be a static procedure done during execution of the system boot code. However, if the procedure outlined in Enabling and configuring sources is followed, the configuration of the DMAMUX may be changed during the normal operation of the system.

Functionally, the DMAMUX channels may be divided into two classes:

- Channels that implement the normal routing functionality plus periodic triggering capability
- Channels that implement only the normal routing functionality

5.3.1 Modes of operation

The following operating modes are available:

- Disabled mode

  In this mode, the DMA channel is disabled. Because disabling and enabling of DMA channels is done primarily via the DMA configuration registers, this mode is used mainly as the reset state for a DMA channel in the DMA channel MUX. It may also be used to temporarily suspend a DMA channel while reconfiguration of the system takes place, for example, changing the period of a DMA trigger.

- Normal mode

  In this mode, a DMA source is routed directly to the specified DMA channel. The operation of the DMAMUX in this mode is completely transparent to the system.

- Periodic Trigger mode

  In this mode, a DMA source may only request a DMA transfer, such as when a transmit buffer becomes empty or a receive buffer becomes full, periodically.

  Configuration of the period is done in the registers of the periodic interrupt timer (PIT). This mode is available only for channels 0 to 3.

5.3.2 DMA channels with periodic triggering capability

Besides the normal routing functionality, the first 4 channels of the DMAMUX provide a special periodic triggering capability that can be used to provide an automatic mechanism to transmit bytes, frames, or packets at fixed intervals without the need for processor intervention.

The trigger is generated by the periodic interrupt timer (PIT); as such, the configuration of the periodic triggering interval is done via configuration registers in the PIT. See the section on periodic interrupt timer for more information on this topic.

Note

Because of the dynamic nature of the system (due to DMA channel priorities, bus arbitration, interrupt service routine lengths, etc.), the number of clock cycles between a trigger and the actual DMA transfer cannot be guaranteed.

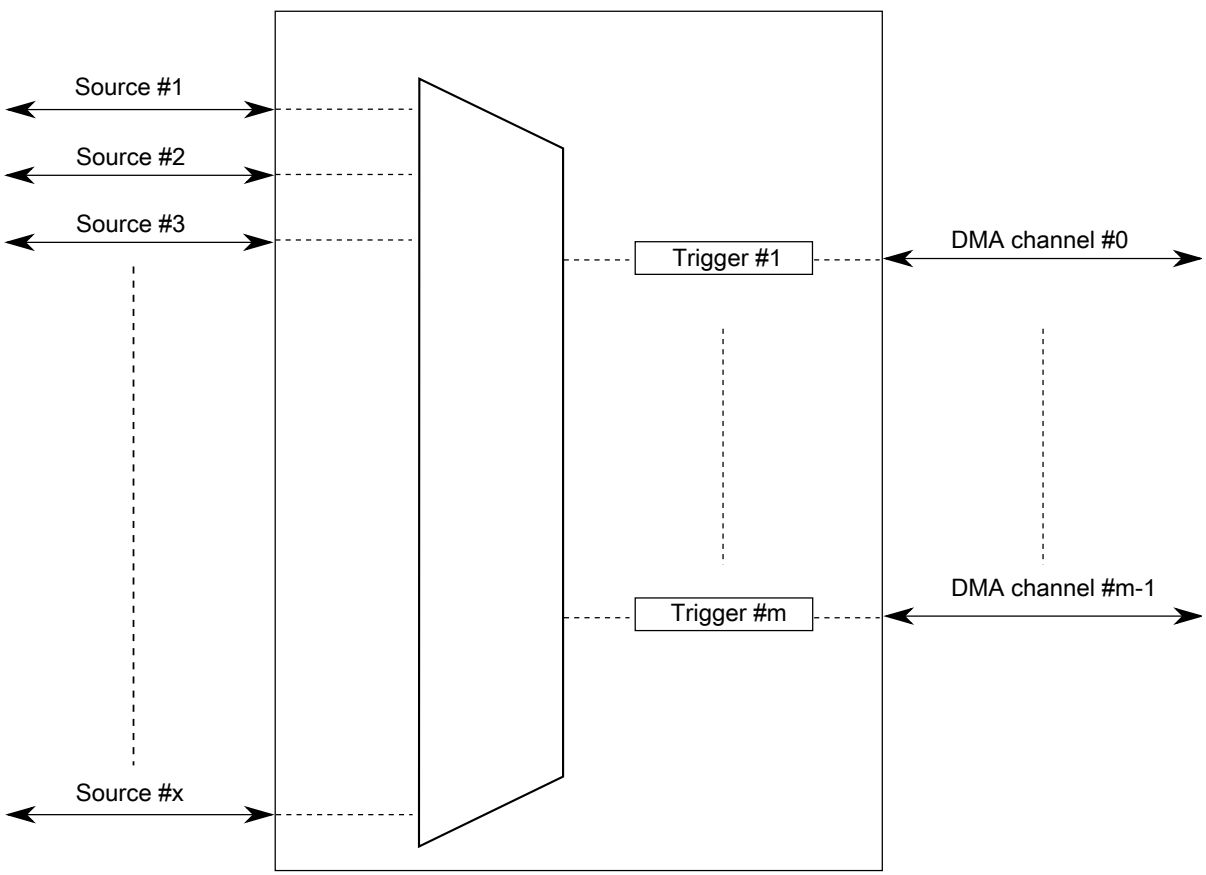

Figure 5-2. DMAMUX triggered channels

The DMA channel triggering capability allows the system to schedule regular DMA transfers, usually on the transmit side of certain peripherals, without the intervention of the processor. This trigger works by gating the request from the peripheral to the DMA until a trigger event has been seen. This is illustrated in the following figure.

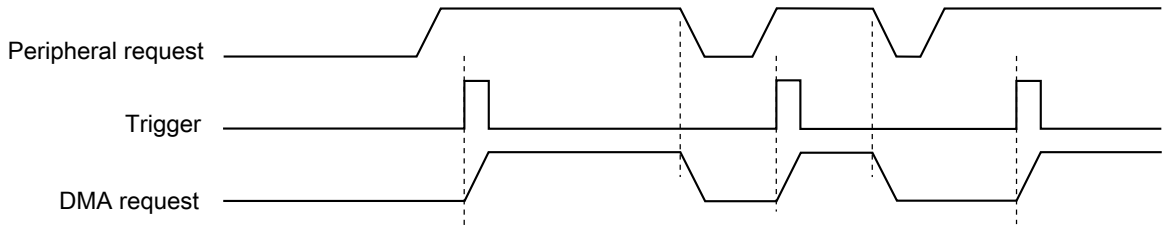

Figure 5-3. DMAMUX channel triggering: normal operation

After the DMA request has been serviced, the peripheral will negate its request, effectively resetting the gating mechanism until the peripheral reasserts its request and the next trigger event is seen. This means that if a trigger is seen, but the peripheral is not requesting a transfer, then that trigger will be ignored. This situation is illustrated in the following figure.

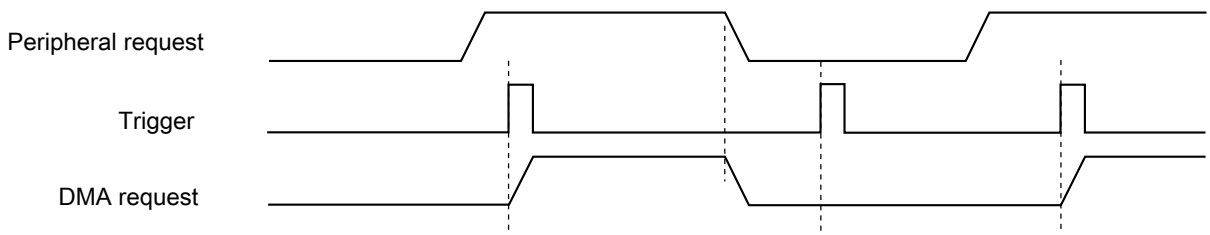

Figure 5-4. DMAMUX channel triggering: ignored trigger

This triggering capability may be used with any peripheral that supports DMA transfers, and is most useful for two types of situations:

- Periodically polling external devices on a particular bus

  As an example, the transmit side of an SPI is assigned to a DMA channel with a trigger, as described above. After it has been set up, the SPI will request DMA transfers, presumably from memory, as long as its transmit buffer is empty. By using a trigger on this channel, the SPI transfers can be automatically performed every 5 µs (as an example). On the receive side of the SPI, the SPI and DMA can be configured to transfer receive data into memory, effectively implementing a method to periodically read data from external devices and transfer the results into memory without processor intervention.

- Using the GPIO ports to drive or sample waveforms

By configuring the DMA to transfer data to one or more GPIO ports, it is possible to create complex waveforms using tabular data stored in on-chip memory. Conversely, using the DMA to periodically transfer data from one or more GPIO ports, it is possible to sample complex waveforms and store the results in tabular form in on-chip memory.

A more detailed description of the capability of each trigger, including resolution, range of values, and so on, may be found in the periodic interrupt timer section.

5.3.3 Always-enabled DMA sources

In addition to the peripherals that can be used as DMA sources, each DMA Channel can be individually configured to function as an Always Enabled source. Unlike the peripheral DMA sources, where the peripheral controls the flow of data during DMA transfers, the always enabled channel provide no such "throttling" of the data transfers. These sources are most useful in the following cases:

- Performing DMA transfers to/from GPIO—Moving data from/to one or more GPIO pins, either unthrottled (that is, as fast as possible), or periodically (using the DMA triggering capability).
- Performing DMA transfers from memory to memory—Moving data from memory to memory, typically as fast as possible, sometimes with software activation.
- Performing DMA transfers from memory to the external bus, or vice-versa—Similar to memory to memory transfers, this is typically done as quickly as possible.
- Any DMA transfer that requires software activation—Any DMA transfer that should be explicitly started by software.

In cases where software should initiate the start of a DMA transfer, an always-enabled DMA channel can be used to provide maximum flexibility. When activating a DMA channel via software, subsequent executions of the minor loop require that a new start event be sent. This can either be a new software activation, or a transfer request from the DMA channel MUX. The options for doing this are:

- Transfer all data in a single minor loop.

By configuring the DMA to transfer all of the data in a single minor loop (that is, major loop counter = 1), no reactivation of the channel is necessary. The disadvantage to this option is the reduced granularity in determining the load that the DMA transfer will impose on the system. For this option, the DMA channel must be disabled in the DMA channel MUX.

- Use explicit software reactivation.

  In this option, the DMA is configured to transfer the data using both minor and major loops, but the processor is required to reactivate the channel by writing to the DMA registers *after every minor loop*. For this option, the DMA channel must be disabled in the DMA channel MUX.

- Use an always-enabled DMA source.

  In this option, the DMA is configured to transfer the data using both minor and major loops, and the DMA channel MUX does the channel reactivation. For this option, the DMA channel should be enabled and configured as "always enabled" channel. Note that the reactivation of the channel can be continuous (DMA triggering is disabled) or can use the DMA triggering capability. In this manner, it is possible to execute periodic transfers of packets of data from one source to another, without processor intervention.

NOTE

When a channel is configured as "Always Enabled", then the peripheral DMA sources for that channel are ignored; i.e. SOURCE field has no effect.

5.3.4 Clocks

The following table describes the clock sources for DMAMUX. Please see Clock Controller Module (CCM) for clock setting, configuration and gating information.

Table 5-2. DMAMUX clock

Clock name	Description
ipg_clk	Peripheral clock
ipg_clk_s	Peripheral access clock

5.3.5 Reset

The reset state of each individual bit is shown in Memory map/register definition. In summary, after reset, all channels are disabled and must be explicitly enabled before use.

5.4 External signals

The DMAMUX has no external pins.

5.5 Application information

This section provides instructions for initializing the DMA channel MUX.

5.5.1 Enabling and configuring sources

To enable a source with periodic triggering:

1. Determine with which DMA channel the source will be associated. Note that only the first 4 DMA channels have periodic triggering capability.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] fields of the DMA channel.
3. Ensure that the DMA channel is properly configured in the DMA. The DMA channel may be enabled at this point.
4. Configure the corresponding timer.
5. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that the CHCFG[ENBL] and CHCFG[TRIG] fields are set.

NOTE

The following is an example. See the chip configuration details for the number of this device's DMA channels that have triggering capability.

To configure source #5 transmit for use with DMA channel 1, with periodic triggering capability:

1. Write 0x00000000 to CHCFG1.
2. Configure channel 1 in the DMA, including enabling the channel.
3. Configure a timer for the desired trigger interval.
4. Write 0xC0000005 to CHCFG1.

The following code example illustrates steps 1 and 4 above:

```
void DMAMUX_Init(uint8_t DMA_CH, uint8_t DMAMUX_SOURCE)
{
    DMAMUX_0.CHCFG[DMA_CH].B.SOURCE = DMAMUX_SOURCE;
    DMAMUX_0.CHCFG[DMA_CH].B.ENBL   = 1;
    DMAMUX_0.CHCFG[DMA_CH].B.TRIG   = 1;
}
```

To enable a source without periodic triggering:

1. Determine with which DMA channel the source will be associated. Note that only the first 4 DMA channels have periodic triggering capability.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] fields of the DMA channel.
3. Ensure that the DMA channel is properly configured in the DMA. The DMA channel may be enabled at this point.
4. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that CHCFG[ENBL] is setwhile CHCFG[TRIG] is cleared.

NOTE

The following is an example. See the chip configuration details for the number of this device's DMA channels that have triggering capability.

To configure source #5 transmit for use with DMA channel 1 with no periodic triggering capability :

1. Write 0x00000000 to CHCFG1.
2. Configure channel 1 in the DMA, including enabling the channel.
3. Write 0x80000005 to CHCFG1.

The following code example illustrates steps 1 and 3 above:

```
In File registers.h:
#define DMAMUX_BASE_ADDR     0x40021000/* Example only ! */
/* Following example assumes long is 32-bits */
volatile unsigned long *CHCFG0 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0000);
volatile unsigned long *CHCFG1 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0004);
volatile unsigned long *CHCFG2 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0008);
volatile unsigned long *CHCFG3 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x000C);
volatile unsigned long *CHCFG4 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0010);
volatile unsigned long *CHCFG5 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0014);
volatile unsigned long *CHCFG6 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0018);
volatile unsigned long *CHCFG7 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x001C);
volatile unsigned long *CHCFG8 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0020);
volatile unsigned long *CHCFG9 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0024);
volatile unsigned long *CHCFG10= (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0028);
volatile unsigned long *CHCFG11= (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x002C);
volatile unsigned long *CHCFG12= (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0030);
volatile unsigned long *CHCFG13= (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0034);
volatile unsigned long *CHCFG14= (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0038);
volatile unsigned long *CHCFG15= (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x003C);

In File main.c:
#include "registers.h"
:
:
*CHCFG1 = 0x00000000;
*CHCFG1 = 0x80000005;
```

To disable a source:

A particular DMA source may be disabled by not writing the corresponding source value into any of the CHCFG registers. Additionally, some module-specific configuration may be necessary. See the appropriate section for more details.

To switch the source of a DMA channel:

1. Disable the DMA channel in the DMA and reconfigure the channel for the new source.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] bits of the DMA channel.
3. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that the CHCFG[ENBL] and CHCFG[TRIG] fields are set.

To switch DMA channel 8 from source #5 transmit to source #7 transmit:

1. In the DMA configuration registers, disable DMA channel 8 and reconfigure it to handle the transfers to peripheral slot 7. This example assumes channel 8 doesn't have triggering capability.
2. Write 0x00000000 to CHCFG8.
3. Write 0x80000007 to CHCFG8. (In this example, setting CHCFG[TRIG] would have no effect due to the assumption that channel 8 does not support the periodic triggering functionality.)

The following code example illustrates steps 2 and 3 above:

```
In File registers.h:
#define DMAMUX_BASE_ADDR     0x40021000/* Example only ! */
/* Following example assumes long is 32-bits */
volatile unsigned long *CHCFG0 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0000);
volatile unsigned long *CHCFG1 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0004);
volatile unsigned long *CHCFG2 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0008);
volatile unsigned long *CHCFG3 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x000C);
volatile unsigned long *CHCFG4 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0010);
volatile unsigned long *CHCFG5 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0014);
volatile unsigned long *CHCFG6 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0018);
volatile unsigned long *CHCFG7 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x001C);
volatile unsigned long *CHCFG8 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0020);
volatile unsigned long *CHCFG9 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0024);
volatile unsigned long *CHCFG10= (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0028);
volatile unsigned long *CHCFG11= (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x002C);
volatile unsigned long *CHCFG12= (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0030);
volatile unsigned long *CHCFG13= (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0034);
volatile unsigned long *CHCFG14= (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0038);
volatile unsigned long *CHCFG15= (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x003C);

In File main.c:
#include "registers.h"
:
:
*CHCFG8 = 0x00000000;
*CHCFG8 = 0x80000007;
```

5.6 Initialization

5.6.1 Configuration options

Table 5-3. Channel Configuration Options

ENBL	TRIG	A_ON	Function	Mode
0	X	X	DMA channel is disabled	Disabled Mode
1	0	0	DMA channel is enabled with no triggering (transparent)	Normal Mode
1	1	0	DMA channel is enabled with triggering	Periodic Trigger Mode
1	0	1	DMA channel is always enabled	Always On Mode
1	1	1	DMA channel is always enabled with triggering	Always On Trigger Mode

5.7 Memory map/register definition

This section provides a detailed description of all memory-mapped registers in the DMAMUX.

5.7.1 DMAMUX register descriptions

5.7.1.1 DMAMUX memory map

DMAMUX0 base address: 4007_4000h

DMAMUX1 base address: 40C1_8000h

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)
0 - 7C	Channel a Configuration Register (CHCFG0 - CHCFG31)	32	RW	0000_0000

5.7.1.2 Channel a Configuration Register (CHCFG0 - CHCFG31)

Each of the DMA channels can be independently enabled/disabled and associated with one of the DMA slots (peripheral slots or always-on slots) in the system.

NOTE

Setting multiple CHCFG registers with the same source value will result in unpredictable behavior. This is true, even if a channel is disabled (ENBL==0).

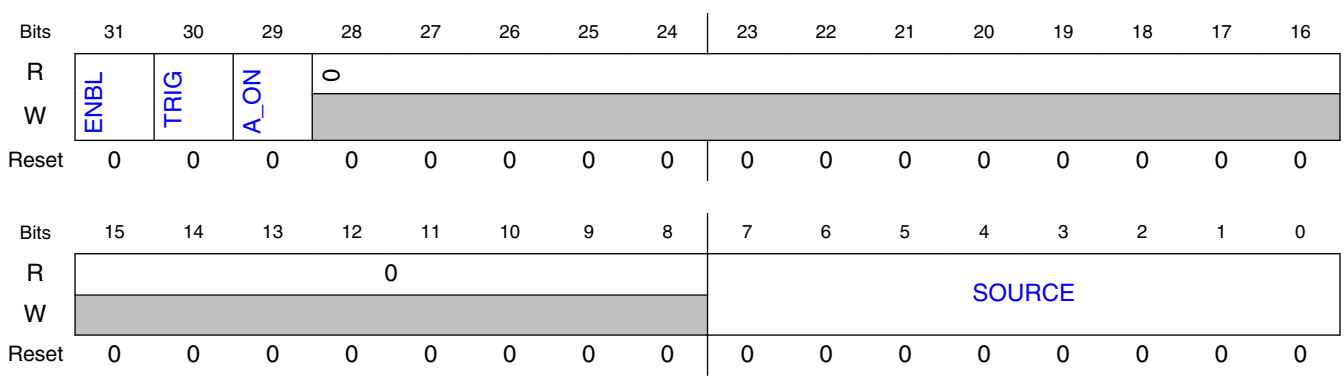
Before changing the trigger or source settings, a DMA channel must be disabled via CHCFGn[ENBL].

5.7.1.2.1 Offset

For a = 0 to 31:

Register	Offset
CHCFGa	0h + (a × 4h)

5.7.1.2.2 Diagram



5.7.1.2.3 Fields

Field	Description
31 ENBL	DMA Mux Channel Enable Enables the channel for DMA Mux. The DMA has separate channel enables/disables, which should be used to disable or reconfigure a DMA channel. 0 - DMA Mux channel is disabled

Table continues on the next page...

Field	Description
	1 - DMA Mux channel is enabled
30 TRIG	DMA Channel Trigger Enable Enables the periodic trigger capability for the triggered DMA channel. 0 - Triggering is disabled. If triggering is disabled and ENBL is set, the DMA Channel will simply route the specified source to the DMA channel. (Normal mode) 1 - Triggering is enabled. If triggering is enabled and ENBL is set, the DMA_CH_MUX is in Periodic Trigger mode.
29 A_ON	DMA Channel Always Enable Enables the DMA Channel to be always ON. If TRIG bit is set, the module will assert request on every trigger. 0 - DMA Channel Always ON function is disabled 1 - DMA Channel Always ON function is enabled
28-8 —	Reserved field
7-0 SOURCE	DMA Channel Source (Slot Number) Specifies which DMA source, if any, is routed to a particular DMA channel. See the chip-specific DMA_CH_MUX information for details about the peripherals and their slot numbers.

6.2 Overview

The enhanced direct memory access (eDMA) controller is a second-generation module capable of performing complex data transfers with minimal intervention from a host processor. The hardware microarchitecture includes:

- A DMA engine that performs:
  - Source address and destination address calculations
  - Data-movement operations
- Local memory containing transfer control descriptors for each of the 32 channels

6.2.1 Block diagram

The following figure illustrates the components of the eDMA system, including the eDMA module ("engine").

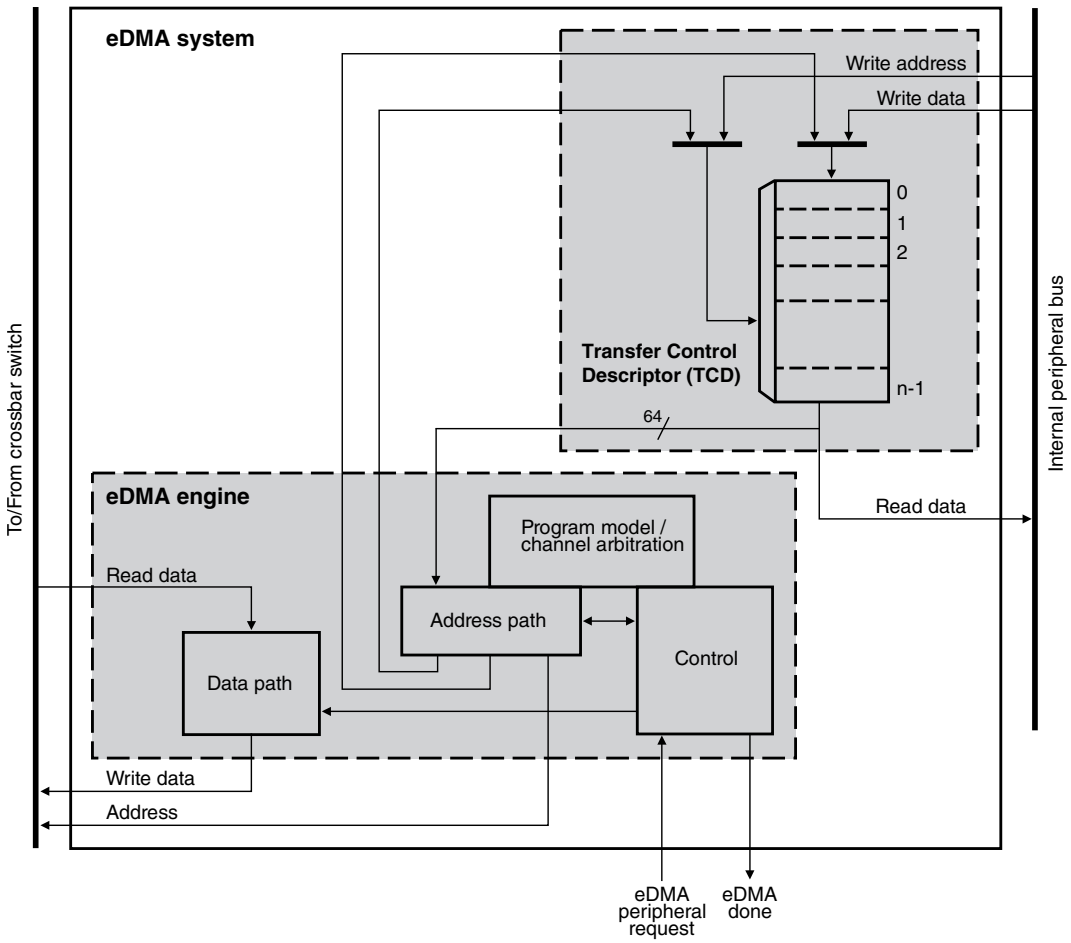

Figure 6-1. eDMA system block diagram

6.2.2 Block parts

The eDMA module comprises two major modules: the eDMA engine and the transfer-control descriptor local memory.

Table 6-2 describes the eDMA engine submodules.

Table 6-2. eDMA engine submodules

Submodule	Function
Address path	The address path block: • Provides registered versions of two channel Transfer Control Descriptors (TCDs)—channel x (normal start) and channel y (preemption start) • Manages all master bus-address calculations

Table continues on the next page...

Table 6-2. eDMA engine submodules (continued)

Submodule	Function
	All channels provide the same functionality. This structure enables preemption of data transfers associated with an active channel (after completion of a read/write sequence) if the eDMA engine asserts a higher priority channel activation. After eDMA activates a channel, it runs until the minor loop completes, unless preempted by a higher priority channel. This provides a mechanism (enabled by DCHPRI*n*[ECP]) in which the eDMA engine can preempt a large data move operation to minimize the time another channel stalls. When the eDMA engine selects a channel to execute, it reads the contents of the channel TCD from local memory and loads it into one of the following: • The address path channel x registers (normal start) • The address path channel y registers (preemption start) After the minor loop execution completes, the address path hardware writes the new values for the TCD*n*_{SADDR, DADDR, CITER} back to local memory. If the major iteration count completes, the eDMA engine performs additional processing, including: • Final address pointer updates • Reloading the TCD*n*_CITER field • A possible fetch of the next TCD*n* from memory as part of a scatter/gather operation.
Data path	The data path block implements the bus master read/write data path. It includes a data buffer and the necessary multiplex logic to support any required data alignment. The internal read data bus is the primary input, and the internal write data bus is the primary output. The address and data path modules directly support the two-stage pipelined internal bus. The address path module represents the first stage of the bus pipeline (address phase). The data path module implements the second stage of the pipeline (data phase).
Programming model/ channel arbitration	This block implements: • The first section of the eDMA programming model • Channel arbitration logic The programming model registers connect to the chip's internal peripheral bus. The eDMA peripheral request inputs and interrupt request outputs also connect to this block (via control logic).
Control	The control block provides all control functions for the eDMA engine. For data transfers in which the source size (SSIZE) and destination size (DSIZE) are equal, the eDMA engine performs a series of source read/destination write operations until it has transferred the number of bytes specified in the minor loop byte count (NBYTES). For TCDs in which the source and destination sizes are not equal, the eDMA engine executes multiple accesses of the smaller size data for each reference of the larger size. For example, if the source size (SSIZE) references 16-bit data and the destination size (DSIZE) is 32-bit data, eDMA performs two reads, then one 32-bit write.

Table 6-3 explains the partitioning of the TCD local memory.

Table 6-3. Transfer control descriptor memory

Submodule	Description
Memory controller	The memory controller logic implements the required dual-ported controller, managing accesses from the eDMA engine as well as references from the internal peripheral bus. If simultaneous accesses occur, the eDMA engine receives priority and the peripheral transaction stalls.
Memory array	The memory array provides TCD storage for the transfer profile for each channel.

6.2.3 Features

The eDMA module is a highly programmable data-transfer engine optimized to minimize any required intervention from the host processor. Use it for applications where you statically know the size of the data to be transferred and do not define the size within the transferred data itself. The eDMA module features:

- All data movement via dual-address transfers: read from source, write to destination
  - Programmable source and destination addresses and transfer size
  - Support for enhanced addressing modes
- 32-channel implementation performs complex data transfers with minimal intervention from a host processor
  - Internal data buffer, used as temporary storage to support 16- and 32-byte transfers
  - Connections to the crossbar switch (AXBS) for bus mastering the data movement
- TCD supports two-deep, nested transfer operations
  - 32-byte TCD stored in local memory for each channel
  - An inner data transfer loop defined by a minor byte transfer count
  - An outer data transfer loop defined by a major iteration count
- Channel activation via one of three methods:
  - Explicit software initiation
  - Initiation via a channel-to-channel linking mechanism for continuous transfers
  - Peripheral-paced hardware requests, one per channel
- Fixed-priority and round-robin channel arbitration
- Channel completion notification via programmable interrupt requests
  - One interrupt per channel. eDMA engine can generate an interrupt when major iteration count completes
  - Programmable error terminations per channel and logically summed together to form one error interrupt to the interrupt controller

- Programmable support for scatter/gather DMA processing
- Support for complex data structures

NOTE

In the discussion of this module, *n* is the channel number.

6.3 Functional description

The operation of the eDMA is described in the following subsections.

6.3.1 Modes of operation

eDMA operates in the following modes:

Table 6-4. Modes of operation

Mode	Description
Normal	In Normal mode, eDMA transfers data from a source to a destination. The source and destination can be a memory block or an I/O block capable of operation with eDMA. A *service request* initiates a transfer of a specific number of bytes (NBYTES) as specified in the TCD. • The *minor loop* is the sequence of read and write operations that transfers the NBYTES of data for a service request. • Each service request executes one iteration of the major loop, transferring NBYTES of data.
Debug	DMA operation is configurable in Debug mode via Control (CR) • If CR[EDBG] = 0, eDMA continues to operate normally when the chip is in debug mode. • If CR[EDBG] = 1, eDMA stops transferring data when the chip enters debug mode. If a channel is active when eDMA enters Debug mode, eDMA continues operation until the channel retires.
Wait	Before entering Wait mode, eDMA attempts to complete any transfer that is in progress. After the transfer completes, the chip enters Wait mode.

6.3.2 eDMA basic data flow

The basic flow of a data transfer can be partitioned into three segments.

As shown in the following diagram, the first segment involves the channel activation:

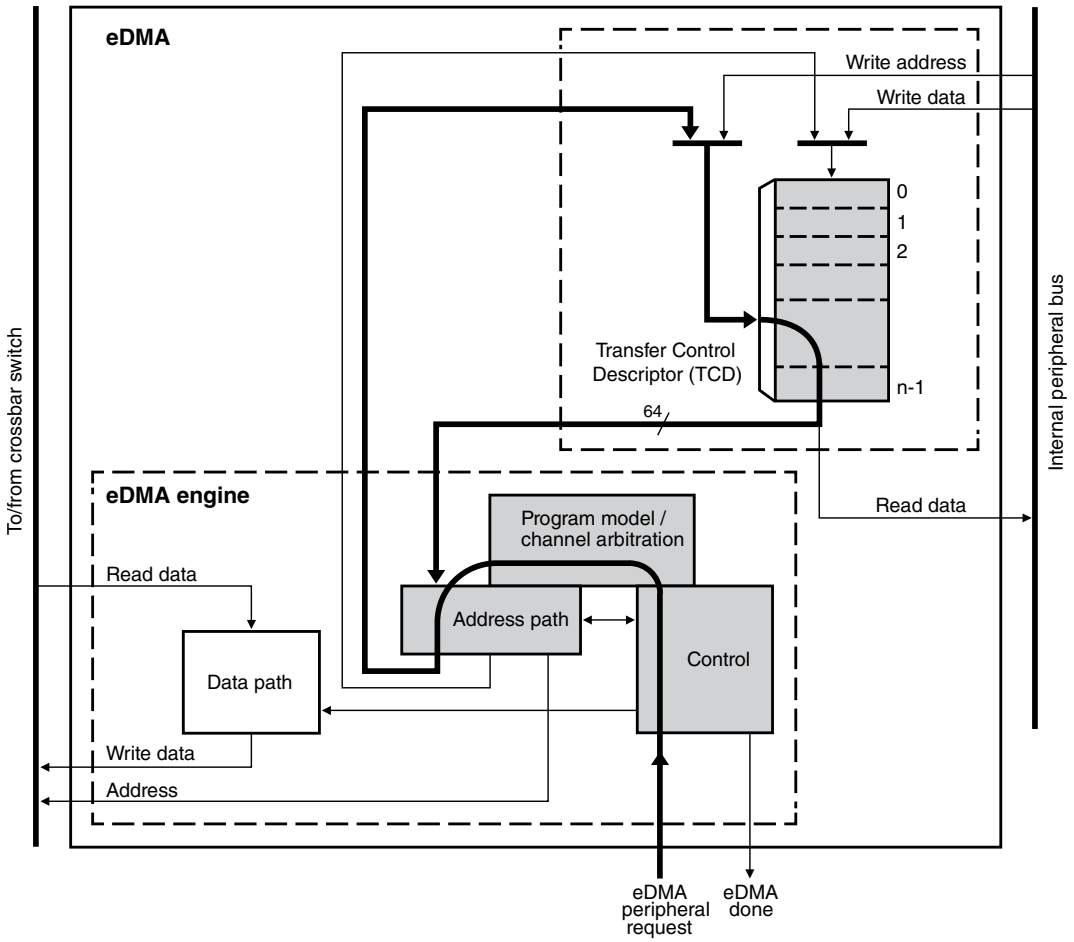

Figure 6-2. eDMA operation, part 1

This example uses the assertion of the eDMA peripheral request signal to request service for channel *n*. Channel activation via software and the TCD*n*_CSR[START] bit follows the same basic flow as peripheral requests. The eDMA request input signal is registered internally and then routed through the eDMA engine: first through the control module, then into the program model and channel arbitration. In the next cycle, the channel arbitration executes, using either the fixed-priority or round-robin algorithm. After arbitration is complete, the activated channel number is sent through the address path and converted into the required address to access the local memory for TCD*n*. Next, the TCD memory is accessed and the required descriptor read from the local memory and loaded into the eDMA engine's internal register file. The TCD memory is 64 bits wide to minimize the time needed to fetch the activated channel descriptor and load it into the internal register file.

The following diagram illustrates the second part of the basic data flow:

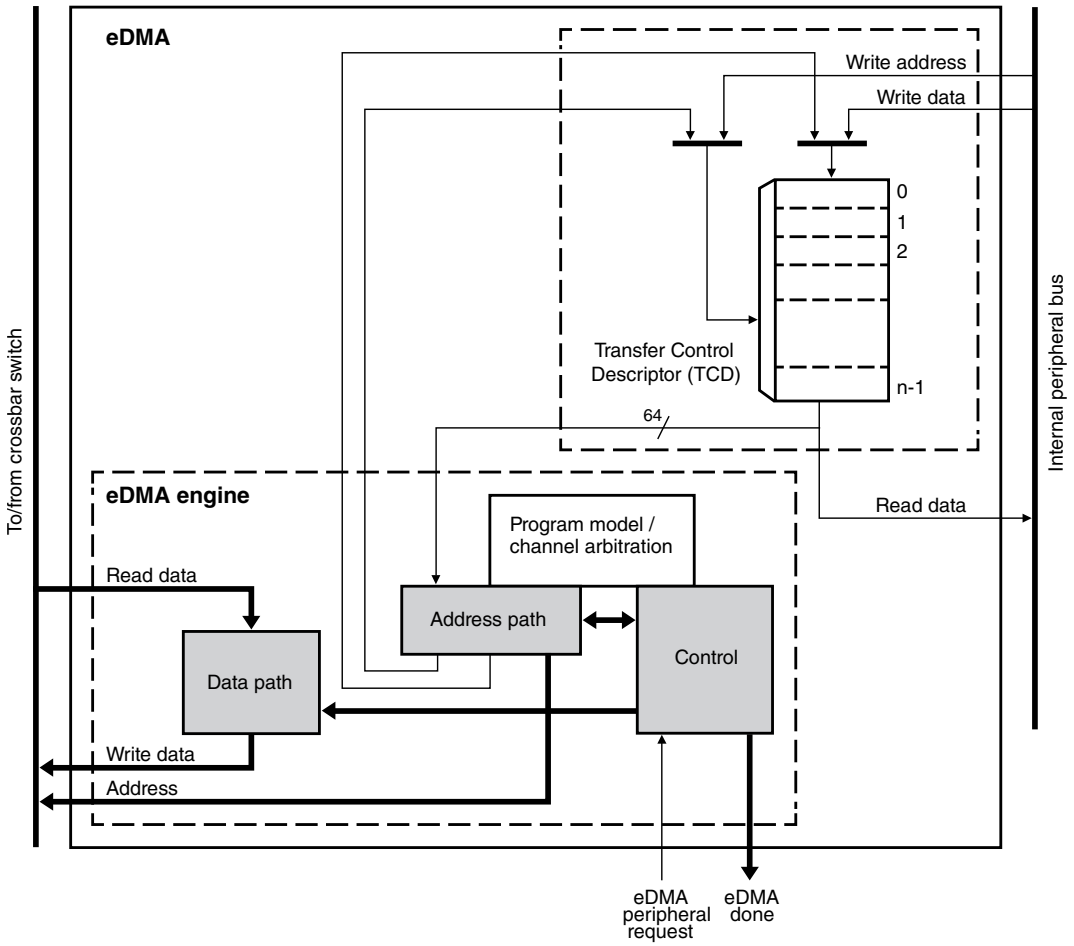

Figure 6-3. eDMA operation, part 2

The modules associated with the data transfer (address path, data path, and control) execute sequentially through the required source reads and destination writes to perform the data movement. The source reads are initiated and the fetched data is temporarily stored in the data path block until it is gated onto the internal bus during the destination write. This source read/destination write processing continues until the minor byte count has transferred.

After the minor byte count has moved, the final phase of the basic data flow is performed. In this segment, the address path logic performs the required updates to certain fields in the appropriate TCD, for example, SADDR, DADDR, CITER. If the major iteration count is exhausted, additional operations are performed. These include the final address adjustments and reloading of the BITER field into the CITER. Assertion of an optional interrupt request also occurs at this time, as does a possible fetch of a new TCD from memory using the scatter/gather address pointer included in the descriptor (if scatter/gather is enabled). The updates to the TCD memory and the assertion of an interrupt request are shown in the following diagram.

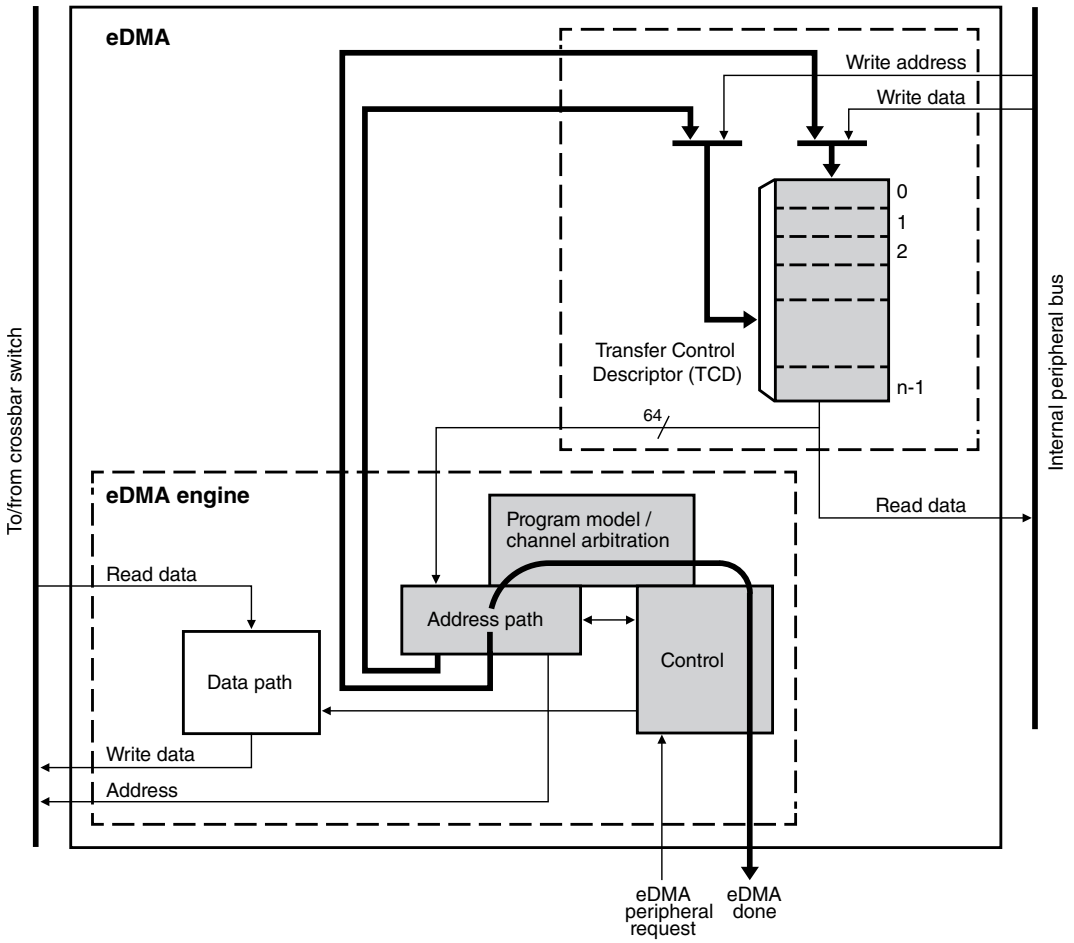

Figure 6-4. eDMA operation, part 3

6.3.3 Fault reporting and handling

Channel errors are reported in the Error Status register (DMAx_ES) and can be caused by:

- A configuration error, which is an illegal setting in the transfer-control descriptor or an illegal priority register setting in Fixed-Arbitration mode, or
- An error termination to a bus master read or write cycle

A configuration error is reported when the starting source or destination address, source or destination offsets, minor loop byte count, or the transfer size represent an inconsistent state. Each of these possible causes is detailed below:

- The addresses and offsets must be aligned on 0-modulo transfer size boundaries.
- The minor loop byte count must be a multiple of the source and destination transfer sizes.

- All source reads and destination writes must be configured to the natural boundary of the programmed transfer size respectively.
- In fixed arbitration mode, a configuration error is caused by any two channel priorities being equal. All channel priority levels must be unique when fixed arbitration mode is enabled.

NOTE

When two channels have the same priority, a channel priority error exists and is reported in the Error Status register. However, the channel number is not reported in the Error Status register. When all of the channel priorities within a group are not unique, the channel number selected by arbitration is undetermined.

To aid in Channel Priority Error (CPE) debug, set the Halt On Error bit in the DMA's Control register. If all channel priorities within a group are not unique, the DMA is halted after the CPE error is recorded. The DMA remains halted and does not process any channel service requests. After all of the channel priorities are set to unique numbers, the DMA may be enabled again by clearing the HALT bit.

- If a scatter/gather operation is enabled upon channel completion, a configuration error is reported if the scatter/gather address (DLAST_SGA) is not aligned on a 32-byte boundary.
- If minor loop channel linking is enabled upon channel completion, a configuration error is reported when the link is attempted if the TCDn_CITER[ELINK] bit does not equal the TCDn_BITER[ELINK] bit.

If enabled, all configuration error conditions, except the scatter/gather and minor-loop link errors, report as the channel activates and asserts an error interrupt request. A scatter/gather configuration error is reported when the scatter/gather operation begins at major loop completion, when properly enabled. A minor loop channel link configuration error is reported when the link operation is serviced at minor loop completion.

If a system bus read or write is terminated with an error, the data transfer is stopped and the appropriate bus error flag set. In this case, the state of the channel's transfer control descriptor is updated by the eDMA engine with the current source address, destination address, and current iteration count at the point of the fault. When a system bus error occurs, the channel terminates after the next transfer. Due to pipeline effect, the next transfer is already in progress when the bus error is received by the eDMA. If a bus error occurs on the last read prior to beginning the write sequence, the write executes using the

data captured during the bus error. If a bus error occurs on the last write prior to switching to the next read sequence, the read sequence executes before the channel terminates due to the destination bus error.

A transfer may be canceled by software with the CR[CX] bit. When a cancel transfer request is recognized, the DMA engine stops processing the channel. The current read-write sequence is allowed to finish. If the cancel occurs on the last read-write sequence of a major or minor loop, the cancel request is discarded and the channel retires normally.

The error cancel transfer is the same as a cancel transfer except the Error Status register (DMAx_ES) is updated with the canceled channel number and ECX is set. The TCD of a canceled channel contains the source and destination addresses of the last transfer saved in the TCD. If the channel needs to be restarted, you must re-initialize the TCD because the aforementioned fields no longer represent the original parameters. When a transfer is canceled by the error cancel transfer mechanism, the channel number is loaded into DMA_ES[ERRCHN] and ECX and VLD are set. In addition, an error interrupt may be generated if enabled.

NOTE

The cancel transfer request enables you to stop a large data transfer when the full data transfer is no longer needed. The cancel transfer bit does not abort the channel. It simply stops the transferring of data and then retires the channel through its normal shutdown sequence. The application software must manage the context of the cancel. If an interrupt is desired (or not), then the interrupt should be enabled (or disabled) before the cancel request. The application software must clean up the transfer control descriptor because the full transfer did not occur.

The occurrence of any error causes the eDMA engine to stop normal processing of the active channel immediately (it goes to its error processing states and the transaction to the system bus still has pipeline effect), and the appropriate channel bit in the eDMA error register is asserted. At the same time, the details of the error condition are loaded into the Error Status register (DMAx_ES). The major loop complete indicators, setting the transfer control descriptor DONE flag and the possible assertion of an interrupt request, are not affected when an error is detected. After the error status has been updated, the eDMA engine continues operating by servicing the next appropriate channel. A channel that experiences an error condition is not automatically disabled. If a channel is terminated by an error and then issues another service request before the error is fixed, that channel executes and terminates with the same error condition.

6.3.4 Channel preemption

Channel preemption is enabled on a per-channel basis by setting DCHPRIn[ECP]. Channel preemption enables the executing channel's data transfers to temporarily be suspended in favor of starting a higher priority channel. After the preempting channel has completed its minor loop data transfers, the preempted channel is restored and resumes execution. After the restored channel completes one read/write sequence, it is again eligible for preemption. If any higher priority channel is requesting service, the restored channel is suspended and the higher priority channel is serviced. Nested preemption, that is, attempting to preempt a preempting channel, is not supported. After a preempting channel begins execution, it cannot be preempted. Preemption is available only when fixed arbitration is selected.

A channel's ability to preempt another channel can be disabled by setting DCHPRIn[DPA]. When a channel's preemption ability is disabled, that channel cannot suspend a lower priority channel's data transfer, regardless of the lower priority channel's ECP setting. This enables a pool of low priority, large data-moving channels to be defined. These low priority channels can be configured to not preempt each other, thus preventing a low priority channel from consuming the preempt slot normally available to a true, high priority channel.

6.3.5 Clocks

The following table describes the clock sources for eDMA. Please see Clock Controller Module (CCM) for clock setting, configuration and gating information.

Table 6-5. eDMA clocks

Clock name	Description
edma_hclk	Module clock
ipg_clk	Peripheral clock

6.4 Initialization/application information

The following sections discuss initialization of the eDMA and programming considerations.

6.4.1 eDMA initialization

To initialize the eDMA:

1. Write to the CR if a configuration other than the default is desired.
2. Write the channel priority levels to the DCHPRI*n* registers if a configuration other than the default is desired.
3. Enable error interrupts in the EEI register if desired.
4. Write the 32-byte TCD for each channel that may request service.
5. Enable any hardware service requests via the ERQ register.
6. Request channel service via either:
   - Software: setting TCD*n*_CSR[START]
   - Hardware: slave device asserting its eDMA peripheral request signal

After any channel requests service, a channel is selected for execution based on the arbitration and priority levels in the programming model. The eDMA engine reads the entire TCD, including the TCD control and status fields, as shown in Table 6-6, for the selected channel into its internal address path module.

As the TCD is read, the first transfer is initiated on the system bus, unless a configuration error is detected. Transfers from the source, as defined by TCD*n*_SADDR, to the destination, as defined by TCD*n*_DADDR, continue until the number of bytes specified by TCD*n*_NBYTES have been transferred.

When the transfer is complete, the eDMA engine's local TCD*n*_SADDR, TCD*n*_DADDR, and TCD*n*_CITER are written back to the main TCD memory and any minor loop channel linking is performed, if enabled. If the major loop is exhausted, further post-processing executes, such as interrupts, major loop channel linking, and scatter/gather operations, if enabled.

Table 6-6. TCD control and status fields

TCD*n*_CSR field name	Description
START	Control bit to start channel explicitly when using a software-initiated DMA service (automatically cleared by hardware)
ACTIVE	Status bit indicating the channel is currently in execution
DONE	Status bit indicating major loop completion (cleared by software when using a software-initiated DMA service)
DREQ	Control bit to disable DMA request at end of major loop completion when using a hardware-initiated DMA service
BWC	Control bits for throttling bandwidth control of a channel
ESG	Control bit to enable scatter/gather feature
INTHALF	Control bit to enable interrupt when major loop is half complete
INTMAJOR	Control bit to enable interrupt when major loop completes

The following figure shows how each DMA request initiates one minor-loop transfer, or iteration, without CPU intervention. DMA arbitration can occur after each minor loop, and one level of minor loop DMA preemption is allowed. The number of minor loops in a major loop is specified by the beginning iteration count (BITER).

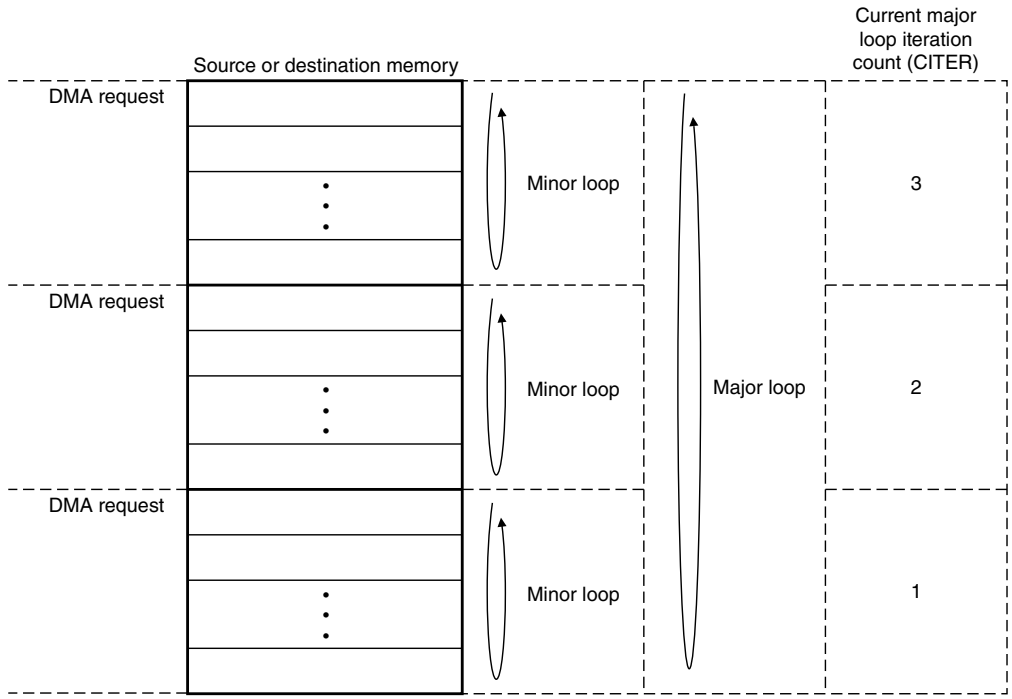

Figure 6-5. Example of multiple loop iterations

The following figure lists the memory array terms and how the TCD settings interrelate.

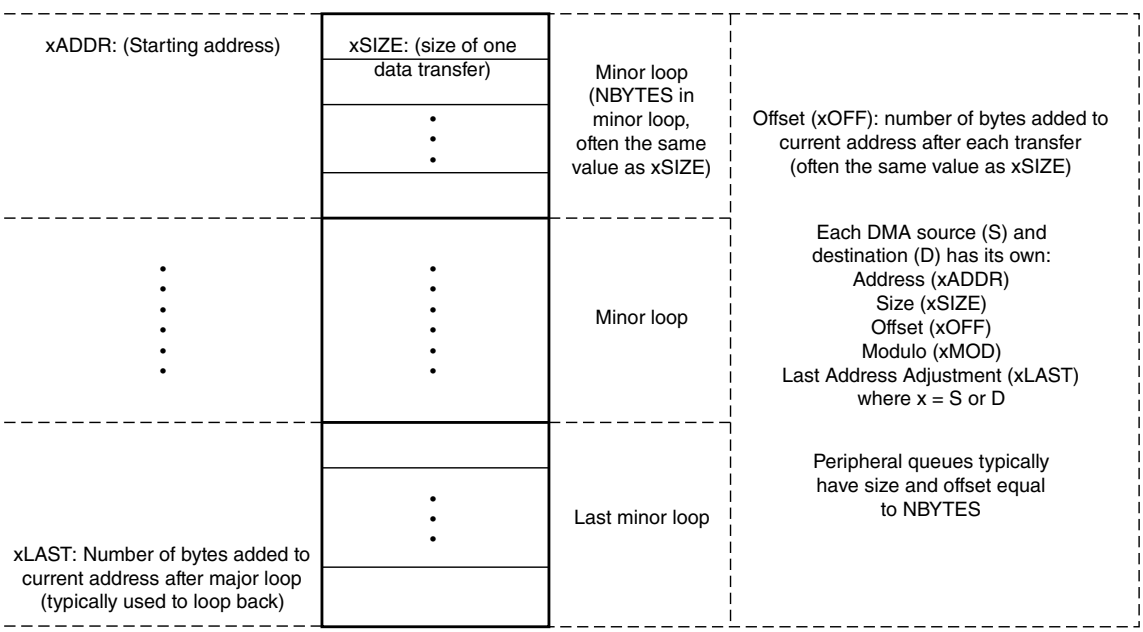

Figure 6-6. Memory array terms

6.4.2 Programming errors

The eDMA performs various tests on the transfer control descriptor to verify consistency in the descriptor data. Most programming errors are reported on a per-channel basis with the exception of channel priority error (ES[CPE]).

For all error types other than group or channel priority errors, the channel number causing the error is recorded in the Error Status register (DMAx_ES). If the error source is not removed before the next activation of the problem channel, the error is detected and recorded again.

Channel priority errors are identified within a group after that group has been selected as the active group. For example:

1. The eDMA is configured for fixed group and fixed channel arbitration modes.
2. Group 1 is the highest priority and all channels are unique in that group.
3. Group 0 is the next highest priority and has two channels with the same priority level.
4. If Group 1 has any service requests, those requests will be executed.
5. After all of Group 1 requests have completed, Group 0 will be the next active group.
6. If Group 0 has a service request, then an undefined channel in Group 0 will be selected and a channel priority error will occur.
7. This repeats until the all of Group 0 requests have been removed or a higher priority Group 1 request comes in.

In this sequence, for item 2, the eDMA acknowledge lines will assert only if the selected channel is requesting service via the eDMA peripheral request signal. If interrupts are enabled for all channels, the user will get an error interrupt, but the channel number for the ERR register and the error interrupt request line may be wrong because they reflect the selected channel. A group priority error is global and any request in any group will cause a group priority error.

If priority levels are not unique, when any channel requests service, a channel priority error is reported. The highest channel/group priority with an active request is selected, but the lowest numbered channel with that priority is selected by arbitration and executed by the eDMA engine. The hardware service request handshake signals, error interrupts, and error reporting are associated with the selected channel.

6.4.3 Arbitration mode considerations

This section discusses arbitration considerations for the eDMA.

6.4.3.1 Fixed group arbitration, Fixed channel arbitration

In this mode, the channel service request from the highest priority channel in the highest priority group is selected to execute. If the eDMA is programmed so that the channels within one group use "fixed" priorities, and that group is assigned the highest "fixed" priority of all groups, that group can take all the bandwidth of the eDMA controller. That is, no other groups will be serviced if there is always at least one DMA request pending on a channel in the highest priority group when the controller arbitrates the next DMA request. The advantage of this scenario is that latency can be small for channels that need to be serviced quickly. Preemption is available in this scenario only.

6.4.3.2 Fixed group arbitration, Round-robin channel arbitration

The highest priority group with a request will be serviced. Lower priority groups will be serviced if no pending requests exist in the higher priority groups.

Within each group, c hannels are serviced starting with the highest channel number and rotating through to the lowest channel number without regard to the channel priority levels assigned within the group.

This scenario could cause the same bandwidth consumption problem as indicated in Fixed group arbitration, Fixed channel arbitration, but all the channels in the highest priority group will be serviced. Service latency will be short on the highest priority group, but could potentially be very much longer as the group priority decreases.

6.4.4 DMA transfer examples

This section presents examples of how to perform DMA transfers with the eDMA.

6.4.4.1 Single request

To perform a simple transfer of n bytes of data with one activation, set the major loop to one (TCD*n*_CITER = TCD*n*_BITER = 1). The data transfer begins after the channel service request is acknowledged and the channel is selected to execute. After the transfer is complete, TCD*n*_CSR[DONE] is set and an interrupt generates if properly enabled.

For example, the following TCD entry is configured to transfer 16 bytes of data. The eDMA is programmed for one iteration of the major loop transferring 16 bytes per iteration. The source memory has an 8-bit memory port located at 0x1000. The

destination memory has a 32-bit port located at 0x2000. The address offsets are programmed in increments to match the transfer size: one byte for the source and four bytes for the destination. The final source and destination addresses are adjusted to return to their beginning values.

```
TCDn_CITER = TCDn_BITER = 1
TCDn_NBYTES = 16
TCDn_SADDR = 0x1000
TCDn_SOFF = 1
TCDn_ATTR[SSIZE] = 0
TCDn_SLAST = -16
TCDn_DADDR = 0x2000
TCDn_DOFF = 4
TCDn_ATTR[DSIZE] = 2
TCDn_DLAST_SGA= -16
TCDn_CSR[INTMAJOR] = 1
TCDn_CSR[START] = 1 (Should be written last after all other fields have been initialized)
All other TCDn fields = 0
```

This generates the following event sequence:

1. User write to the TCD*n*_CSR[START] bit requests channel service.
2. The channel is selected by arbitration for servicing.
3. eDMA engine writes: TCD*n*_CSR[DONE] = 0, TCD*n*_CSR[START] = 0, TCD*n*_CSR[ACTIVE] = 1.
4. eDMA engine reads: channel TCD data from local memory to internal register file.
5. The source-to-destination transfers are executed as follows:
   a. Read byte from location 0x1000, read byte from location 0x1001, read byte from 0x1002, read byte from 0x1003.
   b. Write 32 bits to location 0x2000 → first iteration of the minor loop.
   c. Read byte from location 0x1004, read byte from location 0x1005, read byte from 0x1006, read byte from 0x1007.
   d. Write 32 bits to location 0x2004 → second iteration of the minor loop.
   e. Read byte from location 0x1008, read byte from location 0x1009, read byte from 0x100A, read byte from 0x100B.
   f. Write 32 bits to location 0x2008 → third iteration of the minor loop.
   g. Read byte from location 0x100C, read byte from location 0x100D, read byte from 0x100E, read byte from 0x100F.
   h. Write 32 bits to location 0x200C → last iteration of the minor loop → major loop complete.
6. The eDMA engine writes: TCD*n*_SADDR = 0x1000, TCD*n*_DADDR = 0x2000, TCD*n*_CITER = 1 (TCD*n*_BITER).
7. The eDMA engine writes: TCD*n*_CSR[ACTIVE] = 0, TCD*n*_CSR[DONE] = 1, INT[*n*] = 1.
8. The channel retires and the eDMA goes idle or services the next channel.

6.4.4.2 Multiple requests

The following example transfers 32 bytes via two hardware requests, but is otherwise the same as the previous example. The only fields that change are the major loop iteration count and the final address offsets. The eDMA is programmed for two iterations of the major loop, transferring 16 bytes per iteration. After the channel's hardware requests are enabled in the ERQ register, the slave device initiates channel service requests.

```
TCDn_CITER = TCDn_BITER = 2
TCDn_SLAST = -32
TCDn_DLAST_SGA = -32
```

This would generate the following sequence of events:

1. First hardware, that is, the eDMA peripheral, requests channel service.
2. The channel is selected by arbitration for servicing.
3. eDMA engine writes: TCD*n*_CSR[DONE] = 0, TCD*n*_CSR[START] = 0, TCD*n*_CSR[ACTIVE] = 1.
4. eDMA engine reads: channel TCD*n* data from local memory to internal register file.
5. The source to destination transfers are executed as follows:
   a. Read byte from location 0x1000, read byte from location 0x1001, read byte from 0x1002, read byte from 0x1003.
   b. Write 32 bits to location 0x2000 → first iteration of the minor loop.
   c. Read byte from location 0x1004, read byte from location 0x1005, read byte from 0x1006, read byte from 0x1007.
   d. Write 32 bits to location 0x2004 → second iteration of the minor loop.
   e. Read byte from location 0x1008, read byte from location 0x1009, read byte from 0x100A, read byte from 0x100B.
   f. Write 32 bits to location 0x2008 → third iteration of the minor loop.
   g. Read byte from location 0x100C, read byte from location 0x100D, read byte from 0x100E, read byte from 0x100F.
   h. Write 32 bits to location 0x200C → last iteration of the minor loop.
6. eDMA engine writes: TCD*n*_SADDR = 0x1010, TCD*n*_DADDR = 0x2010, TCD*n*_CITER = 1.
7. eDMA engine writes: TCD*n*_CSR[ACTIVE] = 0.
8. The channel retires → one iteration of the major loop. The eDMA goes idle or services the next channel.
9. Second hardware, that is, eDMA peripheral, requests channel service.
10. The channel is selected by arbitration for servicing.
11. eDMA engine writes: TCD*n*_CSR[DONE] = 0, TCD*n*_CSR[START] = 0, TCD*n*_CSR[ACTIVE] = 1.
12. eDMA engine reads channel TCD data from local memory to internal register file.
13. The source to destination transfers are executed as follows:

a. Read byte from location 0x1010, read byte from location 0x1011, read byte from 0x1012, read byte from 0x1013.
b. Write 32 bits to location 0x2010 → first iteration of the minor loop.
c. Read byte from location 0x1014, read byte from location 0x1015, read byte from 0x1016, read byte from 0x1017.
d. Write 32 bits to location 0x2014 → second iteration of the minor loop.
e. Read byte from location 0x1018, read byte from location 0x1019, read byte from 0x101A, read byte from 0x101B.
f. Write 32 bits to location 0x2018 → third iteration of the minor loop.
g. Read byte from location 0x101C, read byte from location 0x101D, read byte from 0x101E, read byte from 0x101F.
h. Write 32 bits to location 0x201C → last iteration of the minor loop → major loop complete.

14. eDMA engine writes: TCD*n*_SADDR = 0x1000, TCD*n*_DADDR = 0x2000, TCD*n*_CITER = 2 (TCD*n*_BITER).
15. eDMA engine writes: TCD*n*_CSR[ACTIVE] = 0, TCD*n*_CSR[DONE] = 1, INT[n] = 1.
16. The channel retires → major loop complete. The eDMA goes idle or services the next channel.

6.4.4.3 Using the modulo feature

The modulo feature of the eDMA provides the ability to implement a circular data queue in which the size of the queue is a power of 2. MOD is a 5-bit field for the source and destination in the TCD, and it specifies which lower address bits increment from their original value after the address+offset calculation. All upper address bits remain the same as in the original value. A setting of zero for this field disables the modulo feature.

The following table shows how the transfer addresses are specified based on the setting of the MOD field. Here a circular buffer is created where the address wraps to the original value while the 28 upper address bits (0x1234567*x*) retain their original value. In this example the source address is set to 0x12345670, the offset is set to 4 bytes, and the MOD field is set to 4, allowing for a 2^4 byte (16-byte) size queue.

Table 6-7. Modulo example

Transfer number	Address
1	0x12345670
2	0x12345674
3	0x12345678
4	0x1234567C

Table continues on the next page...

Table 6-7. Modulo example (continued)

Transfer number	Address
5	0x12345670
6	0x12345674

6.4.5 Monitoring transfer descriptor status

This section discusses how to monitor eDMA status.

6.4.5.1 Testing for minor loop completion

There are two methods to test for minor loop completion when using software-initiated service requests. The first is to read the TCD*n*_CITER field and test for a change. Another method may be extracted from the sequence shown below. The second method is to test TCD*n*_CSR[START] and TCD*n*_CSR[ACTIVE]. The minor-loop-complete condition is indicated by both bits reading zero after TCD*n*_CSR[START] was set. Polling the TCD*n*_CSR[ACTIVE] bit may be inconclusive, because the active status may be missed if the channel execution is short in duration.

The TCD status bits execute the following sequence for a software activated channel:

Stage	TCD*n*_CSR bits			State
	START	ACTIVE	DONE	
1	1	0	0	Channel service request via software
2	0	1	0	Channel is executing
3a	0	0	0	Channel has completed the minor loop and is idle
3b	0	0	1	Channel has completed the major loop and is idle

The best method to test for minor-loop completion when using service requests initiated by hardware, that is, peripherals, is to read the TCD*n*_CITER field and test for a change. The hardware request and acknowledge handshake signals are not visible in the programmer's model.

The TCD status bits execute the following sequence for a hardware-activated channel:

Stage	TCD*n*_CSR bits			State
	START	ACTIVE	DONE	
1	0	0	0	Channel service request via hardware (peripheral request asserted)
2	0	1	0	Channel is executing
3a	0	0	0	Channel has completed the minor loop and is idle
3b	0	0	1	Channel has completed the major loop and is idle

For both activation types, the major-loop-complete status is explicitly indicated via the TCD*n*_CSR[DONE] bit.

The TCD*n*_CSR[START] bit is cleared automatically when the channel begins execution regardless of how the channel activates.

6.4.5.2 transfer descriptors of active channels

The eDMA reads back the true TCD*n*_SADDR, TCD*n*_DADDR, and TCD*n*_NBYTES values if read when a channel executes. The true values of SADDR, DADDR, and NBYTES are the values the eDMA engine currently uses in its internal register file and not the values in the TCD local memory for that channel. The addresses, SADDR and DADDR, and NBYTES, which decrement to zero as the transfer progresses, can give an indication of the progress of the transfer. All other values are read back from the TCD local memory.

6.4.5.3 Checking channel preemption status

Preemption is available only when fixed arbitration is selected for both group and channel arbitration modes. A preemptive situation is one in which a preempt-enabled channel runs and a higher priority request becomes active. When the eDMA engine is not operating in fixed group, fixed channel arbitration mode, determination of the actively running relative priority outstanding requests become undefined. Channel and/or group priorities are treated as equal, that is, constantly rotating, when Round-Robin Arbitration mode is selected.

The TCD*n*_CSR[ACTIVE] bit for the preempted channel remains asserted throughout the preemption. The preempted channel is temporarily suspended while the preempting channel executes one major loop iteration. If two TCD*n*_CSR[ACTIVE] bits are set simultaneously in the global TCD map, a higher priority channel is actively preempting a lower priority channel.

6.4.6 Channel linking

Channel linking (or chaining) is a mechanism where one channel sets the TCD*n*_CSR[START] bit of another channel (or itself), thus initiating a service request for that channel. When properly enabled, the EDMA engine automatically performs this operation at the major or minor loop completion.

The minor loop channel linking occurs at the completion of the minor loop (or one iteration of the major loop). The TCD*n*_CITER[ELINK] field determines whether a minor loop link is requested. When enabled, the channel link is made after each iteration of the major loop except for the last. When the major loop is exhausted, only the major loop channel link fields are used to determine if a channel link should be made. For example, the initial fields of:

```
TCDn_CITER[ELINK] = 1
TCDn_CITER[LINKCH] = 0xC
TCDn_CITER[CITER] value = 0x4
TCDn_CSR[MAJOR_ELINK] = 1
TCDn_CSR[MAJOR_LINKCH] = 0x3
```

executes as:

1. Minor loop done → set TCD2_CSR[START] bit.
2. Minor loop done → set TCD2_CSR[START] bit.
3. Minor loop done → set TCD2_CSR[START] bit.
4. Minor loop done, major loop done → set TCD3_CSR[START] bit.

When minor loop linking is enabled (TCD*n*_CITER[ELINK] = 1), the TCD*n*_CITER[CITER] field uses a nine-bit vector to form the current iteration count. When minor loop linking is disabled (TCD*n*_CITER[ELINK] = 0), the TCD*n*_CITER[CITER] field uses a 15-bit vector to form the current iteration count. The bits associated with the TCD*n*_CITER[LINKCH] field are concatenated onto the CITER value to increase the range of the CITER.

Note

The TCD*n*_CITER[ELINK] bit and the TCD*n*_BITER[ELINK] bit must be equal or a configuration error is reported. The CITER and BITER vector widths must be equal to calculate the major loop, half-way done interrupt point.

The following table summarizes how a DMA channel can link to another DMA channel, that is, use another channel's TCD, at the end of a loop.

Table 6-8. Channel linking parameters

Desired link behavior	TCD control field name	Description
Link at end of minor loop	CITER[ELINK]	Enable channel-to-channel linking on minor loop completion (current iteration)
	CITER[LINKCH]	Link channel number when linking at end of minor loop (current iteration)
Link at end of major loop	CSR[MAJOR_ELINK]	Enable channel-to-channel linking on major loop completion
	CSR[MAJOR_LINKCH]	Link channel number when linking at end of major loop

6.4.7 Dynamic programming

This section provides recommended methods to change the programming model during channel execution.

6.4.7.1 Dynamically changing the channel priority

The following two options are recommended for dynamically changing channel priority levels:

1. Switch to Round-Robin Channel Arbitration mode, change the channel priorities, then switch back to Fixed Arbitration mode
2. Disable all the channels, change the channel priorities, then enable the appropriate channels.

6.4.7.2 Dynamic channel linking

Dynamic channel linking is the process of setting TCDn_CSR[MAJORELINK] during channel execution (see the diagram in TCD structure). This field is read from the TCD local memory at the end of channel execution, thus enabling you to enable the feature during channel execution.

Because you can change the configuration during execution, a coherency model is needed. Consider the scenario where you attempt to execute a dynamic channel link by enabling TCDn_CSR[MAJORELINK] at the same time the eDMA engine is retiring the channel. TCDn_CSR[MAJORELINK] would be set in the programmer's model, but it would be unclear whether the actual link was made before the channel retired.

The following coherency model is recommended when executing a dynamic channel link request.

1. Write one to TCDn_CSR[MAJORELINK].
2. Read back TCDn_CSR[MAJORELINK].
3. Test the TCDn_CSR[MAJORELINK] request status:
   - If TCDn_CSR[MAJORELINK] = 1, the dynamic link attempt was successful.
   - If TCDn_CSR[MAJORELINK] = 0, the attempted dynamic link did not succeed (the channel was already retiring).

For this request, the TCD local memory controller forces TCDn_CSR[MAJORELINK] to zero on any writes to a channel's TCD.word7 after that channel's TCD.done bit is set, indicating the major loop is complete.

NOTE

You must clear TCDn_CSR[DONE] before writing TCDn_CSR[MAJORELINK]. The eDMA engine automatically clears TCDn_CSR[DONE] after a channel begins execution.

6.4.7.3 Dynamic scatter/gather

Scatter/gather is the process of automatically loading a new TCD into a channel. It enables a DMA channel to use multiple TCDs; this enables a DMA channel to scatter the DMA data to multiple destinations or gather it from multiple sources. When scatter/gather is enabled and the channel has finished its major loop, a new TCD is fetched from system memory and loaded into that channel's descriptor location in eDMA programmer's model, thus replacing the current descriptor.

Because you are able to change the configuration during execution, a coherency model is needed. Consider the scenario where you attempt to execute a dynamic scatter/gather operation by enabling the TCDn_CSR[ESG] bit at the same time the eDMA engine is retiring the channel. The ESG bit would be set in the programmer's model, but it would be unclear whether the actual scatter/gather request was honored before the channel retired.

Two methods for this coherency model are shown in the following subsections. Method 1 has the advantage of reading the MAJORLINKCH field and the ESG bit with a single read. For both dynamic channel linking and scatter/gather requests, the TCD local memory controller forces the TCD MAJOR[ELINK] and ESG bits to zero on any writes to a channel's TCD word 7 if that channel's TCD[DONE] bit is set, indicating the major loop is complete.

NOTE

The user must clear the TCDn_CSR[DONE] bit before writing the MAJORELINK or ESG bits. The TCDn_CSR[DONE] bit is cleared automatically by the eDMA engine after a channel begins execution.

6.4.7.3.1 Method 1 (channel not using major loop channel linking)

For a channel not using major loop channel linking, the coherency model described here may be used for a dynamic scatter/gather request.

When TCDn_CSR[MAJORELINK] is zero, TCDn_CSR[MAJORLINKCH] is not used by the eDMA. In this case, MAJORLINKCH may be used for other purposes. This method uses the MAJORLINKCH field as a TCD identification (ID).

1. When the descriptors are built, write a unique TCD ID in TCDn_CSR[MAJORLINKCH] for each TCD associated with a channel using dynamic scatter/gather.
2. Write one to TCDn_CSR[DREQ].

   Should a dynamic scatter/gather attempt fail, setting the DREQ bit prevents a future hardware activation of the channel. This stops the channel from executing with a destination address (DADDR) that was calculated using a scatter/gather address (written in the next step) instead of a DLAST_SGA final offset value.

3. Write the TCDn_DLASTSGA register with the scatter/gather address.
4. Write one to TCDn_CSR[ESG].
5. Read back the 16-bit TCD control/status field.
6. Test the ESG request status and MAJORLINKCH value in the TCDn_CSR register:

   If ESG = 1, the dynamic link attempt was successful.

   If ESG = 0 and MAJORLINKCH (ID) did not change, the attempted dynamic link did not succeed (the channel was already retiring).

   If ESG = 0 and MAJORLINKCH (ID) changed, the dynamic link attempt was successful (the new TCD's ESG value cleared the ESG bit).

6.4.7.3.2 Method 2 (channel using major loop channel linking)

For a channel using major loop channel linking, the coherency model described here may be used for a dynamic scatter/gather request. This method uses the TCD[DLAST_SGA] field as a TCD identification (ID).

1. Write one to TCDn_CSR[DREQ].

Should a dynamic scatter/gather attempt fail, setting TCDn_CSR[DREQ] prevents a future hardware activation of the channel. This stops the channel from executing with a destination address (DADDR) that was calculated using a scatter/gather address (written in the next step) instead of a DLAST_SGA final offset value.

2. Write the TCDn_DLAST_SGA register with the scatter/gather address.
3. Write one to TCDn_CSR[ESG].
4. Read back TCDn_CSR[ESG].
5. Test the ESG request status:

   If ESG = 1, the dynamic link attempt was successful.

   If ESG = 0, read the 32-bit TCDn_DLAST_SGA field.

   If ESG = 0 and TCDn_DLAST_SGA did not change, the attempted dynamic link did not succeed (the channel was already retiring).

   If ESG = 0 and TCDn_DLAST_SGA changed, the dynamic link attempt was successful (the new TCD’s ESG value cleared the ESG bit).

6.4.8 Suspend/resume a DMA channel with active hardware service requests

The DMA enables you to move data from memory or peripheral registers to another location in memory or peripheral registers without CPU interaction. After the DMA and peripherals have been configured and are active, it is rare to suspend a peripheral's service request dynamically. In this scenario, there are certain restrictions to disabling a DMA hardware service request. For coherency, a specific procedure must be followed. This section provides guidance on how to coherently suspend and resume a Direct Memory Access (DMA) channel when the DMA is triggered by a slave module such as the Serial Peripheral Interface (SPI), ADC, or other module.

6.4.8.1 Suspend an active DMA channel

To suspend an active DMA channel:

1. Stop the DMA service request at the peripheral first. Confirm it has been disabled by reading back the appropriate register in the peripheral.
2. Check the DMA's Hardware Request Status register (DMA_HRSn) to ensure there is no service request to the DMA channel being suspended. Then disable the hardware service request by clearing the ERQ bit on appropriate DMA channel.

6.4.8.2 Resume a DMA channel

To resume a DMA channel:

1. Enable the DMA service request on the appropriate channel by setting the relevant ERQ bit.
2. Enable the DMA service request at the peripheral.

For example, assume the SPI is set as a master for transmitting data via a DMA service request when the SPI_TXFIFO has an empty slot. The DMA transfers the next command and data to the TXFIFO upon the request. You must suspend the DMA/SPI transfer loop and perform the following steps:

1. Disable the DMA service request at the source by writing zero to SPI_RSER[TFFF_RE]. Confirm that SPI_RSER[TFFF_RE] is zero.
2. Ensure there is no DMA service request from the SPI by verifying that DMA_HRS[HRS*n*] is zero for the appropriate channel. If no service request is present, disable the DMA channel by clearing the channel's ERQ bit. If a service request is present, wait until the request has been processed and the HRS bit reads zero.

6.5 Memory map/register definition

The eDMA programming model consists of registers that provide:

- Control and status functions
- Channel configuration functions
- TCD definition functions

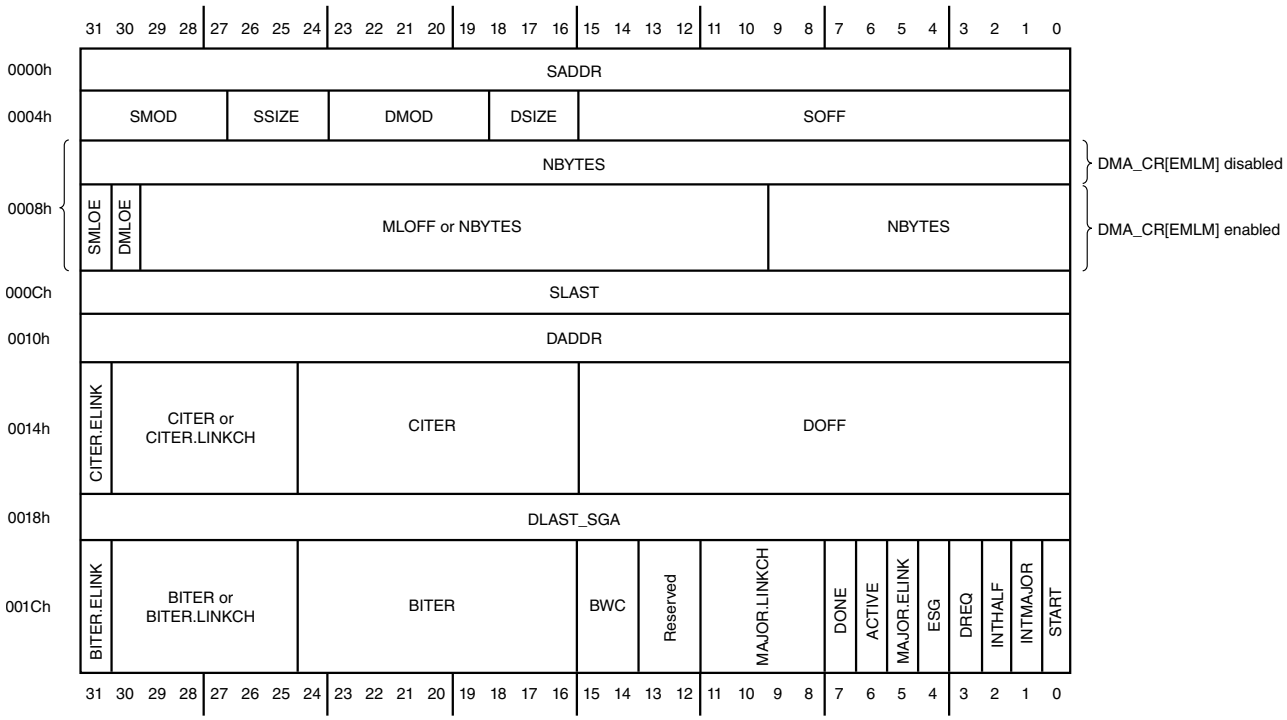
6.5.1 TCD memory

Each channel requires a 32-byte TCD to define the desired data movement operation. The channel descriptors are in local memory in sequential order: channel 0, channel 1, ... channel 31. Each TCD*n* definition comprises 11 registers of 16 or 32 bits.

6.5.2 TCD initialization

Before activating a channel, you must initialize its TCD with the appropriate transfer profile.

6.5.3 TCD structure



6.5.4 Reserved memory and fields

- Reading reserved fields in a register returns the value of zero.
- The eDMA ignores writes to reserved bits in a register.
- Reading or writing a reserved memory location generates a bus error.

6.5.5.2 Control (CR)

This register defines the basic operating configuration of the eDMA module. eDMA arbitrates channel service requests in two groups of 16 channels each:

- Group 1 contains channels 31-16
- Group 0 contains channels 15-0

You can configure arbitration within a group to use either a fixed-priority or a round-robin scheme. For fixed-priority arbitration, eDMA selects and executes the highest-priority channel that requests service. The channel priority registers assign the priorities (see the Channel Priority (DCHPRI0 - DCHPRI31) registers). For round-robin arbitration, the eDMA engine ignores channel priorities and cycles through channels within each group from high to low channel number without regard to priority.

NOTE

For correct operation, you must write to this register only when the eDMA channels are inactive—that is, when TCD*n*_CSR[ACTIVE] = 0.

The group priorities operate in a similar fashion. In group fixed priority arbitration mode, channel service requests in the highest priority group are executed first, where priority level 1 is the highest and priority level 0 is the lowest. The group priorities are assigned in the GRP*n*PRI fields of the Control register (CR). All group priorities must have unique values prior to any channel service requests occurring; otherwise, a configuration error is reported. For group round robin arbitration, eDMA ignores the group priorities and the groups are cycled through (from high to low group number) without regard to priority.

Minor loop offsets are address-offset values to be added to the final source address (TCDn_SADDR) or destination address (TCDn_DADDR) when the minor loop completes. When you enable minor loop offsets, eDMA adds the minor loop offset (MLOFF) value to the final source address (TCDn_SADDR), to the final destination address (TCDn_DADDR), or to both, before it writes the addresses back into the TCD. If the major loop is complete, eDMA ignores the minor loop offset, and uses the major loop address offsets (TCDn_SLAST and TCDn_DLAST_SGA) to compute the next TCDn_SADDR and TCDn_DADDR values.

Enabling minor loop mapping (EMLM = 1) redefines TCDn word2. eDMA uses a portion of TCDn word2 for multiple fields:

- A source enable field (SMLOE) to specify the minor loop offset is to be applied to the source address (TCDn_SADDR) when the minor loop completes
- A destination enable field (DMLOE) to specify the minor loop offset to be applied to the destination address (TCDn_DADDR) when the minor loop completes
- The sign extended minor loop offset value (MLOFF).

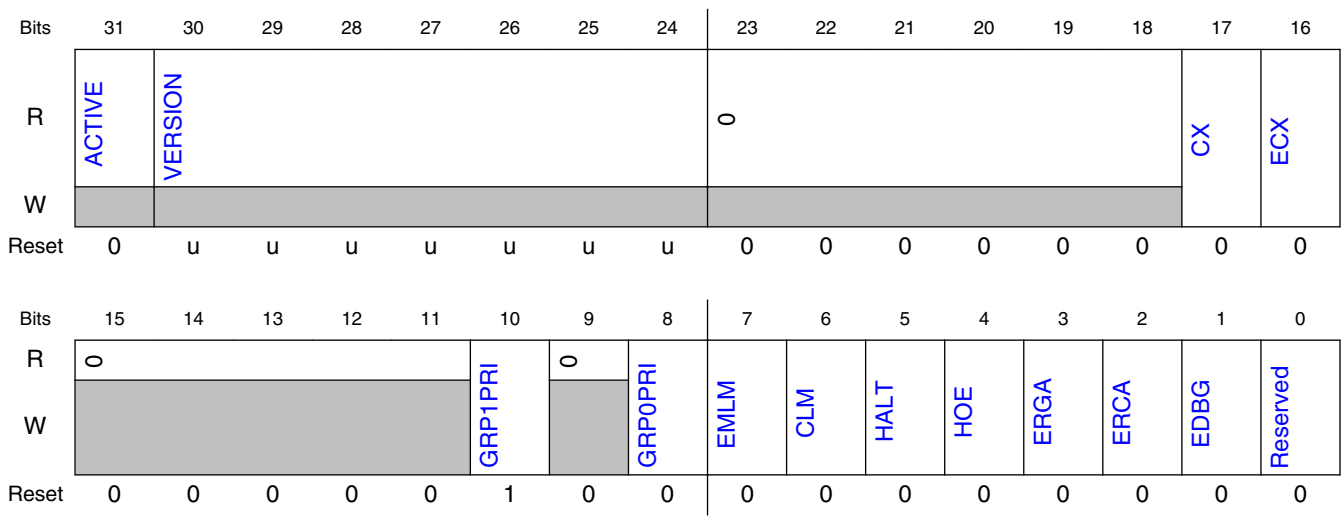
eDMA uses the same offset value (MLOFF) for both source and destination minor loop offsets. When you enable either minor loop offset (SMLOE = 1 or DMLOE = 1), the NBYTES field reduces in size to 10 bits. When you disable both minor loop offsets (SMLOE = 0 and and DMLOE = 0), the NBYTES field is a 30-bit vector.

When you disable minor loop mapping (EMLM = 0), the NBYTES field contains all 32 bits of TCDn word2.

6.5.5.2.1 Offset

Register	Offset
CR	0h

6.5.5.2.2 Diagram



6.5.5.2.3 Fields

Field	Description
31 ACTIVE	eDMA Active Status 0 - eDMA is idle 1 - eDMA is executing a channel
30-24 VERSION	eDMA version number
23-18 —	Reserved
17 CX	Cancel Transfer When you write 1 to this field, the following actions take place: • Stop the executing channel • Force the minor loop to finish. The cancellation takes effect after the last write of the current read/write sequence. This field is automatically written with 0 after the cancellation completes. The cancellation retires the channel normally as if the minor loop completed. 0 - Normal operation

Table continues on the next page...

Field	Description
	1 - Cancel the remaining data transfer
16 ECX	Error Cancel Transfer When you write a 1 to this field, the following actions take place: • Stop the executing channel • Force the minor loop to finish. The cancellation takes effect after the last write of the current read/write sequence. This field is automatically reset to 0 after the cancellation completes. In addition to cancelling the transfer, eDMA: • Treats the cancel as an error condition • Updates the Error Status register (DMAx_ES) • Optionally generates an error interrupt. 0 - Normal operation 1 - Cancel the remaining data transfer
15-11 —	Reserved
10 GRP1PRI	Channel Group 1 Priority Group 1 priority level when fixed priority group arbitration is enabled.
9 —	Reserved
8 GRP0PRI	Channel Group 0 Priority Group 0 priority level when fixed priority group arbitration is enabled.
7 EMLM	Enable Minor Loop Mapping When the value of this field is 0, TCDn.word2 is a 32-bit NBYTES field. When the value of this field is 1, TCDn.word2 includes: • Individual enable fields • An offset field • The NBYTES field. The individual enable fields allow the minor loop offset to be applied to the source address, the destination address, or both. The NBYTES field reduces in size when either offset is enabled. 0 - Disabled 1 - Enabled
6 CLM	Continuous Link Mode When the value of this field is 0, a minor loop channel link made to itself goes through channel arbitration before being activated again. When the value of this field is 1, a minor loop channel link made to itself does not go through channel arbitration before being activated again. When the minor loop completes, the channel activates again if that channel has a minor loop channel link enabled and the link channel is itself. This effectively applies the minor loop offsets and restarts the next minor loop. **NOTE:** Do not use continuous link mode with a channel linking to itself if there is only one minor loop iteration per service request, for example, if the channel's NBYTES value is the same as either the source or destination size. The same data transfer profile can be achieved by simply increasing the NBYTES value, which provides more efficient, faster processing. 0 - Continuous link mode is off 1 - Continuous link mode is on
5 HALT	Halt eDMA Operations When this field is 1 the following actions take place:

Table continues on the next page...

Field	Description
	• eDMA stalls the start of any new channels • Executing channels are allowed to complete. When you write 0 to this field, channel execution resumes. 0 - Normal operation 1 - eDMA operations halted
4 HOE	Halt On Error When this field is 1, any error causes the eDMA engine to write 1 to the HALT field. Subsequently, the eDMA engine ignores all service requests until you write 0 to the HALT field. 0 - Normal operation 1 - Error causes HALT field to be automatically set to 1
3 ERGA	Enable Round Robin Group Arbitration When you write 1 to this field, eDMA uses round robin arbitration for selection among the groups. Otherwise, eDMA uses fixed priority arbitration. 0 - Fixed priority arbitration 1 - Round robin arbitration
2 ERCA	Enable Round Robin Channel Arbitration When you write 1 to this field, eDMA uses round robin arbitration for channel selection. Otherwise, eDMA uses fixed priority arbitration for channel selection. 0 - Fixed priority arbitration within each group 1 - Round robin arbitration within each group
1 EDBG	Enable Debug When this field is 0 and the chip enters Debug mode, eDMA continues operation. When this field is 1, entry of the chip into Debug mode causes the eDMA to stall the start of a new channel. Executing channels are allowed to complete. Channel execution resumes when the chip exits Debug mode or you write 0 to this field. 0 - When the chip is in Debug mode, the eDMA continues to operate. 1 - When the chip is in debug mode, the DMA stalls the start of a new channel. Executing channels are allowed to complete.
0 —	Reserved

6.5.5.3 Error Status (ES)

The ES register provides information concerning the most-recently recorded channel error. Channel errors can be caused by:

- A configuration error, that is:
  - An illegal setting in the transfer-control descriptor
  - An illegal priority register setting in fixed arbitration

- An error termination to a bus master read or write cycle
- A cancel transfer with error field that is 1 when a transfer is canceled via the corresponding cancel transfer control field

See Fault reporting and handling for more details.

6.5.5.3.3 Fields

Field	Description
31 VLD	Logical OR of all ERR status fields 0 - No ERR fields are 1 1 - At least one ERR field has a value of 1, indicating a valid error exists that has not been cleared
30-17 —	Reserved
16 ECX	Transfer Canceled 0 - No canceled transfers 1 - The most-recently recorded entry was a canceled transfer initiated by the error cancel transfer field
15 GPE	Group Priority Error 0 - No group priority error. 1 - The most-recently recorded error was a configuration error among the group priorities. All group priorities are not unique.
14	Channel Priority Error

Table continues on the next page...

Field	Description
CPE	0 - No channel priority error. 1 - The most-recently recorded error was a configuration error in the channel priorities within a group. Channel priorities within a group are not unique.
13 —	Reserved
12-8 ERRCHN	Error Channel Number or Canceled Channel Number The channel number of the most-recently recorded error, excluding GPE and CPE errors or most-recently recorded error canceled transfer.
7 SAE	Source Address Error 0 - No source address configuration error. 1 - The most-recently recorded error was a configuration error detected in the TCDn_SADDR field. TCDn_SADDR is inconsistent with TCDn_ATTR[SSIZE].
6 SOE	Source Offset Error 0 - No source offset configuration error. 1 - The most-recently recorded error was a configuration error detected in the TCDn_SOFF field. TCDn_SOFF is inconsistent with TCDn_ATTR[SSIZE].
5 DAE	Destination Address Error 0 - No destination address configuration error. 1 - The most-recently recorded error was a configuration error detected in the TCDn_DADDR field. TCDn_DADDR is inconsistent with TCDn_ATTR[DSIZE].
4 DOE	Destination Offset Error 0 - No destination offset configuration error. 1 - The most-recently recorded error was a configuration error detected in the TCDn_DOFF field. TCDn_DOFF is inconsistent with TCDn_ATTR[DSIZE].
3 NCE	NBYTES/CITER Configuration Error 0 - No NBYTES/CITER configuration error. 1 - The most-recently recorded error was a configuration error detected in the TCDn_NBYTES or TCDn_CITER fields. TCDn_NBYTES is not a multiple of TCDn_ATTR[SSIZE] and TCDn_ATTR[DSIZE], or TCDn_CITER[CITER] = 0, or TCDn_CITER[ELINK] is not equal to TCDn_BITER[ELINK].
2 SGE	Scatter/Gather Configuration Error When 1, this field indicates the most-recently recorded error was a configuration error detected in the TCDn_DLASTSGA field. eDMA checks This field at the beginning of a scatter/gather operation after major loop completion if TCDn_CSR[ESG] is enabled. TCDn_DLASTSGA is not on a 32-byte boundary. 0 - No scatter/gather configuration error. 1 - The most-recently recorded error was a configuration error detected in the TCDn_DLASTSGA field.
1 SBE	Source Bus Error 0 - No source bus error. 1 - The most-recently recorded error was a bus error on a source read.
0 DBE	Destination Bus Error 0 - No destination bus error. 1 - The most-recently recorded error was a bus error on a destination write.

6.5.5.4 Enable Request (ERQ)

The ERQ register provides a bit map for the 32 channels to enable the request signal for each channel. The state of any given channel enable is directly affected by writes to this register; it is also affected by writes to the SERQ and CERQ registers. These registers are provided so the request enable for a single channel can easily be modified without needing to perform a read-modify-write sequence to this register.

DMA request input signals and this enable request field must be set to 1 before a channel's hardware service request is accepted. The state of the DMA enable request field does not affect a channel service request made explicitly through software or a linked channel request.

NOTE

Disable a channel's hardware service request at the source before writing 0 to the channel's ERQ field.

6	Enable DMA Request 6

Table continues on the next page...

Field	Description
ERQ6	0 - The DMA request signal for channel 6 is disabled 1 - The DMA request signal for channel 6 is enabled
5 ERQ5	Enable DMA Request 5 0 - The DMA request signal for channel 5 is disabled 1 - The DMA request signal for channel 5 is enabled
4 ERQ4	Enable DMA Request 4 0 - The DMA request signal for channel 4 is disabled 1 - The DMA request signal for channel 4 is enabled
3 ERQ3	Enable DMA Request 3 0 - The DMA request signal for channel 3 is disabled 1 - The DMA request signal for channel 3 is enabled
2 ERQ2	Enable DMA Request 2 0 - The DMA request signal for channel 2 is disabled 1 - The DMA request signal for channel 2 is enabled
1 ERQ1	Enable DMA Request 1 0 - The DMA request signal for channel 1 is disabled 1 - The DMA request signal for channel 1 is enabled
0 ERQ0	Enable DMA Request 0 0 - The DMA request signal for channel 0 is disabled 1 - The DMA request signal for channel 0 is enabled

6.5.5.5 Enable Error Interrupt (EEI)

The EEI register provides a bit map for the 32 channels to enable the error interrupt signal for each channel. The state of any given channel's error interrupt enable is directly affected by writes to this register; it is also affected by writes to the SEEI and CEEI registers. These registers are provided so that the error interrupt enable for a single channel can easily be modified without the need to perform a read-modify-write sequence to the EEI register.

The DMA error indicator and the error interrupt enable field must be set to 1 before an error interrupt request for a given channel is sent to the interrupt controller.

12 EEI12	Enable Error Interrupt 12 0 - An error on channel 12 does not generate an error interrupt 1 - An error on channel 12 generates an error interrupt request
11 EEI11	Enable Error Interrupt 11 0 - An error on channel 11 does not generate an error interrupt

Table continues on the next page...

Field	Description
	1 - An error on channel 11 generates an error interrupt request
10 EEI10	Enable Error Interrupt 10 0 - An error on channel 10 does not generate an error interrupt 1 - An error on channel 10 generates an error interrupt request
9 EEI9	Enable Error Interrupt 9 0 - An error on channel 9 does not generate an error interrupt 1 - An error on channel 9 generates an error interrupt request
8 EEI8	Enable Error Interrupt 8 0 - An error on channel 8 does not generate an error interrupt 1 - An error on channel 8 generates an error interrupt request
7 EEI7	Enable Error Interrupt 7 0 - An error on channel 7 does not generate an error interrupt 1 - An error on channel 7 generates an error interrupt request
6 EEI6	Enable Error Interrupt 6 0 - An error on channel 6 does not generate an error interrupt 1 - An error on channel 6 generates an error interrupt request
5 EEI5	Enable Error Interrupt 5 0 - An error on channel 5 does not generate an error interrupt 1 - An error on channel 5 generates an error interrupt request
4 EEI4	Enable Error Interrupt 4 0 - An error on channel 4 does not generate an error interrupt 1 - An error on channel 4 generates an error interrupt request
3 EEI3	Enable Error Interrupt 3 0 - An error on channel 3 does not generate an error interrupt 1 - An error on channel 3 generates an error interrupt request
2 EEI2	Enable Error Interrupt 2 0 - An error on channel 2 does not generate an error interrupt 1 - An error on channel 2 generates an error interrupt request
1 EEI1	Enable Error Interrupt 1 0 - An error on channel 1 does not generate an error interrupt 1 - An error on channel 1 generates an error interrupt request
0 EEI0	Enable Error Interrupt 0 0 - An error on channel 0 does not generate an error interrupt 1 - An error on channel 0 generates an error interrupt request

6.5.5.6 Clear Enable Error Interrupt (CEEI)

The CEEI provides a simple memory-mapped mechanism to write 0 to a given field in the EEI register to disable the error interrupt for a given channel. The data value on a register write causes the corresponding field in the EEI register to be written to 0. Writing 1 to the CAEE field provides a global clear to 0 function, forcing the EEI contents to be written to 0, disabling all DMA request inputs.

If the NOP field is written with 1, the command is ignored. This enables you to write 1 to a single, byte-wide register with a 32-bit write that does not affect the other registers addressed in the write. In such a case the other three bytes of the word must all have their NOP field set to 1 so that these registers are not affected by the write.

Reads of this register return all zeroes.

6.5.5.6.1 Offset

Register	Offset
CEEI	18h

6.5.5.6.2 Diagram

6.5.5.6.3 Fields

Field	Description
7 NOP	No Op Enable 0 - Normal operation 1 - No operation, ignore the other fields in this register
6 CAEE	Clear All Enable Error Interrupts 0 - Write 0 only to the EEI field specified in the CEEI field 1 - Write 0 to all fields in EEI
5 —	Reserved
4-0 CEEI	Clear Enable Error Interrupt Writes 0 to the corresponding field in EEI

6.5.5.7 Set Enable Error Interrupt (SEEI)

The SEEI register provides a simple memory-mapped mechanism to write 1 to a given field in the EEI register to enable the error interrupt for a given channel. The data value on a register write causes the corresponding field in the EEI to be written to 1. Writing 1 to the SAEE field provides a global set to 1 function, forcing the entire EEI register contents to be written with 1.

If the NOP field is 1, the command is ignored. This enables you to write 1 to a single, byte-wide register with a 32-bit write that does not affect the other registers addressed in the write. In such a case the other three bytes of the word must all have their NOP field set to 1 so that these registers are not affected by the write.

Reads of this register return all zeroes.

Table continues on the next page...

Field	Description
5 —	Reserved
4-0 SEEI	Set Enable Error Interrupt Writes 1 to the corresponding field in EEI

6.5.5.8 Clear Enable Request (CERQ)

The CERQ provides a simple memory-mapped mechanism to write 0 to a given field in the ERQ register to disable the DMA request for a given channel. The data value on a register write causes the corresponding field in the ERQ register to be written with 0. Setting the CAER field provides a global clear to 0 function, forcing the entire contents of the ERQ register to be written with 0, disabling all DMA request inputs.

If the NOP field is 1, the command is ignored. This enables you to write 1 to a single, byte-wide register with a 32-bit write that does not affect the other registers addressed in the write. In such a case the other three bytes of the word must all have their NOP field written with 1 so that these registers are not affected by the write.

Reads of this register return all zeroes.

NOTE

Disable a channel's hardware service request at the source before writing 0 to the channel's ERQ field.

6.5.5.8.1 Offset

Register	Offset
CERQ	1Ah

6.5.5.8.3 Fields

Field	Description
7 NOP	No Op Enable 0 - Normal operation 1 - No operation, ignore the other fields in this register
6 CAER	Clear All Enable Requests 0 - Write 0 to only the ERQ field specified in the CERQ field 1 - Write 0 to all fields in ERQ
5 —	Reserved
4-0 CERQ	Clear Enable Request Writes 0 to the corresponding field in ERQ.

6.5.5.9 Set Enable Request (SERQ)

The SERQ provides a simple memory-mapped mechanism to write 1 to a given field in the ERQ register to enable the DMA request for a given channel. The data value on a register write causes the corresponding field in the ERQ register to be set. Writing 1 to the SAER field provides a global set to 1 function, forcing the entire contents of ERQ register to be 1.

If the NOP field is 1, the command is ignored. This enables you to write 1 to a single, byte-wide register with a 32-bit write that does not affect the other registers addressed in the write. In such a case the other three bytes of the word must all have their NOP field written with 1 so that these registers are not affected by the write.

Reads of this register returns all zeroes.

6.5.5.9.3 Fields

Field	Description
7 NOP	No Op Enable 0 - Normal operation 1 - No operation, ignore the other fields in this register
6 SAER	Set All Enable Requests 0 - Write 1 to only the ERQ field specified in the SERQ field 1 - Write 1 to all fields in ERQ
5 —	Reserved
4-0 SERQ	Set Enable Request Writes 1 to the corresponding field in ERQ.

6.5.5.10 Clear DONE Status Bit (CDNE)

The CDNE provides a simple memory-mapped mechanism to write 0 to the DONE field in the TCD of the given channel. The data value on a register write causes the DONE field in the corresponding TCD to be written with 0. Writing 1 to the CADN field provides a global clear function, forcing all DONE fields to be written with 0.

If the NOP field is 1, the command is ignored. This enables you to write 1 to a single, byte-wide register with a 32-bit write that does not affect the other registers addressed in the write. In such a case the other three bytes of the word must all have their NOP field written with 1 so that these registers are not affected by the write.

Reads of this register return all zeroes.

6 CADN	Clears All DONE fields 0 - Writes 0 to only the TCDn_CSR[DONE] field specified in the CDNE field 1 - Writes 0 to all bits in TCDn_CSR[DONE]
5 —	Reserved
4-0 CDNE	Clear DONE field Writes 0 to the corresponding field in TCDn_CSR[DONE]

6.5.5.11 Set START Bit (SSRT)

The SSRT register provides a simple memory-mapped mechanism to write 1 to the START field in the TCD of the given channel. The data value on a register write causes the START field in the corresponding TCD to be written with 1. Writing 1 to the SAST field provides a global set to 1 function, forcing all START fields to be written with 1.

If the NOP field is 1, the command is ignored. This enables you to write 1 to a single, byte-wide register with a 32-bit write that does not affect the other registers addressed in the write. In such a case the other three bytes of the word must all have their NOP field written with 1 so that these registers are not affected by the write.

Reads of this register return all zeroes.

6 SAST	Set All START fields (activates all channels) 0 - Write 1 to only the TCDn_CSR[START] field specified in the SSRT field 1 - Write 1 to all bits in TCDn_CSR[START]
5 —	Reserved
4-0 SSRT	Set START field Sets the corresponding field in TCDn_CSR[START]

6.5.5.12 Clear Error (CERR)

The CERR provides a simple memory-mapped mechanism to write 0 to a given field in the ERR register to disable the error condition field for a given channel. The given value on a register write causes the corresponding field in the ERR register to be written with 0. Writing 1 to the CAEI field provides a global clear to 0 function, forcing the ERR register contents to be written with 0, clearing all channel error indicators. If the NOP field is 1, the command is ignored. This enables you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

6.5.5.12.1 Offset

Register	Offset

Field	Description
7 NOP	No Op Enable 0 - Normal operation 1 - No operation; all other fields in this register are ignored.
6 CAEI	Clear All Error Indicators 0 - Write 0 to only the ERR field specified in the CERR field 1 - Write 0 to all fields in ERR
5 —	Reserved
4-0 CERR	Clear Error Indicator Writes 0 to the corresponding field in ERR

6.5.5.13 Clear Interrupt Request (CINT)

The CINT register provides a simple, memory-mapped mechanism to clear a given field in the INT register to disable the interrupt request for a given channel. The given value on a register write causes the corresponding field in the INT register to be cleared. Setting the CAIR field provides a global clear function, forcing the entire contents of the INT to be cleared, disabling all DMA interrupt requests.

If the NOP field is 1, the command is ignored. This enables you to set a single, byte-wide register with a 32-bit write that does not affect the other registers addressed in the write. In such a case the other three bytes of the word would all have their NOP field set to 1 so that these registers are not affected by the write.

Reads of this register return all zeroes.

6.5.5.14 Interrupt Request (INT)

The INT register provides a bit map for the 32 channels signaling the presence of an interrupt request for each channel. Depending on the appropriate bit setting in the transfer-control descriptors, the eDMA engine generates an interrupt on data transfer completion. The outputs of this register are directly routed to the interrupt controller. During the interrupt-service routine associated with any given channel, it is the software's responsibility to write 0 to the appropriate bit, negating the interrupt request. Typically, a write to the CINT register in the interrupt service routine is used for this purpose.

The state of any given channel's interrupt request is directly affected by writes to this register; it is also affected by writes to the CINT register. On writes to INT, a 1 in any bit position clears the corresponding channel's interrupt request. A 0 in any bit position has no effect on the corresponding channel's current interrupt status. The CINT register is provided so the interrupt request for a single channel can easily be cleared without the need to perform a read-modify-write sequence to the INT register.

2 INT2	Interrupt Request 2 0 - The interrupt request for channel 2 is cleared 1 - The interrupt request for channel 2 is active
1 INT1	Interrupt Request 1 0 - The interrupt request for channel 1 is cleared 1 - The interrupt request for channel 1 is active
0 INT0	Interrupt Request 0 0 - The interrupt request for channel 0 is cleared 1 - The interrupt request for channel 0 is active

6.5.5.15 Error (ERR)

The ERR register provides a bit map for the 32 channels, signaling the presence of an error for each channel. The eDMA engine signals the occurrence of an error condition by setting the appropriate field in this register. The outputs of this register are enabled by the contents of the EEI register, then logically summed across groups of 16 and 32 channels to form several group error interrupt requests, which are then routed to the interrupt controller. During the execution of the interrupt service routine associated with any DMA errors, it is software's responsibility to reset the appropriate bit to 0, negating the error-interrupt request. Typically, a write to the CERR in the interrupt service routine is used for this purpose. The normal DMA channel completion indicators (setting the TCD DONE field to 1 and the possible generation of an interrupt request) are not affected when an error is detected.

The contents of this register can also be polled because a non-zero value indicates the presence of a channel error regardless of the state of the EEI fields. The state of any given channel's error indicators is affected by writes to this register; it is also affected by writes to the CERR. On writes to the ERR, a 1 in any bit position clears the corresponding channel's error status. A 0 in any bit position has no effect on the corresponding channel's current error status. The CERR is provided so the error indicator for a single channel can easily be reset to 0.

6.5.5.16 Hardware Request Status (HRS)

The HRS register provides a bit map for the DMA channels, signaling the presence of a hardware request for each channel. The hardware request status bits reflect the current state of the register and qualified (via the ERQ fields) DMA request signals, as seen by the DMA's arbitration logic. This view into the hardware request signals may be used for debug purposes.

NOTE

These bits reflect the state of the request as seen by the arbitration logic. Therefore, this status is affected by the ERQ bits.

Each HRS field for its respective channel is 1 when a hardware request is present on the channel. After the request is completed and channel is free, the HRS field is automatically changed to 0 by hardware.

1 EDREQ_1	Enable asynchronous DMA request in stop mode for channel 1. 0 - Disable asynchronous DMA request for channel 1 1 - Enable asynchronous DMA request for channel 1
0 EDREQ_0	Enable asynchronous DMA request in stop mode for channel 0. 0 - Disable asynchronous DMA request for channel 0 1 - Enable asynchronous DMA request for channel 0

6.5.5.18 Channel Priority (DCHPRI0 - DCHPRI31)

When fixed-priority channel arbitration is enabled (CR[ERCA] = 0), the contents of these registers define the unique priorities associated with each channel within a group. The channel priorities are evaluated by numeric value; for example, 0 is the lowest priority, 1 is the next higher priority, then 2, 3, and so on. Software must program the channel priorities with unique values; otherwise, a configuration error is reported. The range of the priority value is limited to the values of 0 through 15. When read, the GRPPRI bits of the DCHPRIn register reflect the current priority level of the group of channels in which the corresponding channel resides. GRPPRI bits are not affected by writes to the DCHPRIn registers. The group priority is assigned in the DMA control register.

6.5.5.18.1 Offset

6.5.5.18.4 Fields

Field	Description
7 ECP	Enable Channel Preemption. This field resets to 0. 0 - Channel n cannot be suspended by a higher priority channel's service request 1 - Channel n can be temporarily suspended by the service request of a higher priority channel
6 DPA	Disable Preempt Ability. This field resets to 0. 0 - Channel n can suspend a lower priority channel 1 - Channel n cannot suspend any channel, regardless of channel priority
5-4 GRPPRI	Channel n Current Group Priority Group priority assigned to this channel group when fixed-priority arbitration is enabled. This field is read-only; writes are ignored.
3-0 CHPRI	Channel n Arbitration Priority Channel priority when fixed-priority arbitration is enabled.

6.5.5.19 TCD Source Address (TCD0_SADDR - TCD31_SADDR)

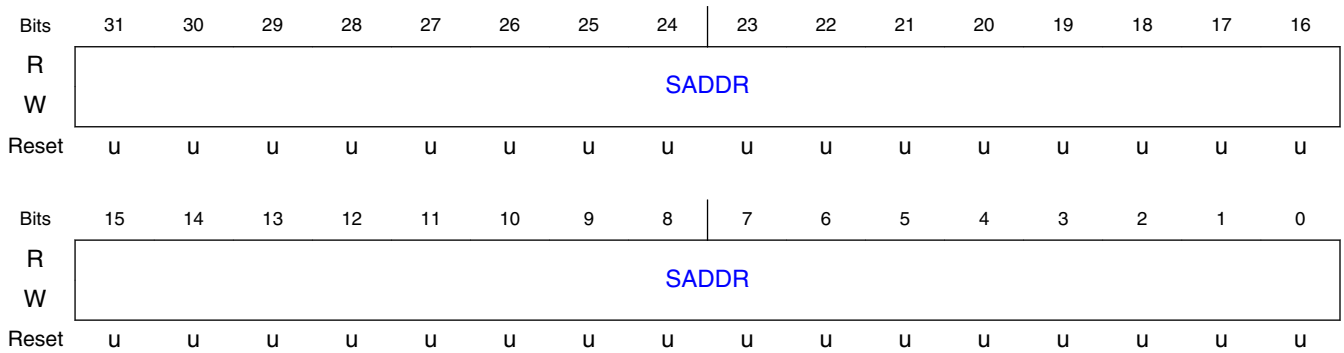
This register contains the source address of the transfer.

6.5.5.19.1 Offset

For n = 0 to 31:

Register	Offset
TCDn_SADDR	1000h + (n × 20h)

6.5.5.19.2 Diagram



6.5.5.19.3 Fields

Field	Description
31-0 SADDR	Source Address Memory address pointing to the source data.

6.5.5.20 TCD Signed Source Address Offset (TCD0_SOFF - TCD31_SOFF)

6.5.5.20.1 Offset

For n = 0 to 31:

Register	Offset
TCDn_SOFF	1004h + (n × 20h)

6.5.5.21.3 Fields

Field	Description
15-11 SMOD	Source Address Modulo

Table continues on the next page...

Field	Description
	Any non-zero value in this field defines a specific address range specified to be the value after SADDR + SOFF calculation is performed on the original register value. Setting this field provides the ability to implement a circular data queue easily. For data queues requiring power-of-2 size bytes, the queue should start at a 0-modulo-size address and the SMOD field should be set to the appropriate value for the queue, freezing the desired number of upper address bits. The value programmed into this field specifies the number of lower address bits allowed to change. For a circular queue application, the SOFF is typically set to the transfer size to implement post-increment addressing with the SMOD function constraining the addresses to a 0-modulo-size range. 00000 - Source address modulo feature is disabled 00001-11111 - Value defines address range used to set up circular data queue
10-8 SSIZE	Source data transfer size **NOTE:** 1. Using a reserved value causes a configuration error. 2. The eDMA defaults to privileged data access for all transactions. 000 - 8-bit 001 - 16-bit 010 - 32-bit 011 - 64-bit 100 - Reserved 101 - 32-byte burst (4 beats of 64 bits) 110 - Reserved 111 - Reserved
7-3 DMOD	Destination Address Modulo See the SMOD definition.
2-0 DSIZE	Destination data transfer size See the SSIZE definition.

6.5.5.22 TCD Minor Byte Count (Minor Loop Mapping Disabled) (TCD0_NBYTES_MLNO - TCD31_NBYTES_MLNO)

This register, or one of the next two registers (TCD_NBYTES_MLOFFNO, TCD_NBYTES_MLOFFYES), that defines the number of bytes to transfer per request. Which register to use depends on whether minor loop mapping is disabled, is enabled but not used for this channel, or is enabled and used.

TCD word 2 is defined as follows if minor loop mapping is disabled (CR[EMLM] = 0).

If minor loop mapping is enabled, see the TCD_NBYTES_MLOFFNO and TCD_NBYTES_MLOFFYES register descriptions for the definition of TCD word 2.

6.5.5.22.1 Offset

For n = 0 to 31:

Register	Offset
TCDn_NBYTES_MLNO	1008h + (n × 20h)

R W	NBYTES															
Reset	u	u	u	u	u	u	u	u	u	u	u	u	u	u	u	u

6.5.5.22.3 Fields

Field	Description
31-0 NBYTES	Minor Byte Transfer Count Number of bytes to be transferred in each service request of the channel. As a channel activates, the appropriate TCD contents load into the eDMA engine, and the appropriate reads and writes are performed until the minor byte transfer count has transferred. This is an indivisible operation and cannot be halted. It can, however, be stalled by using the bandwidth control field, or via preemption. After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, and the major iteration count is decremented and restored to the TCD memory. If the major iteration count is completed, additional processing is performed. **NOTE:** An NBYTES value of 0x0000_0000 is interpreted as a 4 GB transfer.

6.5.5.23 TCD Signed Minor Loop Offset (Minor Loop Mapping Enabled and Offset Disabled) (TCD0_NBYTES_MLOFFNO - TCD31_NBYTES_MLOFFNO)

One of three registers (this register, TCD_NBYTES_MLNO, or TCD_NBYTES_MLOFFYES), that defines the number of bytes to transfer per request. Which register to use depends on whether minor loop mapping is disabled, is enabled but not used for this channel, or is enabled and used.

TCD word 2 is defined as follows if:

- Minor loop mapping is enabled (CR[EMLM] = 1) and
- SMLOE = 0 and DMLOE = 0

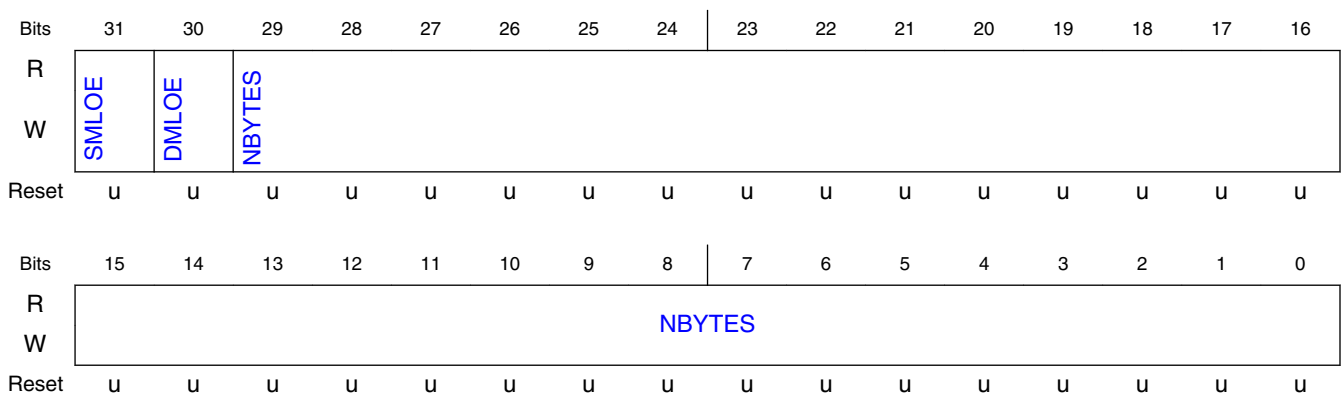
If minor loop mapping is enabled and SMLOE = 1 or DMLOE = 1, refer to the TCD_NBYTES_MLOFFYES register description. If minor loop mapping is disabled, refer to the TCD_NBYTES_MLNO register description.

6.5.5.23.1 Offset

For n = 0 to 31:

Register	Offset
TCDn_NBYTES_MLOFFNO	1008h + (n × 20h)

6.5.5.23.2 Diagram



6.5.5.23.3 Fields

Field	Description
31 SMLOE	Source Minor Loop Offset Enable Specifies whether the minor loop offset is applied to the source address when the minor loop completes. 0 - The minor loop offset is not applied to the SADDR

Table continues on the next page...

Field	Description
	1 - The minor loop offset is applied to the SADDR
30 DMLOE	Destination Minor Loop Offset Enable Specifies whether the minor loop offset is applied to the destination address when the minor loop completes. 0 - The minor loop offset is not applied to the DADDR 1 - The minor loop offset is applied to the DADDR
29-0 NBYTES	Minor Byte Transfer Count Number of bytes to be transferred in each service request of the channel. As a channel activates, the appropriate TCD contents load into the eDMA engine, and the appropriate reads and writes are performed until the minor byte transfer count has transferred. This is an indivisible operation and cannot be halted. It can, however, be stalled by using the bandwidth control field, or via preemption. After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, and the major iteration count is decremented and restored to the TCD memory. If the major iteration count is completed, additional processing is performed.

6.5.5.24 TCD Signed Minor Loop Offset (Minor Loop Mapping and Offset Enabled) (TCD0_NBYTES_MLOFFYES - TCD31_NBYTES_MLOFFYES)

One of three registers (this register, TCD_NBYTES_MLNO, or TCD_NBYTES_MLOFFNO), that defines the number of bytes to transfer per request. Which register to use depends on whether minor loop mapping is disabled, is enabled but not used for this channel, or is enabled and used.

TCD word 2 is defined as follows if:

- Minor loop mapping is enabled (CR[EMLM] = 1) and
- Minor loop offset is enabled (SMLOE or DMLOE = 1)

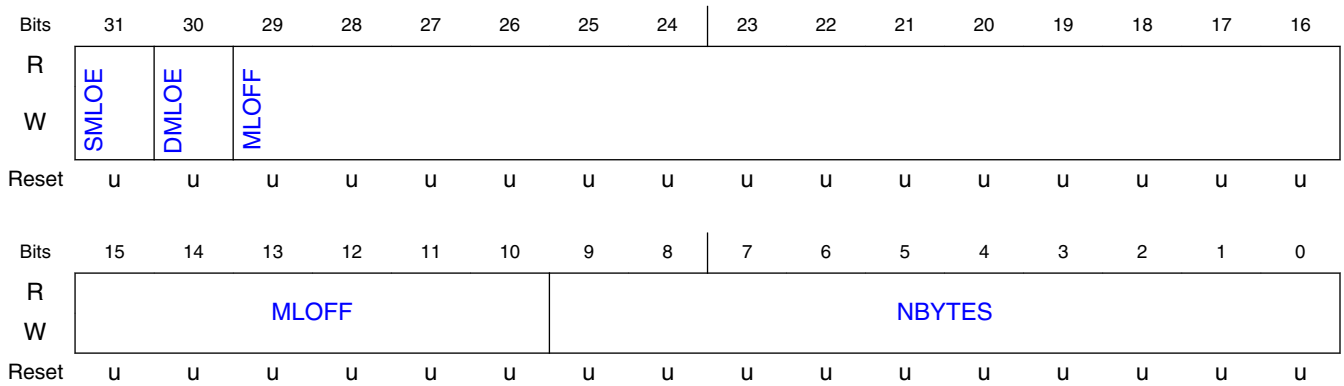
If minor loop mapping is enabled and SMLOE = 0 and DMLOE = 0, refer to the TCD_NBYTES_MLOFFNO register description. If minor loop mapping is disabled, refer to the TCD_NBYTES_MLNO register description.

6.5.5.24.1 Offset

For n = 0 to 31:

Register	Offset
TCDn_NBYTES_MLOFFYES	1008h + (n × 20h)

6.5.5.24.2 Diagram



6.5.5.24.3 Fields

Field	Description
31 SMLOE	Source Minor Loop Offset Enable Specifies whether the minor loop offset is applied to the source address when the minor loop completes. 0 - The minor loop offset is not applied to the SADDR 1 - The minor loop offset is applied to the SADDR
30 DMLOE	Destination Minor Loop Offset Enable Specifies whether the minor loop offset is applied to the destination address when the minor loop completes. 0 - The minor loop offset is not applied to the DADDR 1 - The minor loop offset is applied to the DADDR
29-10 MLOFF	If SMLOE = 1 or DMLOE = 1, this field represents a sign-extended offset applied to the source or destination address to form the next-state value after the minor loop completes.
9-0 NBYTES	Minor Byte Transfer Count Number of bytes to be transferred in each service request of the channel. As a channel activates, the appropriate TCD contents load into the eDMA engine, and the appropriate reads and writes are performed until the minor byte transfer count has transferred. This is an indivisible operation and cannot be halted. It can, however, be stalled by using the bandwidth control field, or via preemption. After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, and the major iteration count is decremented and restored to the TCD memory. If the major iteration count is completed, additional processing is performed.

6.5.5.25 TCD Last Source Address Adjustment (TCD0_SLAST - TCD31_SLAST)

6.5.5.25.1 Offset

For n = 0 to 31:

Register	Offset
TCDn_SLAST	100Ch + (n × 20h)

6.5.5.25.2 Diagram

6.5.5.26.3 Fields

Field	Description
31-0 DADDR	Destination Address Memory address pointing to the destination data.

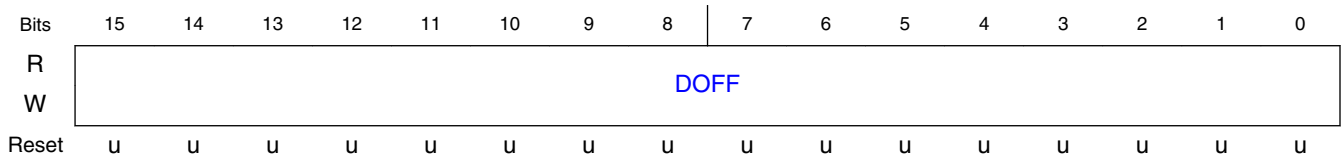
6.5.5.27 TCD Signed Destination Address Offset (TCD0_DOFF - TCD31_DOFF)

6.5.5.27.1 Offset

For n = 0 to 31:

Register	Offset
TCDn_DOFF	1014h + (n × 20h)

6.5.5.27.2 Diagram



6.5.5.27.3 Fields

Field	Description
15-0 DOFF	Destination Address Signed Offset Sign-extended offset applied to the current destination address to form the next-state value as each destination write is completed.

6.5.5.28 TCD Current Minor Loop Link, Major Loop Count (Channel Linking Disabled) (TCD0_CITER_ELINKNO - TCD31_CITER_ELINKNO)

This register contains the minor-loop channel-linking configuration and the channel's current iteration count. It is the same register as TCD Current Minor Loop Link, Major Loop Count (Channel Linking Enabled) (TCD0_CITER_ELINKYES - TCD31_CITER_ELINKYES), but its fields are defined differently based on the state of the ELINK field. If the ELINK field is 0, this register is defined as follows.

6.5.5.28.1 Offset

For n = 0 to 31:

Register	Offset
TCDn_CITER_ELINKNO	1016h + (n × 20h)

6.5.5.28.2 Diagram

6.5.5.28.3 Fields

Field	Description
15 ELINK	Enable channel-to-channel linking on minor-loop complete As the channel completes the minor loop, this field enables linking to another channel, defined by the LINKCH field. The link target channel initiates a channel service request via an internal mechanism that sets TCDn_CSR[START] of the specified channel. If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking. **NOTE:** This field must be equal to BITER[ELINK]; otherwise, a configuration error is reported. 0 - Channel-to-channel linking is disabled 1 - Channel-to-channel linking is enabled
14-0 CITER	Current Major Iteration Count This field is the current major loop count for the channel. It is decremented each time the minor loop is completed and updated in the transfer control descriptor memory. After the major iteration count is exhausted, the channel performs a number of operations, for example, final source and destination address calculations. It optionally generates an interrupt to signal channel completion before reloading the CITER field from the Beginning Iteration Count (BITER) field. **NOTE:** 1. When the CITER field is initially loaded by software, it must be set to the same value as that contained in the BITER field. 2. If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

6.5.5.29 TCD Current Minor Loop Link, Major Loop Count (Channel Linking Enabled) (TCD0_CITER_ELINKYES - TCD31_CITER_ELINKYES)

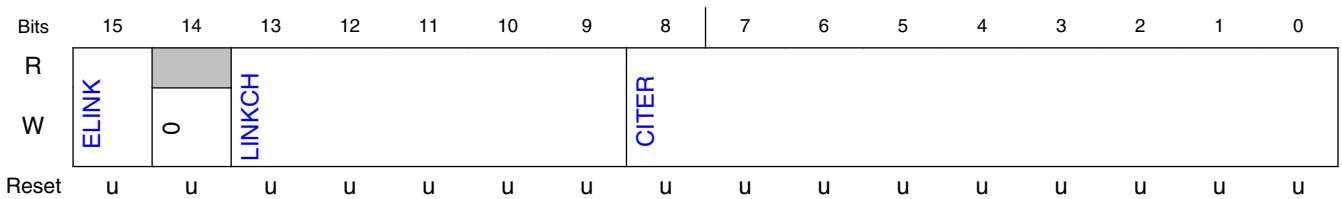
This register contains the minor-loop channel-linking configuration and the channel's current iteration count. It is the same register as TCD Current Minor Loop Link, Major Loop Count (Channel Linking Disabled) (TCD0_CITER_ELINKNO - TCD31_CITER_ELINKNO), but its fields are defined differently based on the state of the ELINK field. If the ELINK field is 1, this register is defined as follows.

6.5.5.29.1 Offset

For n = 0 to 31:

Register	Offset
TCDn_CITER_ELINKYES	1016h + (n × 20h)

6.5.5.29.2 Diagram



6.5.5.29.3 Fields

Field	Description
15 ELINK	Enable channel-to-channel linking on minor-loop complete As the channel completes the minor loop, this field enables linking to another channel, defined by the LINKCH field. The link target channel initiates a channel service request via an internal mechanism that sets TCDn_CSR[START] of the specified channel. If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking. **NOTE:** This field must be equal to BITER[ELINK]; otherwise, a configuration error is reported. 0 - Channel-to-channel linking is disabled 1 - Channel-to-channel linking is enabled
14 —	Reserved
13-9 LINKCH	Minor Loop Link Channel Number If channel-to-channel linking is enabled (ELINK = 1), then after the minor loop is exhausted, the eDMA engine initiates a channel service request to the channel defined by this field, by setting that channel's TCDn_CSR[START].
8-0 CITER	Current Major Iteration Count This field is the current major loop count for the channel. It is decremented each time the minor loop is completed and updated in the transfer control descriptor memory. After the major iteration count is exhausted, the channel performs a number of operations, for example, final source and destination address calculations. It optionally generates an interrupt to signal channel completion before reloading the CITER field from the Beginning Iteration Count (BITER) field.

Field	Description
	NOTE: 1. When the CITER field is initially loaded by software, it must be set to the same value as that contained in the BITER field. 2. If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

6.5.5.30 TCD Last Destination Address Adjustment/Scatter Gather Address (TCD0_DLASTSGA - TCD31_DLASTSGA)

6.5.5.30.1 Offset

For n = 0 to 31:

Register	Offset
TCDn_DLASTSGA	1018h + (n × 20h)

6.5.5.30.2 Diagram

6.5.5.30.3 Fields

Field	Description
31-0 DLASTSGA	Destination last address adjustment, or next memory address TCD for channel (scatter/gather) If (TCDn_CSR[ESG] = 0) then: • This is the adjustment value added to the destination address at the completion of the major iteration count. This value can apply to restore the destination address to the initial value or adjust the address to reference the next data structure. • This field uses two's complement notation for the final destination address adjustment. Otherwise:

Field	Description
	• This address points to the beginning of a 0-modulo 32-byte region containing the next TCD to be loaded into this channel. This channel reload is performed as the major iteration count completes. The scatter/gather address must be 0-modulo 32-byte; otherwise a configuration error is reported.

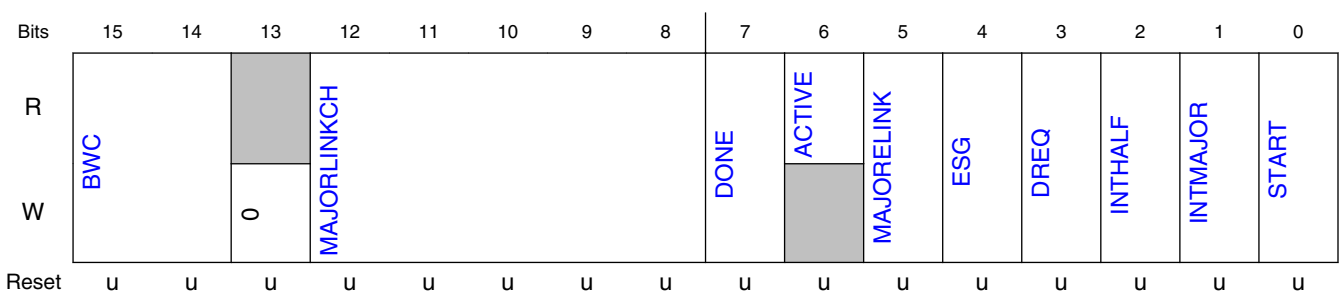
6.5.5.31 TCD Control and Status (TCD0_CSR - TCD31_CSR)

6.5.5.31.1 Offset

For n = 0 to 31:

Register	Offset
TCDn_CSR	101Ch + (n × 20h)

6.5.5.31.2 Diagram



6.5.5.31.3 Fields

Field	Description
15-14	Bandwidth Control
BWC	Throttles the amount of bus bandwidth consumed by the eDMA. Generally, as the eDMA processes the minor loop, it continuously generates read/write sequences until the minor count is exhausted. This field forces the eDMA to stall after the completion of each read/write access to control the bus request bandwidth seen by the crossbar switch. **NOTE:** If the source and destination sizes are equal, this field is ignored between the first and second transfers and after the last write of each minor loop. This behavior is a side effect of reducing start-up latency. 00 - No eDMA engine stalls 01 - Reserved

Table continues on the next page...

Field	Description
	10 - eDMA engine stalls for 4 cycles after each R/W 11 - eDMA engine stalls for 8 cycles after each R/W
13 —	Reserved
12-8 MAJORLINKCH	Major Loop Link Channel Number If (MAJORELINK = 0) then: • No channel-to-channel linking, or chaining, is performed after the major loop counter is exhausted. Otherwise: • After the major loop counter is exhausted, the eDMA engine initiates a channel service request at the channel defined by this field by setting that channel's START bit.
7 DONE	Channel Done This field indicates whether the eDMA has completed the major loop. The eDMA engine sets the value of this field to 1 when the CITER count reaches zero. The value of this field is reset to 0 by the hardware (when the channel is activated) or by software. **NOTE:** This field must be 0 to write the MAJORELINK or ESG fields.
6 ACTIVE	Channel Active This field indicates whether the channel is currently in execution. The eDMA sets the value of this field to 1 when channel service begins, and resets it to 0 as the minor loop completes or when any error condition is detected.
5 MAJORELINK	Enable channel-to-channel linking on major loop complete As the channel completes the major loop, this field controls linking to another channel, defined by MAJORLINKCH. The link target channel initiates a channel service request via an internal mechanism that sets TCDn_CSR[START] of the specified channel. **NOTE:** To support the dynamic linking coherency model, this field is forced to zero when written to when TCDn_CSR[DONE] is set. 0 - Channel-to-channel linking is disabled 1 - Channel-to-channel linking is enabled
4 ESG	Enable Scatter/Gather Processing As the channel completes the major loop, this field controls scatter/gather processing in the current channel. If enabled, the eDMA engine uses DLASTSGA as a memory pointer to a 0-modulo 32-bit address containing a 32-byte data structure loaded as the TCD into local memory. **NOTE:** To support the dynamic scatter/gather coherency model, this field is forced to zero when written to when TCDn_CSR[DONE] is set. 0 - The current channel's TCD is normal format 1 - The current channel's TCD specifies a scatter gather format
3 DREQ	Disable Request If the value of this field is 1, eDMA hardware automatically writes 0 to the corresponding ERQ field when the current major iteration count reaches zero. 0 - The channel's ERQ field is not affected 1 - The channel's ERQ field value changes to 0 when the major loop is complete
2 INTHALF	Enable an interrupt when major counter is half complete. If the value of this field is 1, the channel generates an interrupt request by setting the appropriate field in the INT register when the current major iteration count reaches the halfway point. Specifically, the

Table continues on the next page...

Field	Description
	comparison performed by the eDMA engine is (CITER == (BITER >> 1)). This halfway point interrupt request is provided to support double-buffered, also known as ping-pong, schemes or other types of data movement where the processor needs an early indication of the transfer's progress. **NOTE:** If BITER = 1, do not use INTHALF. Use INTMAJOR instead. 0 - Half-point interrupt is disabled 1 - Half-point interrupt is enabled
1 INTMAJOR	Enable an interrupt when major iteration count completes. If the value of this field is 1, the channel generates an interrupt request by setting the appropriate field in the INT when the current major iteration count reaches zero. 0 - End of major loop interrupt is disabled 1 - End of major loop interrupt is enabled
0 START	Channel Start If the value of this field is 1, the channel is requesting service. eDMA hardware automatically writes 0 to this field after the channel begins execution. 0 - Channel is not explicitly started 1 - Channel is explicitly started via a software initiated service request

6.5.5.32 TCD Beginning Minor Loop Link, Major Loop Count (Channel Linking Disabled) (TCD0_BITER_ELINKNO - TCD31_BITER_ELINKNO)

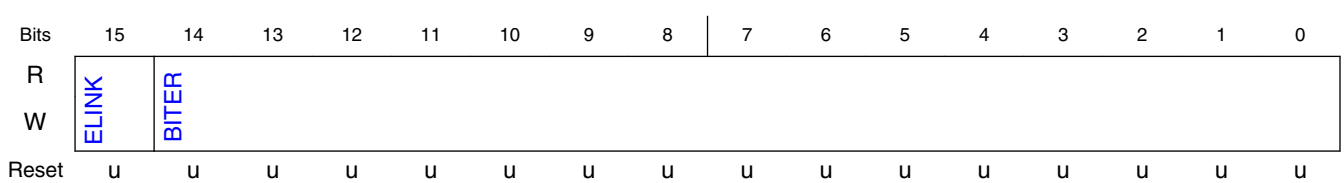
If TCDn_BITER[ELINK] is 0, the TCDn_BITER register is defined as follows.

6.5.5.32.1 Offset

For n = 0 to 31:

Register	Offset
TCDn_BITER_ELINKNO	101Eh + (n × 20h)

6.5.5.32.2 Diagram



6.5.5.32.3 Fields

Field	Description
15 ELINK	Enables channel-to-channel linking on minor loop complete As the channel completes the minor loop, this field enables linking to another channel, defined by BITER[LINKCH]. The link target channel initiates a channel service request via an internal mechanism that sets TCDn_CSR[START] of the specified channel. If channel linking is disabled, the BITER value extends to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking. **NOTE:** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, the contents of this field are reloaded into the CITER field. 0 - Channel-to-channel linking is disabled 1 - Channel-to-channel linking is enabled
14-0 BITER	Starting Major Iteration Count As the TCD is first loaded by software, this 9-bit (ELINK = 1) or 15-bit (ELINK = 0) field must be equal to the value in the CITER field. As the major iteration count is exhausted, the contents of this field are reloaded into the CITER field. **NOTE:** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, the contents of this field are reloaded into the CITER field. If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

6.5.5.33 TCD Beginning Minor Loop Link, Major Loop Count (Channel Linking Enabled) (TCD0_BITER_ELINKYES - TCD31_BITER_ELINKYES)

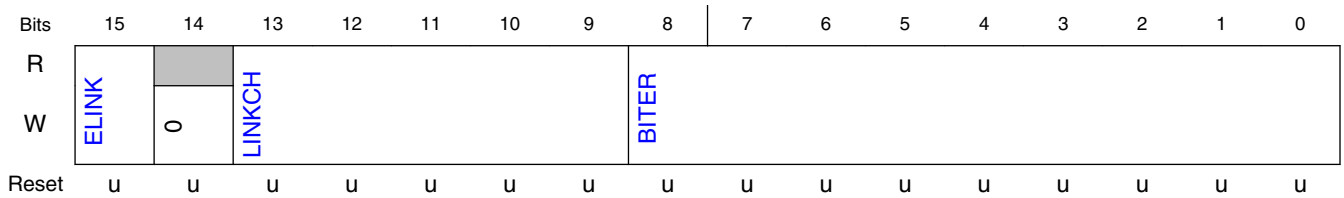
If TCDn_BITER[ELINK] is 1, the TCDn_BITER register is defined as follows.

6.5.5.33.1 Offset

For n = 0 to 31:

Register	Offset
TCDn_BITER_ELINKYES	101Eh + (n × 20h)

6.5.5.33.2 Diagram



6.5.5.33.3 Fields

Field	Description
15 ELINK	Enables channel-to-channel linking on minor loop complete As the channel completes the minor loop, this field enables linking to another channel, defined by BITER[LINKCH]. The link target channel initiates a channel service request via an internal mechanism that sets TCDn_CSR[START] of the specified channel. If channel linking disables, the BITER value extends to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking. **NOTE:** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, the contents of this field are reloaded into the CITER field. 0 - Channel-to-channel linking is disabled 1 - Channel-to-channel linking is enabled
14 —	Reserved
13-9 LINKCH	Link Channel Number If channel-to-channel linking is enabled (ELINK = 1), then after the minor loop is exhausted, the eDMA engine initiates a channel service request at the channel defined by this field, by setting that channel's TCDn_CSR[START]. **NOTE:** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, the contents of this field are reloaded into the CITER field.
8-0 BITER	Starting major iteration count As the TCD is first loaded by software, this 9-bit (ELINK = 1) or 15-bit (ELINK = 0) field must be equal to the value in the CITER field. As the major iteration count is exhausted, the contents of this field are reloaded into the CITER field. **NOTE:** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, the contents of this field are reloaded into the CITER field. If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

Chapter 7
System Security

7.1 Chapter overview

This chapter provides an overview of the following chip security components, explaining the purpose and features of each of them.

- System Boot ROM including High Assurance Boot (HAB)
- Secure Non-Volatile Storage (SNVS) with real-time clock, zero master key, and tamper protection
- Random Number Generator (RNG)
- Cryptographic Acceleration and Assurance Module (CAAM)
- On-chip One-Time Programmable Element Controller (OCOTP_CTRL) with on-chip electrical fuse arrays
- Secure key manager (KEYMGR) and protection
    - Physical Unclonable Function (PUF)
    - UnDocumented Function (UDF)
- JTAG Controller (JTAGC) and SWD debug interfaces
- Inline Encryption Engine (IEE)
- On-the-Fly AES Decryption (OTFAD)
- Resource Domain Controller (RDC) and Extended Resource Domain Controller (XRDC) are used to support both single-core and multi-core use cases with maximum flexible resource management
- Code WatchDog timer (CDOG)

The detailed description of each component can be found in the Security Reference Manual for this chip.

7.2 Feature summary

This figure shows a simplified diagram of the security subsystem:

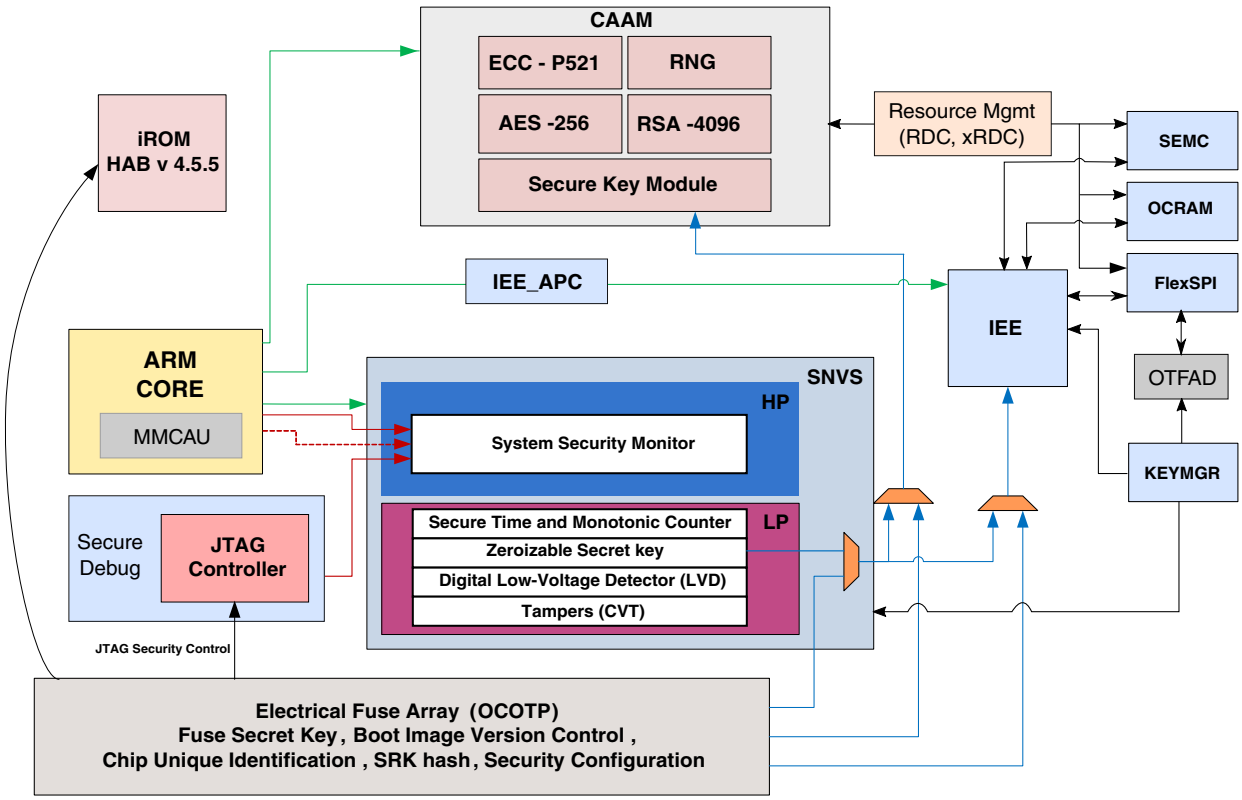


Figure 7-1. Security subsystem (simplified)

All platforms built using this chip share a general need for security, though the specific security requirements vary greatly from platform to platform. For example, portable consumer devices need to protect a different type and cost of assets than automotive or industrial platforms. Each market must be protected against different kinds of attacks. The platform designers need an appropriate set of countermeasures to meet the security needs of their specific platform.

To help the platform designers to meet the requirements of each market, the chip incorporates a range of security features. Most of these features provide protection against specific kinds of attack, and can be configured for different levels according to the required degree of protection. These features are designed to work together or independently. They can be also integrated with the appropriate software to create defensive layers. In addition, the chip includes a general-purpose accelerator that enhances the performance of selected industry-standard cryptographic algorithms.

The security features include:

- High Assurance Boot and encrypted boot
- Secure storage

    - Off-chip storage protection using AES-256 and the chip's unique hardware-only key
    - 4KB Secure RAM (SRAM) in SNVS
    - Zeroizable Master Key (256 bits)
    - SNVS General Purpose Registers (256 bits)
- Cryptographic Acceleration and Assurance Module (CAAM)
    - Symmetric Engines - AES 128, 256 with baseline modes (additional modes include GCM, CMAC), 3DES, DES
    - Public Key Cryptography Engine (PKHA): RSA up to 4096 key length, elliptic curve (supporting NIST, Brainpool)
    - Manufacturing protection
    - 64-bit multiplier for V2X performance requirements (500+ NIST P-256 signatures/sec)
    - Cryptographic Hash Engine: SHA-1, SHA-2 224/256/384/512, MD5, and HMAC
    - Random Number Generator (RNG)
        - True random entropy source
        - NIST-certified Deterministic Random Bit Generator (Hash-based)
    - Secure Hardware-only Cryptographic Key Management
    - Encrypted boot
    - Revision control check based on fuse values
    - Data Encryption Key (DEK) includes IV
    - Real-Time Integrity Checker (RTIC)
- Secure debug
    - 128-bit OTP debug authentication key
- Electrical fuses (OTP Memory)
- Inline Encryption Engine (IEE)
    - SDRAM encryption/decryption
    - Secure scan
    - OCRAM encryption/decryption
    - I/O direct encrypted storage and retrieval (Stream support)
    - FlexSPI decryption only (256-bit AES-XTS mode XIP)
    - Transparency to software during encrypted access (no configuration, control, or interrupts)
    - Secure on-chip key loading using private bus
- AES-128 counter mode On-The-Fly Decryption (OTFAD)
    - 128-bit key and 128-bit data sizes
    - Receives 64-bit encrypted data from FlexSPI
    - Hardware support for unwrapping key blobs
    - Acts as a slave sub-module to FlexSPI
- Secure Non-Volatile Storage (SNVS)

- Secure real-time clock (SRTC)
- Tamper protection
- DryICE

7.3 Resource Management

To support both single-core and multi-core use cases with max flexible resource management, both Resource Domain Controller (RDC) and Extended Resource Domain Controller 2 (XRDC) are used.

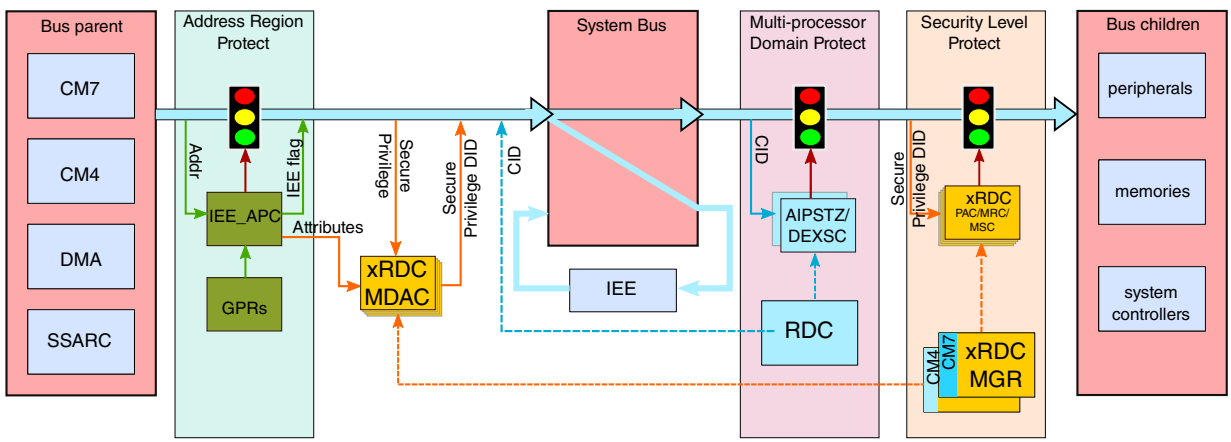

Figure 7-2. Resource Management

- RDC is used as first-level control:
  - Protects the access to resources based on CPU domain assignment in RDC
  - Resources of the chip are assigned to two CPU domains as follows
    - Private resource : Used by either CPUs
    - Shared resource: Used by both CPUs
- XRDC is used as second-level control:
  - Protects the access to resources based on access type (Secure/non-secure access and Privileged/user access)
  - Each CPU has its own XRDC, which supports up to 16 domains

7.4 Secure Key Manager (KEYMGR)

The Key Manager is used to generate, manage, fetch and configure keys for SNVS, OTFADs, and IEE. For better key generation and management, this block integrates UnDocumented Function (UDF) and Physical Unclonable Function (PUF).

- UnDocumented Function (UDF)
  - Provides a deterministic cryptographic function whose characteristics are not standard nor documented.
  - Generates a deterministic, one-way cryptographic function for obfuscation purposes
  - Supports the ability to include cryptographic “salt” to alter UDF calculation
  - Provides mechanisms to lock and reset
- Physical Unclonable Function (PUF)
  - Key generated by silicon entropy, which is silicon-unique and unclonable fingerprint

7.5 High-Assurance Boot (HAB)

The HAB, which is the high-assurance boot feature in the system boot ROM, detects and prevents the execution of unauthorized software (malware) during the boot sequence.

When the unauthorized software is permitted to gain control of the boot sequence, it can be used for a variety of goals, such as exposing stored secrets, circumventing access controls to sensitive data, services, or networks, or for re-purposing the platform. The unauthorized software can enter the platform during upgrades or re-provisioning, or when booting from the USB connections or removable devices.

The HAB protects against unauthorized software by:

- Using digital signatures to recognize the authentic software. This enables you to boot the device to a known initial state and run the software signed by the device manufacturer.
- Using code encryption to protect the confidential software during off-chip storage. When activated, the HAB decrypts the software loaded into the RAM before execution.

7.5.1 HAB process flow

The following figure shows the flow for creating and verifying digital signatures. The top half of this figure shows the signing process, which is performed off-chip. The bottom half shows the verification process performed on-chip during every system boot.

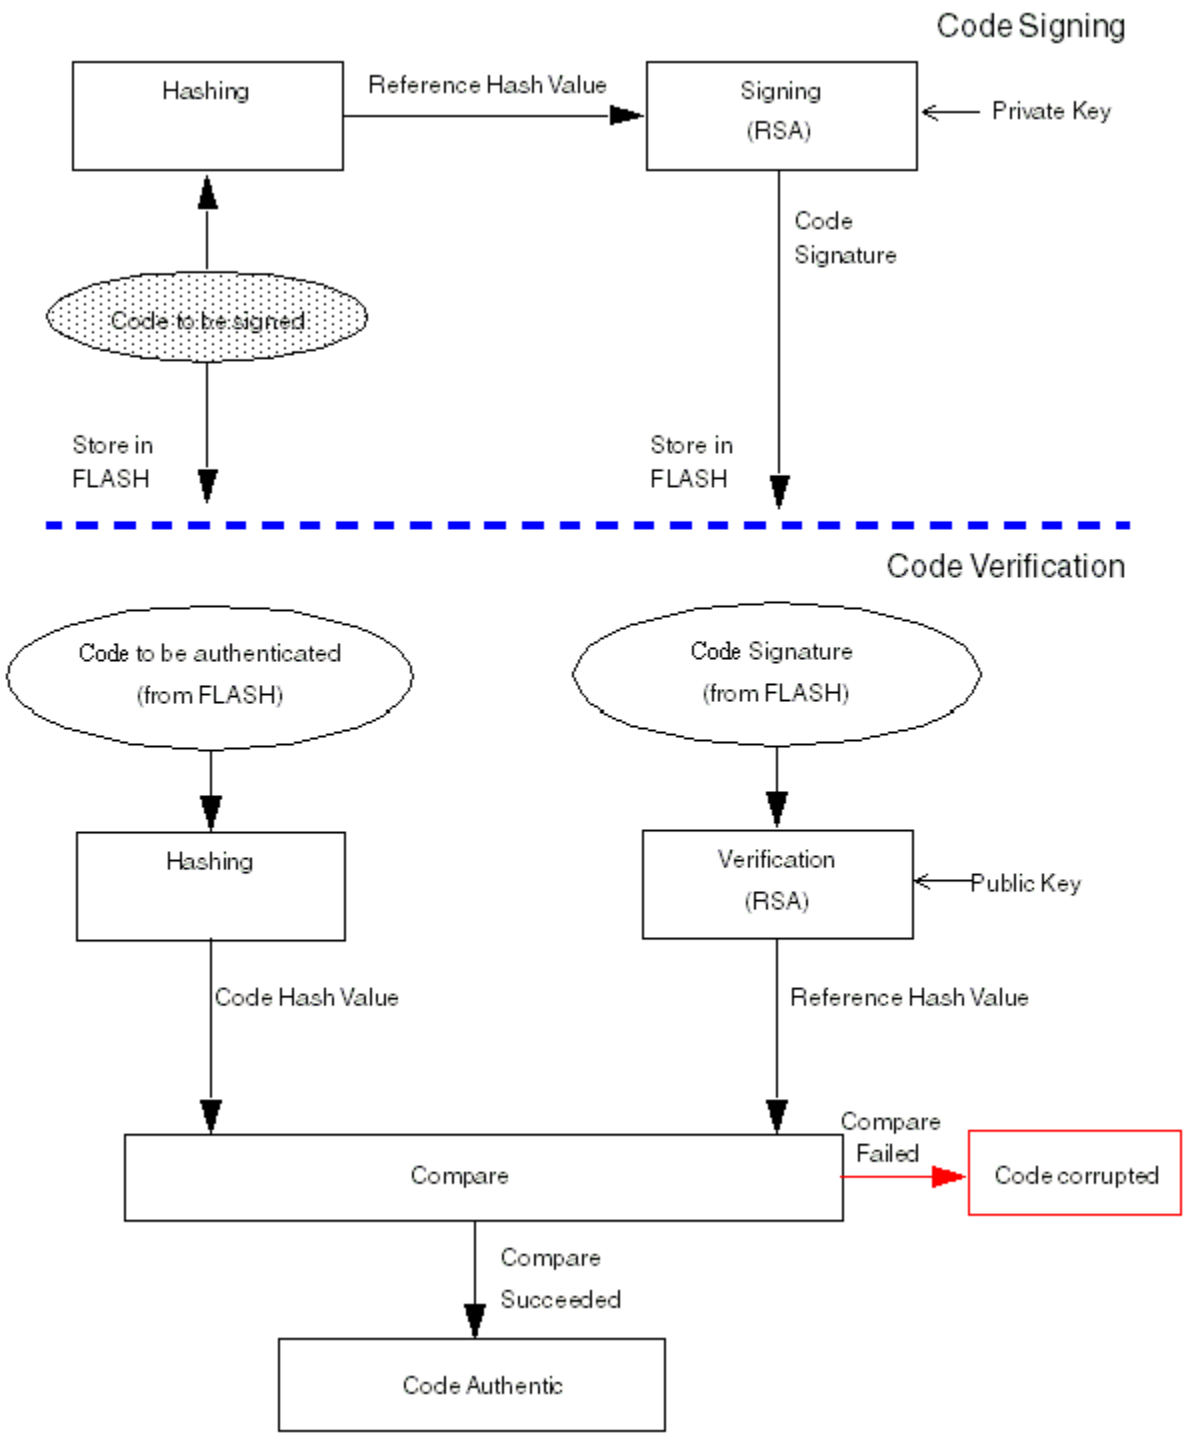

Figure 7-3. Code signing and authentication processes

The original software is programmed into the flash memory (or any other boot device) along with the signature. The HAB uses a public key to recover the reference hash value from the signature; it then compares the reference hash value to the current hash value

calculated from the software in the flash. If the contents of the flash are modified either intentionally or unintentionally, the two hash values do not match and the verification fails.

NOTE

Use OTFAD for providing software confidentiality when the user code executes in place.

7.5.2 HAB feature summary

The HAB features:

- Enforced internal boot via on-chip masked ROM
- Authentication of software loaded from any boot device (including the USB download)
- Authenticated decryption of software loaded from any boot device (including USB download) using the AES keys (128-bit, 256-bit)
- CMS PKCS#1 signature verification using RSA public key (1024, 2048, 3072 or 4096) and the SHA256 hash algorithm
- ECDSA signature verification using ECC public key (P256, P384, P521) and the SHA256 hash algorithm
- Public Key Infrastructure (PKI) support using X.509v3 certificates
- Root public key fingerprint in the manufacturer-programmable on-chip fuses
- Multiple root public keys with revocation by fuses
- Initialization of other security components
- Supports fall-through USB downloader if the primary or recovery boot fails
- Open configuration for development purposes and non-secure platforms
- Closed configuration for shipping secure platforms

On the chip, the HAB is integrated with these security features:

- The HAB initializes the SNVS security monitor state machine. A successful secure boot with the HAB is required for the platform software to gain access to use the CAAM master secret key selected by SNVS.
- The HAB reads the root public key fingerprint, revocation mask, and security configuration from the OCOTP_CTRL.
- Depending on the algorithm, HAB will use the CAAM to accelerate some crypto operations:
  - ECC is accelerated by CAAM
  - RSA is handled by software within HAB

- AES is accelerated by CAAM
- SHA is handled by HAB software or CAAM accelerated depending on the signature command sequence file (CSF)

7.6 Secure Non-Volatile Storage (SNVS) module

- Provides a non-volatile real-time clock maintained by a coin-cell battery during system power down for use in both the secure and non-secure platforms.
- Protects the secure real-time clock against rollback attacks in time-sensitive protocols such as DRM and PKI
- Deters replay attacks in time-independent protocols such as certificate or firmware revocations
- Handles security violation detection and reporting, to defend sensitive data and operations against compromise, both at run-time and during system power-down
- Controls the access to the OTP master secret key used by the CAAM to protect confidential data in the off-chip storage
- Provides non-volatile highly protected storage for an alternative master secret key
- Provides tamper detection
- Provides a 1K bit register (GPRs) protected by tamper
- Supports wakeup source

7.6.1 SNVS architecture

The SNVS is partitioned into two sections: a low-power part (SNVS_LP) and a high-power part (SNVS_HP).

The SNVS_LP block is in the always-powered-up domain. It is isolated from the rest of the logic by isolation cells which are library-instantiated cells that insure that the powered-up logic is not corrupted when the power goes down in the rest of the chip.

The SNVS_LP has these functional units:

- Zeroizable Master Key
- Secure non-rollover real-time counter with alarm
- Non-rollover monotonic counter
- Digital Low-Voltage Detector (LVD)
- General-purpose register
- Control and status registers
- 4KB Secure RAM (SRAM)
- Tamper detection

The SNVS_HP is in the chip power-supply domain. The SNVS_HP provides an interface between the SNVS_LP and the rest of the system. The access to the SNVS_LP registers can be gained through the SNVS_HP only when it is powered up according to the access permission policy.

The SNVS_HP has these functional units:

- IP bus interface
- SNVS_LP interface
- System Security Monitor (SSM)
- Zeroizable Master Key programming mechanism
- Master Key control block
- Non-secure real-time counter with alarm
- Control and status registers
- High Assurance Counter (HAC)

7.6.2 DryICE

The SNVS interface contains mixed logic called DryICE, which provides a 32 kHz system clock, and has voltage, temperature, and clock (VTC) tamper detection monitors. Once a tamper is detected for VTC, a security violation will be sent to the main digital SNVS peripheral. Please see the IOMUXC SNVS GPRs for related DryICE programming.

Table 7-1. DryICE Tampers

Tamper Monitor	Description
Voltage Detector	Checks whether voltages from battery and regulator are normal or not. If the voltage is out-of-range, the out-of-range flag will assert high to SNVS Digital tamper logic.
Temperature Detector	Determins whether the current temperature is appropriate. If the temperature is out-of-range, the out-of-range flag will assert high to SNVS Digital tamper logic.
Clock Detector	Monitors whether the internal 32 kHz crystal oscillator is in it's normal operation. If the XTALOSC 32 kHz clock stops or is out-of-range, the internal 32 kHz source will be switched, and the out-of-range flag will assert high to SNVS Digital tamper logic.

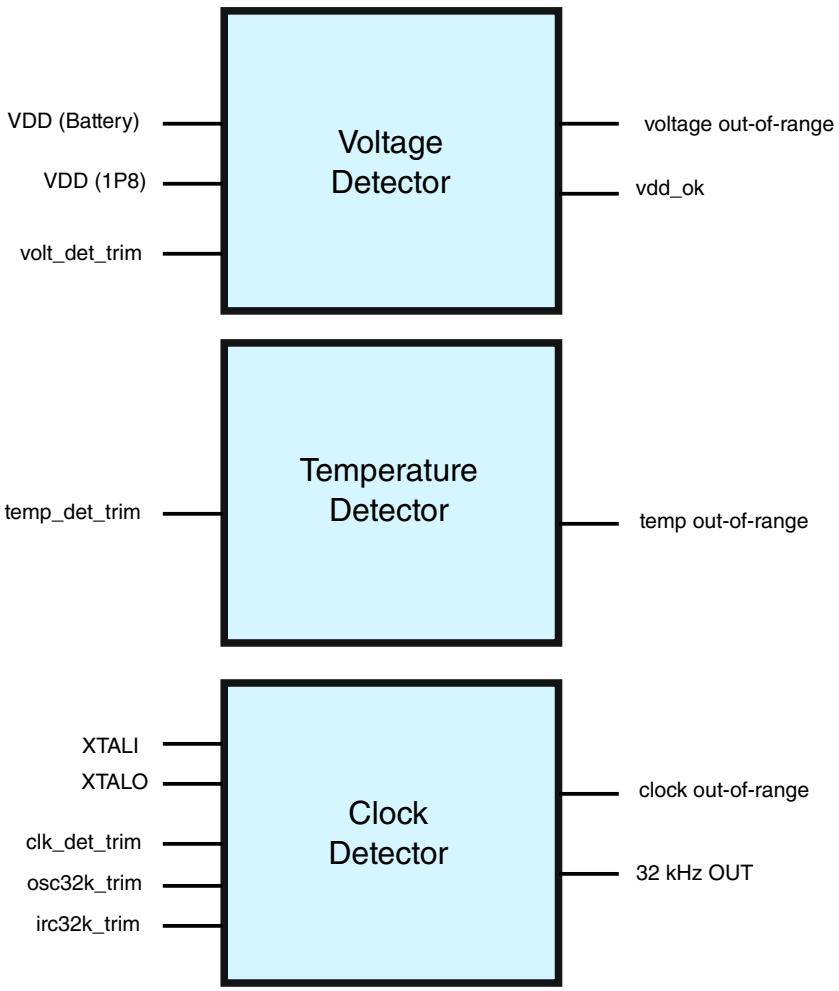

Figure 7-4. DryICE Block Diagram

7.7 Cryptographic Acceleration and Assurance Module (CAAM)

7.7.1 CAAM Overview

CAAM is a cryptographic acceleration module that accelerates block encryption algorithms, stream cipher algorithms, hashing algorithms, and random number generation. It has an integrated DMA engine that allows CAAM to fetch its command programs, read input data and write the resulting output.

CAAM works with the SNVS to provide platform assurance features, including support for High Assurance Boot, detection of and response to potential tamper events, and short term and long-term protection of secret data such as public keypairs, Digital Rights Management keys and proprietary software.

CAAM provides the following features:

- Public Key Cryptography Engine (PKHA)
  - RSA up to 4096 key length; Elliptic Curve (up to P-521)
  - Manufacturing Protection
  - Elliptic supports NIST, Brainpool
  - 64-bit Multiplier for V2X performance requirements (500+ NIST P-256 signatures/sec)
- Symmetric Engines
  - AES 128, 192, 256 with baseline modes
  - AES additional modes include GCM, CMAC
  - 3DES, DES
- Cryptographic Hash Engine
  - SHA-1, SHA-2 224/256/384/512, MD5
  - HMAC
- Random Number Generation (RNG)
  - True random Entropy Source
  - NIST-certified Deterministic Random Bit Generator (Hash-based)

7.8 On-Chip OTP Controller (OCOTP_CTRL)

The OCOTP_CTRL provides the primary user-visible mechanism for interfacing with the on-chip fuses. These fuses' uses include:

- Unique chip identifiers
- Mask revision numbers
- Cryptographic keys
- Security configuration
- Boot characteristics
- Various control signals requiring permanent non-volatility

The OCOTP_CTRL provides:

- Shadow cache of fuse values, loaded at reset, before the system boot
- Ability to read and override the fuse values in the shadow cache (does not affect the fuse element)
- Ability to read the fuses directly (ignoring the shadow cache)
- Ability to write (program) the fuses by software or JTAG
- Fuses and shadow cache bits enforce read-protect, override-protect, and write-protect
- Lock fuses for selected fuse fields
- Scan protection
- Volatile software-accessible signals which can be used for software control of hardware elements (not requiring non-volatility).

7.9 Debug

The debug interface is connected to the DAP and CoreSight debug modules to allow debug through the JTAG interface. The key features of the system debug is listed below. For more information on the CoreSight debug components, please see the System Debug chapter in the Reference Manual.

- 5-pin JTAG and SWD interface (fuse configured)
- Non-intrusive and halt-mode trace / debug options
- Secure Debug with 128-bit protection key
- ARM real-time trace interface (TPIU)

The security levels are selected via the eFuse configuration.

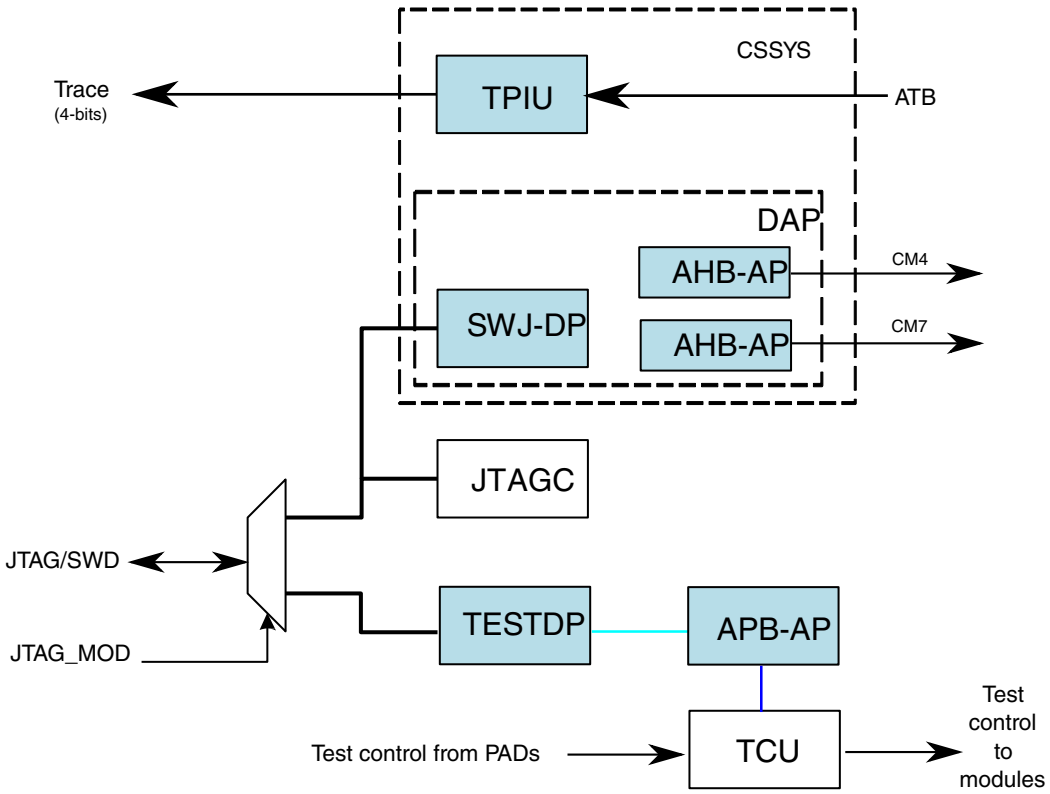

Figure 7-5. System-Level Debug Architecture

7.9.1 JTAG Controller (JTAGC)

There is only one JTAG interface on the chip. Two JTAG modes are supported, which are selected via the JTAG_MOD pin:

- Debug Mode (JTAG_MOD == 0)
  - DAP and JTAGC share the same JTAG by using exclusive instructions.
  - TESTDP will be bypassed.
- Test Mode (JTAG_MOD == 0)
  - TESTDP is the only TAP controller in the daisy chain (IEEE1149.1 compliant).

The JTAGC provides debug access to hardware blocks, including the arm processor and the system bus. This enables program control and manipulation as well as visibility to the chip peripherals and memory.

The JTAG port must be accessible during initial platform development, manufacturing tests, and general troubleshooting. Given its capabilities, the JTAGC provides these security levels:

- JTAG Disabled - JTAG use is permanently blocked.
- No Debug Mode - All security sensitive JTAG features are permanently blocked.

- Secure JTAG Mode - JTAG use is restricted (as in the No-Debug level) unless a secret-key challenge/response protocol is successfully executed.
- JTAG Enabled - JTAG use is unrestricted.

The security levels are selected via the eFuse configuration.

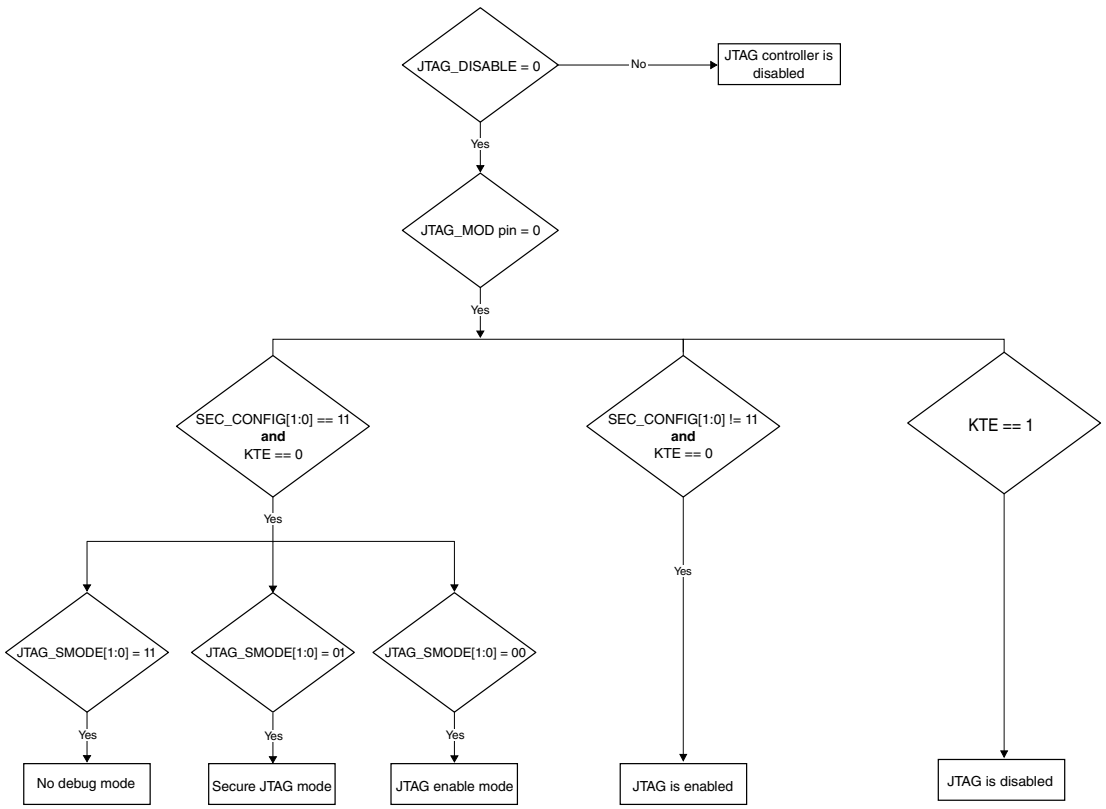

Figure 7-6. Secure JTAGC Configuration

7.10 Inline Encryption Engine (IEE)

IEE provides a means to perform inline encryption and decryption.

It provides the following features:

- SDRAM encryption/decryption
- FlexSPI decryption only
- Secure scan
- Secure on-chip key loading
- I/O direct encrypted storage and retrieval (Stream Support)

7.11 On-the-Fly AES Decryption (OTFAD)

OTFAD works with FlexSPI to provide superior cryptographic decryption capabilities without compromising system performance.

It has the following features:

- AES-128 Counter Mode On-the-Fly Decryption
  - 128-bit key and 128-bit data sizes
  - Receives 64-bit encrypted data from FlexSPI
- Functionally acts as a slave submodule to the FlexSPI
  - Programming model mapped into the upper 1 KB of the FlexSPI's IPS address space

7.12 Memory-Mapped Cryptographic Acceleration Unit (MMCAU)

The Memory-Mapped Cryptographic Acceleration Unit (MMCAU) is a coprocessor that supports the hardware implementation of a set of specialized operations to improve the throughput of software-based security encryption/decryption operations and message digest functions. The MMCAU supports acceleration of the DES, 3DES, AES, MD5, SHA-1, and SHA-256 algorithms. This module is provided with an optimized C-function library that provides the appropriate software building blocks to implement higher-level security functions. The MMCAU is connected to the CM4 core's private peripheral bus (PPB). This bus is not accessible to the CM7 core, so the MMCAU can only be used by the CM4 core.

7.13 Code Watchdog Timer (CDOG)

The Code Watchdog Timer (CDOG) module helps protect the integrity of software by detecting unexpected changes (faults) in code execution flow. The CDOG provides two primary mechanisms for detecting side-channel attacks and the execution of unexpected instruction sequences:

- Secure Counter (SECURE_COUNTER)
- Instruction Timer (INSTRUCTION_TIMER)

The Secure Counter is a 32-bit accumulating register that holds a dynamically changing value that can periodically be evaluated to determine if a program is executing as expected. If a mismatch is detected, a fault is generated. The Instruction Timer is a 32-bit

count-down timer that an application uses to set the number of instructions that software expects to execute. The Instruction Timer counts off the instructions as they are executed (clocks) and if the number is exhausted before the CDOG is serviced, a fault is generated.

Chapter 8
System Debug

8.1 Overview

This section describes the hardware and software debug and application development features and resources of the chip. It describes the following:

- Core/platform-specific resources
- Resources associated with complex IP blocks
- Chip-wide resources
- Interface to the external debug and development tools

The debug and trace architecture is designed around the following:

- Arm CoreSight architecture, adapted to SoC (for core debug), including a cross-trigger subsystem for cross-domain triggering of debug resources
- JTAG port used to interact with core under the debug by means of JTAGC, the JTAG Controller
- DAP, the debug access port that supports the interface to the Arm RealView Debugging tools and other third-party tools
- TPIU, a trace port interface unit that efficiently accesses the program trace information from the system
- Various chip-wide resources, such as debug features built into the IP blocks and critical signal visibility available through alternate pin functions or observability muxes

8.2 Chip and Arm Platform Debug Architecture

The Arm Debug architecture is based on the CoreSight architecture by Arm. The CoreSight architecture provides a system-wide solution to real-time debug and trace.

The CoreSight architecture is embodied in a set of CoreSight components and compliant processors that form the CoreSight systems. Its architecture maintains the traditional requirements of debug and trace:

- To access the debug functionality without software interaction
- To connect to a running system without performing a reset

Full access to the processor debug capability is available by the Arm debug register map through the Advanced Peripheral Bus (APB) slave port. The core includes a Processor Debug Unit which stops program execution, examines and alters the processor and coprocessor state, examines and alters the memory and input/output peripheral state, and restarts the processor core.

The following diagram shows the system level debug architecture:

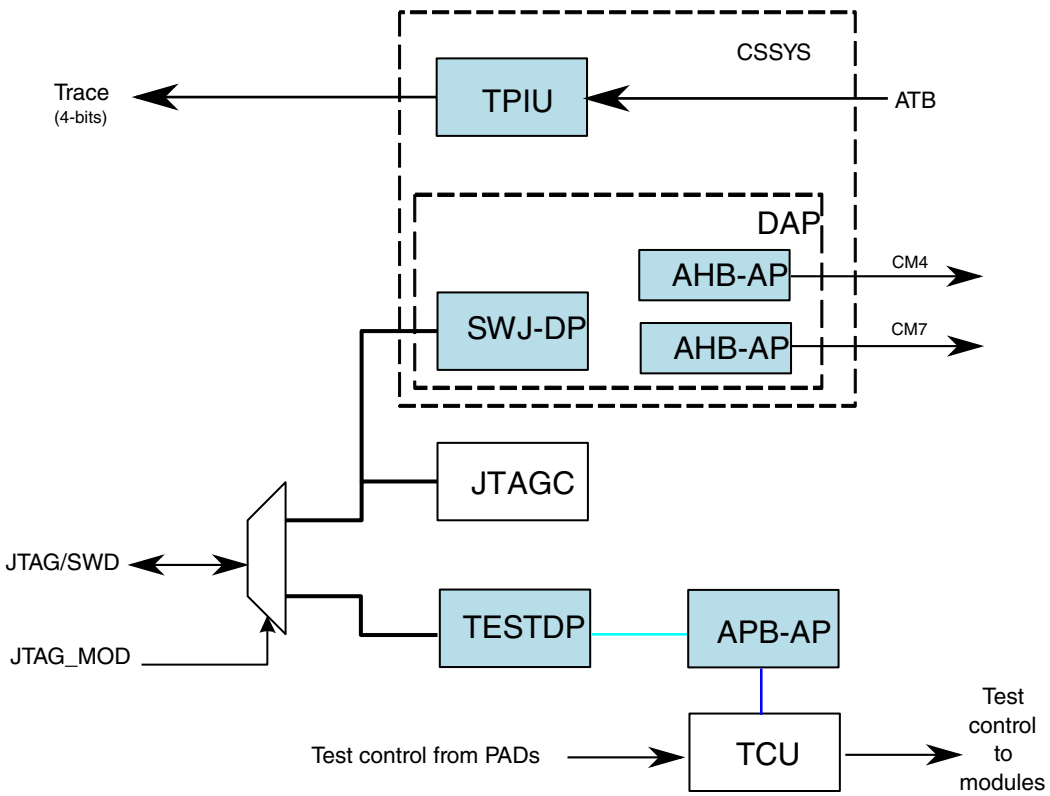

Figure 8-1. System Level Debug Architecture

Table 8-1. List of supported MEM-APs

APSEL	Access Port	IDR
0	CM7 (AHB-AP)	0x84770001
1	CM4 (AHB-AP)	0x24770011
2	APB-AP	0x54770002

8.2.1 Debug Features

- EmbeddedICE-RT logic
  - Support for both the monitor-mode and halt-mode debugging:
  - Core run/halt control, debug status/control
  - Breakpoint/watchpoint control
  - Core-mapped and memory-mapped resource examination/modification
- Data communication channel between the Arm core and the host debugger via JTAG or SWD and the Debug Access Port (DAP) module

The chip includes Arm CoreSight components for debug and trace solutions.

8.2.2 Debug system components

The CoreSight components include:

- ETM (Embedded Trace Macrocell) supporting instruction trace
- ITM (Instrumentation Trace Macrocell)
- TPIU (Trace Port Interface)
- Cross Triggering logic for event routing (CTIs)
- Timestamp Generator (TSGEN)
- Data Watchpoint and Trace (DWT)

Other related IPs and functionality:

- Flash Patch and Breakpoint unit (FPB)

FPB for CM4 cannot be used since the flash address is beyond 0x20000000.

8.2.2.1 AMBA Trace Bus (ATB)

ATB transfers trace data though the chip CoreSight infrastructure. The trace sources are ATB masters and the sinks are ATB slaves. The Arm (via PTM) cores are the data generators. Link components such as the Trace Funnel and Replicator provide both the master and slave interfaces.

The ATB protocol supports:

- Stalling of trace sources to enable the CoreSight components to funnel and combine the sources into a single trace stream

- Association of the trace data with the generating source using trace source IDs. The CoreSight system can trace up to 111 different items at any time
- Capture and transfer of multiple byte bus widths, currently to 32 bits
- A flushing mechanism to force the historic trace to drain from any sources, links, or sinks up to the point that the request is initiated

8.2.2.2 CoreSight Trace Port Interface (TPIU)

TPIU is one of the CoreSight trace sink components. It acts as a bridge between the on-chip trace data and a data stream that is then driven out the trace port.

TPIU uses the ATB interface to accept trace data from a trace source, either directly or by using a trace funnel. TPIU has 4 bit port connected to the chip pad.

The APB interface is the programming interface for the TPIU configuration.

The features of the sub-blocks are as follows:

- Formatter—Inserts source ID signals into the data packet stream so that the trace data can be re-associated with the trace source.
- Asynchronous FIFO—Enables trace data to be driven out at a speed that is not dependent on the on-chip bus clock.
- Register Bank—Contains the management, control and status registers for triggers, flushing behavior and external control.
- Trace out—The Trace out block serializes the formatted data before it goes off-chip.
- Pattern Generator—The Pattern Generator unit provides a simple set of defined bit sequences or patterns that can be output over the Trace Port and be detected by the TPA or other associated Trace Capture Device (TCD). The TCD can use these patterns to indicate if it is possible to increase or decrease the trace port clock speed.

The output of the TPIU is connected via external pins (MPS of TRACEDATA (ARM_TRACEn), which can be 1, 2, or 4 bits). The system may utilize double data rate pins to either use a lower clock speed than that of the 32-bit ATB interface, or use fewer than 4 data pins for the output, based on the ability of the technology used. Given the speed of the ATB, 4 data pins with double data rate is recommended, with the external interface running at half the speed of the ATB. The speed of the external interface is from TRACECLKIN (CSTRACE_CLK_ROOT). TRACECLK (ARM_TRACE_CLK) is equal to TRACECLKIN / 2, and is divided in the TPIU to clock trace data at the trace capture unit.

TPIU used to be part of the Arm platform sub blocks in previous versions of i.MX products, placing the TPIU off platform allows future debug trace sources from the chip level to connect to the TPIU by means of a funnel.

For more information, see Arm Cortex M4 Platform chapter.

For more information, see Arm Cortex M7 Integration and Implementation Manual.

8.2.2.3 Embedded Trace Macrocell v3.5 (ETM)

The Cortex-M4 Embedded Trace Macrocell (ETM-M4) is a debug component that enables a debugger to reconstruct program execution. The CoreSight ETM-M4 supports only instruction trace. You can use it either with the CoreSight Trace Point Interface Unit (TPIU).

The main features of an ETM are:
- Tracing of 16-bit and 32-bit Thumb instructions
- Four EmbeddedICE watchpoint inputs
- A Trace Start/Stop block with EmbeddedICE inputs
- One reduced function counter
- Two external inputs
- A 24-byte FIFO queue
- Global timestamping

8.2.2.4 ITM

The Cortex-M4 ITM is an application-driven trace source that supports printf style debugging to trace Operating System (OS) and application events, and emits diagnostic system information. The ITM emits trace information as packets. There are four sources that can generate packets. If multiple sources generate packets at the same time, the ITM arbitrates the order in which packets are output. The four sources in decreasing order of priority are:

1. Software trace—Software can write directly to ITM stimulus registers. This emits packets.
2. Hardware trace—The DWT generates these packets, and the ITM emits them.
3. Time stamping—Timestamps are emitted relative to packets. The ITM contains a 21-bit counter to generate the timestamp. The Cortex-M4 clock or the bitclock rate of the Serial Wire Viewer (SWV) output clocks the counter.
4. Global system timestamping. Timestamps can optionally be generated using a system-wide 48-bit count value. The same count value can be used to insert timestamps in the ETM trace stream, allowing coarse-grain correlation.

8.2.2.5 Embedded Trace Macrocell (ETM)

Instruction trace, also known as ETM (Embedded Trace Macrocell) trace, is a continuously collected sequence of every executed instruction for a selected portion of the application. ETM generates trace packets and sends them to the trace bus. ETM does not actually output every address or instruction that the processor has reached or executed; it usually generates compressed information about the program flow and outputs full addresses only if needed (for example, if a branch has taken place). Because the debugger knows the application code image, the debugger can then reconstruct the full instruction sequence from the trace data.

For more information about ETM, refer to *Arm® CoreSight™ ETM-M7 Revision r0p1 Technical Reference Manual*.

8.2.2.6 Instrumentation Trace Macrocell

The ITM (Instrumentation Trace Macrocell) generates trace information as packets. There are four sources that can generate packets. If multiple sources generate packets at the same time, the ITM arbitrates the order in which packets are output. The four sources in decreasing order of priority are:

- Synchronization: DWT provides periodic requests to make ITM generate synchronization packet. Trace capture hardware uses it to identify the alignment of packet bytes in the bit-stream.
- Software Trace: Application software can write console messages directly to ITM stimulus ports, and output them to the host as trace packets.
- Hardware trace: The DWT generates these packets, and the ITM outputs them.
- Timestamping: ITM can generate timestamp packets that are inserted in to the trace stream, to help the host debugger to find out the timing of events. Timestamps are generated relative to packets. The ITM receives a 64-bit counter to generate the timestamp.

Trace data from ITM will be forwarded to TPIU and streamed out via the trace port.

For more information about ITM, refer to *Armv7-M Architecture Reference Manual*.

8.2.2.7 Cross-Trigger Interface (CTI)

The Cross-Trigger Interface (CTI) component is provided by Arm. A brief description of the CTI is provided below.

This chip contains three CTIs in the following sections:

- CM7 platform
- CM4 platform
- CSSYS

The CTIs in ARM cores have 8 trigger inputs and 8 trigger outputs that connect to logic in the domain to be debugged or profiled. Each CTI includes a 4-channel interface to the CTM. The CSSYS CTI also contains an 8 trigger IN/OUT along with the 4-channel interface to CTM.

The diagram below shows the high-level connections.

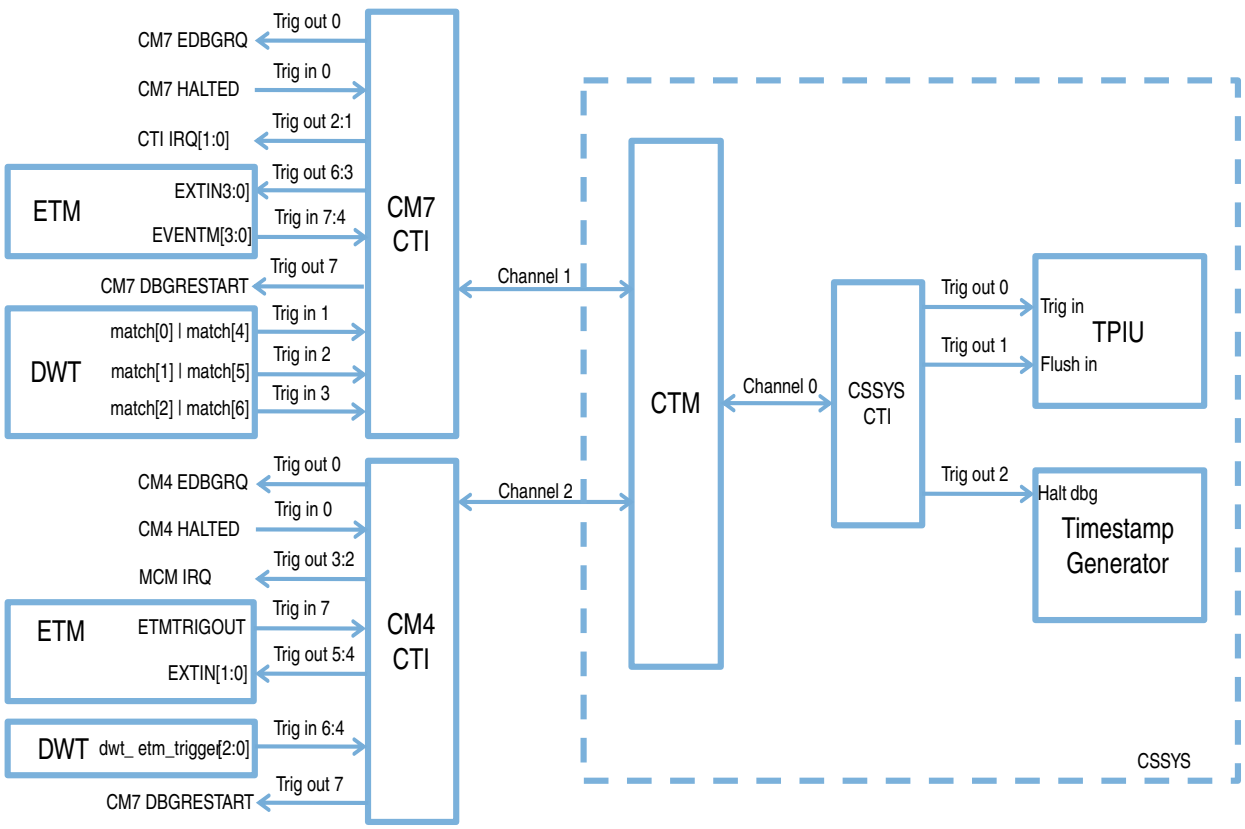

Figure 8-2. High-level connections

8.2.2.8 Cross-Trigger Matrix (CTM)

The CTM (Cross-Trigger Matrix) is provided by ARM. A brief description is provided below. See the ARM documentation for more detail.

The CTM is a relatively simple block with no configuration options. There is one instance of CTM present in the ARM platform. It routes Cross Trigger Interfaces (CTI) from Cortex-M7 and Cortex-M4 to Coresight CTI.

8.2.3 Chip-Specific JTAGC Features

8.2.3.1 JTAG Disable Mode

In addition to three different JTAG security modes that are implemented internally in the JTAG Controller, there is an option to disable the JTAGC functionality by e-fuse configuration. This creates additional JTAG mode "JTAG Disabled" with highest level of JTAG protection. In this mode all JTAG features are disabled.

8.2.3.2 JTAG ID

Table 8-2. i.MX JTAG ID

Device	Silicon revision	JTAG ID
i.MX RT1170	Rev 1.0	088C_601Dh

8.2.3.3 JTAG-to-SWD change sequence

1. Send more than 50 TCK cycles with TMS (SWD_IO) = 1
2. Send the 16-bit sequence on TMS (SWD_IO) = 0111_1001_1110_0111 (MSB transmitted first)
3. Send more than 50 TCK cycles with TMS (SWD_IO) = 1

NOTE

See the ARM documentation for the CoreSight DAP Lite for restrictions.

8.2.4 JTAG controller main features

- IEEE P1149.1 interface to off-chip test and development equipment
- Three levels of security, ranging from no security to no JTAG accessibility to the chip

NOTE

The security levels are detailed in the Security Reference Manual (SRM).

8.2.5 TAP port

The JTAGC supports the following standard JTAG pins:

- TRSTB
- TDI
- TDO
- TCK
- TMS

The figure below shows the TAP structure:

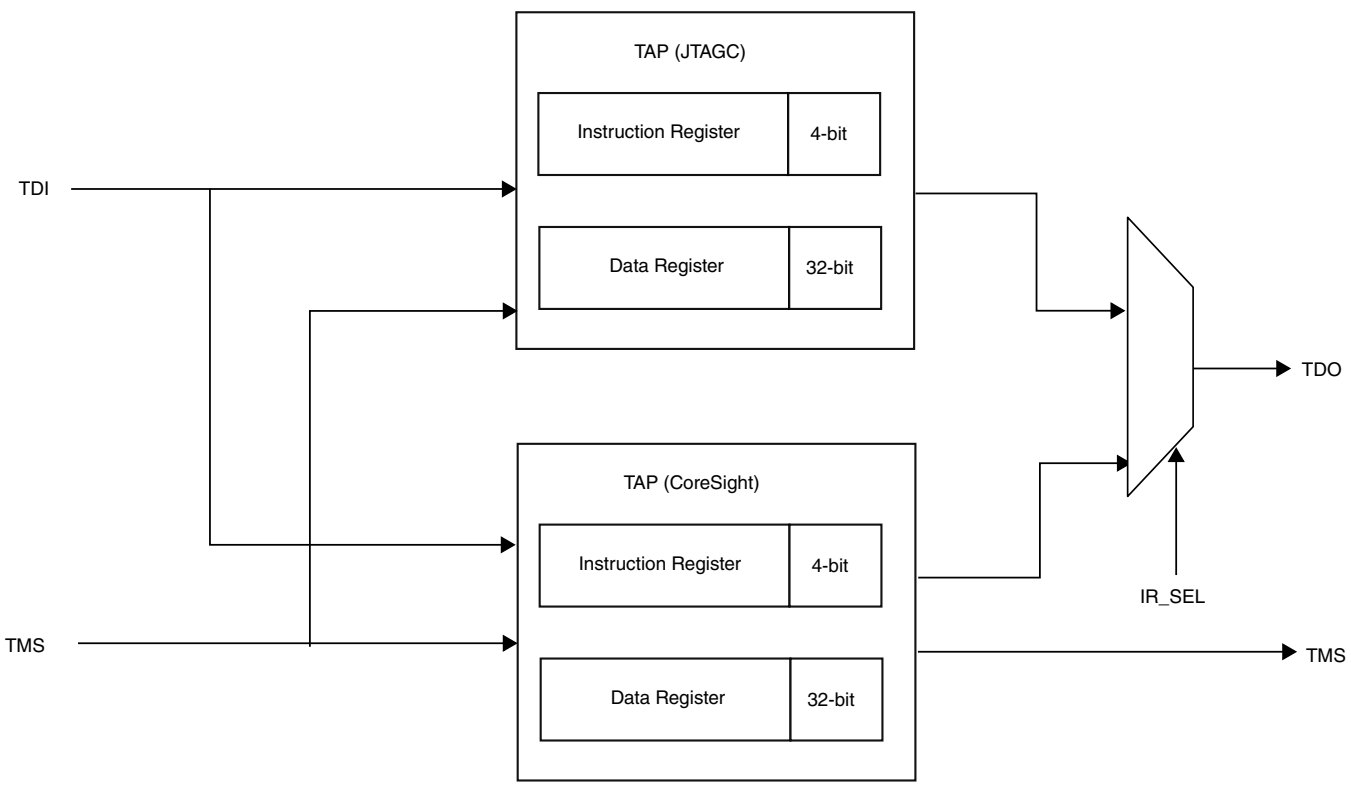

Figure 8-3. Tap structure

Refer to Arm technical documentation for more details.

8.3 Miscellaneous

The Miscellaneous function described in this section provide useful general capabilities.

8.3.1 Clock/Reset/Power

The DAP, ITM, and ETM existing in CM7 power domain will be powered off along with CM7. Similarly, the DAP, ITM, and ETM existing in the CM4 power domain and will be powered off along with CM4. The JTAG controller, TPIU and CoreSight DAP are in WAKEUPMIX power domain.

The debug components can receive resets from the following sources:

- Debug Reset (CDBGRSTREQ bit within the SWJ-DP CTRL/STAT register of the DAP) in the TCLK domain. This allows the debug tools to reset the debug logic.
- System POR reset

Chapter 9

9.2 Overview

The JTAGC block provides the means to test chip functionality and connectivity while remaining transparent to system logic when not in test mode. Testing is performed via a boundary scan technique, as defined in the IEEE 1149.1-2001 standard. All data input to and output from the JTAGC block is communicated in serial format.

9.2.1 Block diagram

The following is a simplified block diagram of the JTAG Controller (JTAGC) block. See the chip-specific configuration information within this chapter as well as Register description for more information about the JTAGC registers.

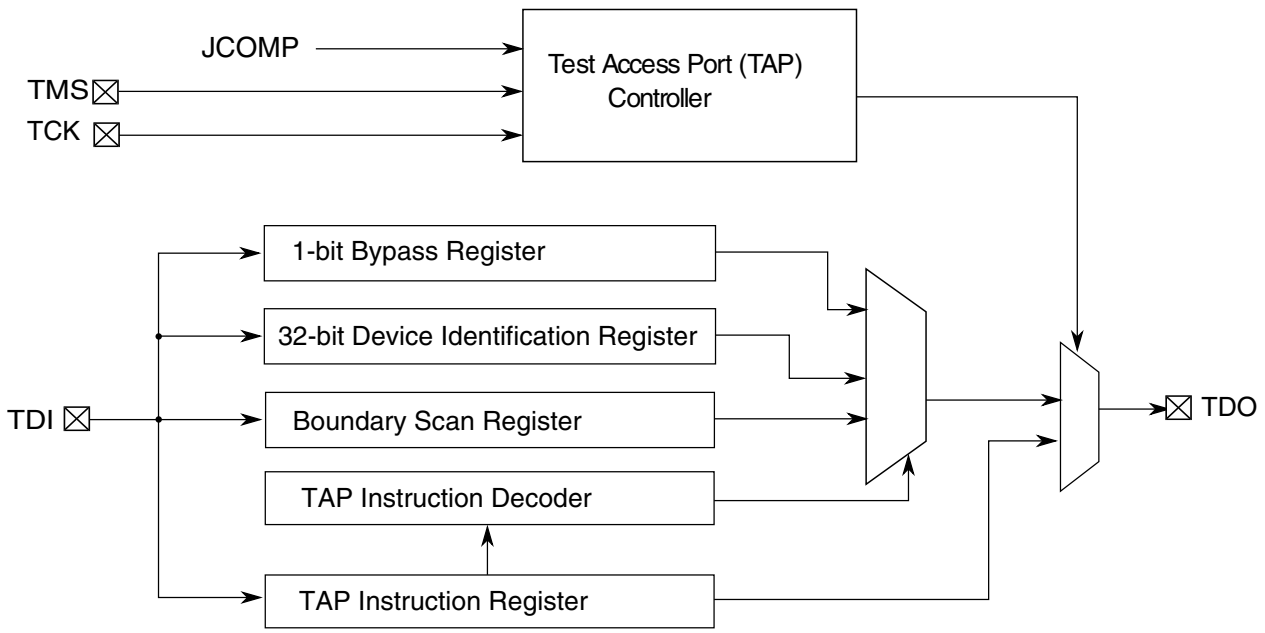

Figure 9-1. JTAG (IEEE 1149.1) block diagram

9.2.2 Features

The JTAGC block is compliant with the IEEE 1149.1-2001 standard, and supports the following features:

- IEEE 1149.1-2001 TAP interface
  - Four pins (TDI, TMS, TCK, and TDO)
- JCOMP input that provides reset control
- Instruction register that supports several IEEE 1149.1–2001 defined instructions as well as several public and private device-specific instructions (see JTAGC block instructions for a list of supported instructions).
- Bypass register, boundary scan register, and device identification register
- TAP controller state machine that controls the operation of the data registers, instruction register, and associated circuitry

9.3 Functional description

This section explains the JTAGC functional description.

9.3.1 Modes of operation

The JTAGC block uses JCOMP and a power-on reset indication as its primary reset signals. Several IEEE 1149.1–2001 defined test modes are supported, as well as a bypass mode.

9.3.1.1 Reset

The JTAGC block is placed in reset when:

- Power-on reset is asserted
- JCOMP is negated
- TMS input is held high for enough consecutive rising edges of TCK to sequence the TAP controller state machine into the Test-Logic-Reset state

Holding TMS high for five consecutive rising edges of TCK guarantees entry into the Test-Logic-Reset state regardless of the current TAP controller state. Asserting power-on reset or setting JCOMP to a value other than the value required to enable the JTAGC block results in asynchronous entry into the reset state.

When in reset, the following actions occur:

- The TAP controller is forced into the Test-Logic-Reset state, thereby disabling the test logic and allowing normal operation of the on-chip system logic to continue unhindered.
- The instruction register is loaded with the IDCODE instruction.

9.3.1.2 IEEE 1149.1–2001 defined test modes

The JTAGC block supports several IEEE 1149.1–2001 defined test modes. A test mode is selected by loading the appropriate instruction into the instruction register when the JTAGC is enabled. Supported test instructions include EXTEST, HIGHZ, CLAMP, SAMPLE, and SAMPLE/PRELOAD.

Each instruction defines the set of data register(s) that may operate and interact with the on-chip system logic when the instruction is current. Only one test data register path is enabled to shift data between TDI and TDO for each instruction.

The boundary scan register is enabled for serial access between TDI and TDO when the EXTEST, SAMPLE, or SAMPLE/PRELOAD instructions are active. The single-bit bypass register shift stage is enabled for serial access between TDI and TDO when the following instructions are active:

- BYPASS
- HIGHZ
- CLAMP

The functionality of each test mode is explained in more detail in JTAGC block instructions.

9.3.1.3 Bypass mode

When no test operation is required, the BYPASS instruction can be loaded to place the JTAGC block into bypass mode. When in bypass mode, the single-bit bypass shift register is used to provide a minimum-length serial path to shift data between TDI and TDO.

9.3.2 JTAGC reset configuration

When in reset, the TAP controller is forced into the Test-Logic-Reset state, thus disabling the test logic and allowing normal operation of the on-chip system logic. In addition, the instruction register is loaded with the IDCODE instruction.

9.3.3 IEEE 1149.1-2001 (JTAG) TAP

The JTAGC block uses the IEEE 1149.1-2001 TAP for accessing registers. This port can be shared with other TAP controllers on the MCU. Ownership of the port is determined by the value of the currently loaded instruction.

Data is shifted between TDI and TDO through the selected register starting with the least significant bit, as illustrated in the following figure. This applies for the instruction register, test data registers, and the bypass register.

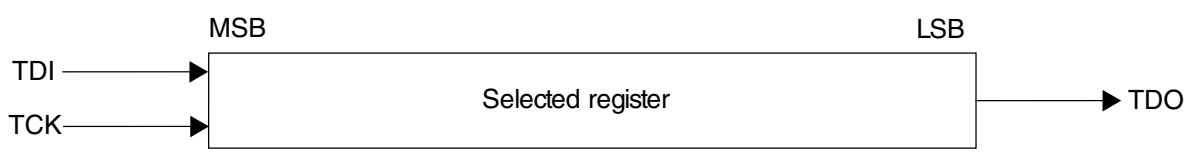

Figure 9-2. Shifting data through a register

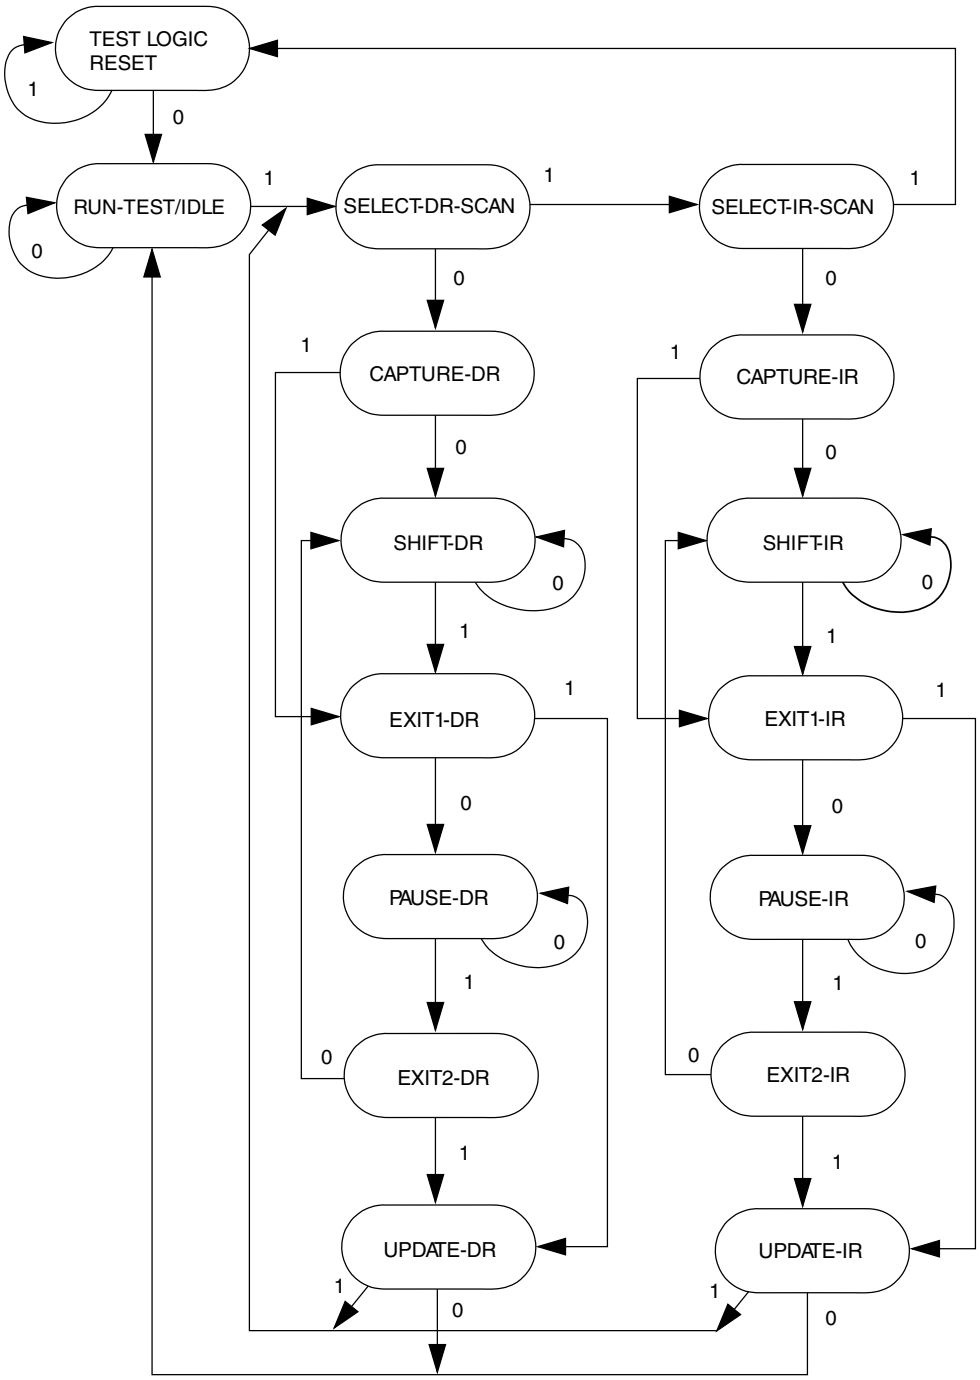
9.3.4 TAP controller state machine

The TAP controller is a synchronous state machine that interprets the sequence of logical values on the TMS pin.

The following figure shows the machine's states. The value shown next to each state is the value of the TMS signal sampled on the rising edge of the TCK signal. As the figure shows, holding TMS at logic 1 when clocking TCK through a sufficient number of rising edges also causes the state machine to enter the Test-Logic-Reset state.



The value shown adjacent to each state transition in this figure represents the value of TMS at the time of a rising edge of TCK.

Figure 9-3. IEEE 1149.1-2001 TAP controller finite state machine

9.3.4.1 Enabling the TAP controller

The JTAGC TAP controller is enabled by setting JCOMP to a logic 1 value.

9.3.4.2 Selecting an IEEE 1149.1-2001 register

Access to the JTAGC data registers is achieved by loading the instruction register with any of the JTAGC block instructions when the JTAGC is enabled. Instructions are shifted in via the Select-IR-Scan path and loaded in the Update-IR state. At this point, all data register access is performed via the Select-DR-Scan path.

The Select-DR-Scan path is used to read or write the register data by shifting in the data (LSB first) during the Shift-DR state. When reading a register, the register value is loaded into the IEEE 1149.1-2001 shifter during the Capture-DR state. When writing a register, the value is loaded from the IEEE 1149.1-2001 shifter to the register during the Update-DR state. When reading a register, there is no requirement to shift out the entire register contents. Shifting may be terminated after the required number of bits have been acquired.

9.3.5 JTAGC block instructions

The JTAGC block implements the IEEE 1149.1-2001 defined instructions listed in the following table. This section gives an overview of each instruction. See the IEEE 1149.1-2001 standard for more details. All undefined opcodes are reserved.

Table 9-2. 4-bit JTAG instructions

Instruction	Code[3:0]	Instruction summary
IDCODE	0000	Selects device identification register for shift
SAMPLE/PRELOAD	0010	Selects boundary scan register for shifting, sampling, and preloading without disturbing functional operation
SAMPLE	0011	Selects boundary scan register for shifting and sampling without disturbing functional operation
EXTEST	0100	Selects boundary scan register and applies preloaded values to output pins. **NOTE:** Execution of this instruction asserts functional reset.
HIGHZ	0101	Selects bypass register and tristates all output pins. **NOTE:** Execution of this instruction asserts functional reset.
ABORT (Arm JTAG-DP Reserved)	1000	This instruction goes the Arm JTAG-DP controller. See the Arm JTAG-DP documentation for more information.
DPACC (Arm JTAG-DP Reserved)	1010	This instruction goes the Arm JTAG-DP controller. See the Arm JTAG-DP documentation for more information.
APACC (Arm JTAG-DP Reserved)	1011	This instruction goes the Arm JTAG-DP controller. See the Arm JTAG-DP documentation for more information.
CLAMP	1101	Selects bypass register and applies preloaded values to output pins.

Table continues on the next page...

Table 9-2. 4-bit JTAG instructions (continued)

Instruction	Code[3:0]	Instruction summary
		NOTE: Execution of this instruction asserts functional reset.
IDCODE (Arm JTAG-DP Reserved)	1110	This instruction goes the Arm JTAG-DP controller. See the Arm JTAG-DP documentation for more information.
BYPASS	1111	Selects bypass register for data operations

9.3.5.1 IDCODE instruction

IDCODE selects the 32-bit device identification register as the shift path between TDI and TDO. This instruction allows interrogation of the MCU to determine its version number and other part identification data. IDCODE is the instruction placed into the instruction register when the JTAGC block is reset.

9.3.5.2 SAMPLE/PRELOAD instruction

The SAMPLE/PRELOAD instruction has two functions:

- The SAMPLE portion of the instruction obtains a sample of the system data and control signals present at the MCU input pins, and just before the boundary scan register cells at the output pins. This sampling occurs on the rising edge of TCK in the Capture-DR state when the SAMPLE/PRELOAD instruction is active. The sampled data is viewed by shifting it through the boundary scan register to the TDO output during the Shift-DR state. Both the data capture and the shift operation are transparent to system operation.
- The PRELOAD portion of the instruction initializes the boundary scan register cells before selecting the EXTEST or CLAMP instructions to perform boundary scan tests. This is achieved by shifting in initialization data to the boundary scan register during the Shift-DR state. The initialization data is transferred to the parallel outputs of the boundary scan register cells on the falling edge of TCK in the Update-DR state. The data is applied to the external output pins by the EXTEST or CLAMP instruction. System operation is not affected.

9.3.5.3 SAMPLE instruction

The SAMPLE instruction obtains a sample of the system data and control signals present at the MCU input pins, and just before the boundary scan register cells at the output pins. This sampling occurs on the rising edge of TCK in the Capture-DR state when the SAMPLE instruction is active. The sampled data is viewed by shifting it through the boundary scan register to the TDO output during the Shift-DR state. There is no defined action in the Update-DR state. Both the data capture and the shift operation are transparent to system operation.

9.3.5.4 EXTEST external test instruction

EXTEST selects the boundary scan register as the shift path between TDI and TDO. It allows testing of off-chip circuitry and board-level interconnections by driving preloaded data contained in the boundary scan register onto the system output pins. Typically, the preloaded data is loaded into the boundary scan register using the SAMPLE/PRELOAD instruction before the selection of EXTEST. EXTEST asserts the internal system reset for the MCU to force a predictable internal state when performing external boundary scan operations.

9.3.5.5 TEST_LEAKAGE instruction

The TEST_LEAKAGE instruction forces the jtag_leakage output signal to high. It is intended to tristate all output pad buffers and disable all of the part's pad input buffers except JCOMP and TEST. The jtag_leakage signal is asserted at the falling edge of TCK following the TAP controller state machine transition from the Update-IR state to the Run-Test-Idle state. When asserted, the part disables TCK, TMS, and TDI inputs and forces them to a logic 1. The TAP controller state machine remains in the Run-Test-Idle state until the JCOMP input is set to a value other than the JTAGC enable encoding. TEST_LEAKAGE also asserts the internal system reset for the MCU to force a predictable internal state.

9.3.5.6 ENABLE_SOC_DATA1 instruction

The ENABLE_SOC_DATA1 instruction captures SoC data and selects the SOC_DATA register for connection as the shift path between TDI and TDO.

9.3.5.7 HIGHZ instruction

HIGHZ selects the bypass register as the shift path between TDI and TDO. When HIGHZ is active all output drivers are placed in an inactive drive state (for example, high impedance). HIGHZ also asserts the internal system reset for the MCU to force a predictable internal state.

9.3.5.8 CLAMP instruction

CLAMP allows the state of signals driven from MCU pins to be determined from the boundary scan register when the bypass register is selected as the serial path between TDI and TDO. CLAMP enhances test efficiency by reducing the overall shift path to a single bit (the bypass register) when conducting an EXTEST type of instruction through the boundary scan register. CLAMP also asserts the internal system reset for the MCU to force a predictable internal state.

9.3.5.9 BYPASS instruction

BYPASS selects the bypass register, creating a single-bit shift register path between TDI and TDO. BYPASS enhances test efficiency by reducing the overall shift path when no test operation of the MCU is required. This allows more rapid movement of test data to and from other components on a board that are required to perform test functions. When the BYPASS instruction is active the system logic operates normally.

9.3.6 Security

The JTAGC provides debug access to several hardware blocks including processors and system bus, which may allow contol and visibility into system peripherals and memory. To prevent unauthorized transactions or visibility that may be used to compromise the system, the JTAGC provides ways of regulating JTAG access.

The JTAG security modes are configured using eFuse configuration. Fuse burning is an irreversible process, and can't be reverted to the un-burned state once burned. The following security mode configurations are supported:

Table 9-3. JTAGC Security Modes

Security Mode	Description
JTAG Disabled Mode	JTAG Disabled Mode is the highest protection mode. JTAG use is permanently blocked.

Table continues on the next page...

Table 9-3. JTAGC Security Modes (continued)

Security Mode	Description
No Debug Mode	No Debug Mode is the next highest protection mode after JTAG Disabled Mode. All security sensitive JTAG features are permanently blocked. JTAG features that aren't disabled in this mode allow internal tests and board connectivity checks that don't reduce the security level of the chip.
Secure JTAG Mode	Secure JTAG Mode offers high security protection, while allowing JTAG functionality. JTAG use is restricted unless a secret-key challenge/response protocol is successfully executed. The intent of this mode is to allow field return testing. When a secured JTAG device is returned for debugging, this mode allows authorized re-activiation of the JTAG.
JTAG Enabled Mode	JTAG Enabled Mode offers low security protection. JTAG use is unrestricted and all JTAG features are enabled.

9.3.6.1 Challenge/Response Mechanism in System JTAG Mode

When JTAGC is in Secure JTAG Mode, the authentication process is as follows:

1. Shift ENABLE_SOC_DATA instruction to IR.
2. Passing through Capture-DR state of the JTAGC and by performing Shift-DR operations Challenge code can be accessed from TDO.
3. Shift ENABLE_CENSOR_CTRL instruction to IR. By performing Shift-DR, operations enter Response code value through TDI. As Update-DR state is entered, Response code is compared with the correct one.

In Fixed Challenge-Response Pair Mode, each part has its individual Challenge-Response pair, which is determined at manufacturing time, and does not change later on. The JTAGC compares the user's response to the expected response.

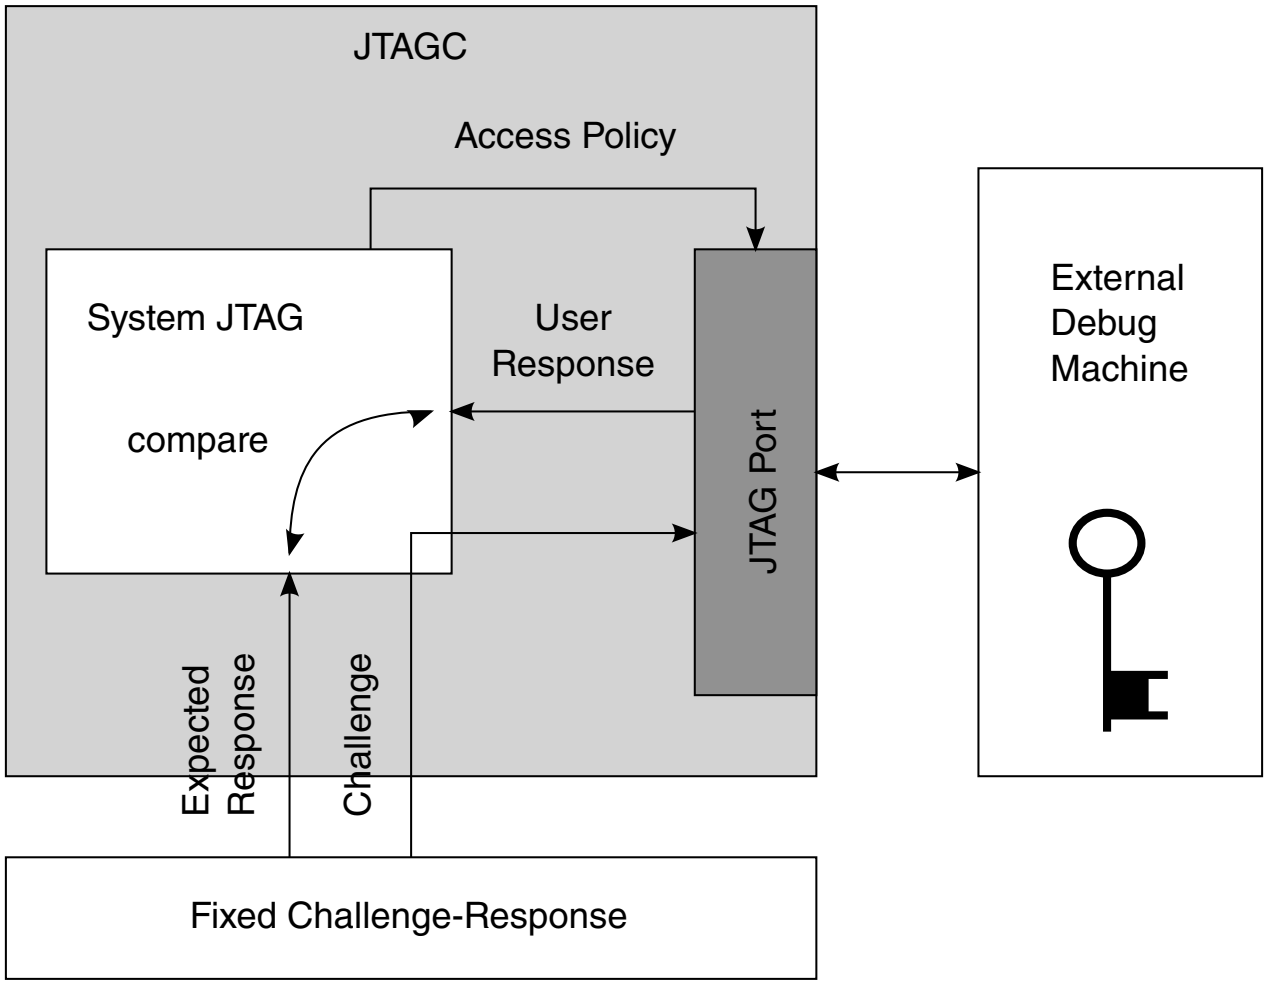


Figure 9-4. Secure JTAG with Fixed Challenge-response Pair

9.3.6.2 Software Enabled JTAG

To increase the flexibility of the JTAGC, an option to enable the JTAG via software is added and is available only in the Secure JTAG Mode. By writing '1' to HAB_JDE (HAB JTAG DEBUG ENABLE) bit in the eFuse controller, the JTAG is opened, regardless of its security mode. It is the responsibility of software to assert or negate this bit. Additionally, a corresponding lock bit is available to ensure that only trusted software is able to set the JDE bit. When the LOCK bit is set, no future change of JDE is possible, until the next POR (power-on-reset) cycle. The platform initialization software should set the LOCK bit for the JDE bit before transferring control to the application code.

The Software JTAG enable allows JTAG enabling without activating the Challenge-Respone mechanism. The JTAG software enable does not allow debug in case of boot or memory fault, as it requires reset before entering debug. This feature can be permanently blocked by burning the dedicated eFuse.

NOTE

The Software enabled JTAG feature reduces the overall security level of the system as it relies on software protections. If this feature is not required, it is strongly recommended to burn the JTAG_HEO eFuse which disables this feature.

9.3.6.3 Kill Trace

The kill trace signal disables any output of the ETM block. The ETM can be accessed either via JTAG port and/or by direct software code. Blocking the JTAG port also yields assertion of the kill trace signal. This resulted in blocking of trace port. The intention of this action is to block any attempt to break into the system via software manipulation of the debug modules. The kill trace, when active, prevents trace output, even in cases where it can be activated via chip pin. The kill trace feature needs to be activated by burning a dedicated eFuse. If the fuse is left intact, kill trace is never activated, as illustrated in the figure below.

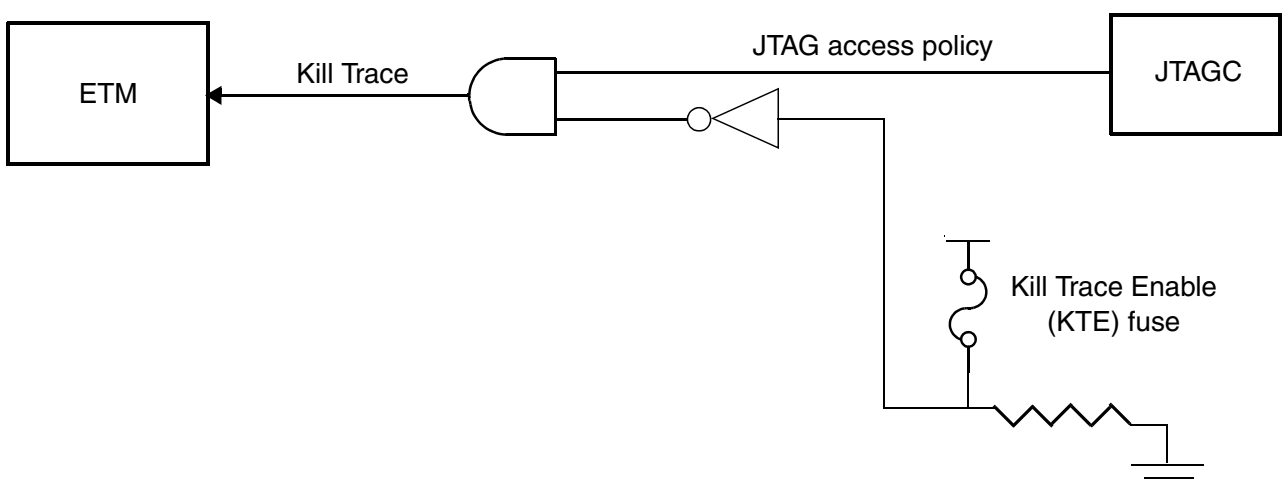

Figure 9-5. Kill Trace eFuse

The kill trace is asserted when the Kill Trace Enable (KTE) fuse is burned and an internal signal in JTAGC is asserted. The internal signal occurs when at least one of the following is true:

- Secure JTAG Mode and no code has been entered

- Secure JTAG Mode with burned Bypass and Re-enable fuses
- Secure JTAG Mode with incorrect response entered
- No Debug Mode
- TRST_B signal is active
- POR hasn't been asserted

9.3.7 Boundary scan

The boundary scan technique allows signals at component boundaries to be controlled and observed through the shift-register stage associated with each pad. Each stage is part of a larger boundary scan register cell, and cells for each pad are interconnected serially to form a shift-register chain around the border of the design. The boundary scan register consists of this shift-register chain, and is connected between TDI and TDO when the EXTEST, SAMPLE, or SAMPLE/PRELOAD instructions are loaded. The shift-register chain contains a serial input and serial output, as well as clock and control signals.

9.4 External signal description

The JTAGC consists of a set of signals that connect to off-chip development tools and allow access to test support functions. The JTAGC signals are outlined in the following table and described in the following sections.

Table 9-4. JTAG signal properties

Name	I/O	Function	Reset state
TCK	Input	Test clock	Weak pulldown
TDI	Input	Test data in	Weak pullup
TDO	Output	Test data out	High Z[1]
TMS	Input	Test mode select	Weak pullup
JCOMP	Input	JTAG compliancy	Weak pulldown

1. TDO output buffer enable is negated when the JTAGC is not in the Shift-IR or Shift-DR states. A weak pull may be implemented at the TDO pad for use when JTAGC is inactive.

9.4.1 Test clock input (TCK)

Test Clock Input (TCK) is an input pin used to synchronize the test logic and control register access through the TAP.

9.4.2 Test data input (TDI)

Test Data Input (TDI) is an input pin that receives serial test instructions and data. TDI is sampled on the rising edge of TCK.

9.4.3 Test data output (TDO)

Test Data Output (TDO) is an output pin that transmits serial output for test instructions and data. TDO is tristateable and is actively driven only in the Shift-IR and Shift-DR states of the TAP controller state machine, which is described in TAP controller state machine.

9.4.4 Test mode select (TMS)

Test Mode Select (TMS) is an input pin used to sequence the IEEE 1149.1-2001 test control state machine. TMS is sampled on the rising edge of TCK.

9.4.5 JCOMP JTAG compliancy

The JCOMP signal provides IEEE 1149.1-2001 compatibility and provides the ability to share the TAP. The JTAGC TAP controller is enabled when JCOMP is set to the JTAGC enable encoding—otherwise the JTAGC TAP controller remains in reset.

9.5 Initialization/application information

The test logic is a static logic design, and TCK can be stopped in either a high or low state without loss of data. However, the system clock is not synchronized to TCK internally. Any mixed operation using both the test logic and the system functional logic requires external synchronization.

To initialize the JTAGC block and enable access to registers, the following sequence is required:

1. Set the JCOMP signal to the JTAGC enable value, thereby enabling the JTAGC TAP controller.
2. Load the appropriate instruction for the test or action to be performed.

9.6 Register description

This section provides a detailed description of the JTAGC block registers accessible through the TAP interface, including data registers and the instruction register. Individual bit-level descriptions and reset states of each register are included. These registers are not memory-mapped and can only be accessed through the TAP.

9.6.1 Instruction register

The JTAGC block uses a 4-bit instruction register as shown in the following figure.

The instruction register allows instructions to be loaded into the block to select the test to be performed, or the test data register to be accessed, or both. Instructions are shifted in through TDI when the TAP controller is in the Shift-IR state, and latched on the falling edge of TCK in the Update-IR state. The latched instruction value can only be changed in the Update-IR and Test-Logic-Reset TAP controller states.

Synchronous entry into the Test-Logic-Reset state results in the IDCODE instruction being loaded on the falling edge of TCK. Asynchronous entry into the Test-Logic-Reset state results in asynchronous loading of the IDCODE instruction. During the Capture-IR TAP controller state, the instruction shift register is loaded with the value 0b1, making this value the register's read value when the TAP controller is sequenced into the Shift-IR state.

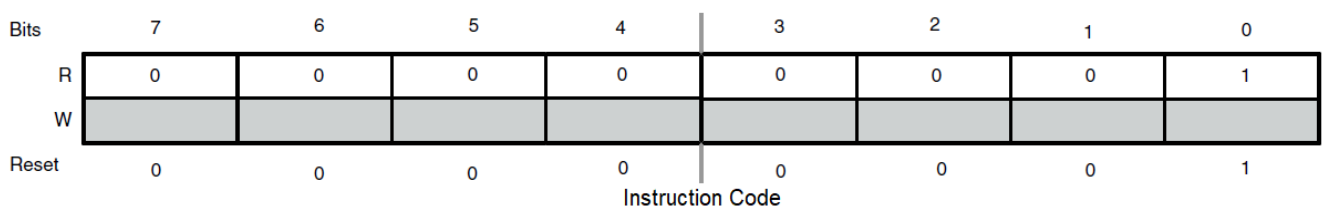

Figure 9-6. Instruction register

9.6.2 Bypass register

The bypass register is a single-bit shift register path selected for serial data transfer between TDI and TDO when the following instructions are active:

- BYPASS
- HIGHZ
- CLAMP

After entry into the Capture-DR state, the single-bit shift register is set to a logic 0. Therefore, the first bit shifted out after selecting the bypass register is always a logic 0.

9.6.3 Device identification register

The device identification (JTAG ID) register, shown in the following figure, allows the revision number, part number, manufacturer, and design center responsible for the design of the part to be determined through the TAP.

The device identification register is selected for serial data transfer between TDI and TDO when the IDCODE instruction is active. Entry into the Capture-DR state when the device identification register is selected loads the IDCODE into the shift register to be shifted out on TDO in the Shift-DR state. No action occurs in the Update-DR state.

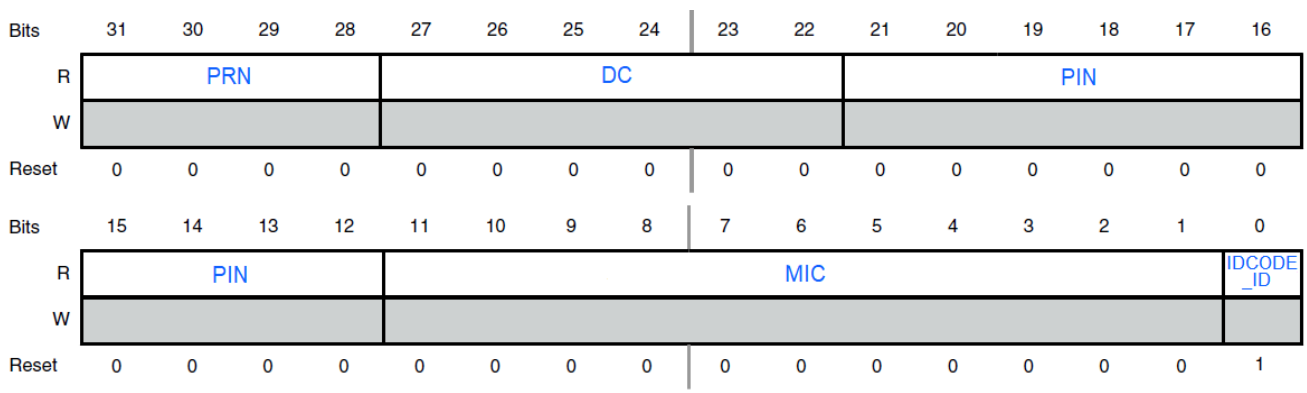

Figure 9-7. Device identification register

The following table describes the device identification register functions. The device identification register values are described in the chip-specific JTAGC information.

Table 9-5. Device identification register field descriptions

Field	Function
PRN	Part revision number Contains the revision number of the part.
DC	Design center Indicates the design center.
PIN	Part identification number Contains the part number of the device.
MIC	Manufacturer identity code Contains the reduced Joint Electron Device Engineering Council (JEDEC) ID .
IDCODE ID	IDCODE register ID Identifies this register as the device identification register and not the bypass register. Always set to 1.

9.6.4 Boundary scan register

The boundary scan register is connected between TDI and TDO when the EXTEST, SAMPLE, or SAMPLE/PRELOAD instructions are active. It is used to:

- Capture input pin data
- Force fixed values on output pins
- Select a logic value and direction for bidirectional pins

Each bit of the boundary scan register represents a separate boundary scan register cell, as described in the IEEE 1149.1-2001 standard and discussed in Boundary scan. The size of the boundary scan register and bit ordering is device-dependent and can be found in the device BSDL file.

Chapter 10
System Boot

10.1 Chip-specific Boot Information

This device has various peripherals supported by the ROM bootloader.

Table 10-1. ROM Bootloader Peripheral PinMux

Peripheral	Instance	Port (IO function)	PAD	Mode	Note
LPUART	1	LPUART1_TX	GPIO_AD_24	ALT0	Can be used for serial downloader mode. Refer to Serial Boot (Serial Downloader) for more information.
		LPUART1_RX	GPIO_AD_25	ALT0	
LPSPI	1	LPSPI1_SCK	GPIO_AD_28	ALT0	Serial NOR/EEPROM connected to one of the LPSPI ports can be used as a recovery device. Refer to Recovery devices for more information. **NOTE:** Recovery device boot is disabled by default. The RECOVERY_BOOT_EN fuse must be blown in order to enable this option. The SPI INSTANCE fuse selects the SPI instance.

FlexSPI RESET	-	GPIO4_IO03 (Primary RESET Pin)	GPIO_SD_B1_00	ALT5	The FlexSPI RESET pin is used as the dedicated RESET pin to restore the Serial NOR/NAND device connected to the FlexSPI interface. The FlexSPI RESET pin is enabled if the RESET_PIN_EN fuse bit is blown.
		GPIO_MUX2_IO08 (Secondary RESET Pin)	GPIO_EMC_B1_40	ALT5	

Table 10-1. ROM Bootloader Peripheral PinMux

Peripheral	Instance	Port (IO function)	PAD	Mode	Note
					The pin option is selected by RESET_PIN_SEL fuse bit.

NOTE

1. The boot ROM always tries to access Serial NOR/NAND flash using SS0 as the chip selection signal, as well as PORTA by default. It can access the Serial NOR/NAND device via CS0 and PORTB, if the FLASH_CONNECTION_SEL fuse is blown with a value of 2.
2. For Octal NOR/NAND, connected to FlexSPI1, the upper 4-bit pads must connect to the PORTB_DATA pads.
3. For Octal NOR/NAND, connected to FlexSPI2, the upper 4-bit pads must connect to the same PORT with the upper 4-bit pads.
4. PORTB_SCLK serves as PORTA_SCLK_B for the 1.8V HyperFLASH/HyperRAM.
5. A_SS1/B_SS1 is not supported by default.
6. The FlexSPI RESET pin is not used by default. This feature can be enabled by the RESET_PIN_EN and RESET_PIN_SEL fuses.

10.1.1 ROM settings and considerations for user applications and debugging

The boot ROM configures the clocks of the boot core, bus, and other required controllers to a high frequency of clock roots during boot for high-performance consideration. When the user application needs to re-configure the clock roots, PLLs or the PFDs, the SoC may crash if the clocks are not handled properly. To avoid such potential issues, below are some suggestions:

- Switch the root clock of the boot core, bus, and other affected controllers to a fixed clock root. before configuring the clocks.
- Configure the clock of each peripheral explicitly instead of relying on the default settings listed in the Reference Manual.

The following tables provide the clock frequency configurations for Cortex-M7/Cortex-M4 core boot.

Table 10-2. Normal Frequency Clock Configurations for Cortex-M7 Core Boot

BOOT_FREQ (0x9A0[3])	LPB_BOOT (0x9A0[5:4])	Core Clock Frequency (MHz)
0	0	400
	1	200
	2	100
	3	50
1	0	696
	1	348
	2	174
	3	87

Table 10-3. Normal Frequency Clock Configurations for Cortex-M4 Core Boot

BOOT_FREQ (0x9A0[3])	LPB_BOOT (0x9A0[5:4])	Core Clock Frequency (MHz)
0	0	200
	1	100
	2	50
	3	25
1	0	240
	1	120
	2	60
	3	30

The following table provides the list of registers that are updated by ROM during ROM execution.

Table 10-4. Registers modified by ROM

Module	Register	Value	Note
CCM	CLOCK_ROOT0_CONTROL	The value varies at different frequencies	CM7 clock root
	CLOCK_ROOT1_CONTROL		CM4 clock root
	CLOCK_ROOT2_CONTROL		Bus clock root
	CLOCK_ROOT3_CONTROL		Bus LPSR clock root
	CLOCK_ROOT20_CONTROL		FlexSPI1 clock root
	CLOCK_ROOT25_CONTROL		LPUART1 clock root
	CLOCK_GROUP0_CONTROL	0x00020002	FLEXRAM clock group
PLL	PLL_480_CTRL	0x2020201B	-
	PLL_480_PFD	0x1820110D	
	PLL_528_CTRL	0x20802008	

Table continues on the next page...

Table 10-4. Registers modified by ROM (continued)

Module	Register	Value	Note
	PLL_528_PFD	0x6058505B	
OSC	OSC_400M_CTRL1	0x00000000	-
	OSC_400M_CTRL2	0x00000001	
	OSC_24M_CTRL	0x40000014	
USB-PHY	USBPHYx_CTRL	0x2818C000	ROM sets the USB-PHY registers if the device runs under serial downloader mode.
	USBPHYx_PLL_SIC	0x80F03040	
	USBPHYx_PWD	0x00000000	

The registers in the modules listed below may be updated if they are in use for specific boot modes. ROM does not restore the registers in these modules after they are updated. The user application should not rely on the default values of the registers in these modules.

- FlexSPI1 - if the device boots from memory connected to FlexSPI1.
- FlexSPI2 - if the device boots from memory connected to FlexSPI2.
- uSDHC1 - if the device boots from memory connected to uSDHC1.
- uSDHC2 - if the device boots from memory connected to uSDHC2.
- SEMC - if the device boots from memory connected to SEMC.
- MECC - if the MECC_ENABLE Fuse bit is blown.
- FLEXRAM - if the FLEXRAMECC_ENABLE Fuse bit is blown.
- CAAM - HAB library uses some features in CAAM, and they cannot be restored before leaving ROM.
- SNVS - if the SNVS state was changed by ROM in HAB closed mode.
- ANADIG_OSC - The OSC related configurations are not restored.
- ANADIG_MISC - The AI interface related settings are not restored.
- ANADIG_PMU - The ANADIG PMU related settings are not restored.
- CCM - The clock settings for the modules, such as the CM7 core, are not restored.
- ANADIG_PLL - The ANADIG_PLL related settings are not restored (e.g. PLL_480_CTRL, PLL_480_PFD, PLL_528_CTRL, PLL_528_PFD).
- SCB->SHCSR - The UsageFault, MemManageFault, and BusFault enabling flags are not cleared.
- IOMUXC - cannot fully be restored because some settings are still in use before leaving ROM.
- IOMUXC_GPR - used in the IEE related test cases, cannot be cleared before leaving ROM.
- WDOG3/WDOG4 - disabled by ROM.
- CDOG – CDOG was enabled and used as the hardware secure counter during ROM execution, and ROM partially restores before leaving ROM due to the IP restriction.
- SRC GPR - ROM occupies SRC GPR0-GPR4 and GPR9.

10.1.2 Debug behavior

The debug port is disabled on the SoC out of reset. ROM enables the debug port in either of the following conditions:

- ROM is ready to jump to a valid user application.
- A debug request is received from the debug tool in the serial downloader mode or before finishing the image validity check.

10.1.3 Manufacturing protection

The Manufacturing protection (MP) key pair is generated by HAB. ROM will request generation of the (MP) key pair.

10.2 Overview

The boot process begins at any Reset where the hardware reset logic forces the Arm core (boot core is determined by BT_CORE_SEL fuse setting) to begin execution starting from the on-chip boot ROM.

If the BT_CORE_SEL fuse is blown, ROM will be executing from the M4 core instead of the M7 core. Booting from the M4 core can be slower due to the slower ROM execution time with the M4, especially if using HAB.

The boot ROM code uses the state of the internal register BOOT_MODE[1:0] as well as the state of various eFuses and/or GPIO settings to determine the boot flow behavior of the device.

The main features of the ROM include:

- Support for booting from various boot devices
- Serial downloader support (USB-HID and UART)
- Device Configuration Data (DCD)
- Digital signature based High-Assurance Boot (HAB)
- eXternal Memory Configuration Data (XMCD)
- Encrypted execute-in-place (XIP) on Serial NOR via FlexSPI interface powered by:
  - Inline Encryption Engine (IEE)
  - On-the-Fly AES Decryption (OTFAD)

The boot ROM supports boot device as below:

- Serial NOR Flash via FlexSPI

- Serial NAND Flash via FlexSPI
- SLC RAWNAND Flash via SEMC
- SD/MMC via uSDHC
- SPI NOR/EEPROM via LPSPI

The boot ROM uses the state of the BOOT_MODE and eFuses to determine the boot device. For development purposes, the eFuses used to determine the boot device may be overridden using the GPIO pin inputs.

The boot ROM code also allows the downloading of programs to be run on the device. An example is a provisioning program that can make further use of the serial connection to provide a boot device with a new image. Typically, the provisioning program is downloaded to the internal RAM and allows to program the boot devices, such as the FlexSPI NOR flash. The ROM serial downloader uses a high-speed USB in a non-stream mode connection.

The Device Configuration Data (DCD) feature allows the boot ROM code to obtain the SOC configuration data from an external program image residing on the boot device. As an example, the DCD can be used to program the SDRAM controller for optimal settings improving the boot performance. The DCD is restricted to the memory areas and peripheral addresses that are considered essential for the boot purposes (see Write data command).

The External Memory Configuration Data (XMCD) allows the boot ROM code to configure the SDRAM connected to the SEMC controller, or the HyperRAM/APMemory PSRAM via the FlexSPI controller from an external program image residing on the boot device. The XMCD aims to simplify the external RAM enablement, and it is a replacement for the legacy Device Configuration Data (DCD).

A key feature of the boot ROM is the ability to perform a secure boot, also known as a High-Assurance Boot (HAB). This is supported by the HAB security library which is a subcomponent of the ROM code. The HAB uses a combination of hardware and software together with the Public Key Infrastructure (PKI) protocol to protect the system from executing unauthorized program images. Before the HAB allows the user image to execute, the image must be signed. The signing process is done during the image build process by the private key holder and the signatures are then included as a part of the final program image. If configured to do so, the ROM verifies the signatures using the public keys included in the program image. In addition to supporting the digital signature verification to authenticate the program images, encrypted boot is also supported. The encrypted boot can be used to prevent the cloning of the program image directly off the boot device. A secure boot with HAB can be performed on all boot devices supported on the chip in addition to the serial downloader. The HAB library in the boot ROM also provides the API functions, allowing the additional boot chain components (e.g., bootloader, application) to extend the secure boot chain. The out-of-fab setting for the

SEC_CONFIG is the open configuration, in which the ROM/HAB performs the image authentication, but all authentication errors are ignored and the image is still allowed to execute.

10.3 Boot modes

During boot, the ROM's behavior is defined by the boot mode pin settings, as described in Boot mode pin settings.

10.3.1 Boot mode pin settings

The device has four boot modes (one is reserved for NXP use). The boot mode is selected based on the binary value stored in the internal BOOT_MODE register.

The BOOT_MODE register is initialized by sampling the BOOT_MODE0(GPIO_LPSR_02) and BOOT_MODE1(GPIO_LPSR_03) inputs on the rising edge of the POR_B. After these inputs are sampled, their subsequent state does not affect the contents of the internal BOOT_MODE register. The state of the internal BOOT_MODE register may be read from the BMOD[1:0] field of the SRC Boot Mode Register (SRC_SBMR2). The available boot modes are: Boot From Fuses, Serial Downloader, and Internal Boot. See this table for settings:

Table 10-5. Boot MODE pin settings

BOOT_MODE[1:0]	Boot Type
00	Boot From Fuses
01	Serial Downloader
10	Internal Boot
11	Reserved

10.3.2 High-level boot sequence

The figure found here show the high-level boot ROM code flow.

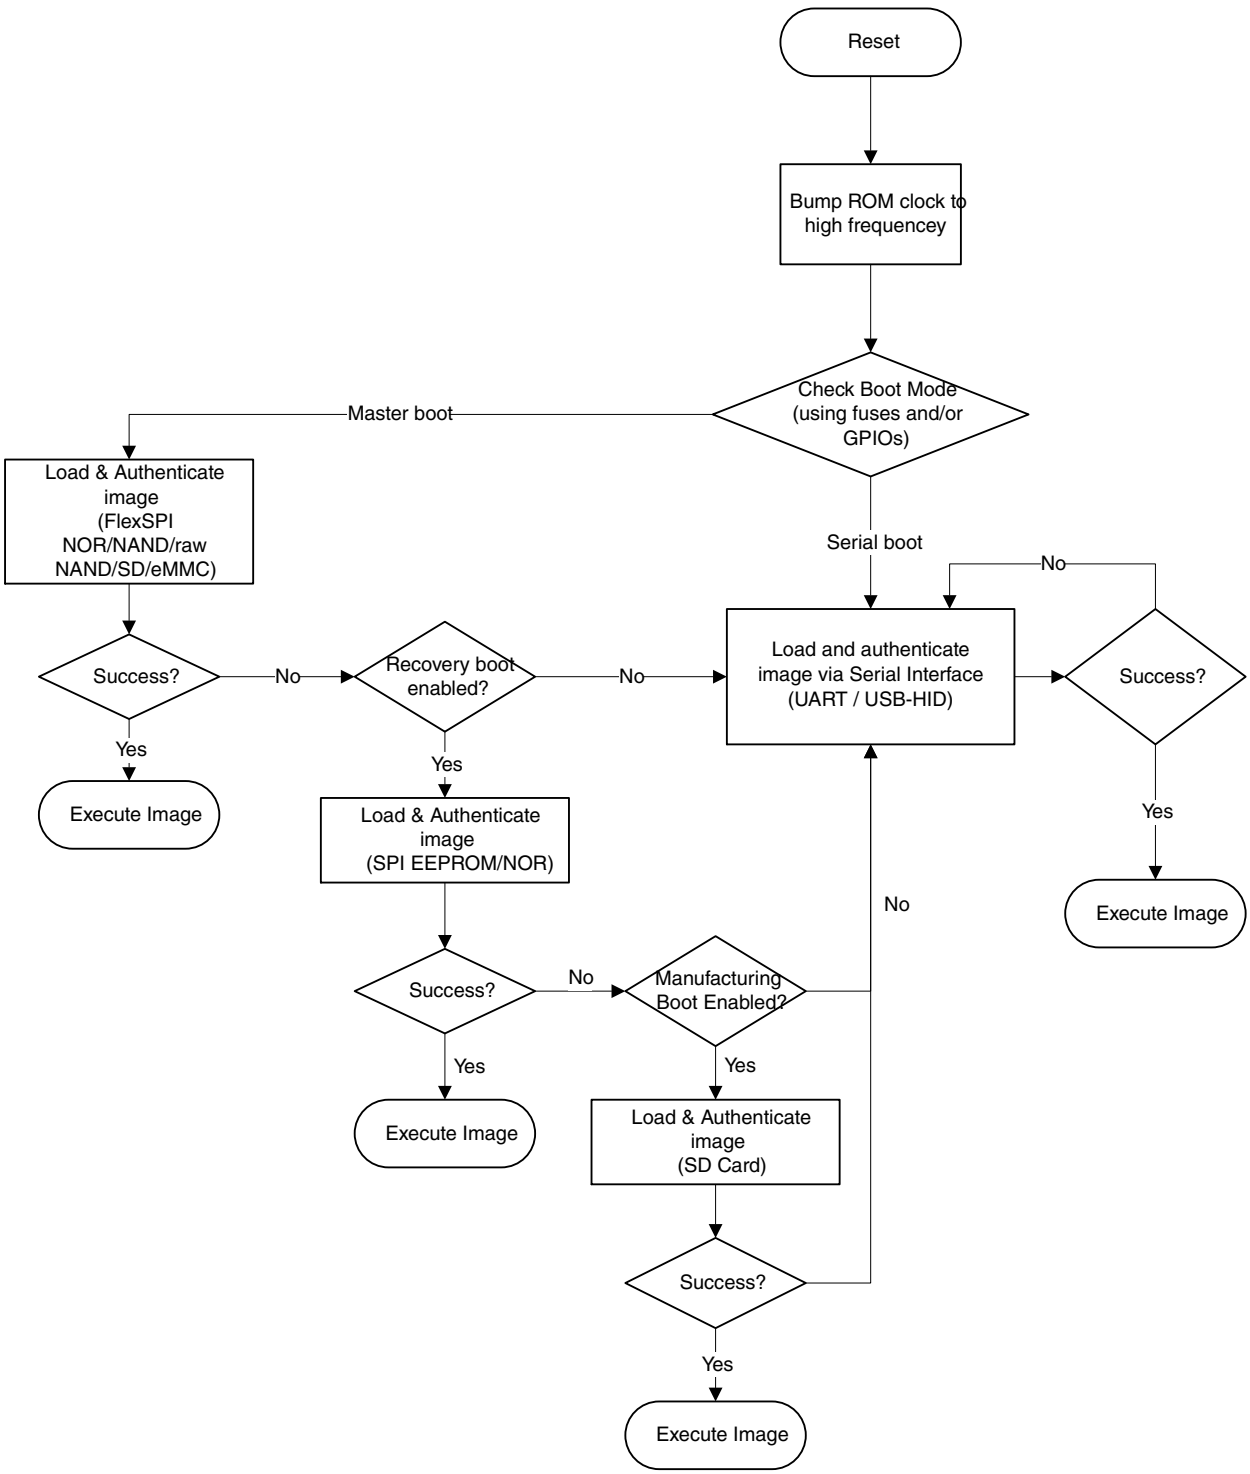

Figure 10-1. Boot flow

10.3.3 Boot From Fuses mode (BOOT_MODE[1:0] = 00b)

A value of 00b in the BOOT_MODE[1:0] register selects the Boot From Fuses mode.

This mode is similar to the Internal Boot mode described in Internal Boot mode (BOOT_MODE[1:0] = 10b) with one difference. In this mode, the override from the GPIO boot pins are ignored. The boot ROM code uses the boot eFuse settings only. This mode also supports a secure boot using HAB.

If set to Boot From Fuses, the boot flow is controlled by the BT_FUSE_SEL eFuse value. If BT_FUSE_SEL = 0, indicating that the boot device (for example, flash) was not programmed yet, the boot flow jumps directly to the Serial Downloader. If BT_FUSE_SEL = 1, the normal boot flow is followed, where the ROM attempts to boot from the selected boot device.

The first time a board is used, the default eFuses may be configured incorrectly for the hardware on the platform. In such case, the Boot ROM code may try to boot from a device that does not exist. This may cause an electrical/logic violation on some pads. Using the Boot From Fuses mode addresses this problem.

Setting the BT_FUSE_SEL=0 forces the ROM code to jump directly to the Serial Downloader. This allows a bootloader to be downloaded which can then provision the boot device with a program image and blow the BT_FUSE_SEL and the other boot configuration eFuses. After the reset, the boot ROM code determines that the BT_FUSE_SEL is blown (BT_FUSE_SEL = 1) and the ROM code performs an internal boot according to the new eFUSE settings. This allows the user to set BOOT_MODE[1:0]=00b on a production device and burn the fuses on the same device (by forcing the entry to the Serial Downloader), without changing the value of the BOOT_MODE[1:0] or the pullups/pulldowns on the BOOT_MODE pins.

10.3.4 Serial Downloader (BOOT_MODE[1:0] = 01b)

The Serial Downloader provides a means to download a Program Image to the on-chip RAM over USB or UART serial connection. In this mode, typically a host PC can communicate to the ROM bootloader using serial download protocol. Serial downloader and the protocol are discussed in Serial Downloader.

10.3.5 Internal Boot mode (BOOT_MODE[1:0] = 10b)

A value of 10b in the BOOT_MODE[1:0] register selects the Internal Boot mode. In this mode, the processor continues to execute the boot code from the internal boot ROM.

The boot code performs the hardware initialization, loads the program image from the chosen boot device, performs the image validation using the HAB library (see Boot security settings), and then jumps to an address derived from the program image. If an error occurs during the internal boot, the boot code jumps to the Serial Downloader (see Serial Downloader (BOOT_MODE[1:0] = 01b)). A secure boot using the HAB is possible in all the three boot modes.

When set to the Internal Boot, the boot flow may be controlled by a combination of eFuse settings with an option of overriding the fuse settings using the General Purpose I/O (GPIO) pins. The GPIO Boot Select FUSE (BT_FUSE_SEL) determines whether the ROM uses the GPIO pins for a selected number of configuration parameters or eFuses in this mode.

- If BT_FUSE_SEL = 1, all boot options are controlled by the eFuses described in Boot eFuse descriptions.
- If BT_FUSE_SEL = 0, the specific boot configuration parameters may be set using the GPIO pins rather than eFuses. The fuses that can be overridden when in this mode are indicated in the GPIO column of Boot eFuse descriptions. GPIO boot overrides provides the details of the GPIO pins.

The use of the GPIO overrides is intended for development since these pads are used for other purposes in the deployed products. NXP recommends controlling the boot configuration by the eFuses in the deployed products and reserving the use of the GPIO mode for the development and testing purposes only.

10.3.6 Boot security settings

The internal boot modes use one of three security configurations.

- Closed: This level is intended for use with shipping-secure products. All HAB functions are executed and the security hardware is initialized (the Security Controller or SNVS enters the Secure state), the DCD is processed if present, and the program image is authenticated by the HAB before its execution. All detected errors are logged, and the boot flow is aborted with the control being passed to the serial downloader. At this level, the execution does not leave the internal ROM unless the target executable image is authenticated.
- Open: This level is intended for use in non-secure products or during the development phases of a secure product. All HAB functions are executed in the same

way as for a closed system. The security hardware is initialized (except for the SNVS which is left in the Non-Secure state), the DCD is processed if present, and the program image is authenticated by the HAB before its execution. All detected errors are logged, but have no influence on the boot flow which continues as if the errors did not occur. This configuration is useful for a secure product development because the program image runs even if the authentication data is missing or incorrect, and the error log can be examined to determine the cause of the authentication failure.

- Field Return: This level is intended for the parts returned from the shipped products.

10.4 Device configuration

This section describes the external inputs that control the behavior of the Boot ROM code.

This includes the boot device selection (FlexSPI NOR FlexSPI NAND,SD, MMC, and so on), boot device configuration (SD bus width, speed, and so on), and other. In general, the source for this configuration comes from the eFuses embedded inside the chip. However, certain configuration parameters can be sourced from the GPIO pins, allowing further flexibility during the development process.

10.4.1 Boot eFuse descriptions

This table is a comprehensive list of the configuration parameters that the ROM uses.

Table 10-6. Boot eFuse descriptions

Fuse	Configuration	Definition	GPIO[1]	Shipped value	Settings[2]
BT_FUSE_SEL	OEM	In the Internal Boot mode BOOT_MODE[1:0] = 10, the BT_FUSE_SEL fuse determines whether the boot settings indicated by a Yes in the GPIO column are controlled by the GPIO pins or the eFuse settings in the On-Chip OTP Controller (OCOTP). In the Boot From Fuse mode BOOT_MODE[1:0] = 00, the BT_FUSE_SEL fuse indicates whether the bit configuration eFuses are programmed.	NA	0	If BOOT_MODE[1:0] = 10b: • 0 - The bits of the SBMR are overridden by the GPIO pins. • 1 - The specific bits of the SBMR are controlled by the eFuse settings. If BOOT_MODE[1:0] = 00b: • 0—The BOOT configuration eFuses are not programmed yet. The boot flow jumps to the serial downloader. • 1—The BOOT configuration eFuses are programmed. The regular boot flow is performed.

Table continues on the next page...

Table 10-6. Boot eFuse descriptions (continued)

Fuse	Configuration	Definition	GPIO[1]	Shipped value	Settings[2]
UNIQUE_ID[63:0]	NXP	Device Unique ID, 64-bit UID	NA	Unique ID	Settings vary—used by HAB
BOOT_CFG1[7:0]	OEM	Boot configuration 1	Yes	0	Specific to the selected boot mode
BOOT_CFG2[3:0]	OEM	Boot configuration 2	Yes	0	Specific to the selected boot mode
LPB_BOOT	OEM	Low-Power Boot	No	0	Divide (Core / Bus) based on Boot frequencies: 00 - Div by 1 01 - Div by 2 10 - Div by 4 11 - Div by 8
WDOG_ENABLE	OEM	Watchdog reset counter enable	No	0	WDOG1 enable: 0—The watchdog reset counter is disabled during boot. 1—The watchdog reset counter is enabled during boot.
PAD_SETTINGS	OEM	Override values for the SD/MMC and NAND boot modes	No	0	Override these IO PAD settings: • PAD_SETTINGS[0]—Slew Rate • PAD_SETTINGS[3:1]—Drive Strength • PAD_SETTINGS[5:4]—Speed Settings • PAD_SETTINGS[6]— Pull Up / Down Configuration • PAD_SETTINGS[7]—Hysteresis Enable

1. This setting is overridden by the GPIO settings when the BT_FUSE_SEL fuse is intact. See GPIO Boot Overrides for the corresponding GPIO pin.
2. 0 = intact fuse and 1= blown fuse

10.4.2 GPIO boot overrides

This table provides a list of the GPIO boot overrides:

Table 10-7. GPIO Boot Overrides

Package Pin	Direction on reset	eFuse
GPIO_DISP_B1_06	Input	BOOT_CFG1[0]
GPIO_DISP_B1_07	Input	BOOT_CFG1[1]

Table continues on the next page...

Table 10-7. GPIO Boot Overrides (continued)

Package Pin	Direction on reset	eFuse
GPIO_DISP_B1_08	Input	BOOT_CFG1[2]
GPIO_DISP_B1_09	Input	BOOT_CFG1[3]
GPIO_DISP_B1_10	Input	BOOT_CFG1[4]
GPIO_DISP_B1_11	Input	BOOT_CFG1[5]
GPIO_DISP_B2_00	Input	BOOT_CFG1[6]
GPIO_DISP_B2_01	Input	BOOT_CFG1[7]
GPIO_DISP_B2_02	Input	BOOT_CFG2[0]
GPIO_DISP_B2_03	Input	BOOT_CFG2[1]
GPIO_DISP_B2_04	Input	BOOT_CFG2[2]
GPIO_DISP_B2_05	Input	BOOT_CFG2[3]

NOTE

Refer to the Fusemap chapter for more information on fuses mapped to the GPIO pins.

The input pins above are sampled at boot, and can be used to override the corresponding eFuse values, depending on the setting of the BT_FUSE_SEL fuse.

10.4.3 Device Configuration Data (DCD)

The DCD is the configuration information contained in the program image (external to the ROM) that the ROM interprets to configure various on-chip peripherals. See Device Configuration Data (DCD) for more details on DCD.

10.5 Device initialization

This section describes the details of the ROM and provides the initialization details.

This includes details on:

- The ROM memory map
- The RAM memory map
- On-chip blocks that the ROM must use or change the POR register default values
- Clock initialization
- Enabling the L1 I/D cache
- Exception handling and interrupt handling

10.5.1 Internal ROM/RAM memory map

These figures show the internal ROM and RAM memory map:

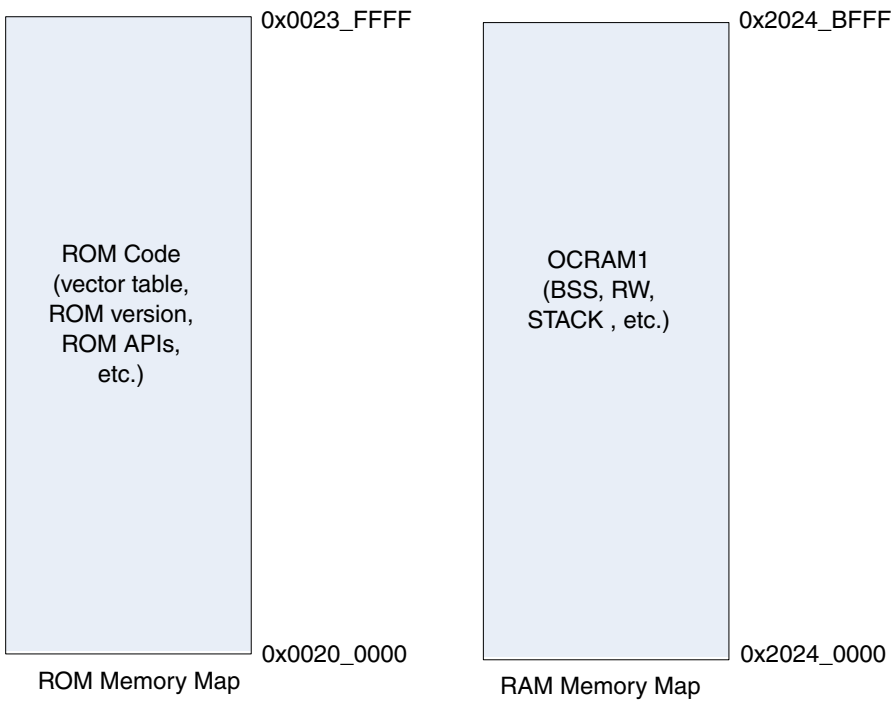

Figure 10-2. Internal ROM and RAM memory map

NOTE

The RAM space occupied by ROM cannot be used as part of the boot image. The entire OCRAM1 region can be used freely after the boot. The above OCRAM1 region must be reserved if the user application needs to call the HAB API/FlexSPI NOR API for image authentication.

10.5.2 Boot block activation

The boot ROM affects a number of different hardware blocks which are activated and play a vital role in the boot flow.

The ROM configures and uses the following blocks (listed in an alphabetical order) during the boot process. Note that the blocks actually used depend on the boot mode and the boot device selection:

Block	Description
CCM	Clock Control Module
FlexSPI	Flexible SPI Interface which supports serial NOR, Serial NAND and serial RAM devices
OCOTP	On Chip One Time Programmable Controller containing the eFuses
IOMUXC	I/O Multiplexer Control which allows the GPIO use to override the eFuse boot settings
IOMUX GPR	I/O Multiplexer control General Purpose Registers
LPSPI	Low Power SPI interface which supports serial NOR/EEPROM devices
SNVS	Secure Non-Volatile Storage
SRC	System Reset Controller
USB	Used for Serial download of a boot device provisioning program
uSDHC	Ultra-Secure Digital Host Controller
WDOG 1	WatchDog Timer
CAAM	Cryptographic Acceleration and Assurance Module
PIT	Periodic Interrupt Timer

10.5.3 Enabling Caches

The boot ROM includes a feature that enables the caches to improve the boot speed.

L1 instruction cache is enabled at the start of image download. The L1 data cache is enabled at the start of image authentication. Both the caches are disabled by ROM before leaving the ROM execution.

By default, the L1-ICache and DCache are enabled by ROM. However, there are fuse bits that can be programmed for ROM not to enable the L1 I/DCache at boot.

The Cache features are controlled by the BT_ICACHE_DISABLE fuse and BT_DCACHE_DISABLE fuses. By default, both fuses are not blown meaning the ROM uses the L1-ICache and L1-DCache of the Arm core. This improves the performance of the HAB signature verification software.

10.5.4 Exception error handling

10.5.4.1 Fault handling

All types of Faults cause the NVIC_SystemReset(), including the following:

- HardFault, BusFault, MemMangeFault, UsageFault
- ROM boot flow mismatch (treated as a side-channel attack)

10.5.4.2 Boot failure

ROM indicates the following failures if the boot failure indicator feature is enabled by the BOOT_FAIL_IND_EN and "Boot Failure Indicator Pin Select" fuse fields.

- The primary/recovery/manufacturing boot failed before entering serial downloader
- The HAB API call failed

ROM resets the device immediately upon detection of an illegal boot flow.

10.5.5 Persistent bits

Some modes of the boot ROM require the registers that keep their values after a warm reset. The SRC General-Purpose registers are used for this purpose.

See this table for persistent bits list and description:

Table 10-8. Persistent bits

Bit name	Bit location	Description
PERSIST_SECONDARY_BOOT	SRC_GPR9[30]	This bit identifies which image must be used—primary and secondary. Used only for eMMC/SD/FlexSPI NOR boot.
PERSIST_REDUNDANT_BOOT	SRC_GPR9[27:26]	This field identifies which image must be used - 0/1/2/3. Used for both SPI NAND and SLC raw NAND devices.
FLASH_STATE_CTX	SRC_GPR2[31:0]	Flash status context. This field logs the flash state during boot, so that the flash driver can retrieve the state of the flash and operate the flash devices properly.
ROM_API_CTX	SRC_GPR3[31:0]	ROM API context. Reserved for ROM API use.

10.6 Boot devices

The chip supports the following boot flash devices:

- Serial NOR flash via FlexSPI Interface
- Serial NAND Flash via FlexSPI Interface
- NAND Flash with SEMC interface, located on CS0, 8-bit/16-bit bus width.
- SD/MMC/eSD/SDXC/eMMC5.0 via uSDHC interface, supporting high capacity cards
- Serial NOR/EEPROM boot via LPSPI

The selection of the external boot device type is controlled by the BOOT_CFG1[7:4] eFUSEs. See this table for more details:

Table 10-9. Boot device selection

BOOT_CFG1[7:4]	Boot device
0000b	Serial NOR boot via FlexSPI
01xxb	SD Boot via uSDHC
10xxb	eMMC/MMC boot via uSDHC
001xb	SLC NAND boot via SEMC
11xxb	Serial NAND boot via FlexSPI

NOTE

A user can use the LPSPI to boot from Serial NOR/EEPROM. Booting from Serial NOR/EEPROM via an LPSPI port is not intended as the primary device, but as a recovery boot device if the primary boot device fails.

In order to enable a recovery boot device, EEPROM_RECOVERY_EN fuse must be set to 1, and other fuses listed in Serial NOR/EEPROM eFUSE configuration must be properly set.

10.6.1 Serial NOR Flash Boot via FlexSPI

10.6.1.1 Serial NOR eFUSE Configuration

Table 10-10. Fuse definition for Serial NOR over FlexSPI

Fuse	Config	Definitions	GPIO	Shipped Value	Settings
BOOT_CFG1[0]	OEM	xSPI FLASH Auto Probe	Yes	0	0 – Disabled 1 – Enabled
BOOT_CFG1[1]	OEM	Encrypted XIP	Yes	0	0 – Disabled 1 – Enabled
BOOT_CFG1[3:2]	OEM	xSPI FLASH Auto Probe Type	Yes	0	0 – QuadSPI NOR 1 – MXIC Octal 2 – Micron Octal 3 – Adesto Octal
BOOT_CFG1[7:4]	OEM	Boot device selection	Yes	0	0 – Serial NOR device is selected as boot device

Table continues on the next page...

Table 10-10. Fuse definition for Serial NOR over FlexSPI (continued)

Fuse	Config	Definitions	GPIO	Shipped Value	Settings
BOOT_CFG2[2:0]	OEM	xSPI Flash Type	Yes	0	000b–Boot with default 0x03 Read Enabled 001b–Reserved 010b–HyperFlash 1V8 011b–HyperFlash 3V0 100b–MXIC Octal Read 101b–Micron Octal Read
BOOT_CFG2[3]	OEM	FLEXSPI instance	Yes	0	0 – FLEXSPI1 1 – FLEXSPI2
0xC80[2:0] (BOOT_CONFIG_ MISC)	OEM	xSPI FLASH Frequency	No	0	0 – 100MHz 1 – 120MHz 2 – 133MHz 3 – 166MHz 5 – 80MHz 6 – 60MHz Others – Reserved
0xC80[4:3] (BOOT_CONFIG_ MISC)	OEM	Hold time before access the Flash device	No	0	0 – 500us 1 – 1ms 2 – 3ms 3 – 10ms
0xC80[5]	OEM	RESET_PIN_SEL Reset pin selection	No	0	0 - Primary reset pin 1 - Secondary reset pin Please refer to Table 10-1 for details.
0xC80[6]	OEM	JEDEC_HW_RESET_EN Enable JEDEC hardware reset sequence	No	0	0 - JEDEC hardware reset sequence is not performed 1 - JEDEC hardware reset sequence is performed before accessing the flash device
0xC80[7]	OEM	RESET_PIN_EN Enable reset pin	No	0	0 - External reset pin is not enabled 1 - External reset pin is enabled
0xC80[11:8] (BOOT_CONFIG_ MISC)	OEM	xSPI FLASH Dummy Cycle	No	0	0 – Dummy cycles is auto-probed Others – User specified dummy cycles for Read command
0xC80[15:12] (BOOT_CONFIG_ MISC)	OEM	xSPI FLASH image size	No	0	0 – Image size equals to Secondary Image offset 1 – 1MB

Table continues on the next page...

Table 10-10. Fuse definition for Serial NOR over FlexSPI (continued)

Fuse	Config	Definitions	GPIO	Shipped Value	Settings
					2 – 2MB ... – ... 12 – 12MB 13 – 256KB 14 – 512KB 15 – 768KB
0xC80[23:16] (BOOT_CONFIG_ MISC)	OEM	xSPI FLASH_SEC_IMAGE_OFFSET	No	0	Offset = 256KB × fuse value
0x9A0[9:8]		FLASH_CONNECTION_SEL Select the FLASH connection options	No		0 - Connected via PORTA CS0 1 - Parallel Mode 2 - Connected Via PORTB CS0
0x9A0[10]		FLEXSPI_PIN_GROUP_SEL FlexSPI Pin Group Selection	No		0 - Primary group 1 - Secondary group

NOTE

If the xSPI FLASH Auto Probe feature is enabled, the following is the logic how this feature works with other fuse combinations:

- Flash Type - If Flash type is 0, the "xSPI FLASH Auto Probe Type" takes effect for the Flash type selection. If Flash Type is greater than 1, the "Flash Type" fuse is used for Flash type selection, ROM will issue specific command to probe the presence of Serial NOR FLASH.
- xSPI FLASH Frequency - This field is used for specifying the Flash working frequency.

10.6.1.2 FlexSPI Serial NOR Flash Boot Operation

The Boot ROM attempts to boot from Serial NOR flash if the BOOT_CFG1 [7:4] fuses are programmed to 0b’0000 as shown in the Serial NOR eFUSE Configuration table, then the ROM will initialize FlexSPI interface. FlexSPI interface initialization is a two-step process.

1. The ROM expects the 512-byte FlexSPI NOR configuration parameters (as explained in the next section) to be present at offset 0x400 in Serial NOR flash attached to FLEXSPI_A_SS0_B. The ROM can probe the presence of Serial NOR Flash and generate these configuration parameters accordingly via the combination of Fuses in the table above, or reads these configuration parameters using the read command specified by BOOT_CFG 2[2:0] with serial clock operating at 30 MHz.
2. ROM configures FlexSPI interface with the parameters provided in configuration block read from Serial NOR flash and starts the boot procedure. Refer to Table 10-18 for details regarding FlexSPI configuration parameters and to the FlexSPI NOR boot flow chart for detailed boot flow chart of FlexSPI NOR.

Both booting an XIP and non XIP image are supported from Serial NOR Flash. For XIP boot, the image has to be built for FlexSPI address space; and for non XIP, the image can be built to execute from internal RAM.

The Boot ROM supports booting from the secondary image in the Serial NOR flash, once the first image is failed to boot. To enable this feature, xSPI_FLASH_SEC_IMAGE_OFFSET must be burned.

NOTE

A non-XIP image's execute address space should NOT be overlapped with the reserved OCRAM region described in the section "Internal ROM/RAM memory map". And it is also highly recommended to avoid using address space near 0x00000000, typically up to 0x00000003.

10.6.1.3 FlexSPI NOR boot flow chart

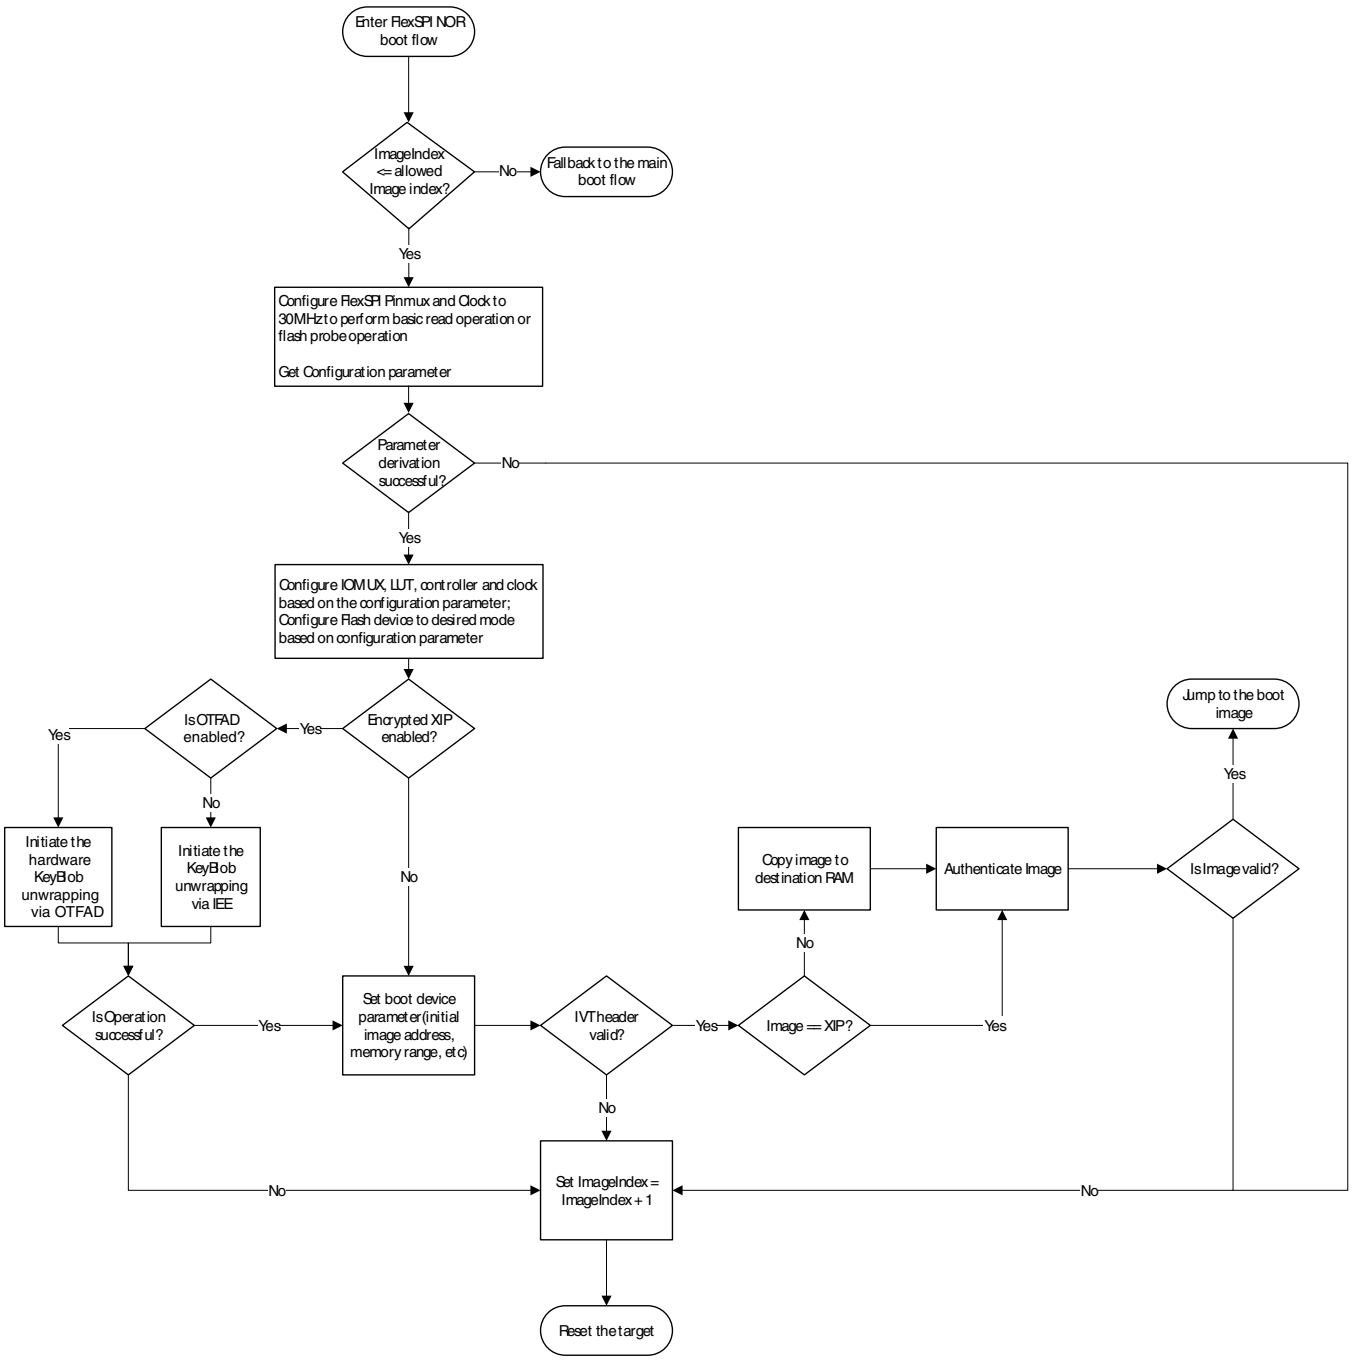

Figure 10-3. FlexSPI NOR boot flow

10.6.1.4 FlexSPI NOR Dual Image Boot

10.6.1.4.1 Overview

Dual Image Boot enables robust OTA/in-field firmware updates with automatic rollback. Two bootable images are stored in FlexSPI NOR at distinct offsets (“slots”). At power-on, the Boot ROM reads image versions, tries the newer image first, and falls back to the other image on failure. A FlexSPI internal remap mechanism maps the chosen image to the FlexSPI base address so both images can share the same linker script.

10.6.1.4.2 Memory Layout

Physical slots:

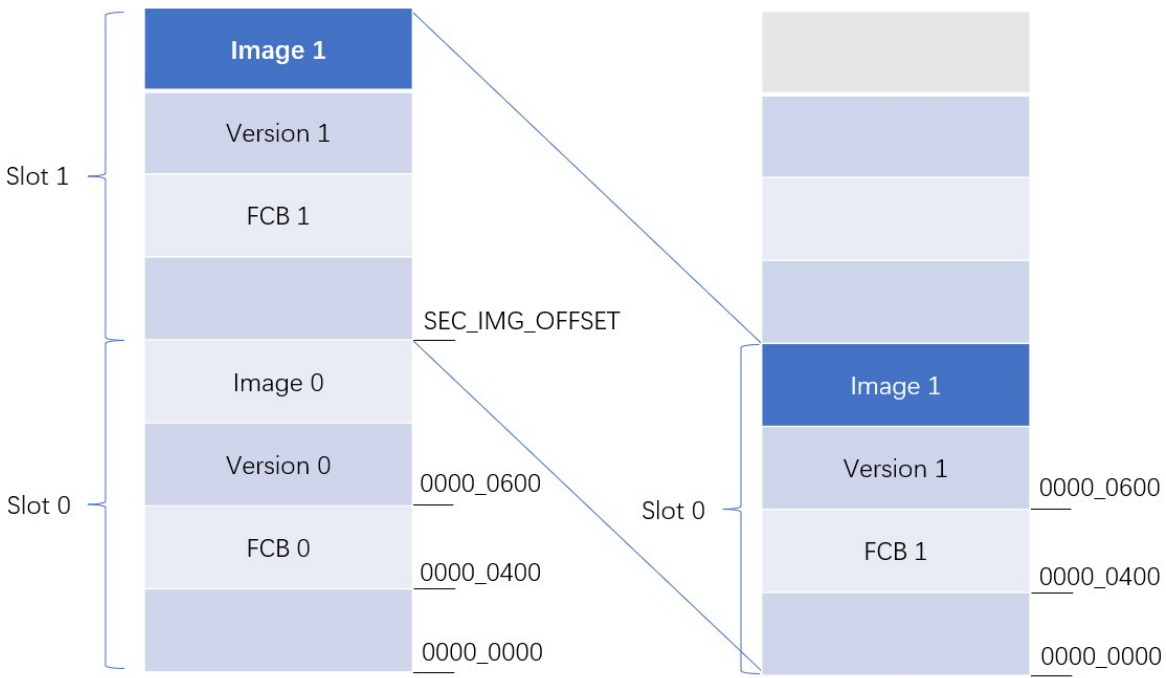

Figure 10-4. FlexSPI remap

- FCB = Flash Configuration Block.
- Version = monotonically increasing value in image header used by ROM for selection.
- Slot size/alignment: Use 256 KB alignment for ROM compatibility and performance.

10.6.1.4.3 Slot configuration: Secondary Image Offset and image size

Program xSPI_FLASH_SEC_IMG_OFFSET and xSPI_FLASH_IMG_SIZE before using dual-image boot.

SEC_IMAGE_OFFSET = (Second_Image_Offset_in_KB) / 256 Example: second image at 0x0004_0000 (256 KB) → 256 KB / 256 = 0x1.

This value is consumed by the Boot ROM to determine the remap offset and size for the secondary slot.

10.6.2 Serial NAND Flash Boot over FlexSPI

The boot ROM supports a number of Serial NAND Flash devices from different vendors. The Embedded Error Correction and Control (ECC) module in SPI NAND devices are used to detect and correct the errors.

10.6.2.1 Serial NAND eFUSE Configuration

The boot ROM determines the configuration of external Serial NAND flash by parameters, either provided by eFUSE, or sampled on GPIO pins during boot. See below table for parameters details.

Table 10-11. Fuse definition for Serial NAND over FlexSPI

Fuse	Config	Definitions	GPIO	Shipped Value	Settings
BOOT_CFG1[1:0]	OEM	Search Stride for FCB and DBBT Search strides in terms of page	Yes	0	0 - 64 1 - 128 2 - 256 3 - 32
BOOT_CFG1[3:2]	OEM	Hold Time before access to Serial NAND	Yes	0	0 - Hold time determined by Read Status command 1 - 500us 2 - 1ms 3 - 3ms
BOOT_CFG1[4]	OEM	Column address width	Yes	0	0 - 12 bits 1 - 13 bits
BOOT_CFG1[5]	OEM	Default safe communication frequency	Yes	0	0 – High Speed (50MHz) 1 – Low Speed (30MHz)
BOOT_CFG1[7:6]	OEM	Primary boot device selection	Yes	0	00 – Serial NOR 11 – Serial NAND
BOOT_CFG2[0]	OEM	Boot Search Count of FCB and DBBT	Yes	0	0 - 1 1 - 2
BOOT_CFG2[2:1]	OEM	CS de-asserted interval between two commands	Yes	0	0 – 100ns 1 – 200ns

Table continues on the next page...

Table 10-11. Fuse definition for Serial NAND over FlexSPI (continued)

Fuse	Config	Definitions	GPIO	Shipped Value	Settings
					2 – 400ns 3 – 50ns
BOOT_CFG2[3]	OEM	FlexSPI instance	Yes		0 - FlexSPI1 1 - FlexSPI2
0x9A0[9:8]	OEM	FLASH_CONNECTION_SEL	No	0	Flash connection section. 0 - PORTA 2 - PORTB
0x9A0[10]	OEM	FLEXSPI_PIN_GROUP_SEL	No	0	FlexSPI Pin group selection. 0 - Primary group 1 - 2nd pin group
0xC80[4:0]	OEM	PAGE_READ_TIME	No	0	ROM waits an interval between page read and read cache command. 0 - 75µs Others - PAGE_READ_TIME * 10µs This fuse takes effect if the BYPASS_READ_STATUS fuse is blown.
0xC80[7]	OEM	SPI NAND BOOT - Override Busy Offset	No	0	0 – Use default busy bit offset 0 1 – Override default busy bit offset using Busy bit offset
0xC80[13:8]	OEM	SPI NAND BOOT - Busy Bit offset	No	0	
0xC80[14]	OEM	BYPASS_ECC_READ	No	0	Bypass ECC read if the default does not support ECC feature.
0xC80[15]	OEM	BYPASS_READ_STATUS	No	0	Bypass the FLASH busy check via read status command. Use PAGE_READ_TIME FUSE field instead.
0xC80[23:16]	OEM	Page Read Command	No	0	Available only if it is not 0

Table continues on the next page...

Table 10-11. Fuse definition for Serial NAND over FlexSPI (continued)

Fuse	Config	Definitions	GPIO	Shipped Value	Settings
0xC80[31:24]	OEM	Cache Read command	No	0	Available only if it is not 0

NOTE

BOOT_CFGx sampled on GPIO pins depends on BT_FUSE_SEL setting.

NOTE

All the fuse fields on 0xC80 are defined for the NAND FLASH device which does not support the de-facto SPI NAND standard. For all the existing ECC-free SPI NAND FLASH, these fuse fields are not needed.

10.6.2.2 FlexSPI NAND Flash Boot Flow and Boot Control Blocks (BCB)

There are two BCB data structures:

- FCB
- DBBT

As part of the NAND media initialization, the ROM driver uses safe NAND timings to search for a Firmware Configuration Block (FCB) that contains the optimum NAND timings, page address of Discovered Bad Block Table (DBBT) Search Area and start page address of primary and secondary firmware.

The built-in HW ECC in Serial NAND device is used during data read, the FCB data structure is protected using CRC checksum. Driver reads raw 2048 bytes of first sector and runs through CRC check that determines whether FCB data is valid or not.

If the FCB is found, the optimum NAND timings are loaded for further reads. If the ECC fails, or the fingerprints do not match, the Block Search state machine increments page number to Search Stride number of pages to read for the next BCB until SearchCount pages have been read.

If search fails to find a valid FCB, the NAND driver responds with an error and the boot ROM enters into serial download mode.

The FCB contains the page address of DBBT Search Area, and the page address for primary and secondary boot images. DBBT is searched in DBBT Search Area just like how FCB is searched. After the FCB is read, the DBBT is loaded, and the primary or secondary boot image is loaded using starting page address from FCB.

Figure 10-5 shows the state diagram of FCB search.

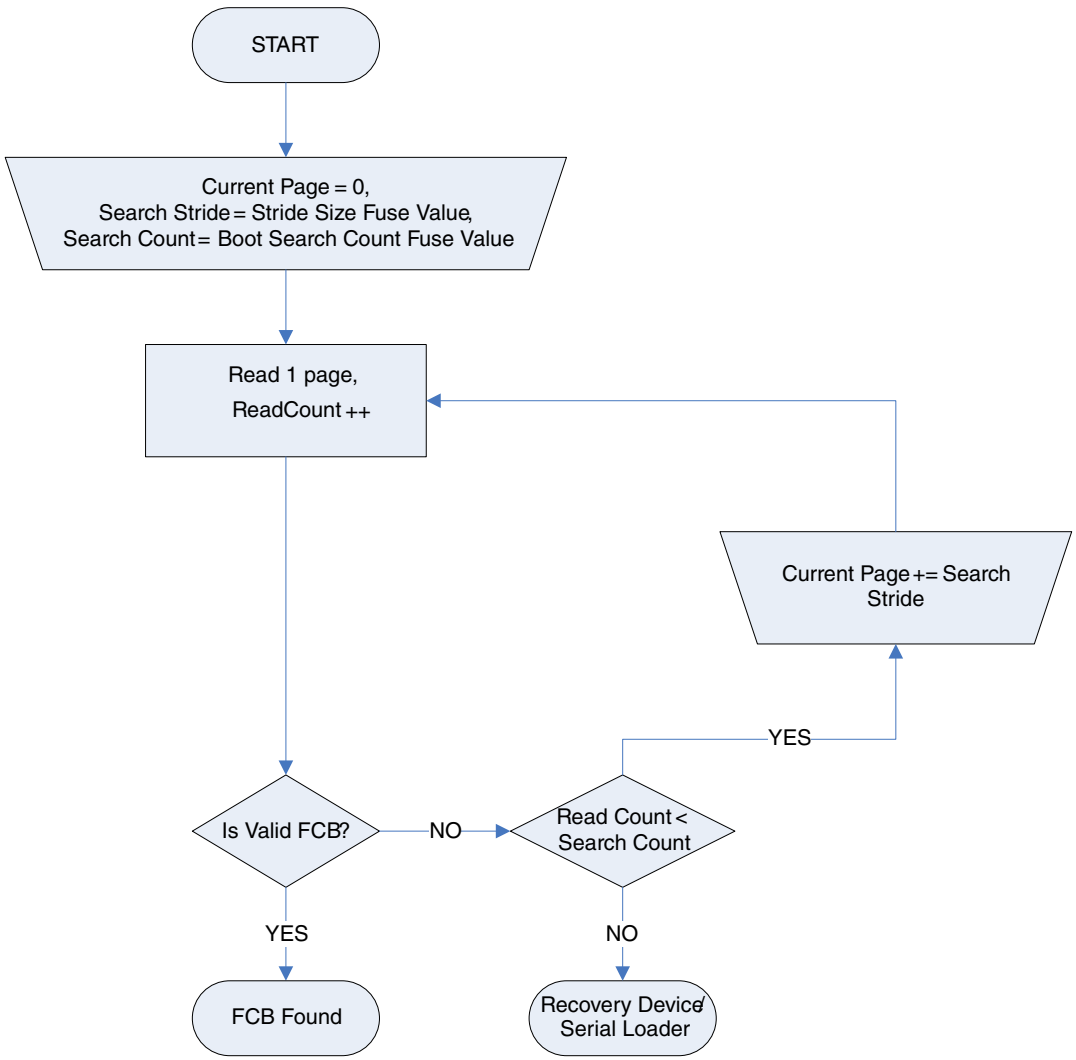

Figure 10-5. FCB Search Flow

After FCB is found, the boot ROM searches for the Discovered Bad Blocks Table (DBBT). If DBBTSearchStartPage is 0 in the FCB, then ROM assumes that there are no bad blocks in the NAND device boot area. See Figure 10-6 for the DBBT search flow.

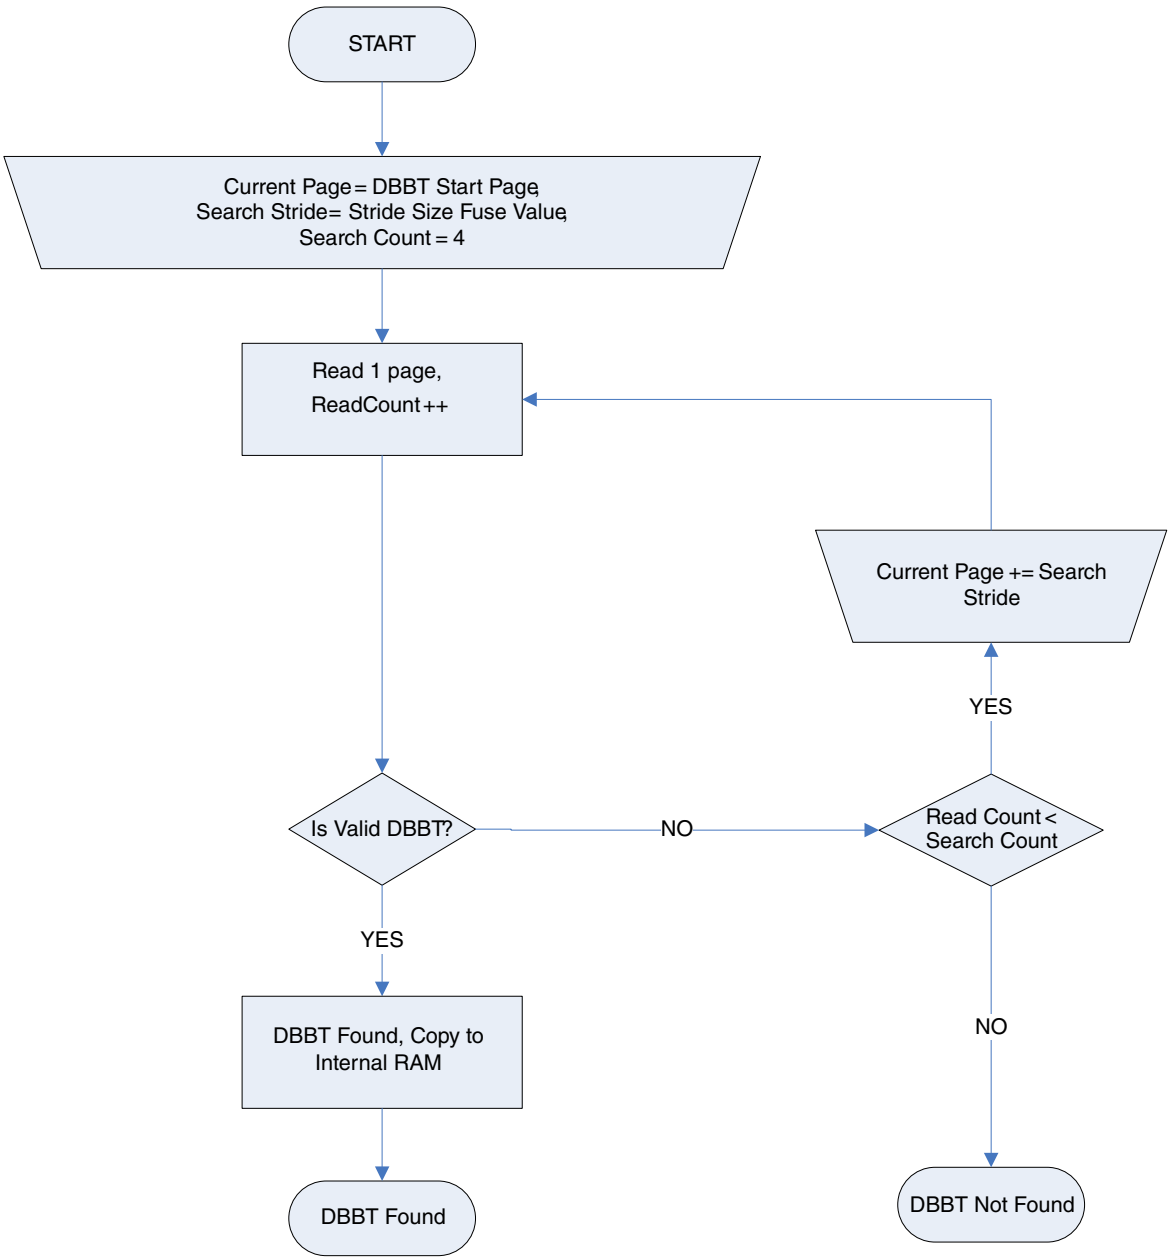

Figure 10-6. DBBT Search Flow

If during primary image read there is a page with a number of errors higher than ECC can correct, the boot ROM will turn on PERSIST_SECONDARY_BOOT bit and perform SW reset (After SW reset, secondary image is used).

If during secondary image read there is a page with number of errors higher than ECC can correct, the boot ROM goes to serial downloader.

10.6.2.3 Firmware Configuration Block

The FCB is at the first page in the first good block. The FCB should be present at each search stride of the search area.

The search area contains copies of the FCB at each stride distance, in case the first Serial NAND block becomes corrupted, the ROM will find its copy in the next Serial NAND block. The search area should span over at least two Serial NAND blocks. The location information for DBBT search area and images are all specified in the FCB. The following table shows the Flash Control Block Structure.

Table 10-12. Flash Control Block Structure

Name	Offset	Size Bytes	Description
crcChecksum	0x000	4	Checksum
fingerprint	0x004	4	0x4E46_4342 ASCII: “NFCB”
version	0x008	4	0x0000_0001
DBBTSearchStartPage	0x00C	4	Start Page address for bad block table search area
searchStride	0x010	2	Search stride for DBBT and FCB search. Not used by ROM Max value is 8.
searchCount	0x012	2	Copies of DBBT and FCB. Not used by ROM, max value is 8.
firmwareCopies	0x014	4	Firmware copies Valid range 1-4.
Reserved	0x018	40	Reserved for future use Must be set to 0.
firmwareInfoTable	0x40	64	This table consists of (up to 8 entries): **Field** / **Size** / **Description** StartPage / 4 / Start page of this firmware pageCount / 4 / Pages in this firmware

Table continues on the next page...

Table 10-12. Flash Control Block Structure (continued)

Name	Offset	Size Bytes	Description
			NOTE: The StartPage must be the first page of a NAND block.
Reserved	0x080	128	Reserved Must be set to 0
spiNandConfigBlock	0x100	512	Serial NAND configuration block over FlexSPI
Reserved	0x300	256	Must be set to 0

NOTE

1. The “crcChecksum” is calculated with an MPEG2 variant of CRC-32. See Table 10-13 for more details.
2. The “crcChecksum” calculation starts from fingerprint to the end of FCB, 1020 bytes in total.
3. The “spiNandConfigBlock” is FlexSPI NAND configuration block which consists of common FlexSPI memory configuration block and Serial NAND specified configuration parameters.

Table 10-13. CRC-32 variant algorithm

Property	Description
Width	32 bits
Polynomial	0x04C11DB7
Init Value	0xFFFFFFFF
Reflect in	False
Reflect Out	False
XOR Out	0x00000000

10.6.2.4 Discovered Bad Blocks Table (DBBT)

Table 10-14. DBBT Structure

Name	Offset	Size in Bytes	Decription
crcChecksum	0x000	4	Checksum
Fingerprint	0x004	4	32-bit word with a value of 0x4442_4254, in ASCII “DBBT”

Table continues on the next page...

Table 10-14. DBBT Structure (continued)

Name	Offset	Size in Bytes	Decription
Version	0x008	4	32-bit version number, this version of DBBT is 0x00000001
-	0x00C	4	Reserved
badBlockNumber	0x010	4	Number of bad blocks
Reserved	0x014	12	Must be filled with 0x00s
Bad Block entries	0x020	1024 (256*4)	Each bad block entry is a 32-bit value specifying the number of a found bad block. The number of valid bad block entries is specified by the badBlockNumber field, where valid bad block entries are stored sequentially starting at the beginning of the bad block entries segment. Unused bad block entries (those beyond the badBlockNumber) should be filled with 0xFs.

NOTE

1. Maximum badBlockNumber is 256.
2. The "crcChecksum" is calculated with the same algorithm as the one in FCB, from Fingerprint to the end of DBBT, 1052 bytes in total.

10.6.2.5 Bad block handling in ROM

During the firmware boot, at the block boundary, the Bad Block table is searched for a match to the next block.

If no match is found, the next block can be loaded. If a match is found, the block must be skipped and the next block checked.

10.6.3 Serial NOR and NAND Configuration based on FlexSPI Interface

The ROM SW supports Serial NOR and Serial NAND based on FlexSPI module, using a 448-bytes common FlexSPI configuration block and several specified parameters for Serial NOR and Serial NAND respectively. See the following sections for more details.

10.6.3.1 FlexSPI Configuration Block

FlexSPI Configuration block consists of parameters regarding specific Flash devices including read command sequence, quad mode enablement sequence (optional), etc.

Table 10-15. FlexSPI Configuration block

Name	Offset	Size(bytes)	Description
Tag	0x000	4	0x42464346, ascii: 'FCFB'
Version	0x004	4	[07:00] bugfix = 0 [15:08] minor [23:16] major = 1 [31:24] ascii 'V'
-	0x008	4	Reserved
readSampleClkSrc	0x00C	1	0 – internal loopback 1 – loopback from DQS pad 3 – Flash provided DQS
csHoldTime	0x00D	1	Serial Flash CS Hold Time Recommend default value is 0x03
csSetupTime	0x00E	1	Serial Flash CS setup time Recommended default value is 0x03
columnAdressWidth	0x00F	1	3 – For HyperFlash 12/13 – For Serial NAND, see the NAND FLASH datasheet to find the correct value 0 – Other devices
deviceModeCfgEnable	0x010	1	Device Mode Configuration Enable feature 0 – Disabled 1 – Enabled
deviceModeType	0x011	1	0 - Generic 1 - Quad Enable 2 - SPI-to-xSPI mode 3 - xSPI-to-SPI mode 4 - SPI-to-NoCmd mode
waitTimeCfgCommands	0x012	2	Wait time for all configuration commands, unit 100us. Available for device that support v1.1.0 FlexSPI configuration block. If it is greater than 0, ROM will wait waitTimeCfgCommands * 100us for all device memory configuration commands instead of using read status to wait until these commands complete.
deviceModeSeq	0x014	4	Sequence parameter for device mode configuration Bit[7:0] - number of LUT sequences for Device mode configuration command

Table continues on the next page...

Table 10-15. FlexSPI Configuration block (continued)

Name	Offset	Size(bytes)	Description
			Bit[15:8] - starting LUT index of Device mode configuration command Bit[31:16] - must be 0
deviceModeArg	0x018	4	Device Mode argument, effective only when deviceModeCfgEnable = 1
configCmdEnable	0x01C	1	Config Command Enable feature 0 – Disabled 1 – Enabled
-	0x01D	3	Reserved
configCmdSeqs	0x020	12	Sequences for Config Command, allow 3 separate configuration command sequences.
-	0x02C	4	Reserved
cfgCmdArgs	0x030	12	Arguments for each separate configuration command sequence.
-	0x03C	4	Reserved
controllerMiscOption	0x040	4	Bit0 – differential clock enable Bit1 – CK2 enable, must set to 0 in this silicon Bit2 – ParallelModeEnable Bit3 – wordAddressableEnable Bit4 – Safe Configuration Frequency enable set to 1 for the devices that support DDR Read instructions Bit5 – Pad Setting Override Enable Bit6 – DDR Mode Enable, set to 1 for device supports DDR read command Bit 7 - DLLCR settings • 1: Use delay cell settings for PPI SDR Mode • 2: Use DLL Bit 8 - Second Pin group Bit 9 - Second DQS pin group Bit 10 - Write Mask Enable Bit 11 - Write Opt1 Clear
deviceType	0x044	1	1 – Serial NOR 2 – Serial NAND 3 - Serial RAM (HyperRAM/APMemory)
sflashPadType	0x045	1	1 – Single pad 2 – Dual pads 4 – Quad pads 8 – Octal pads
serialClkFreq	0x046	1	Chip specific value, for this silicon 1 – 30 MHz

Table continues on the next page...

Table 10-15. FlexSPI Configuration block (continued)

Name	Offset	Size(bytes)	Description
			2 – 50 MHz 3 – 60 MHz 4 – 80 MHz 5 – 100 MHz 6 – 120 MHz 7 – 133 MHz 8 – 166 MHz Other value: 30 MHz
lutCustomSeqEnable	0x047	1	0 – Use pre-defined LUT sequence index and number 1 - Use LUT sequence parameters provided in this block
-	0x048	8	Reserved
sflashA1Size	0x050	4	For SPI NOR, need to fill with actual size For SPI NAND, need to fill with actual size * 2
sflashA2Size	0x054	4	The same as above
sflashB1Size	0x058	4	The same as above
sflashB2Size	0x05C	4	The same as above
csPadSettingOverride	0x060	4	Set to 0 if it is not supported
sclkPadSettingOverride	0x064	4	Set to 0 if it is not supported
dataPadSettingOverride	0x068	4	Set to 0 if it is not supported
dqsPadSettingOverride	0x06C	4	Set to 0 if it is not supported
timeoutInMs	0x070	4	Maximum wait time during read busy status 0 – Disabled timeout checking feature Other value – Timeout if the wait time exceeds this value
commandInterval	0x074	4	Unit: ns Currently, it is used for SPI NAND only at high frequency
dataValidTime	0x078	4	Time from clock edge to data valid edge, unit ns. This field is used when the FlexSPI Root clock is less than 100 MHz and the read sample clock source is device provided DQS signal without CK2 support. [31:16] data valid time for DLLB in terms of 0.1 ns [15:0] data valid time for DLLA in terms of 0.1 ns
busyOffset	0x07C	2	busy bit offset, valid range :0-31
busyBitPolarity	0x07E	2	0 – busy bit is 1 if device is busy 1 – busy bit is 0 if device is busy
lookupTable	0x080	256	Lookup table
lutCustomSeq	0x180	48	Customized LUT sequence, see below table for details.
	0x1B0	16	Reserved for future use

Note:

1. To customize the LUT sequence for some specific device, users need to enable “lutCustomSeqEnable” and fill in corresponding “lutCustomSeq” field specified by command index below.
2. For Serial (SPI) NOR, the pre-defined LUT index is as follows:

Table 10-16. LUT sequence definition for Serial NOR

Command Index	Name	Index in lookup table	Description
0	Read	0	Read command Sequence
1	ReadStatus	1	Read Status command
2	WriteEnable	3	Write Enable command sequence
3	EraseSector	5	Erase Sector Command
4	PageProgram	9	Page Program Command
5	ChipErase	11	Full Chip Erase
6	Dummy	15	Dummy Command as needed
7-12	Reserved	2,4,6,7,8,10,12,13,14	All reserved indexes can be freely used for other purpose
13	NOR_CMD_LUT_SEQ_IDX_READ_SFDP	13	Read SFDP sequence in lookupTable id stored in config block
14	NOR_CMD_LUT_SEQ_IDX_RESTORE_NOCMD	14	Restore 0-4-4/0-8-8 mode sequence id in lookupTable stored in config block

3. For Serial (SPI) NAND, the pre-defined LUT index is as follows:

Table 10-17. LUT sequence definition for Serial NAND

Command Index	Name	Index in lookup table	Description
0	ReadFromCache	0	Read from cache
1	ReadStatus	1	Read Status
2	WriteEnable	3	Write Enable
3	BlockErase	5	Erase block
4	ProgramLoad	9	Program Load
5	ReadPage	11	Read page to cache
6	ReadEccStatus	13	Read ECC Status
7	ProgramExecute	14	Program Execute
8	ReadFromCacheOdd	4	Read from Cache while page in odd plane

Table continues on the next page...

Table 10-17. LUT sequence definition for Serial NAND (continued)

Command Index	Name	Index in lookup table	Description
9	ProgramLoadOdd	10	Program Load for pages within odd blocks
	Reserved	2,6,7,8,12,15	All reserved indexes can be freely used for other purposes

NOTE

1. All the pre-defined LUT indexes are only applicable to boot stage. User application can use the whole 16 LUT entries freely based on their requirement.
2. The FlexSPI NOR ROM APIs occupy LUT index 0-5. User application should **NOT** use these LUT indexes if the ROM API is called in their application frequently.

10.6.3.2 Serial NOR configuration block (512 bytes)

Table 10-18. Serial NOR configuration block

Name	Offset	Size (Bytes)	Description
memCfg	0	448	The common memory configuration block, see FlexSPI configuration block for more details
pageSize	0x1C0	4	Page size in terms of bytes, not used by ROM
sectorSize	0x1C4	4	Sector size in terms of bytes, not used by ROM
ipCmdSerialClkFreq	0x1C8	1	Chip specific value, not used by ROM 0 – No change, keep current serial clock unchanged 1 – 30 MHz 2 – 50 MHz 3 – 60 MHz 4 – 80 MHz 5 – 100 MHz 6 – 120 MHz – 133 MHz
isUniformBlockSize	0x1C9	1	Device has uniform block size

Table continues on the next page...

Table 10-18. Serial NOR configuration block (continued)

Name	Offset	Size (Bytes)	Description
			0 - No, block size != sector size 1 - Yes, block size = sector size
isDataOrderSwapped	0x1CA	1	The data order is swapped in OPI DDR mode 0 - Not swapped 1 - Swapped (this is applicable to Macronix MX25UM512/256/128 series only)
Reserved	0x1CB	5	Reserved
blockSize	0x1D0	4	blockSize
flashStateCtx	0x1D4	4	Flash State Context after being configured [7:0] Flash POR Mode: 0x00 - Extended SPI mode 0x42 - QPI DDR mode 0x82 - OPI DDR mode -- [15:8] Flash Current Mode: 0x00 - Extended SPI mode 0x42 - QPI DDR mode 0x82 - OPI DDR mode -- [23:16] Reserved -- [31:24] Flash Restoring Sequence: 0x6 - Send 0x66_0x99 (Micron Octal Flash) 0x7 - Send 0x6699_0x9966 (Macronix Octal Flash) 0x8 - Send 0x06 0xFF (Adesto Octal Flash)
Reserved	0x1D8	24	Reserved

10.6.3.3 Serial NAND configuration block (512 bytes)

Table 10-19. Serial NAND configuration block

Name	Offset	Size (Bytes)	Description
memCfg	0	448	The common memory configuration block, see FlexSPI configuration block for more details
pageDataSize	0x1C0	4	Page size in terms of bytes, usually, it is 2048 or 4096
pageTotalSize	0x1C4	4	It equals to 2 ^ width of column adddress
pagesPerBlock	0x1C8	4	Pages in one block
bypassReadStatus	0x1CC	1	0 – Read Status Register 1 – Bypass Read status register
bypassEccRead	0x1CD	1	0 – Perform ECC read 1 – Bypass ECC read
hasMultiPlanes	0x1CE	1	0 – Only 1 plane 1 – Has two planes
skippOddBlocks	0x1CF	1	0 – Read Odd blocks 1 – Skip Odd blocks
eccCheckCustomEnable	0x1D0	1	0 – Use the common ECC check command and ECC related masks 1 - Use ECC check related masks provided in this configuration block
ipCmdSerialClkFreq	0x1D1	1	Chip specific value, not used by ROM 0 – No change, keep current serial clock unchanged 1 – 30 MHz 2 – 50 MHz 3 – 60 MHz 4 – 75 MHz 5 – 80 MHz 6 – 100 MHz 7 – 133 MHz 8 – 166 MHz
readPageTimeUs	0x1D2	2	Wait time during page read, this field will take effect on if the bypassReadStatus is set to 1. **NOTE:** Only applicable to ROM.

Table continues on the next page...

Table 10-19. Serial NAND configuration block (continued)

Name	Offset	Size (Bytes)	Description
eccStatusMask	0x1D4	4	ECC Status Mask
eccFailureMask	0x1D8	4	ECC Check Failure mask
blocksPerDevice	0x1DC	4	Blocks in a Serial NAND
Reserved	0x1ED	32	Reserved for future use

Below is an example of Serial NAND configuration block for Winbond W25N01GVZEIG:

```
const flexspi_nand_config_t kSerialNandCfgBlk =
{
    .memConfig =
    {
        .tag = FLEXSPI_CFG_BLK_TAG,
        .version = FLEXSPI_CFG_BLK_VERSION,
        .readSampleClkSrc = kFlexSPIReadSampleClk_LoopbackInternally,
        .dataHoldTime = 3,
        .dataSetupTime = 3,
        .columnAddressWidth = 12,
        .deviceModeCfgEnable = 1,
        .deviceModeSeq = { 1, 2 },
        .deviceType = kFlexSpiDeviceType_SerialNAND,
        .sflashPadType = kSerialFlash_4Pads,
        .serialClkFreq = kFlexSpiSerialClk_50MHz,
        .lutCustomSeqEnable = 0,
        .sflashA1Size = 128 * 1024 * 1024U * 2, // Flash size = 2 * actual data size
(exclude spare space)
        .lookupTable =
        {
            // Read cache 4 I/0
            [4 * NOR_CMD_LUT_SEQ_IDX_READ] = FLEXSPI_LUT_SEQ(CMD_SDR, FLEXSPI_1PAD, 0xEB,
CADDR_SDR, FLEXSPI_4PAD, 0x10),
            [4 * NOR_CMD_LUT_SEQ_IDX_READ + 1] = FLEXSPI_LUT_SEQ(DUMMY_SDR, FLEXSPI_4PAD,
0x04, READ_SDR, FLEXSPI_4PAD, 0x80),
            // Clear Status1 flag
            [4 * 2] = FLEXSPI_LUT_SEQ(CMD_SDR, FLEXSPI_1PAD, 0x1F, CMD_SDR, FLEXSPI_1PAD,
0xA0),
            [4 * 2 + 1] = FLEXSPI_LUT_SEQ(CMD_SDR, FLEXSPI_1PAD, 0x00, STOP, FLEXSPI_1PAD,
0x00),
            // Read Page
            [4 * NAND_CMD_LUT_SEQ_IDX_READPAGE] = FLEXSPI_LUT_SEQ(CMD_SDR, FLEXSPI_1PAD,
0x13, RADDR_SDR, FLEXSPI_1PAD, 0x18),
            // Read Status
            [4 * NAND_CMD_LUT_SEQ_IDX_READSTATUS] = FLEXSPI_LUT_SEQ(CMD_SDR, FLEXSPI_1PAD,
0x0F, CMD_SDR, FLEXSPI_1PAD, 0xC0),
            [4 * NAND_CMD_LUT_SEQ_IDX_READSTATUS + 1] = FLEXSPI_LUT_SEQ(READ_SDR,
FLEXSPI_1PAD, 0x01, STOP, FLEXSPI_1PAD, 0),

            // Write Enable
            [4 * NAND_CMD_LUT_SEQ_IDX_WRITEENABLE] = FLEXSPI_LUT_SEQ(CMD_SDR, FLEXSPI_1PAD,
0x06, STOP, FLEXSPI_1PAD, 0),

            // Page Program Load 4x
            [4 * NAND_CMD_LUT_SEQ_IDX_PROGRAMLOAD] = FLEXSPI_LUT_SEQ(CMD_SDR, FLEXSPI_1PAD,

0x0F, CMD_SDR, FLEXSPI_1PAD, 0xC0),
            [4 * NAND_CMD_LUT_SEQ_IDX_READECCSTAT + 1] = FLEXSPI_LUT_SEQ(READ_SDR,
FLEXSPI_1PAD, 0x01, STOP, FLEXSPI_1PAD, 0),
        },
    },
    .pageDataSize = 2048,
    .pageTotalSize = 4096,
    .pagesPerBlock = 64,
};
```

10.6.4 Parallel NAND flash Boot over SEMC

The boot ROM supports a number of Parallel SLC NAND flash devices from different vendors. Both the Error Correction and Control (ECC) module in NAND device and software ECC algorithm (SECDED) in boot ROM can be used to detect the errors, based on the fuse settings.

10.6.4.1 Parallel NAND eFuse Configuration

The boot ROM determines the configuration of external Parallel NAND flash by parameters, either provided by eFuse, or sampled on GPIO pins, during boot. See below table for parameters details:

Table 10-20. Fuse definition for Parallel NAND over SEMC

Fuse	Config	Definitions	GPIO	Shipped Value	Settings
BOOT_CFG1[0]	OEM	Boot Search count of FCB and DBBT	Yes	0	0 – 1 1 – 2
BOOT_CFG1[4:1]	OEM	Search stride for FCB and DBBT in terms of pages	Yes	0000	0000 – 64 Others – 2 ^ BOOT_SEARCH_STRIDE
BOOT_CFG1[7:5]	OEM	Primary boot device selection	Yes	000	001 – Parallel NAND
BOOT_CFG>2[0]	OEM	NAND ONFI compliant	Yes	0	0 – ONFI 1.0 1 – Non-ONFI
BOOT_CFG2 [1]	OEM	SEMC EDO Mode	Yes	0	0 – EDO Mode 1 – Non-EDO Mode
BOOT_CFG2 [2]	OEM	SEMC Access Command	Yes	0	0 – IPG 1 – AXI
0x6E0[20:19]	OEM	SEMC BCH mode	No	0	0 - BCH is not enabled 1 - BCH4

Table continues on the next page...

Table 10-20. Fuse definition for Parallel NAND over SEMC (continued)

Fuse	Config	Definitions	GPIO	Shipped Value	Settings
					2 - BCH8
0xC80[3]	OEM	I/O port size			0 - 8 bit 1 - 16 bit
0xC80[4]	OEM	ECC algorithm selection	Yes	0	0 - NAND flash-built-in ECC 1 - Software ECC (SECDED) **NOTE:** For “ECC selection” option, it can only be set as Device ECC When NAND device has built-in ECC module and the ECC module is enabled by default.
0xC80[5]	OEM	RDY pin polarity	No		0 – Low active 1 – High active
0xC80[6]	OEM	Ready check type	No		0 – Status Register 1 – R/B# pin
0xC80[7]	OEM	SEMC clock frequency			0 - 133MHz (2nd max) 1 - 166MHz (Max)
0xC80[10:8]	OEM	Row Column address mode	No	000	Applicable only for Non-ONFI device 00x – 5 bytes (CA2+RA3) 010 – 4 bytes (CA2+RA2) 011 – 3 bytes (CA2+RA1) 10x – 4 bytes (CA1+RA3) 110 – 3 bytes (CA1+RA2) 111 – 2 bytes (CA1+RA1)
0xC80[13:11]	OEM	Column address width	No	000	Applicable only for Non-ONFI device 000 – 12 bits 001 – 09 bits 010 – 10 bits 011 – 11 bits 100 – 13 bits 101 – 14 bits 110 – 15 bits 111 – 16 bits
0xC80[14]	OEM	Status command type	No	0	Applicable only for Non-ONFI device 0 – Common

Table continues on the next page...

Table 10-20. Fuse definition for Parallel NAND over SEMC (continued)

Fuse	Config	Definitions	GPIO	Shipped Value	Settings
					1 – Enhanced
0xC80[18:16]	OEM	Pages in block	No	000	Applicable only for Non-ONFI device 000 – 128 pages 001 – 8 pages 010 – 16 pages 011 – 32 pages 100 – 64 pages 101 – 256 pages 110 – 512 pages 111 – 1024 pages
0xC80[20:19]	OEM	PCS Selection	No	0	PCS Selection 0 - CS0 1 - CS1 2 - CS2 3 - CS3
0xC80[24]	OEM	Device ECC initial status	No	0	Applicable only for ONFI 1.0 device 0 – Enabled 1 – Disabled
0xC80[27:25]	OEM	ONFI timing mode	No		000 - Mode0 -10MHz 001 - Mode1 -20MHz 010 - Mode2 -28MHz 011 - Mode3 -33MHz 100 - Mode4 -40MHz 101 - Mode5 -50MHz 11x - Fastest Mode

10.6.4.2 Parallel NAND Flash Boot Control Blocks (BCB)

There are two BCB data structures:

- Firmware Configuration Block (FCB)
- Discovered Bad Blocks Table (DBBT)

As part of the Parallel NAND media initialization, the ROM driver uses proper Parallel NAND parameters specified by FUSE to search for an FCB that contains the complete Parallel NAND parameters, page address of DBBT Search Area and Image info, including image copies, start page address and image size in terms of pages for each image.

FCB data structure is protected using Embedded ECC module in Parallel NAND devices or software ECC in ROM. The ROM driver reads 2048 bytes of first sector and checks the ECC check status to determine whether FCB data is valid or not.

If the FCB is found, the complete NAND parameters (Parallel NAND configuration block) are loaded for further reads, if the ECC fails, or the fingerprint does not match, or the CRC checksum does not match, the Block Search state machine increments page number to Search Stride number of pages to read for the next FCB until Search Count pages have been read.

If search fails to find a valid FCB, the Parallel NAND driver responds with an error and the boot ROM enters into Recovery boot mode (Secondary boot, if it is enabled, or Serial download mode).

The FCB contains the page address of DBBT Search Area, and the info for images. DBBT is searched in DBBT Search area just like how FCB is searched. After the FCB is read, the DBBT is loaded, then the boot image is loaded using starting page address from FCB.

10.6.4.3 Firmware Configuration Block (FCB)

The FCB is at the first page in the first good block. The FCB should be present at each search stride of the search area.

The search area contains copies of the FCB at each stride distance, in case the first Serial NAND block becomes corrupted, the ROM will find its copy in the next Parallel NAND block. The search area should span over at least two Parallel NAND blocks. The location information for DBBT search area and images are all specified in the FCB. Below Table shows the FCB Structure.

Name	offset	Size (Bytes)	Description
bcbHeader	0x000	12	See Table 10-21 for details
DBBTSerachAreaStartPage	0x00c	4	Start Page address for bad block table search area
searchStride	0x010	2	Search stride for DBBT and FCB search. Not used by ROM Max value is 8.

Table continues on the next page...

searchCount	0x012	2	Copies of DBBT and FCB. Not used by ROM, max value is 8.
firmwareCopies	0x014	4	Firmware copies Valid range 1-4.
-	0x018	40	Reserved
firmwareTable	0x040	64	For details see Table 10-22
-	0x080	128	Reserved
nandConfig	0x100	256	Parallel NAND configuration block over SEMC
-	0x200	512	Reserved

Table 10-21. Header Description

Field	Size	Description
crcChecksum	4	Checksum
fingerprint	4	0x4E46_4342 ASCII: “NFCB”
version	4	0x0000_0001

Table 10-22. Table Descriptions

Field	Size	Description
startPage	4	Start page of this firmware
pagesInFirmware	4	Pages in this firmware

NOTE

- The “crcChecksum” is calculated with an MPEG2 variant of CRC-32.
- The “crcChecksum” calculation starts from fingerprint to the end of FCB, 1020 bytes in total.
- The “nandConfig” is SEMC NAND configuration block which consists of common SEMC memory configuration block and Parallel NAND specified configuration parameters. See Parallel NAND eFuse Configuration for more details.

10.6.4.4 Discovered Bad Blocks Table (DBBT)

Table 10-23. DBBT Structure

Name	offset	Size (Bytes)	Description
bcbHeader	0x000	12	See Table 10-24 for details
-	0x00C	4	Reserved
badBlockNumber	0x010	4	Number of bad blocks
-	0x014	12	Reserved
badBlockTable	0x020	1024 (256*4)	Each bad block entry is a 32-bit value specifying the number of a found bad block. The number of valid bad block entries is specified by the badBlockNumber field, where valid bad block entries are stored sequentially starting at the beginning of the bad block entries segment. Unused bad block entries (those beyond the badBlockNumber) should be filled with 0xFs.

Table 10-24. Header Description

Field	Size	Description
crcChecksum	4	Checksum
fingerprint	4	0x4442_4254 ASCII: “DBBT”
version	4	0x0000_0001

NOTE

- Maximum bad block number is 256.
- The "crcChecksum" is calculated with the same algorithm as the one in FCB, from Fingerprint to the end of DBBT, 1052 bytes in total.

10.6.4.5 Bad block handling in ROM

During firmware boot, at the block boundary, the Bad Block table is searched for a match to the next block.

If no match is found, the next block can be loaded. If a match is found, the block must be skipped and the next block is checked.

10.6.5 Parallel NAND configuration based on SEMC interface

The ROM SW supports Parallel NAND based on SEMC module, using an 80-bytes common SEMC configuration block and several specified parameters for Parallel NAND. See the following sections for more details.

10.6.5.1 SEMC Configuration Block

SEMC Configuration block consists of all parameters related to specific Flash devices.

Table 10-25. SEMC control block structure

Name	offset	Size (Bytes)	Description
tag	0x000	4	0x434D4553, ascii:"SEMC"
version	0x004	4	0x00010000 [07:00] bugfix = 0 [15:08] minor = 0 [31:16] major = 1

10.6.6 Expansion device

The ROM supports booting from the MMC/eMMC and SD/eSD compliant devices.

10.6.6.1 Expansion device eFUSE configuration

The SD/MMC/eSD/eMMC/SDXC boot can be performed using the USDHC ports. The port can be configured based on either the setting of the BOOT_CFG1[1] (Port Select) fuse or its corresponding GPIO overrides.

All USDHC ports support the fast boot. See this table for details:

Table 10-28. USDHC eFuse Descriptions

Fuse	Config	Definition	GPIO	Shipped value	Settings
BOOT_CFG1[0]	OEM	Fast boot support	Yes	0	MMC 0 - Normal boot 1 - Fast boot
BOOT_CFG1[1]	OEM	USDHC port selection	Yes	0	0 - USDHC-1 1 - USDHC-2
BOOT_CFG1[2]	OEM	SD loopback clock source sel (for SDR50 and SDR104 only)	Yes	0	0 - through the SD pad 1 - direct
BOOT_CFG1[3]	OEM	SD power cycle enable	Yes	0	0 - No power cycle 1 - Power cycle enabled via the SD_RST pad
BOOT_CFG1[5:4]	OEM	SD/MMC speed mode, and eMMC acknowledge enabled selection	Yes	00	MMC: 0x - Normal speed mode 1x - High-speed mode x0 - eMMC fast boot acknowledge disable x1 - eMMC fast boot acknowledge enable SD: 00 - Normal/SDR12 01 - High/SDR25 10 - SDR50 11 - SDR104
BOOT_CFG1[7:6]	OEM	Boot device selection	Yes	00	01 - SD/eSD/SDXC boot from the USDHC interface 10 - MMC/eMMC boot from the USDHC interface
BOOT_CFG2[0]	OEM	SD2 voltage selection	Yes	0	MMC: 0 - 3.3 V 1 - 1.8 V
BOOT_CFG2[2:1]	OEM	SD MMC bus width selection	Yes	00	SD: x0 - 1-bit x1 - 4-bit **NOTE:** To use 1-bit mode, the user has to disconnect the SD card's DATA3 line from SoC. MMC: 00 - 4-bit

Table continues on the next page...

Table 10-28. USDHC eFuse Descriptions (continued)

					01 - 8-bit 10 - 4-bit DDR (MMC 4.4) 11 - 8-bit DDR (MMC 4.4)
0x970[0]	OEM	eMMC pre-idle enabled selection	Yes	0	0 - Issue pre-idle command 1 - Do not issue
0x970[1]	OEM	USDHC2 reset polarity selection	Yes	0	0 - Reset active low 1 - Reset active high
0x970[2]	OEM	USDHC1 reset polarity selection	Yes	0	0 - Reset active low 1 - Reset active high
0x970[3]	OEM	USDHC1 voltage selection	Yes	0	0 - 3.3 V 1 - 1.8 V
0x970[5]	OEM	Power stable cycle selection	Yes	0	0 - 5 ms 1 - 2.5 ms
0x970[7:6]	OEM	Power cycle selection	Yes	00	00 - 20 ms 01 - 10 ms 10 - 5 ms 11 - 2.5 ms
0x970[9:8]	OEM	SD calibration step	Yes	00	SD 00 - 1 delay cell 01 - 2 delay cells 10 - 4 delay cells 11 - 6 delay cells
0x970[10]	OEM	DLL override selection	Yes	0	0 - DLL Slave Mode for SD/eMMC (delay 10, step 2) 1 - DLL Override Mode for SD/ eMMC
0x970[15]	OEM	Disable SDMMC Manufacture mode	Yes	0	0 - Enable 1 - Disable

The boot code supports these standards:

- MMCv4.4 or less
- eMMCv4.4 or less
- SDv2.0 or less
- eSDv2.10 rev-0.9, with or without FAST_BOOT
- SDXCv3.0

The MMC/SD/eSD/SDXC/eMMC can be connected to any of the USDHC blocks and can be booted by copying 4 KB of data from the MMC/SD/eSD/eMMC device to the internal RAM. After checking the Image Vector Table header value (0xD1) from program image, the ROM code performs a DCD check. After a successful DCD

extraction, the ROM code extracts from the Boot Data Structure the destination pointer and length of image to be copied to the RAM device from where the code execution occurs.

The maximum image size to load into the SD/MMC boot is 32 MB. This is due to a limited number of uSDHC ADMA Buffer Descriptors allocated by the ROM.

NOTE

The initial 4 KB of the program image must contain the IVT, DCD, and the Boot Data structures.

Table 10-29. SD/MMC frequencies

	SD	MMC	MMC (DDR mode)
Identification (KHz)	347.22		
Normal-speed mode (MHz)	25	20	25
High-speed mode (MHz)	50	40	50
UHSI SDR50 (MHz)	100		
UHSI SDR104 (MHz)	200		

NOTE

The boot ROM code reads the application image length and the application destination pointer from the image.

10.6.6.2 MMC and eMMC boot

This table provides the MMC and eMMC boot details.

Table 10-30. MMC and eMMC boot details

Normal boot mode	During the initialization (normal boot mode), the MMC frequency is set to 347.22 KHz. When the MMC card enters the identification portion of the initialization, the voltage validation is performed, and the ROM boot code checks the high-voltage settings and the card capacity. The ROM boot code supports both the high-capacity and low-capacity MMC/ eMMC cards. After the initialization phase is complete, the ROM boot code switches to a higher frequency (20 MHz in the normal boot mode or 40 MHz in the high-speed mode). The eMMC is also interfaced via the USDHC and follows the same flow as the MMC. The boot partition can be selected for an MMC4.x card after the card initialization is complete. The ROM code reads the BOOT_PARTITION_ENABLE field in the Ext_CSD[179] to get the boot partition to be set. If there is no boot partition mentioned in the BOOT_PARTITION_ENABLE field or the user partition was mentioned, the ROM boots from the user partition.

Table continues on the next page...

Table 10-30. MMC and eMMC boot details (continued)

eMMC4.3 or eMMC4.4 device supporting special boot mode	If using an eMMC4.3 or eMMC4.4 device that supports the special boot mode, it can be initiated by pulling the CMD line low. If the BOOT ACK is enabled, the eMMC4.3/eMMC4.4 device sends the BOOT ACK via the DATA lines and the ROM can read the BOOT ACK [S010E] to identify the eMMC4.3/eMMC4.4 device. The eMMC4.3/eMMC4.4 device with the "boot mode" feature can only be supported via the ESDHCV3-3 and with or without the BOOT ACK. If the BOOT ACK is enabled, the ROM waits 50 ms to get the BOOT ACK and if the BOOT ACK is received by the ROM. If BOOT ACK is disabled ROM waits 1 second for data. If the BOOT ACK or data was received, the eMMC4.3/eMMC4.4 is booted in the "boot mode", otherwise the eMMC4.3/eMMC4.4 boots as a normal MMC card from the selected boot partition. This boot mode can be selected by the BOOT_CFG1[0] (fast boot) fuse. The BOOT ACK is selected by the BOOT_CFG1[4].
eMMC4.4 device	If using the eMMC4.4 device, the Double Data Rate (DDR) mode can be used. This mode can be selected by the BOOT_CFG2[2:1] (bus width) fuse.

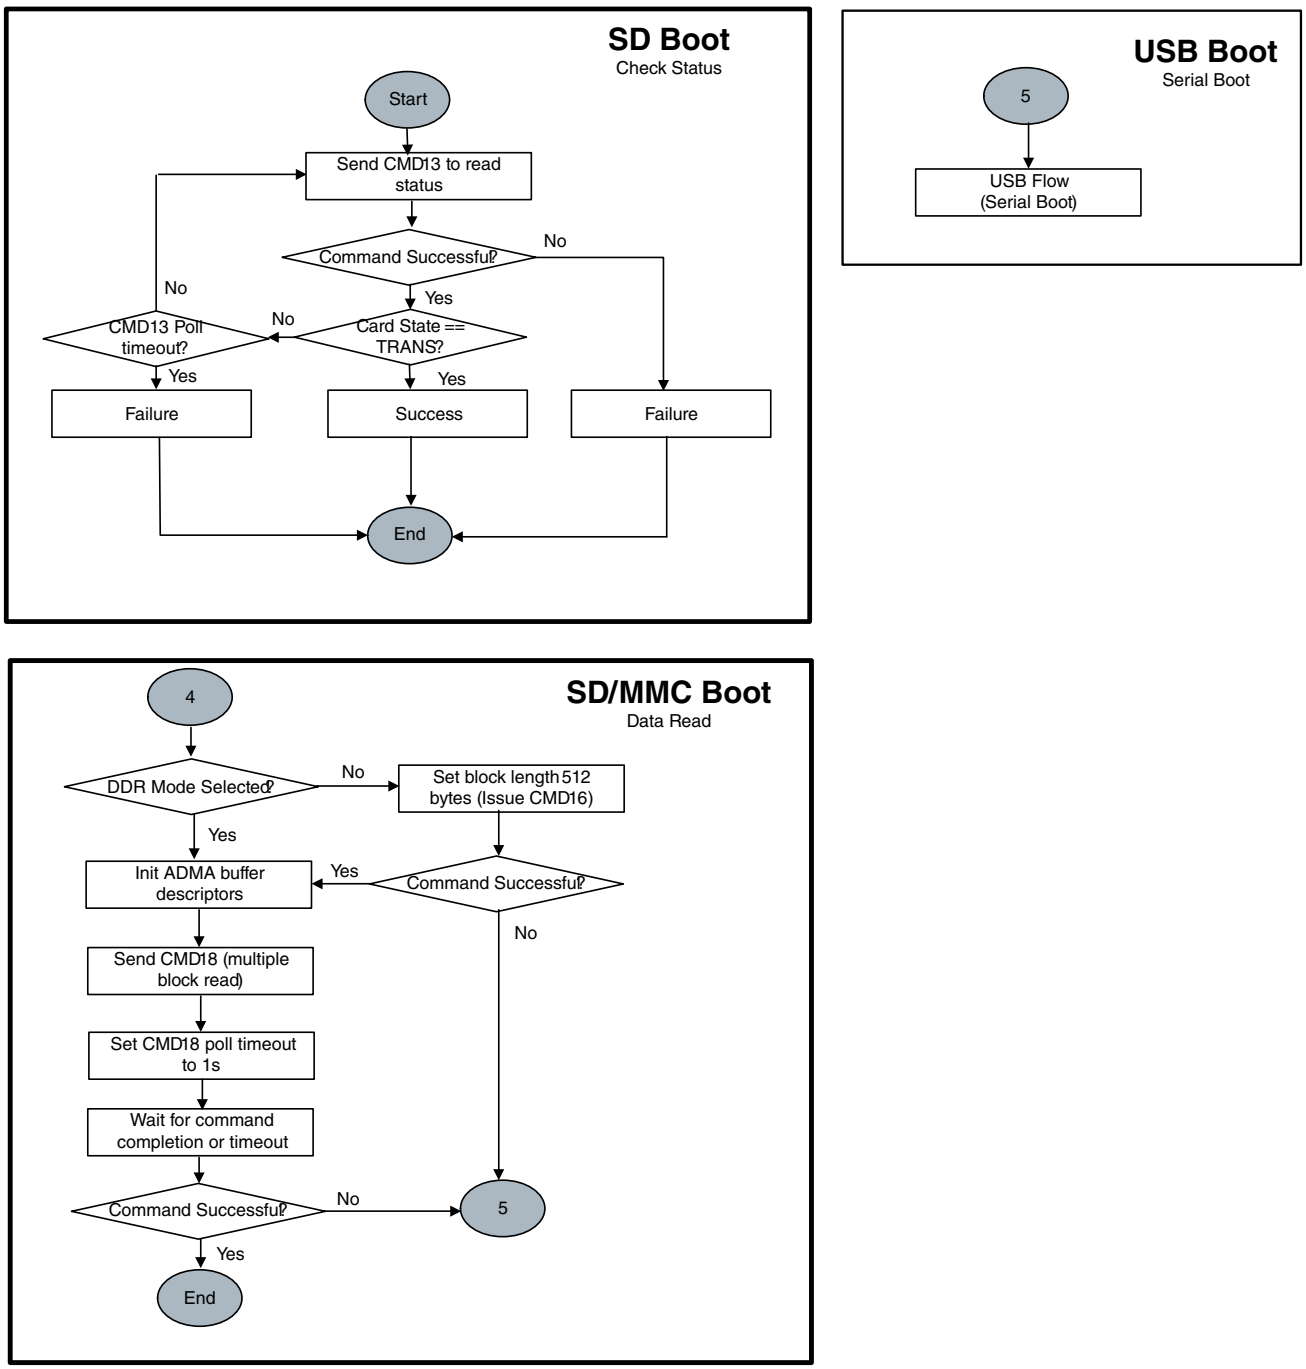

Figure 10-12. Expansion device (SD/eSD) boot flow (5 of 6)

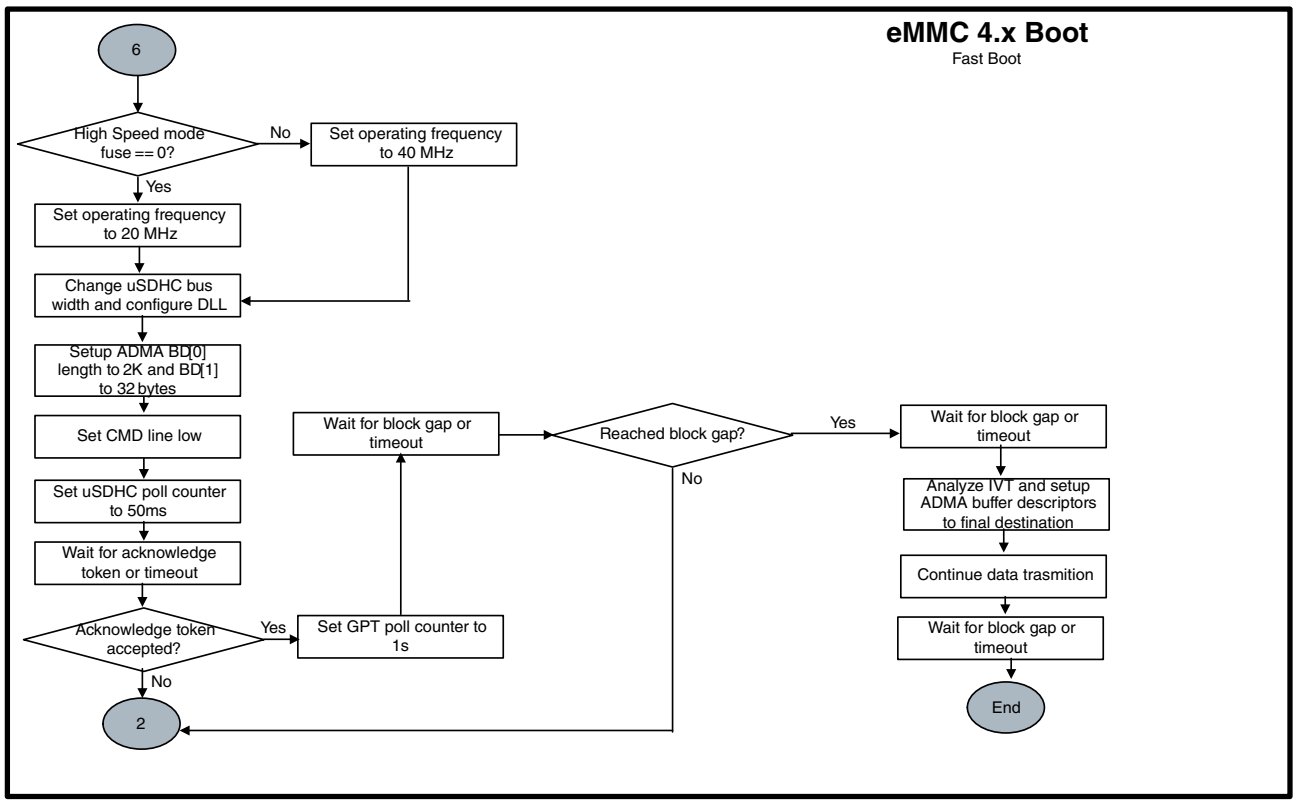

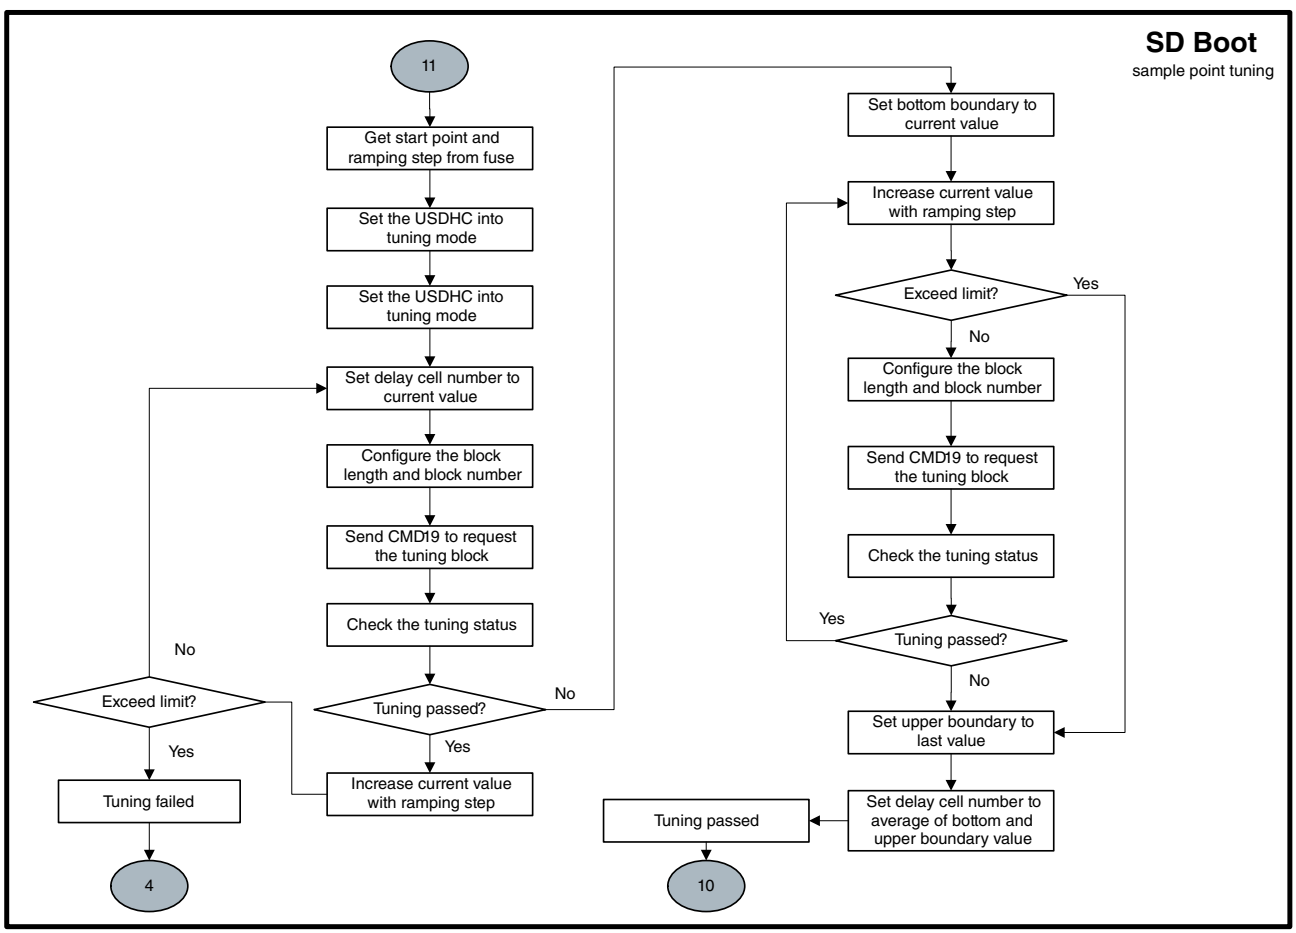

Figure 10-13. Expansion device boot flow (6 of 6)

10.6.6.3 SD, eSD, and SDXC

After the normal boot mode initialization begins, the SD/eSD/SDXC frequency is set to 347.22 kHz. During the identification phase, the SD/eSD/SDXC card voltage validation is performed. During the voltage validation, the boot code first checks with the high-voltage settings; if that fails, it checks with the low-voltage settings.

The capacity of the card is also checked. The boot code supports the high-capacity and low-capacity SD/eSD/SDXC cards after the voltage validation card initialization is done.

During the card initialization, the ROM boot code attempts to set the boot partition for all SD, eSD, and SDXC devices. If this fails, the boot code assumes that the card is a normal SD or SDXC card. If it does not fail, the boot code assumes it is an eSD card. After the initialization phase is over, the boot code switches to a higher frequency (25 MHz in the normal-speed mode or 50 MHz in the high-speed mode). The ROM also supports the FAST_BOOT mode booting from the eSD card. This mode can be selected by the BOOT_CFG1[0] (Fast Boot).

For the UHSI cards, the clock speed fuses can be set to SDR50 or SDR104 on USDHC1, USDHC2 ports. This enables the voltage switch process to set the signaling voltage to 1.8 V during the voltage validation. The bus width is fixed at a 4-bit width and a sampling point tuning process is needed to calibrate the number of the delay cells. If the SD Loopback Clock eFuse is set, the feedback clock comes directly from the loopback SD clock, instead of the card clock (by default). The SD clock speed can be selected by the BOOT_CFG1[5:4], and the SD Loopback Clock is selected by the BOOT_CFG1[2].

The UHSI calibration start value (MMC_DLL_DLY[6:0]) and the step value SD_CALIBRATION_STEP[1:0] can be set to optimize the sample point tuning process.

If the SD Power Cycle Enable eFuse is 1, the ROM sets the SD_RST pad low, waits for 5 ms, and then sets the SD_RST pad high. If the SD_RST pad is connected to the SD power supply enable logic on board, it enables the power cycle of the SD card. This may be crucial in case the SD logic is in the 1.8 V states and must be reset to the 3.3 V states.

The SDR50 and SDR104 boots are not supported on the USDHC1 and USDHC2 ports because there are no reset signals for those ports when connected in the IOMUX.

10.6.6.4 Redundant boot support for expansion device

The ROM supports the redundant boot for an expansion device. The primary or secondary image is selected, depending on the PERSIST_SECONDARY_BOOT setting. (see Table 10-8).

If the PERSIST_SECONDARY_BOOT is 0, the boot ROM uses address 0x0 for the primary image.

If the PERSIST_SECONDARY_BOOT is 1, the boot ROM reads the secondary image table from address 0x200 on the boot media and uses the address specified in the table.

Table 10-31. Secondary image table format

Reserved (chipNum)
Reserved (driveType)
tag
firstSectorNumber
Reserved (sectorCount)

Where:

- The tag is used as an indication of the valid secondary image table. It must be 0x00112233.
- The firstSectorNumber is the first 512-byte sector number of the secondary image.

For the secondary image support, the primary image must reserve the space for the secondary image table. See this figure for the typical structures layout on an expansion device.

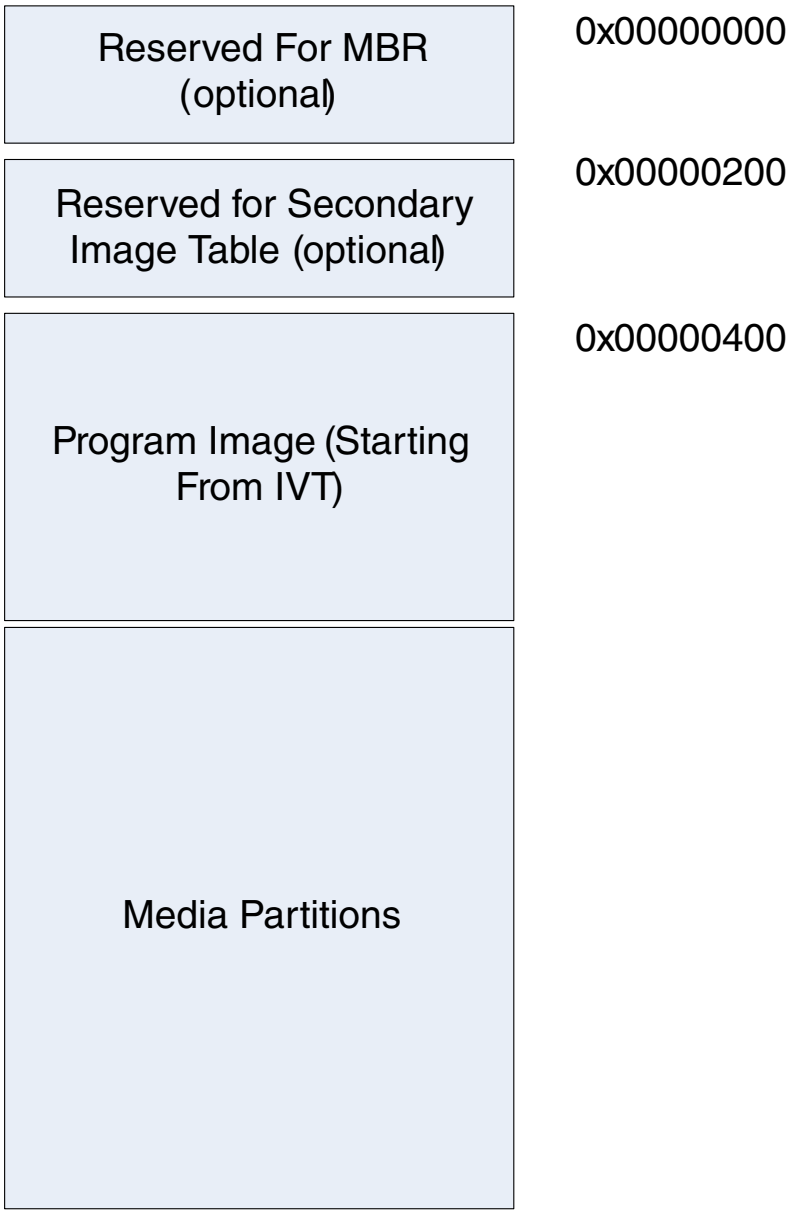

Figure 10-14. Expansion device structures layout

For the Closed mode, if there are failures during primary image authentication, the boot ROM turns on the PERSIST_SECONDARY_BOOT bit (see Table 10-8) and performs the software reset. (After the software reset, the secondary image is used.)

10.6.7 Serial NOR/EEPROM through LPSPI

The chip supports booting from serial memory devices, such as EEPROM and serial flash, using the LPSPI.

These ports are available for serial boot: LPSPI interfaces.

10.6.7.1 Serial NOR/EEPROM eFUSE configuration

The boot ROM code determines the type of device using the following parameters, provided by the eFUSE settings during boot.

Table 10-32. Serial NOR/EEPROM boot eFUSE descriptions

Fuse	Config	Definition	GPIO	Shipped value	Settings
RECOVERY_BOOT_EN (0xC70[24])	OEM	EEPROM recovery enable	No	0	0 - Disabled 1 - Enabled
SPI INSTANCE (0xC70[26:25])	OEM	Port select	No	00	00 - LPSPI1 01 - LPSPI2 10 - LPSPI3 (if applicable in the device) 11 - LPSPI4 (if applicable in the device)
SPI_MEM_SPEED (0xC70[28:27])	OEM	LPSPI Speed select	No	00	00 - 20 MHz 01 - 10 MHz 10 - 5 MHz 11 - 2 MHz

The LPSPI*n* block can be used as a boot device using the LPSPI interface for the serial ROM boot. The SPI interface is configured to operate at speed specified by SPI_MEM_SPEED fuse field.

The boot ROM copies 4 KB of data from the serial ROM device to the internal RAM. After checking the Image Vector Table header value (0xD1) from the program image, the ROM code performs a DCD check. After a successful DCD extraction, the ROM code extracts the destination pointer and length of image from the Boot Data Structure to be copied to the RAM device from where the code execution occurs.

NOTE

The Initial 4 KB of program image must contain the IVT, DCD, and the Boot Data Structures.

10.7 Program image

This section describes the data structures that are required to be included in the user's program image. The program image consists of:

- Image vector table—a list of pointers located at a fixed address that the ROM examines to determine where the other components of the program image are located.
- Boot data—a table that indicates the program image location, program image size in bytes, and the plugin flag.
- Device configuration data—IC configuration data.
- User code and data.

10.7.1 Image Vector Table and Boot Data

The Image Vector Table (IVT) is the data structure that the ROM reads from the boot device supplying the program image containing the required data components to perform a successful boot.

The IVT includes the program image entry point, a pointer to Device Configuration Data (DCD) and other pointers used by the ROM during the boot process. The ROM locates the IVT at a fixed address that is determined by the boot device connected to the Chip. The IVT offset from the base address for each boot device type is defined in the table below. The location of the IVT is the only fixed requirement by the ROM. The remainder or the image memory map is flexible and is determined by the contents of the IVT.

Table 10-33. Image Vector Table Offset and Initial Load Region Size

Boot Device Type	Image Vector Table Offset
FlexSPI NOR	4 Kbyte = 0x1000 bytes
SD/MMC/eSD/eMMC/SDXC	1 Kbyte = 0x400 bytes
SPI NOR/EEPROM SEMC NAND FlexSPI NAND	1 Kbyte = 0x400 bytes
Serial boot	0Kbyte = 0 byte

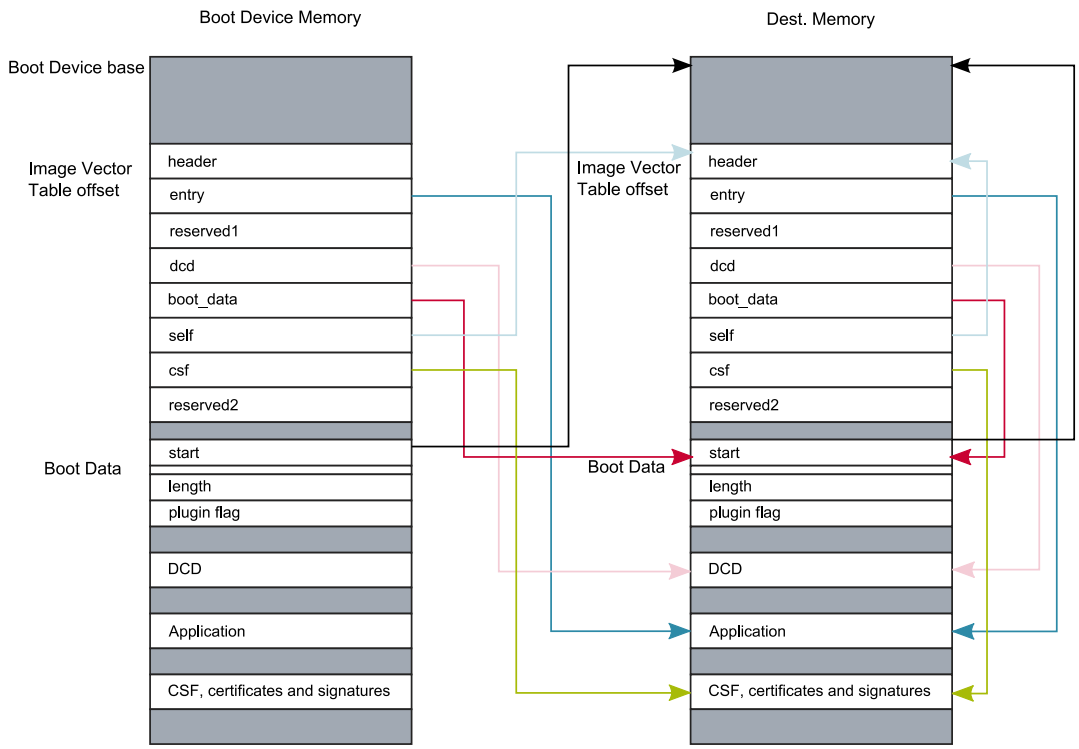

Figure 10-15. Image Vector Table

10.7.1.1 Image vector table structure

The IVT has the following format where each entry is a 32-bit word:

Table 10-34. IVT format

Name	Offset	Size(Bytes)	Description
header	0	4	IVT header
entry	4	4	Absolute address of the first instruction to execute from the image
reserved1	8	4	Reserved and should be zero
dcd	12	4	Absolute address of the image DCD. The DCD is optional so this field may be set to NULL if no DCD is required. See Device Configuration Data (DCD) for further details on the DCD.
boot data	16	4	Absolute address of the boot data

Table continues on the next page...

Table 10-34. IVT format (continued)

Name	Offset	Size(Bytes)	Description
self	20	4	Absolute address of the IVT. Used internally by the ROM
csf	24	4	Absolute address of the Command Sequence File (CSF) used by the HAB library. See High-Assurance Boot (HAB) for details on the secure boot using HAB. This field must be set to NULL if a CSF is not provided in the image
reserved2	28	36	Reserved and should be zero
XMCD	64	4	XMCD data structure offset

Figure 10-16 shows the IVT header format:

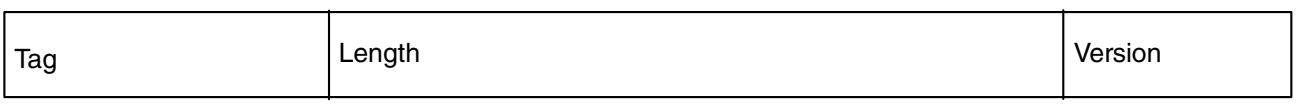

Figure 10-16. IVT header format

where:

```
Tag: A single byte field set to 0xD1
Length: a two byte field in big endian format containing the overall length of the IVT,
in bytes, including the header. (the length is fixed and must have a value of 32 bytes)
Version: A single byte field set to 0x40/0x41/0x42/0x43/0x44/0x45
```

10.7.1.2 Boot data structure

The boot data must follow the format defined in the table found here, each entry is a 32-bit word.

Table 10-35. Boot data format

start	Absolute address of the image
length	Size of the program image
plugin	Plugin flag (must be 0, not supported in this device, this field is ignored by the ROM)

10.7.2 Device Configuration Data (DCD)

Upon reset, the chip uses the default register values for all peripherals in the system. However, these settings typically are not ideal for achieving the optimal system performance and there are even some peripherals that must be configured before they can be used.

The DCD is a configuration information contained in the program image (external to the ROM) that the ROM interprets to configure various peripherals on the chip.

For example, some components (such as SDRAM) require some sequence of register programming as a part of the configuration before it is ready to be used. The DCD feature can be used to program the SEMC register to the optimal settings.

The ROM determines the location of the DCD table based on the information located in the Image Vector Table (IVT). See Image Vector Table and Boot Data for more details. The DCD table shown below is a big-endian byte array of the allowable DCD commands. The maximum size of the DCD is limited to 1768 B.

Figure 10-17. DCD data format

The DCD header is 4 B with the following format:

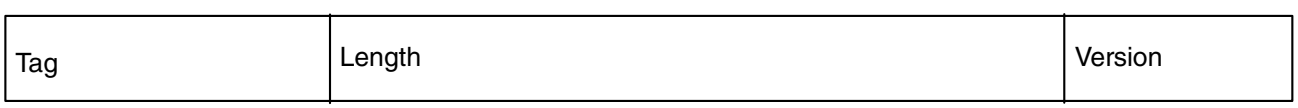

Figure 10-18. DCD header format

where:

```
Tag: A single-byte field set to 0xD2
Length: a two-byte field in the big-endian format containing the overall length of the DCD
(in bytes) including the header
Version: A single-byte field set to 0x41
```

10.7.2.1 Write data command

The write data command is used to write a list of given 1-, 2- or 4-byte values (or bitmasks) to a corresponding list of target addresses.

The Value/Mask fields are always 32-bits. If the parameter field specifies a smaller size, then the extra bytes must be zero.

The format of the write data command (in a big-endian byte array) is shown in this table:

Table 10-36. Write data command format

Tag	Length	Parameter
Address		
Value/Mask		
[Address]		
[Value/Mask]		
...		
[Address]		
[Value/Mask]		

where:

```
Tag: a single-byte field set to 0xCC
Length: a two-byte field in a big-endian format, containing the length of the Write Data
Command (in bytes) including the header
Address: the target address to which the data must be written
Value/Mask: the data value (or bitmask) to be written to the preceding address
```

The parameter field is a single byte divided into bitfields as follows:

Table 10-37. Write data command parameter field

7	6	5	4	3	2	1	0
flags					bytes		

where

```
bytes: the width of the target locations in bytes (either 1, 2, or 4)
flags: control flags for the command behavior
Data Mask = bit 3: if set, only specific bits may be overwritten at the target address
(otherwise all bits may be overwritten)
Data Set = bit 4: if set, the bits at the target address are overwritten with this flag
(otherwise it is ignored)
```

One or more target address and value/bitmask pairs can be specified. The same bytes' and flags' parameters apply to all locations in the command.

When successful, this command writes to each target address in accordance with the flags as follows:

Table 10-38. Interpretation of write data command flags

"Mask"	"Set"	Action	Interpretation
0	0	*address = val_msk	Write value
0	1	*address = val_msk	Write value
1	0	*address &= ~val_msk	Clear bitmask
1	1	*address |= val_msk	Set bitmask

NOTE

If any of the target addresses does not have the same alignment as the data width indicated in the parameter field, none of the values are written.

If any of the values are larger or any of the bitmasks are wider than permitted by the data width indicated in the parameter field, none of the values are written.

If any of the target addresses do not lie within the allowed region, none of the values are written. The list of allowable blocks and target addresses for the chip are provided below.

Table 10-39. Valid DCD address ranges

Address range	Start address	Last address
IOMUX Control (IOMUXC) registers	0x400E_8000	0x400E_8717
ANADIG PLL registers	0x40C8_4000	0x40C8_4393
CCM registers	0x40CC_0000	0x40CC_751F
SEMC registers	0x400D_4000	0x400D_412F
GPT1 registers	0x400E_C000	0x400E_C027
FlexSPI1 registers	0x400C_C000	0x400C_C42B
FlexSPI2 registers	0x400D_0000	0x400D_042B

10.7.2.2 Check data command

The check data command is used to test for a given 1-, 2-, or 4-byte bitmasks from a source address.

The check data command is a big-endian byte array with the format shown in this table:

Table 10-40. Check data command format

Tag	Length	Parameter
Address		
Mask		
[Count]		

where:

```
Tag: a single-byte field set to 0xCF
Length: a two-byte field in the big-endian format containing the length of the check data
command (in bytes) including the header
Address: the source address to test
Mask: the bit mask to test
Count: an optional poll count; If the count is not specified, this command polls
indefinitely
until the exit condition is met. If count = 0, this command behaves as for the NOP.
```

The parameter field is a single byte divided into bitfields, as follows:

Table 10-41. Check data command parameter field

7	6	5	4	3	2	1	0
flags					bytes		

where

```
bytes: the width of target locations in bytes (either 1, 2, or 4)
flags: control flags for the command behavior
Data Mask = bit 3: if set, only the specific bits may be overwritten at a target address
(otherwise all bits may be overwritten)
Data Set = bit 4: if set, the bits at the target address are overwritten with this flag
(otherwise it is ignored)
```

This command polls the source address until either the exit condition is satisfied, or the poll count is reached. The exit condition is determined by the flags as follows:

Table 10-42. Interpretation of check data command flags

"Mask"	"Set"	Action	Interpretation
0	0	(*address & mask) == 0	All bits clear
0	1	(*address & mask) == mask	All bits set
1	0	(*address & mask)!= mask	Any bit clear
1	1	(*address & mask)!= 0	Any bit set

NOTE

If the source address does not have the same alignment as the data width indicated in the parameter field, the value is not read.

If the bitmask is wider than permitted by the data width indicated in the parameter field, the value is not read.

10.7.2.3 NOP command

This command has no effect.

The format of the NOP command is a big-endian four-byte array, as shown in this table:

Table 10-43. NOP command format

Tag	Length	Undefined

where:

```
Tag: a single-byte field set to 0xC0
Length: a two-byte field in big endian containing the length of the NOP command in bytes
(fixed to a
value of 4)
Undefined: this byte is ignored and can be set to any value.
```

10.8 External Memory Configuration Data (XMCD)

For comprehensive or feature-rich applications, the on-chip RAM may not be enough for the application use. Usually, such an application requires a large capacity of RAM and needs to run on the external RAM for high execution performance. However, enabling the external RAM on the SoC is relatively complicated, and the settings are SoC specific. The Boot ROM on the SoC simplifies the external RAM configuration by introducing the XMCD. The XMCD data structure resides at offset 0x40 starting from IVT header.

The XMCD consists of a XMCD header and a memory specific configuration block. On this SoC, the following types of external RAM devices are supported. Each type of RAM device has a specific configuration block.

- HyperRAM/APMemory via FlexSPI – FlexSPI RAM configuration block
- SDRAM via SEMC – SEMC SDRAM Configuration block

10.8.1 XMCD header

The XMCD header resides at the fixed offset 0x40 from the IVT header. The header definition is as follows.

Table 10-44. XMC Header Definition

[31:28] Tag	[27:24] Version	[23:20] Memory Interface	[19:16] Instance	[15:12] Configuration Block Type	[11:0] Configuration block size
Valid value = 0xC	Fixed value of '0'	0 - FlexSPI 1 - SEMC	SoC defined instances	0 - Simplified Configuration Option Block 1 - Full Configuration Block	Configuration block size (including the XMC Header itself).

NOTE

There is an optional integrity check of the XMC by programming the CRC checksum to the fuse. The ROM can perform the integrity check before adopting the XMC block settings. It calculates the CRC check based on the value of the "Configuration block size" field. ROM determines whether to enable the XMC integrity check by checking the XMC_CHECK_EN(0x970[14]) fuse field and the fuse word 0xC90. Details of the CRC algorithm used for the integrity check are provided in the following table.

Table 10-45. CRC Algorithm Details

Description	Value
Width	32
Polynomial	0x04C11BD7
Init Value	0xFFFFFFFF
Reflect In	FALSE
Reflect Out	FALSE
XOR Out	0x00000000

The following procedure shows the steps in the CRC calculation:

1. CRC initialization
   - Set the initial CRC as 0xFFFFFFFF, which clears the CRC byte count to 0.
2. CRC calculation
   - Start the calculation from the first byte of the XMC header. Total calculation bytes are "Configuration block size" bytes.
3. CRC finalization

- Check if the CRC byte count is 4-bytes aligned. If it is not 4-bytes aligned, then pad it with the necessary zeroes to finalize the CRC. Otherwise, return to the current computed CRC.

10.8.2 FlexSPI RAM configuration block

The XMCD offers a simplified FlexSPI RAM configuration option block which can meet the typical usage of the HyperRAM or APMemory devices.

However, the user application may need to enable the advanced features of the external RAM which cannot be configured by the simplified configuration option. In this case, the XMCD also offers the complete 512-bytes FlexSPI RAM configuration block which supports flexible configuration.

10.8.2.1 Simplified FlexSPI RAM configuration option

The simplified FlexSPI RAM configuration option structure is shown in the following tables.

Table 10-46. Simplified FlexSPI RAM Configuration Option 0

[31:28] Tag	[27:24] Option Size	[23:20] device type	[19:16] Reserved	[15:12] Misc.	[11:8] Maximum Frequency	[7:0] Size in MB
Fixed to 0x0C	0 - Option words = 1 1 - Option words = 2 Others-Rereved	0 - HyperRAM 1 - APMemory	Reserved	For HyperRAM 0 - 1.8V 1 - 3V	1 - 30MHz 2 - 50MHz 3 - 60MHz 4 - 80MHz 5 - 100MHz 6 - 120MHz 7 - 133MHz 8 - 166MHz Others – Reserved	0 - Auto detection Others - Size in MB

Table 10-47. Simplified FlexSPI RAM Configuration Option 1

[31:28] RAM_CONNECTION	[27:24] Reserved	[23:20] DQS_PINMUX_GROUP	[19:16] PINMUX ROUP	[15:8] Reserved	[7:4] write dummy cycles	[3:0] read dummy cycles
0 - PORTA 1 - PORTB	Reserved	0 - Default Group	0 - Primary group	Reserved	0 - Auto detection	0 - Auto detection

Table 10-47. Simplified FlexSPI RAM Configuration Option 1

[31:28] RAM_CONNECTION	[27:24] Reserved	[23:20] DQS_PINMUX_GROUP	[19:16] PINMUX ROUP	[15:8] Reserved	[7:4] write dummy cycles	[3:0] read dummy cycles
		1 - Secondary group	1 - Secondary group		Others - Specified dummy cycles	Others - Specified dummy cycles

NOTE

The [23:20] field must be set to 0 because the secondary group of DQS can't be used.

10.8.2.2 Full FlexSPI RAM configuration block

The following table lists the data structure of the full 512-bytes FlexSPI RAM Configuration Block.

Table 10-48. Full HyperRAM/APMemory Configuration Block Structure

Name	Offset	Size(Bytes)	Description
Tag	0x000	4	0x42464346, ascii: "FCFB"
Version	0x004	4	[07:00] bugfix [15:08] minor [23:16] major = 1 [31:24] ascii 'V'
Reserved	0x008	4	Reserved
readSampleClkSrc	0x00c	1	0 – Internal loopback 1 – loopback from DQS pad 2 - Reserved 3 – Flash provided DQS
csHoldTime	0x00d	1	Serial Flash CS Hold Time Recommend default value is 0x03
csSetupTime	0x00e	1	Serial Flash CS setup time Recommended default value is 0x03
columnAdressWidth	0x00f	1	3 – For HyperFlash/HyperRAM 12/13 – For Serial NAND. See datasheet to find correct value. 0 – Other devices
deviceModeCfgEnable	0x010	1	Device Mode Configuration Enable feature 0 – Disabled 1 – Enabled
deviceModeType	0x11	1	Device Mode Type

Table 10-48. Full HyperRAM/APMemory Configuration Block Structure (continued)

Name	Offset	Size(Bytes)	Description
busyOffset	0x07c	2	Busy bit offset. Valid range :0-31.
busyBitPolarity	0x07e	2	0 – 1 represents busy 1 – 0 represents busy
lookupTable	0x080	16*4*4	Lookup table: The sequence index of read must be set to 0. The sequence index of write must be set to 4.
lutCustomSeq	0x180	4*12	Customized LUT sequence. See the note at the end of the table for details.
Reserved	0x1b0	5*16	Reserved

NOTE

- LUT for read must be placed at LUT entry 0.
- LUT for write must be placed at LUT entry 9.

10.8.2.3 Example of XMCD for HyperRAM support

The following table shows an example of XMCD for HyperRAM support.

Table 10-49. Example XMCD block for HyperRAM

Offset	Field	Description
0	0xC001_0008	Tag = 0x0C Version = 0 Memory Interface: FLEXSPI Instance: 1 - First Instance Configuration block type: Simplified Configuration block size: 8 (4-byte header + 4-byte option block)
1	0xC000_0700	Tag = 0x0C Option_Size = 0 DeviceType: HyperRAM Reserved: 0 Misc: HyperRAM 1V8 Max Freq: 7 Memory Size: Auto-detection

10.8.3 SDRAM support

The XMCD also supports the SDRAM configuration via the SEMC SDRAM Configuration Block, which offers both the simplified configuration option and the fully customizable configuration block.

10.8.3.1 SEMC SDRAM configuration block structure

The SEMC SDRAM configuration block structure is shown in the following table.

Table 10-50. SDRAM Configuration Block structure

Offset	Width (bytes)	Field	Description
0	1	magic_number	Must be 0xA1
1	1	version	Set to 1 for this implementation
2	1	config_option	0x00 - Simplified configuration. Select SDRAM CS0 as default and can only configure clk_MHz, sdram0_size_kB, and port_size. 0xFF - Full configuration. Must configure all fields.
3	1	clk_MHz	Set the working frequency in the unit of MHz
4	4	sdram0_size_kB	Set the memory size of SDRAM CS0 in the unit of kilobytes. Range: 4~4*1024*1024
8	1	port_size	Port size of SDRAM 0 - 8bit 1 - 16bit 2 - 32bit Others - Invalid value
9	1	pin_config_pull	Pull config of the SDRAM GPIO pin 0 – forbidden 1 – pull up 2 – pulldown 3 – no pull Others - Invalid value
10	1	pin_config_drive_strength	Driver config of SDRAM GPIO pin 0 – high driver 1 – normal driver Others - Invalid value
11	1	mux_rdy	SDRAM CSn device selection 1 - SDRAM CS1 2 - SDRAM CS2 3 - SDRAM CS3 Others – Invalid for SDRAM, select other external devices

Table continues on the next page...

Table 10-50. SDRAM Configuration Block structure (continued)

Offset	Width (bytes)	Field	Description
			NOTE: To select CS1/CS2/CS3, you can only use one of the five items: mux_rdy, mux_csx0, mux_csx1,mux_csx2 ,mux_csx3. If using one item, the other items cannot be used, set them to 0.
12	1	mux_csx0	SDRAM CSn device selection 1 - SDRAM CS1 2 - SDRAM CS2 3 - SDRAM CS3 Others – Invalid for SDRAM, select other external devices
13	1	mux_csx1	SDRAM CSn device selection 1 - SDRAM CS1 2 - SDRAM CS2 3 - SDRAM CS3 Others – Invalid for SDRAM, select other external devices
14	1	mux_csx2	SDRAM CSn device selection 1 - SDRAM CS1 2 - SDRAM CS2 3 - SDRAM CS3 Others – Invalid for SDRAM, select other external devices
15	1	mux_csx3	SDRAM CSn device selection 1 - SDRAM CS1 2 - SDRAM CS2 3 - SDRAM CS3 Others – Invalid for SDRAM, select other external devices
16	1	bank	Bank numbers of SDRAM device 0 – 4 banks 1 – 2 banks Others - Invalid value
17	1	burst_len	Burst length 0 – 1 1 – 2 2 – 4 3 – 8 Others - Invalid value
18	1	column_addr_bit_num	Column address bit number 0 – 12bit 1 – 11bit 2 – 10bit 3 – 9bit

Table continues on the next page...

Table 10-50. SDRAM Configuration Block structure (continued)

Offset	Width (bytes)	Field	Description
			4 – 8bit Others - Invalid value
19	1	cas _ latency	CAS Latency 1 – 1 2 – 2 3 – 3 Others - Invalid value
20	1	write_recovery_ns	Write recovery time in unit of nanosecond. This could help to meet tWR timing requirement by the SDRAM device.
21	1	refresh_recovery_ns	Refresh recovery time in unit of nanosecond. This could help to meet tRFC timing requirement by the SDRAM device.
22	1	act2readwrite_ns	Act to read/write wait time in unit of nanosecond. This could help to meet tRCD timing requirement by the SDRAM device.
23	1	precharge2act_ns	Precharge to active wait time in unit of nanosecond. This could help to meet tRP timing requirement by SDRAM device.
24	1	act2act_banks_ns	Active to active wait time between two different banks in unit of nanosecond. This could help to meet tRRD timing requirement by the SDRAM device.
25	1	refresh2refresh_ns	Auto refresh to auto refresh wait time in unit of nanosecond. This could help to meet tRFC timing requirement by the SDRAM device.
26	1	selfref_recovery_ns	Self refresh recovery time in unit of nanosecond. This could help to meet tXSR timing requirement by the SDRAM device.
27	1	act2prechage_min_ns	ACT to Precharge minimum time in unit of nanosecond This could help to meet tRAS(min) timing requirement by SDRAM device.
28	4	act2prechage_max_ns	ACT to Precharge maximum time in unit of nanosecond. This could help to meet tRAS(max) timing requirement by the SDRAM device.
32	4	refreshperiod_perrow_ns	Refresh timer period in unit of nanosecond/ Set to (tREF(ms) * 1000000/rows) value.
36	4	mode_register	Define the specific mode of operation of SDRAM. Set to the value required by SDRAM device. **NOTE:** The low bits of the input value must correspond to the low bits of the mode register.
40	4	sdram0_base	Base address of SDRAM CS0

Table continues on the next page...

Table 10-50. SDRAM Configuration Block structure (continued)

Offset	Width (bytes)	Field	Description
			Range: 0x80000000~0xDFFFFFFF **NOTE:** SDRAM CS0~CS3 addresses cannot overlap and when CSn is not being used, set the address to 0.
44	4	sdram1_base	Base address of SDRAM CS1 Range: 0x80000000~0xDFFFFFFF
48	4	sdram2_base	Base address of SDRAM CS2 Range: 0x80000000~0xDFFFFFFF
52	4	sdram3_base	Base address of SDRAM CS3 Range: 0x80000000~0xDFFFFFFF
56	4	sdram1_size_kB	Set the memory size of SDRAM CS1 in unit of kbytes Range: 4~4*1024*1024
60	4	sdram2_size_kB	Set the memory size of SDRAM CS2 in unit of kbytes Range: 4~4*1024*1024
64	4	sdram3_size_kB	Set the memory size of SDRAM CS3 in unit of kbytes Range: 4~4*1024*1024

10.8.3.2 Example for SDRAM support (32-bit)

The following table shows an example for the SDRAM support (32-bit) on this device.

Table 10-51. Example SDRAM Configuration Block

Offset	Field	Description
0	0xC010_000D	Tag = 0xC Version = 0 Memory Interface: SEMC Instance: 0 - ignored Configuration block type: 0 - Ignored (Handled inside the SDRAM configuration structure) Configuration block size: 13 (4-byte header + 9-byte option block)
1	0xA600_01A1	Magic_number = 0xA1 Version = 1 Config_option: Simplified SDRAM clock: 166MHz
2	0x0001_0000	SDRAM CS0 size: 64MBytes
3	0x02	Port_size: 32-bit

10.9 Serial Boot (Serial Downloader)

The Serial boot provides a means to download a boot image to the chip and execute the image over the following serial peripherals:

- LPUART
- USB-HID

The default enabled peripherals for active peripheral detection is determined by the combination of eFUSEs and Boot Mode pins.

The boot ROM can detect the active peripherals and shut down all inactive peripherals before any communications between the host and the device.

The high-level serial boot flow is provided below. Details of communication protocols, sequences, and flows can be found in the following sections.

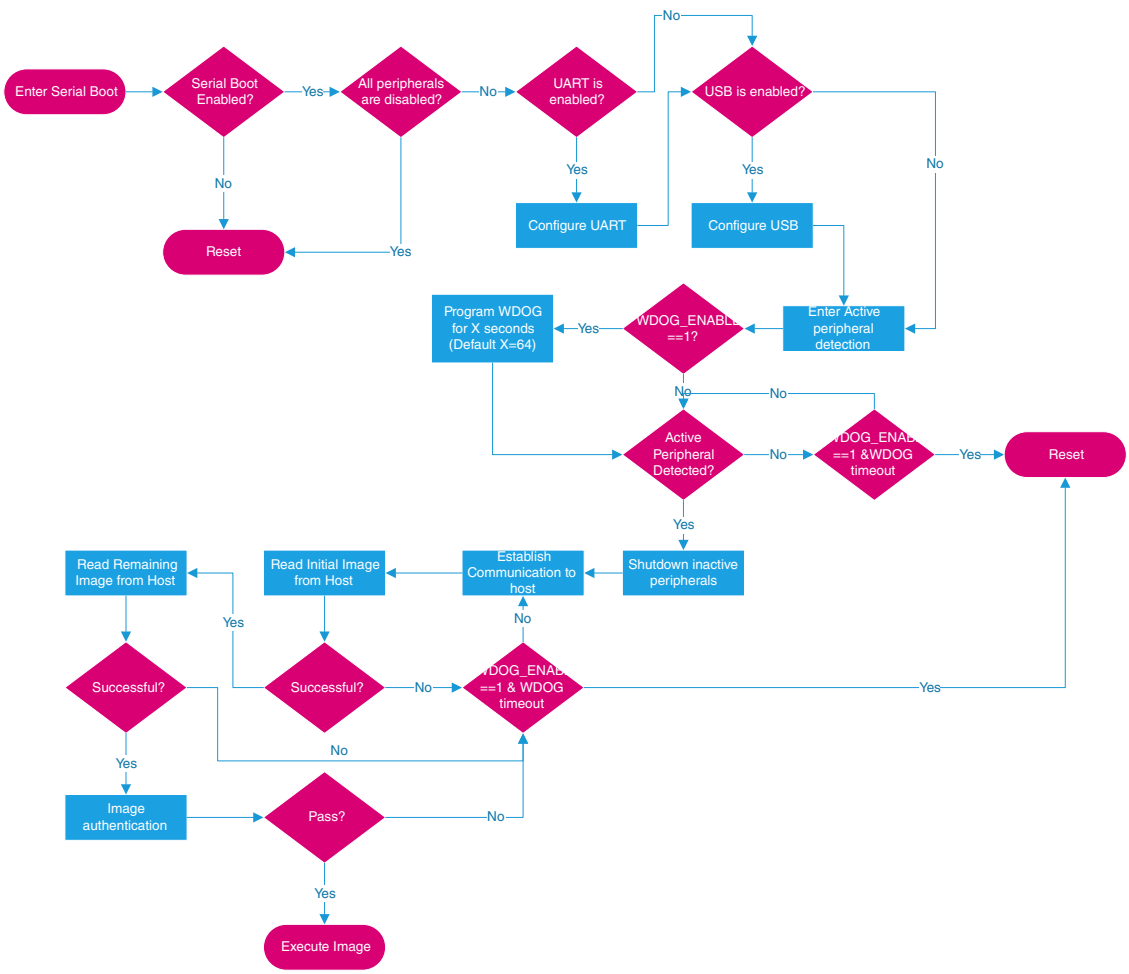

Figure 10-19. Serial Boot Flow

The communication protocol for serial boot mode is compatible with the widely-used MCUBOOT protocol in the NXP MCU products. Using simplified protocol, only two types of phase are supported:

1. **Command-only phase**. “get-property” command is supported, but the supported properties are limited to:
   - Bootloader version
   - Target version
   - Maximum payload size in the packet
   - Security State
   - Last Status

   For all other properties queried by the host, the boot ROM responds with unknown property error code.
2. **Data-only phase**. Boot ROM treats the data from the host as data streaming; no command phase is needed in this phase.

10.9.1 MCU-BOOT protocol

The section demonstrates the general protocol for the packet transfers between the host and the boot ROM. The description includes the transfer of packets for different transactions, such as command with no data phase and data only phase. The next section describes various packet types used in a transaction.

- Each command sent from the host is replied to with a response command.
- Each data sent from the host is replied with an ACK at the packet level.
- In all protocols (described in the following subsections), the Ack sent in response to a Command or Data packet can arrive at any time before, during, or after the Command/Data packet has processed.

Command-only phase

The protocol for command-only phase content:

- Command packet (from the host)
- Response command packet (to host)

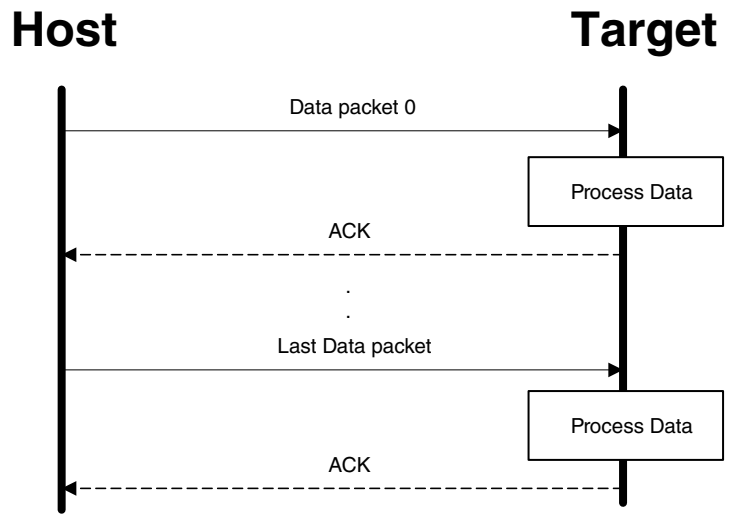

Figure 10-20. Protocol for a command-only phase

Data-only phase

The protocol for data-only phase content:

- A data packet (from the host)

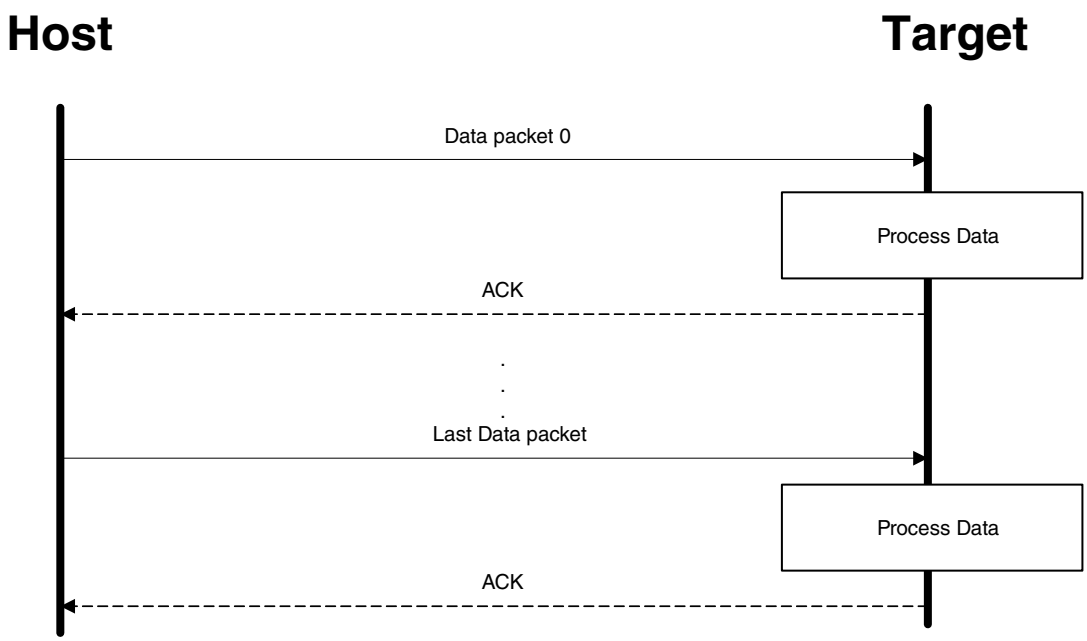

Figure 10-21. Protocol for a data-only phase

There are 2 types of packet protocol defined for the peripherals with or without built-in flow control.

- **Serial packet protocol**. It is defined for UART. A packet level flow control mechanism and error-detection mechanism is designed in this protocol.
- **HID packet protocol**. It is defined for USB-HID, the USB built-in flow control and error-detection is used behind this protocol.

In each protocol, several packet types are defined to let the boot ROM:
- Establish the communication to a host
- Recognize different phases (command-only/ data-only)

10.9.1.1 Packet Types for Serial Packet Protocol

There are 5 types of packets supported by the Serial Packet Protocol:
- Ping packet
- Ping Response packet
- Framing packet
- Command packet
- Data packet

10.9.1.1.1 Ping packet

The ping packet is the first packet sent from a host to target, in order to establish a connection on a UART peripheral for auto-baudrate detection. For other peripherals, it is optional.

Table 10-52. Ping packet format

Byte #	Value	Name
0	0x5A	Start Byte
1	0xA6	Packet Type: Ping packet

10.9.1.1.2 Ping response packet

In response to a Ping packet, the target sends a Ping Response packet.

Table 10-53. Ping response packet format

Byte #	Value	Parameter
0	0x5A	Start Byte
1	0xA7	Packet Type: Ping Response packet
2		Protocol version: bug fix
3		Protocol version: minor
4		Protocol version: major

Table continues on the next page...

Table 10-53. Ping response packet format (continued)

Byte #	Value	Parameter
5		Protocol name: 'P' (0x50)
6		Reserved: set to 0
7		Reserved: set to 0
8		crc16_low
9		crc16_high

NOTE

1. Please refer to CRC algorithm for details regarding the CRC algorithm.
2. Byte 0 - 7 are including in the CRC calculation.

Example ping packet:

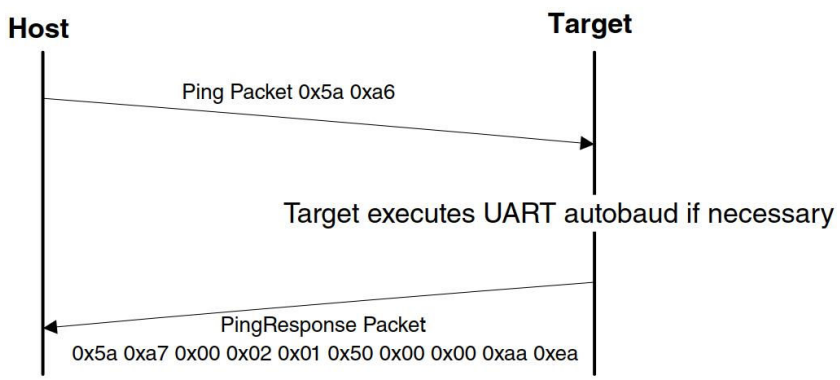

Figure 10-22. Ping Command Protocol

10.9.1.1.3 Framing Packet

The framing packet is for flow control and error detection, for the communications links that do not have such features built-in. The framing packet structure sits between the link layer and the command layer. It wraps command and data packets as well.

NOTE

Command packet is optional in ROM

Every framing packet containing data sent in one direction results in a synchronizing response framing packet in the opposite direction.

The framing packet described in the section is for serial peripherals, including UART

The framing packet format for serial packet is provided below:

Table 10-54. Framing packet format

Byte #	Data type	Value	Field	Notes
0	Framing header	0x5a	Start Byte	Must be 0x5A
1		0xA5/0xA4	Packet Type	0xA5 for Data packet 0xA4 for command packet
2		2	Payload Size	16-bit little-endian, max size is 512 bytes
4		2	CRC-16 checksum	CRC checksum covers the whole packet including start byte, packet type, payload size, and payload data, but does not contain the CRC checksum bytes
6…n	Payload	payload data	The payload of the data	Max size is 512

A particular framing packet that contains only a start byte and a packet type is employed for synchronization between the host and target. The format details are provided below:

Table 10-55. Special Framing Packet Format

Byte #	Value	Parameter
0	0x5A	Start Byte
1	0xAn	Packet Type: 0xA1 - Ack: The previous packet was received successfully; the sending of more data is allowed 0xA2 - NAK: The previous packet was corrupted, and needs to be re-sent. 0xA3 - Abort: Data transfer is aborted.

10.9.1.1.4 CRC algorithm

This section provides details about the CRC-16 algorithm.

The CRC is computed over each byte in the framing packet header, excluding the crc16 field itself, plus all the payload bytes. The CRC algorithm is the XMODEM variant of CRC-16.

The Characteristics of the XMODEM variants are:

Table 10-56. Characteristics of the XMODEM variant

Name	Value
width	16
polynomial	0x1021
init value	0x0000
reflect in	false
reflect out	false

Table continues on the next page...

Table 10-56. Characteristics of the XMODEM variant (continued)

Name	Value
xor out	0x0000
check result	0x31C3

10.9.1.1.5 Command Packet

The command packet carries a 32-bit command header and a list of 32-bit parameters.

Command Packet Format (32 bytes)										
Command Header (4 bytes)				28 bytes for Parameters (Max 7 parameters)						
Tag	Flags	Rsvd	Param Count	Param1 (32-bit)	Param2 (32-bit)	Param3 (32-bit)	Param4 (32-bit)	Param5 (32-bit)	Param6 (32-bit)	Param7 (32-bit)
byte 0	byte 1	byte 2	byte 3							

Command Header Format

Byte #	Command Header Field	
0	Command or Response tag	The command header is 4 bytes long, with these fields.
1	Flags	
2	Reserved. Should be 0x00.	
3	ParameterCount	

Figure 10-23. Command Packet and Command Header Format

The header is followed by 32-bit parameters up to the value of the ParameterCount field specified in the header. Because a command packet is 32 bytes long, only 7 parameters can fit into the command packet.

Command packets are also used by the target to send responses back to the host. Command packets and data packets are embedded into framing packets for all the transfers.

The supported command and response list is provided in the following tables:

Table 10-57. Supported command list

Command	Name
0x07	GetProperty

Table 10-58. Supported response list

Response	Name
0xA0	Generic Response
0xA7	GetProperty Response - used for sending a response to GetProperty command only

10.9.1.1.6 Data Packet

The data packet carries just the data that the host sends to target. The data packet is also wrapped within a framing packet to ensure the correct packet data is received.

The contents of a data packet are simply the data itself. There are no other fields so that the most data per packet can be transferred. Framing packets are responsible for ensuring that the correct packet data is received.

The host must send the data packet with the maximum payload size until the last packet, the packet with smaller payload size is treated as the last packet during the transfer.

10.9.1.1.7 Response packet

The responses are carried using the same command packet format wrapped with framing packet data. Types of responses supported in the boot ROM include:

- GenericResponse
- GetPropertyResponse

GenericResponse: After the boot ROM has processed a command, the boot ROM sends a generic response with status and command tag information to the host. The generic response is the last packet in the command protocol sequence. The generic response packet contains the framing packet data and the command packet data (with generic response tag = 0xA0) and a list of parameters. The parameter count field in the header is always set to 2, for status code and command tag parameters.

The GenericResponse parameters are provided below:

Table 10-59. GenericResponse parameters

Byte #	Parameter	Description
0 - 3	Status code	The status codes are errors encountered during the execution of a command by the target. If a command succeeds, then a success code is returned.
4 - 7	Command tag	The command tag parameter identifies the response to the command sent by the host.

NOTE

GenericResponse in ROM is only used as a response for all unsupported commands, in which:
- Status = 10000 (Unknown command)
- Command tag = command tag in the Command header.

GetPropertyResponse: The target sends the GetPropertyResponse packet in response to the host query that uses the GetProperty command. The GetPropertyResponse packet contains the framing packet data and the command packet data, with the command/response tag set to a GetPropertyResponse tag value (0xA7).

The parameter count field in the header is set to greater than 1, to always include the status code and one or many property values.

The GetPropertyResponse parameters are provided below:

Table 10-60. GetPropertyResponse parameters

Byte #	Value	Parameter
0 - 3		Status code
4 - 7		Property code
. . .		. . .
		Can be up to maximum 6 property values. Limited to the size of the 32-bit command packet and property type.

The possible status are:
- 0 - kStatus_Success
- 10300 - Unknown Property

10.9.1.2 Packet Types for USB-HID protocol

There are 3 types of packets supported in USB-HID protocol:

- Framing packet
- Command packet
- Data packet

10.9.1.2.1 HID reports

There are 4 HID reports defined and used by the boot ROM USB HID protocol. The report ID determines the direction and type of packet sent in the report. Otherwise, the contents of all reports are the same.

The HID reports for the USB-HID protocol are provided below:

Table 10-61. HID reports for the USB-HID protocol

Report ID	Packet Type	Direction
1	Command	OUT (Host -> Device)
2	Data	OUT (Host -> Device)
3	Command	IN (Device -> Host)

10.9.1.2.2 Framing packet

The framing packet has a 4-byte framing header, in which the report ID and the packet length is used for the packet type definition and the real payload size.

Table 10-62. USB-HID Framing Packet

Byte #	Data Type	Value	Note
0	Framing Header	Report ID	
1		Padding byte	Must be 0
2		Packet Length LSB	Max size is limited to 1016 bytes
3		Packet Length MSB	
4	Payload	Packet [0]	
5		Packet [1]	
		…	
N+4-1		Packet [N-1]	

10.9.1.2.3 Command packet

The Report ID needs to be '1' for Command, and it must be '3' for Response. The payload definition is the same with Serial Packet Protocol.

10.9.1.2.4 Data packet

The Report ID must be '2' in data packet. The payload definition is the same with Serial Protocol.

10.9.2 Serial Boot via UART

10.9.2.1 UART Configuration details

Provided below are the details of UART configuration in boot ROM:

- **8-N-1** (8-bit data, No parity bit, 1 stop bit)
- Auto-baud detection is supported during Serial Boot. Maximum baudrate can be up to 1 Mbps in high speed boot mode.
- The host tool needs to send out the data packet with maximum payload size (512 bytes) set in framing packet by packet, except for the last packet. ROM will end the transfer if the payload size is less than the maximum payload size.
- The first packet on UART must be Ping to perform auto-baud detection.

10.9.2.2 Example Communication sequences

1. **Ping** (for auto-baud detection)
   Host: Ping packet [5a **a6**]
   Device: Ping response < 5a **a7** 00 02 01 50 00 00 aa ea>
2. **Command packet** (Get-Property 1)
   Host: Command [5a **a4** 0c 00 4b 33 07 00 00 02 01 00 00 00 00 00 00 00]
   - 5a - Start Byte
   - **a4** - Packet Type: Command packet
   - 0c 00 - Payload size(0x000c)
   - 4b 33 - CRC checksum(0x334b)
   - 07 00 00 02 01 00 00 00 00 00 00 00 - Payload (Get-property 1)

   Device: Ack <5a **a1**>
   - 5a - Start Byte

      Device: Ack <5a **a1**>

Figure 10-24. Example Communication sequences

10.9.3 Serial Boot via USB-HID

10.9.3.1 USB configuration details

The USB OTG function device driver supports a high speed (HS for UTMI) non-stream mode with a maximal packet size of 512 B and a low-level USB OTG function.

The VID/PID and strings for the USB device driver are listed in the following table.

Table 10-63. VID/PID and strings for USB device driver

Descriptor	Value
VID	0x1FC9 (NXP vendor ID)
PID[1]	0x013D
String Descriptor1 (manufacturer)	NXP Semiconductors
String Descriptor2 (product)	S Blank
String Descriptor4	NXP Flash
String Descriptor5	NXP Flash

1. Allocation based on the BPN (Before Part Number)

10.9.3.2 Endpoints

The HID peripheral uses 3 endpoints:

- Control (0)
- Interrupt IN (1)
- Interrupt OUT (2)

The interrupt OUT endpoint is optional for HID class devices, but the boot ROM uses it as a pipe, where the firmware can NAK send requests from the USB host.

10.9.3.3 Example Communication sequences

1. **Command packet** (Get-Property 1)
   Host: Command [**01** 00 0c 00 07 00 00 02 01 00 00 00 00 00 00 00]
   - **01** - Command report, Direction: OUT, Host to device
   - 00 - Padding byte
   - 0c 00 - Payload size(0x000c)
   - 07 00 00 02 01 00 00 00 00 00 00 00 - payload

   Device: Ack (USB Hardware Ack)
   Device: GetPropertyResponse <**03** 00 0c 00 a7 00 00 02 00 00 00 00 00 01 02 4b 00 00 00 00 00 … 00>
   - **03 -** Command report, Direction: IN, Device to host
   - 00 - Padding byte
   - 0c 00 - Payload size(0x000c)
   - a7 00 00 02 00 00 00 00 00 01 02 4b - Payload (GetPropertyResponse, status=0, property=0x4b020100)
   - 00 00 00 00 00 … 00 - Padding bytes

   Host: Ack (USB Hardware Ack)
2. **Load Image**
   1. First Data packet:
      Host: Data packet [**02** 00 f8 03 d1 00 20 41 01 a4 00 00 00 00 00 00 00 …]
      02 - Data report, Direction: OUT, Host to device
      00 - Padding byte
      f8 03 - Payload size(0x03f8)
      d1 00 20 41 01 a4 00 00 00 00 00 00 00 … - Payload
      Device: Ack (USB Hardware Ack)
   2. Report the remaining data transfer following the same flow as the first data packet.
   3. Last Data packet:
      Host: Data packet [**02** 00 d4 00 20 c5 28 d9 00 f0 0b f8 00 …]
      02 - Data report, Direction: OUT, Host to device
      00 - Padding byte
      d4 00 - Payload size(0x00d4)
      20 c5 28 d9 00 f0 0b f8 00 … - Payload
      Device: Ack (USB Hardware Ack)

Figure 10-25. Example Communication sequences

10.10 Recovery devices

The chip supports recovery devices. If the primary boot device fails, the boot ROM tries to boot from the recovery device using one of the LPSPI ports.

To enable the recovery device, the recovery boot fuse must be set. Additionally, the serial EEPROM fuses must be set as described in Serial NOR/EEPROM through LPSPI.

10.11 SD/MMC manufacture mode

When the internal boot and recover boot (if enabled) failed, the boot goes to the SD/MMC manufacture mode before the serial download mode. In the manufacture mode, one bit bus width is used despite of the fuse setting.

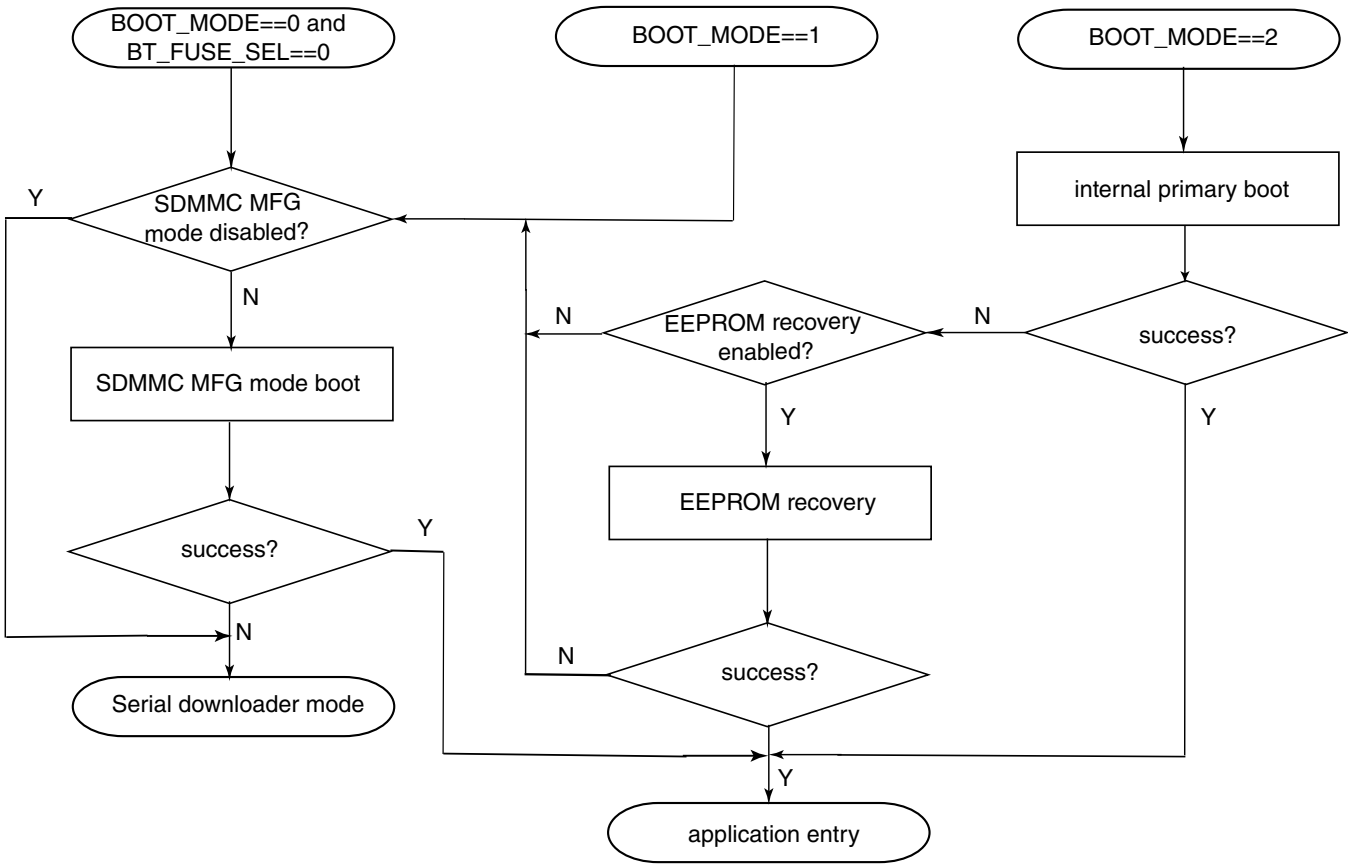

Figure 10-26. SD/MMC manufacture boot flow

10.12 High-Assurance Boot (HAB)

The High Assurance Boot (HAB) component of the ROM protects against the potential threat of attackers modifying the areas of code or data in the programmable memory to make it behave in an incorrect manner. The HAB also prevents the attempts to gain access to features which must not be available.

The integration of the HAB feature with the ROM code ensures that the chip does not enter an operational state if the existing hardware security blocks detected a condition that may be a security threat or if the areas of memory deemed to be important were modified. The HAB uses the RSA/ECDSA digital signatures to enforce these policies.

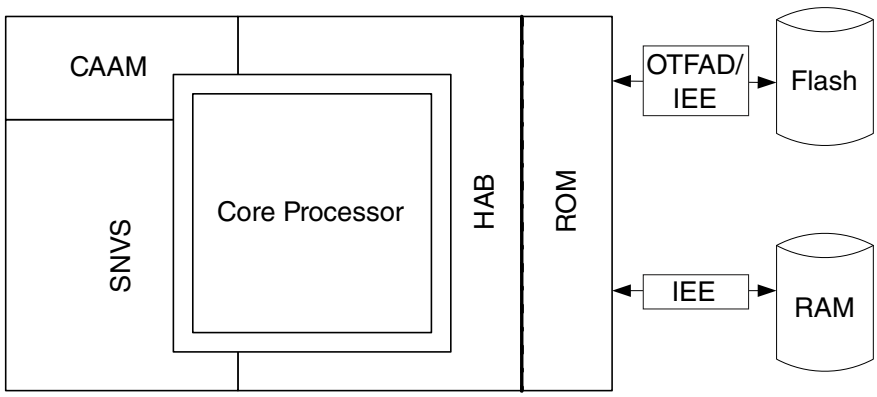

Figure 10-27. Secure boot components

The figure above illustrates the components used during a secure boot using HAB. The HAB interfaces with the SNVS to make sure that the system security state is as expected. The HAB also uses the hardware block to accelerate the SHA-256 message digest operations performed during the signature verifications. The HAB also includes a software implementation of SHA-256 for cases where a hardware accelerator cannot be used. The supported RSA key sizes are 1024, 2048, 3072, and 4096 bits. The supported ECDSA key sizes are P256, P384, and P521. The main features supported by the HAB are:

- X.509 public key certificate support
- CMS signature format support

NOTE

NXP provides the reference Code Signing Tool (CST) for key generation and code signing for use with the HAB library. The CST can be found by searching for "IMX_CST_TOOL" at http://www.nxp.com

10.12.1 HAB API vector table addresses

For devices that perform a secure boot, the HAB library may be called by the boot stages that execute after the ROM code.

The HAB API vector table for this device is at address 0x0021_1C0C for i.MX RT1170A, for i.MX RT1170B is at address 0x0021_1C14 .

Allowable address range for AHAB:

Table 10-64. Allowable address range for AHAB

Index	Region name	Start address	End address	Size
0	M7 ITCM SRAM	0x0007FFFF	0x00000004	512 KB
1	M4 ITCM + M7	0x2007FFFF	DTCM 0x1FFE0000	640 KB
2	M4 OCRAM	0x2023FFFF	0x20200000	256 KB
3	OCRAM (Free)	0x203FFFFF	0x2024C000	1.75 MB
4	FLEXSPI1 AMBA	0x3FFFFFFF	0x30000000	256 MB
5	M4 FLEXSPI1 ALIAS	0x17FFFFFF	0x08000000	256 MB
6	FLEXSPI2 AMBA	0x7F7FFFFF	0x60000000	504 MB
7	SEMC	0xDFFFFFFF	0x80000000	1.5 GB

10.13 ROM APIs

10.13.1 Introduction

The ROM bootloader provides a set of ROM APIs to simplify the In-Application Programming (IAP).

The ROM bootloader supports the following APIs:

- runBootloader API
- FlexSPI NOR FLASH Driver API

The ROM API root pointer is located at address 0x0021_001C. Please see the following figure for details of the ROM API layout.

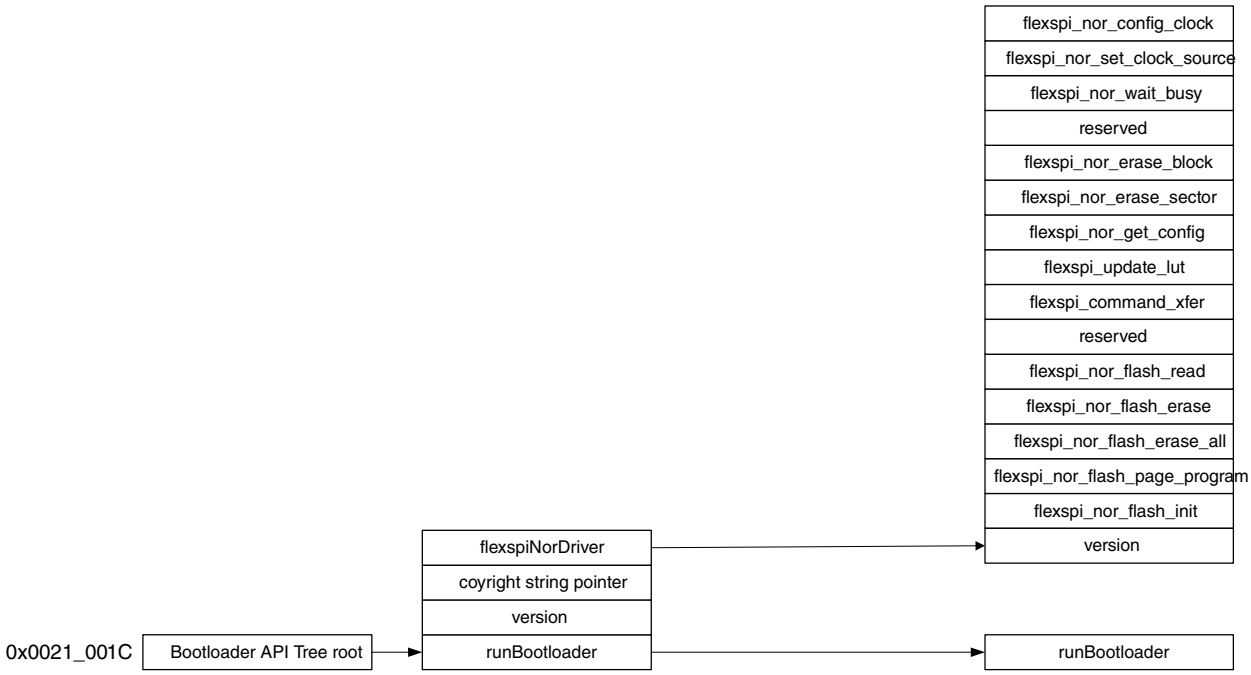

Figure 10-28. ROM API Structure

The ROM API structure definitions are as below:

1. Bootloader API Entry Structure

```
typedef struct BootloaderTree
{
    void (*runBootloader)(void *arg);                  //!< Function to start the bootloader executing.
    standard_version_t version;                        //!< Bootloader version number.
    const char *copyright;                             //!< Copyright string.
    const flexspi_nor_flash_driver_t *flexspiNorDriver; //!< FlexSPI NOR FLASH Driver API.
} bootloader_tree_t;
```

2. FlexSPI NOR Driver API structure

```
typedef struct
{
    uint32_t version;
    status_t (*init)(uint32_t instance, flexspi_nor_config_t *config);
    status_t (*page_program)(uint32_t instance, flexspi_nor_config_t *config, uint32_t dstAddr, const uint32_t *src);
    status_t (*erase_all)(uint32_t instance, flexspi_nor_config_t *config);
    status_t (*erase)(uint32_t instance, flexspi_nor_config_t *config, uint32_t start, uint32_t length);
    status_t (*read)(uint32_t instance, flexspi_nor_config_t *config, uint32_t *dst, uint32_t start, uint32_t bytes);
    uint32_t reserved;
    status_t (*xfer)(uint32_t instance, flexspi_xfer_t *xfer);
    status_t (*update_lut)(uint32_t instance, uint32_t seqIndex, const uint32_t *lutBase, uint32_t numberOfSeq);
    status_t (*get_config)(uint32_t instance, flexspi_nor_config_t *config, serial_nor_config_option_t *option);
    status_t (*erase_sector)(uint32_t instance, flexspi_nor_config_t *config, uint32_t address);
    status_t (*erase_block)(uint32_t instance, flexspi_nor_config_t *config, uint32_t address);
    void (*hw_reset)(uint32_t instance, uint32_t resetLogic);
    status_t (*wait_busy)(uint32_t instance, flexspi_nor_config_t *config, bool isParallelMode, uint32_t address);
    status_t (*set_clock_source)(uint32_t instance, uint32_t clockSrc);
    void (*config_clock)(uint32_t instance, uint32_t freqOption, uint32_t sampleClkMode);
} flexspi_nor_flash_driver_t;
```

10.13.2 FlexSPI NOR APIs

The ROM bootloader provides a set of Serial NOR FLASH APIs to simplify the external FLASH enablement on the chip. The version of the FlexSPI NOR API in the chip's ROM bootloader is 1.7.0.

NOTE

1. The RAM space occupied by ROM must be reserved if the user application needs to call the FlexSPI APIs.
2. FlexSPI APIs will re-initialize the FLEXSPI module. If the user application initialized the FLEXSPI module before calling FlexSPI APIs, re-initialization might be required after calling FlexSPI APIs.

10.13.2.1 FlexSPI NOR prototypes

10.13.2.1.1 flexspi_nor_flash_init

Initialize the Serial NOR device via FLEXSPI:

```
status_t flexspi_nor_flash_init(uint32_t instance, flexspi_nor_config_t *config)
{
    return g_bootloaderTree->flexSpiNorDriver->init(instance, config);
}
```

Please see example code in FLASH API Example.

10.13.2.1.2 flexspi_nor_flash_page_program

Program data to specified Flash address:

```
status_t flexspi_nor_flash_page_program(uint32_t instance, flexspi_nor_config_t *config,
uint32_t dstAddr, const uint32_t *src)
{
    return g_bootloaderTree->flexSpiNorDriver->program(instance, config, dstAddr, src);
}
```

Please see example code in FLASH API Example.

10.13.2.1.3 flexspi_nor_flash_erase_all

Erase the whole Flash array via FLEXSPI:

```
status_t flexspi_nor_flash_erase_all(uint32_t instance, flexspi_nor_config_t *config)
{
    return g_bootloaderTree->flexSpiNorDriver->erase_all(instance, config);
}
```

Example code:

```
flexspi_nor_flash_erase_all(1,config);
```

10.13.2.1.4 flexspi_nor_get_config

Get the Flash configuration block via the serial_nor_config_option_t block. Please see serial_nor_config_t definitions for more details.

```
status_t flexspi_nor_get_config(uint32_t instance, flexspi_nor_config_t *config,
serial_nor_config_option_t *option)
{
    return g_bootloaderTree->flexSpiNorDriver->get_config(instance, config, option);
}
```

Please see example code in FLASH API Example.

10.13.2.1.5 flexspi_nor_flash_erase

Erase specified Flash region. The minimum erase unit is one sector.

```
status_t flexspi_nor_flash_erase(uint32_t instance, flexspi_nor_config_t *config, uint32_t
start, uint32_t length)
{
```

```
    return g_bootloaderTree->flexSpiNorDriver->erase(instance, config, start, length);
}
```

Please see example code in FLASH API Example.

10.13.2.1.6 flexspi_nor_flash_read

Read the FLASH via FLEXSPI using IP read command:

```
status_t flexspi_nor_flash_read(uint32_t instance, flexspi_nor_config_t *config, uint32_t
*dst, uint32_t start, uint32_t bytes)
{
    return g_bootloaderTree->flexSpiNorDriver->read(instance, config, dst, start, bytes);
}
```

Example code:

```
uint32_t pageBuffer[256/sizeof(uint32_t)];
flexspi_nor_flash_read(1, config, pageBuffer, 0, sizeof(pageBuffer));
```

10.13.2.1.7 flexspi_update_lut

Update the specified LUT entries:

```
status_t flexspi_update_lut(uint32_t instance, uint32_t seqIndex, const uint32_t *lutBase,
uint32_t numberOfSeq)
{
    return g_bootloaderTree->flexSpiNorDriver->update_lut(instance, seqIndex, lutBase,
numberOfSeq);
}
```

Example code:

```
uint32_t chipEraseLUT[4] = {0x0460, 0, 0, 0};
flexspi_update_lut(1, 1, chipEraseLUT, 1);
```

10.13.2.1.8 flexspi_command_xfer

Execute LUT sequence specified by xfer:

```
status_t flexspi_command_xfer(uint32_t instance, flexspi_xfer_t *xfer)
{
    return g_bootloaderTree->flexSpiNorDriver->xfer(instance, xfer);
}
```

flexspi_xfer_t definition is as below:

```
//!@brief FlexSPI Transfer Context
typedef struct _FlexSpiXfer
{
    flexspi_operation_t operation; //!< FlexSPI operation
    uint32_t baseAddress;          //!< FlexSPI operation base address
    uint32_t seqId;                //!< Sequence Id
    uint32_t seqNum;               //!< Sequence Number
    bool isParallelModeEnable;     //!< Is a parallel transfer
    uint32_t *txBuffer;            //!< Tx buffer
```

```
    uint32_t txSize;              //!< Tx size in bytes
    uint32_t *rxBuffer;           //!< Rx buffer
    uint32_t rxSize;              //!< Rx size in bytes
} flexspi_xfer_t;
```

flexspi_operation_t definition is as below:

```
typedef enum _FlexSPIOperationType
{
    kFlexSpiOperation_Command,
    kFlexSpiOperation_Config,
    kFlexSpiOperation_Write,
    kFlexSpiOperation_Read,
    kFlexSpiOperation_End = kFlexSpiOperation_Read,
} flexspi_operation_t;
```

Example code, assuming the LUT index 1 is the Flash WriteEnable command.

```
flexspi_xfer_t flashXfer =
{
    kFlexSpiOperation_Command, 0, 1, 1, false, NULL, 0, NULL, 0
};
flexspi_command_xfer(0, &flashXfer);
```

10.13.2.1.9 flexspi_nor_set_clock_source

Set the clock source of the specified FLEXSPI instance:

```
status_t flexspi_nor_set_clock_source(uint32_t instance, uint32_t source)
{
    return g_botloaderTree->flexSpiNorDriver->set_clock_source(instance, source);
}
```

Example code:

```
#define CLOCK_SOURCE_RC400M (2u)
flexspi_nor_set_clock_source(1, CLOCK_SOURCE_RC400M);
```

10.13.2.1.10 flexspi_nor_configure_clock

Configure the FLEXSPI NOR clock to specified frequency:

```
status_t flexspi_nor_configure_clock(uint32_t instance, uint32_t freq, uint32_t
sampleClkMode)
{
    return g_bootloaderTree->flexSpiNorDriver->config_clock(instance, freq, sampleClkMode);
}
```

Example code:

```
enum
{
    kFlexSpiSerialClk_30MHz = 1,
    kFlexSpiSerialClk_50MHz = 2,
    kFlexSpiSerialClk_60MHz = 3,
    kFlexSpiSerialClk_80MHz = 4,
    kFlexSpiSerialClk_100MHz = 5,
```

```
    kFlexSpiSerialClk_120MHz = 6,
    kFlexSpiSerialClk_133MHz = 7,
    kFlexSpiSerialClk_166MHz = 8,
};
enum
{
    kFlexSpiClk_SDR, //!< Clock configure for SDR mode
    kFlexSpiClk_DDR, //!< Clock configurat for DDR mode
};
flexspi_nor_configure_clock(1, kFlexSpiSerialClk_100MHz, kFlexSpiClk_DDR);
```

10.13.2.1.11 serial_nor_config_t definitions

serial_nor_config_t is defined as below:

```
typedef struct _serial_nor_config_option
{
  union
  {
    struct
    {
      uint32_t max_freq : 4;         //!< Maximum supported Frequency
      uint32_t misc_mode : 4;        //!< miscellaneous mode
      uint32_t quad_mode_setting : 4; //!< Quad mode setting
      uint32_t cmd_pads : 4;         //!< Command pads
      uint32_t query_pads : 4;       //!< SFDP read pads
      uint32_t device_type : 4;      //!< Device type
      uint32_t option_size : 4;      //!< Option size, in terms of uint32_t, size = (option_size + 1) * 4
      uint32_t tag : 4;              //!< Tag, must be 0x0E
    } B;
    uint32_t U;
  } option0;

  union
  {
    struct
    {
      uint32_t dummy_cycles : 8;     //!< Dummy cycles before read
      uint32_t reserved0 : 8;
      uint32_t pinmux_group : 4;     //!< The pinmux group selection
      uint32_t dqs_pinmux_group : 4; //!< The DQS Pinmux Group Selection
      uint32_t reserved1 : 4;
      uint32_t flash_connection : 4; //!< Flash connection option: 0 -  Single Flash connected to port A, 1 -
      //! Parallel mode, 2 - Single Flash connected to Port B
    } B;
    uint32_t U;
  } option1;

} serial_nor_config_option_t;
```

Detailed information of serial_nor_config_option_t structure is shown in the following table.

Table 10-65. serial_nor_config_option_t definition

Offset	Field	Description
0	Option0	See Table 10-66 for more details
4	Option1	Optional, valid only if the Option Size field in Option0 is non-zero. See Table 10-67 for more details.

Table 10-66. Option0 definition

Field	Bits	Description
tag	31:28	The tag of the config option, fixed to 0x0C
option_size	27:24	Size in bytes = (Option Size + 1) × 4 It is 0 if only option0 is required
device_type	23:20	Device Detection Type 0 - Read SFDP for SDR commands 1 - Read SFDP for DDR Read commands 2 - HyperFLASH 1V8 3 - HyperFLASH 3V 4 - Macronix Octal DDR 6 - Micron Octal DDR 8 - Adesto EcoXiP DDR
query_pad	19:16	Data pads during Query command (read SFDP or read MID) 0 - 1 2 - 4 3 – 8
cmd_pad	15:12	Data pads during Flash access command 0 - 1 2 - 4 3 – 8
quad_mode_sett ing	11:8	Quad Mode Enable Setting 0 - Not configured 1 - Set bit 6 in Status Register 1 2 - Set bit 1 in Status Register 2 3 - Set bit 7 in Status Register 2 4 - Set bit 1 in Status Register 2 vis 0x31 command **NOTE:** This field is valid only if a device is compliant with JESD216 only (9 longword SDFP table).
misc_mode	7:4	Set to 0.
max_freq	3:0	Max Flash Operation speed 0 - Do not change FlexSPI clock setting Others - *See System Boot chapter for more details*. **NOTE:** The field has a restriction that the FlexSPI clock source must be PLL480_PFD0. Keep it as 0 and manually configure the FLEXSPI clock if another clock source is selected in user application.

Table 10-67. Option1 definition

Field	Bits	Description
flash_connection	31:28	Flash connection selection 0 - Single FLASH connected to Port A 1 - Parallel mode 2 - Single FLASH connected to Port B
reserved	27:20	Reserved
pin_group	19:16	PinMux group 0 - Primary pin group 1 - Secondary pin group
reserved	15:8	Reserved
dummy_cycles	7:0	Dummy cycles for the read command 0 - Use detected dummy cycle Others - dummy cycles provided in flash datasheet

NOTE

- These APIs only support FLASH devices connected to SS0.
- The APIs always use 30MHz clock for the programming option. Users will need to change the "ipcmdSerialClkFreq" field in flexspi_nor_config_t field after flexspi_nor_get_config option, if a higher programming speed is expected.
- User application needs to set "max_freq" to 0 and manually configure the FLEXSPI clock before calling the flexspi_nor_get_config API, if the expected FLEXSPI clock source is not the default clock source configured by the ROM bootloader.
- The pad drive strength is configured to full-driver mode (See IOMUXC chapter for more details). Users can change the "dataPadOverride" and "sclkPadOverride" setting in flexspi_nor_config_t structure after calling flexspi_nor_get_config, if necessary.

10.13.2.1.12 Status codes for the FlexSPI NOR API

The following table lists all the error and status codes for the FlexSPI NOR API.

Table 10-68. Status and error codes for the FlexSPI NOR API

Status	Code	Description
kStatus_Success	0	Operation succeeded without error
kStatus_Fail	1	The operation failed with a generic error
kStatus_InvalidArgument	4	The requested argument is invalid
kStatus_Timeout	5	A timeout occurred
kStatus_FLEXSPI_SequenceExecutionT imeout	7000	The command timed out
kStatus_FLEXSPI_InvalidSequence	7001	Invalid LUT sequence
kStatus_FLEXSPI_DeviceTimeout	7002	The busy time exceeded the specified timeout value
kStatus_FLEXSPINOR_ProgramFail	20100	Program Command failed
kStatus_FLEXSPINOR_EraseSectorFail	20101	Erase sector command failed
kStatus_FLEXSPINOR_EraseAllFail	20102	Erase All command failed
kStatus_FLEXSPINOR_WaitTimeout	20103	The wait time exceeded the specified timeout value
kStatus_FlexSPINOR_NotSupported	20104	The operation is not supported
kStatus_FlexSPINOR_WriteAlignmentEr ror	20105	Write address is unaligned to page size
kStatus_FlexSPINOR_CommandFailure	20106	Command failed
kStatus_FlexSPINOR_SFDP_NotFound	20107	SFDP table was not found, used for flexspi_nor_flash_get_config API
kStatus_FLEXSPINOR_Flash_NotFoun d	20109	Cannot detect a FLASH device
kStatus_FLEXSPINOR_DTRRead_Dum myProbeFailed	20110	The dummy cycle for DDR/DTR read cannot be probed.

10.13.2.1.13 Typical options for the Serial NOR devices in the market

The following list provides typical options for the serial NOR flash devices in the market.

- QuadSPI NOR - Quad SDR Read: option0 = 0xc0000007 (133MHz)
- QuadSPI NOR - Quad DDR Read: option0 = 0xc0100003 (60MHz)
- HyperFLASH 1V8: option0 = 0xc0233008 (166MHz)
- HyperFLASH 3V0: option0 = 0xc0333005 (100MHz)
- MXIC OPI DDR (OPI DDR enabled by default): option=0xc0433007(133MHz)
- Micron Octal DDR: option0=0xc0600005 (100MHz)
- Micron OPI DDR: option0=0xc0603007 (133MHz), SPI->OPI DDR
- Micron OPI DDR (DDR read enabled by default): option0 = 0xc0633007 (133MHz)
- Adesto OPI DDR: option0=0xc0803007(133MHz)

10.13.2.1.14 FLASH API Example

The following is a typical use case of the FlexSPI NOR API.

```
flexspi_nor_config_t config;
serial_nor_config_option_t option;
status_t status;

uint32_t address = 0x40000; // 256KB uint32_t
sector_size = 0x1000; // 4KB
uint32_t page_buffer[256/ sizeof(uint32_t)];
uint32_t instance = 1;

option.option0.U = 0xC0000007; // QuadSPI NOR, Frequency: 133MHz

status = flexspi_nor_get_config(instance, &config, &option);
if (status != kStatus_Success)
{
    return status;
}

status = flexspi_nor_flash_init(instance, &config);
if (status != kStatus_Success)
{
    return status;
}
status = flexspi_nor_flash_erase(instance, &config, address , sector_size); // Erase 1
sector
if (status != kStatus_Success)
{
    return status;
}

// Fill data into the page_buffer;
for (uint32_t i=0; i<sizeof(page_buffer)/sizeof(page_buffer[0]); i++)
{
    page_buffer[i] = (i << 24) | (i << 16) | (i << 8) | i;
}
// Program data to destination
status = flexspi_nor_flash_page_program(instance, &config, address, page_buffer); // program
1 page
if (status != kStatus_Success)
{
    return status;
}

// Do cache maintenance here if the D-Cache is enabled
// Use memory mapped access to verify whether data are programmed into Flash correctly
uint32_t mem_address = 0x3000_0000 + address;

if (0 == memcmp((void*)mem_address, page_buffer, sizeof(page_buffer))
{
    // Success

}
else
{
    // Report error
}
```

10.13.3 Enter Bootloader API

The ROM bootloader provides an API for the user application to safely boot from a newly updated application after In-Application Programming (IAP) or re-enter serial downloader mode for an image update.

API prototype

```
void runBootloader(void* arg)
{
    g_bootloaderTree-> runBootloader(arg);
}
```

Table 10-69. ARG definition

Field	Offset	Description
Tag	[31:24]	Fixed value: 0xEB (Enter Boot)
boot mode	[23:20]	0 - Determined by BMODE in SMBR2 or other Fuse combinations 1 - Serial downloader
Serial downloader media	[19:16]	0 - Auto detection 1 - USB 2 - UART
Reserved	[15:04]	Reserved
Boot image selection	[03: 00]	0 - Image 0 1 - Image 1 2 - Image 2 3 - Image 3 **NOTE:** It takes effect only if the boot mode is 0. For FlexSPI NOR boot, the maximum Image index is 1. The address and length of the backup image is specified in the fuse. Image 0 is always the latest image. Image 1 always implies the backup image. If the dual image boot feature is not implemented, the backup image means the 2nd image, otherwise, the backup image means the "old" image. For the NAND FLASH devices, the maximum image index is 3. The Image address is specified in FCB.

Typical use cases:

1. Enter Serial downloader mode and select USB as the communication peripheral:

```
uint32_t arg = 0xeb110000;
runBootloader (&arg);
```

2. Select Image1 as the boot image after reliable update in user application:

```
uint32_t arg = 0xeb000001;
runBootloader (&arg);
```

Chapter 11
External Signals and Pin Multiplexing

11.1 Overview

The chip contains a limited number of pins, most of which have multiple signal options. These signal-to-pin and pin-to-signal options are selected by the input-output multiplexer called IOMUX. The IOMUX is also used to configure other pin characteristics, such as voltage level, drive strength, and hysteresis.

The muxing options table lists the external signals grouped by the module instance, the muxing options for each signal, and the registers used to route the signal to the chosen pad.

11.1.1 Muxing Options

NOTE

For information on external signals for ADC module, refer to Chip-specific LPADC information

Table 11-1. Muxing Options

Instance	Port	Pad	Mode
ACMP1	ACMP1_OUT	GPIO_AD_17	ALT1
	ACMP1_IN1	GPIO_AD_00	No muxing

1. This GPIO instance contains a mux that selects between normal GPIO or CM7 fast GPIO. See IOMUXC_GPR_GPR40-41 for more details.
2. This GPIO instance contains a mux that selects between normal GPIO or CM7 fast GPIO. See IOMUXC_GPR_GPR42-43 for more details.
3. For GPIO13_IO3-GPIO13_IO12, GPIO functions are not available on devices that support tamper.
4. Tamper is only available on select part numbers. Refer to the Datasheet for details.

11.1.2 Pin Assignments

NOTE

For GPIO_MUX2 and GPIO_MUX3 instances, the users can select between normal GPIO or CM7 fast GPIO.

12.2 Overview

The IOMUX Controller (IOMUXC), together with the IOMUX, enables the IC to share one pad to several functional blocks. This sharing is done by multiplexing the pad's input and output signals.

Every module requires a specific pad setting (such as pull up or down), and for each pad, there are up to 12 muxing options (called ALT modes). The pad settings parameters are controlled by the IOMUXC.

The IOMUX consists only of combinatorial logic combined from several basic IOMUX cells. Each basic IOMUX cell handles only one pad signal's muxing.

The figure below illustrates the IOMUX/IOMUXC connectivity in the system.

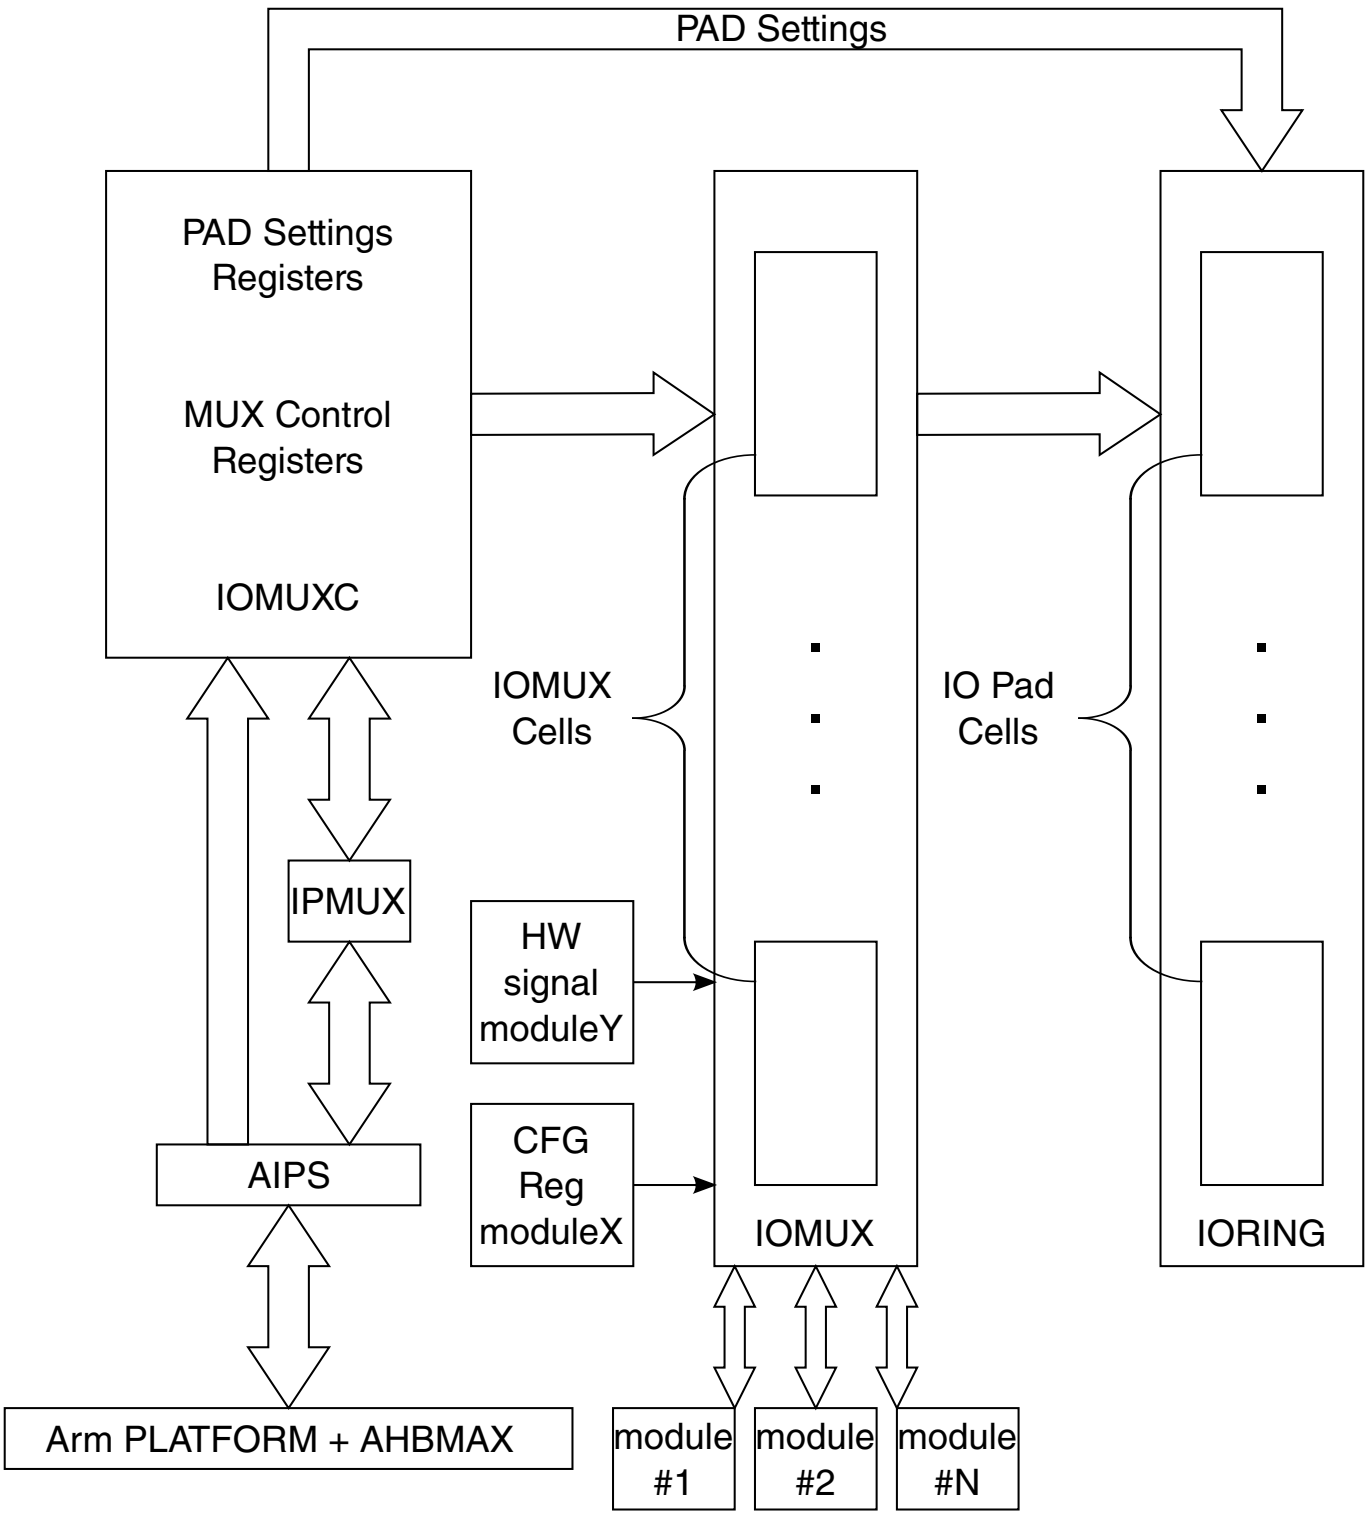

Figure 12-1. IOMUX SoC Level Block Diagram

12.2.1 Block Diagram

The high level illustration of the IO cells is shown in Figure 12-3

12.2.2 Features

The IOMUXC features include:

- 32-bit software mux control registers (IOMUXC_SW_MUX_CTL_PAD_<PAD NAME>) to configure 1 of 12 alternate (ALT) MUX_MODE fields of each pad or a predefined group of pads and to enable the forcing of an input path of the pad(s) (SION bit).
- 32-bit software pad control registers (IOMUXC_SW_PAD_CTL_PAD_<PAD_NAME>) to configure specific pad settings of each pad, or a predefined group of pads.
- 32-bit general purpose registers - GPRxx, 32-bit registers according to SoC requirements for any usage.
- 32-bit input select control registers to control the input path to a module when more than one pad drives this module input.

Each SW MUX/PAD CTL IOMUXC register handles only one pad or one pad's group.

Only the minimum number of registers required by software are implemented by hardware. For example, if only ALT0 and ALT1 modes are used on Pad x then only one bit register will be generated as the MUX_MODE control field in the software mux control register of Pad x.

The software mux control registers may allow the forcing of pads to become input (input path enabled) regardless of the functional direction driven. This may be useful for loopback and GPIO data capture.

12.3 Functional description

This section provides a complete functional description of the block.

The IOMUX consists of a number of basic iomux cell units. If only one functional mode is required for a specific pad, would have been no need for IOMUX and the signals can be connected directly from the module to the I/O. The IOMUX cell is required whenever two or more functional modes are required for a specific pad or when one functional mode and the one test mode are required.

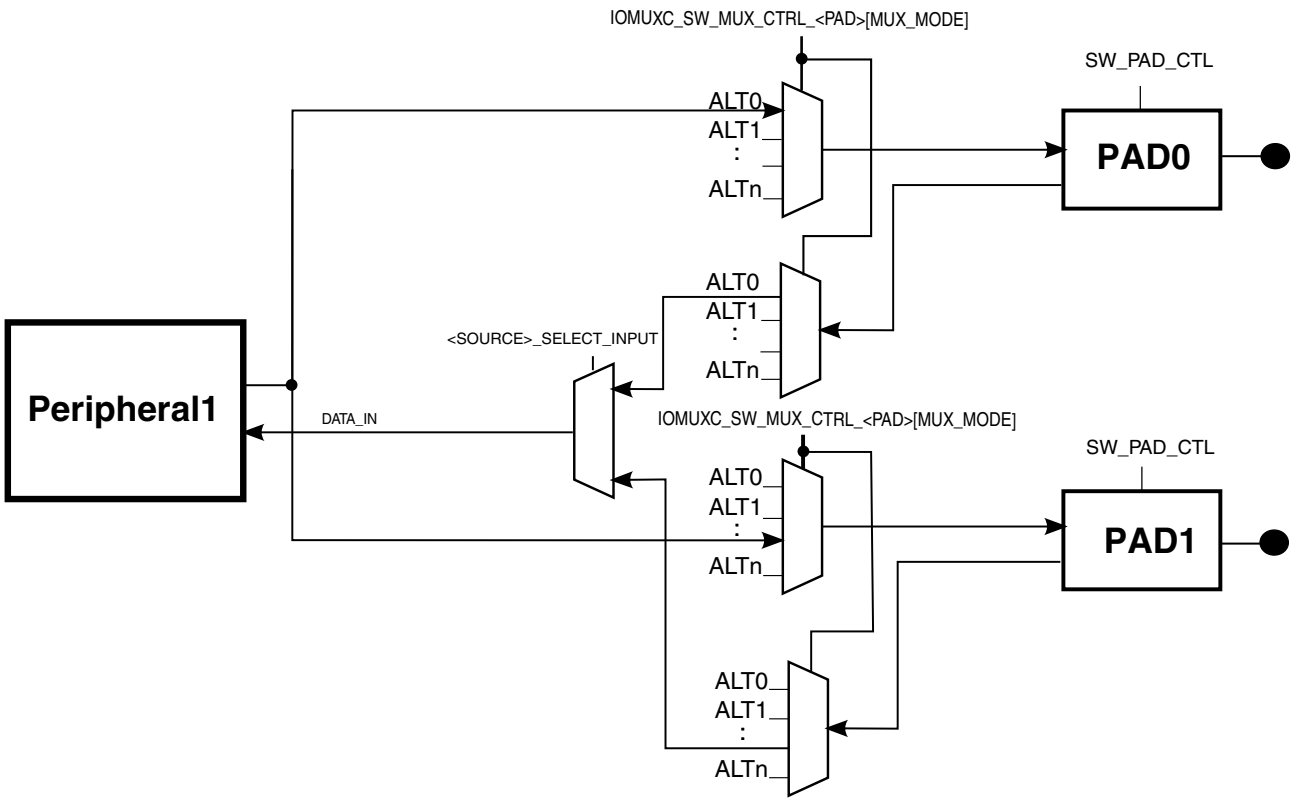

Figure 12-2. IOMUX Cell Block Diagram

12.3.1 ALT6 and ALT7 extended muxing modes

The ALT7 and ALT6 extended muxing modes allow any signal in the system (such as fuse, pad input, JTAG, or software register) to override any software configuration and to force the ALT6/ALT7 muxing mode.

It also allows an IOMUX software register to control a group of pads.

12.3.2 SW Loopback through SION bit

A limited option exists to override the default pad functionality and force the input path to be active regardless of the value driven by the corresponding module. This can be done by setting the SION (Software Input On) bit in the IOMUXC_SW_MUX_CTL register (when available) to "1".

Uses include:

- LoopBack - Module x drives the pad and also receives pad value as an input.

12.3.3 Daisy chain - multi pads driving same module input pin

In some cases, more than one pad may drive a single module input pin. Such cases require the addition of one more level of IOMUXing; all of these input signals are muxed, and a dedicated software controlled register controls the mux in order to select the required input path.

A module port involved in "daisy chain" requires two software configuration commands, one for selecting the mode for this pad (programable via the IOMUXC_SW_MUX_CTL_<PAD> registers) and one for defining it as the input path (via the daisy chain registers).

This means that a module port involved in "daisy chain" requires two software configuration commands, one for selecting the mode for this pad (programable via the IOMUXC_SW_MUX_CTL_<PAD> registers) and one for defining it as the input path (via the daisy chain registers).

The daisy chain is illustrated in the figure below.

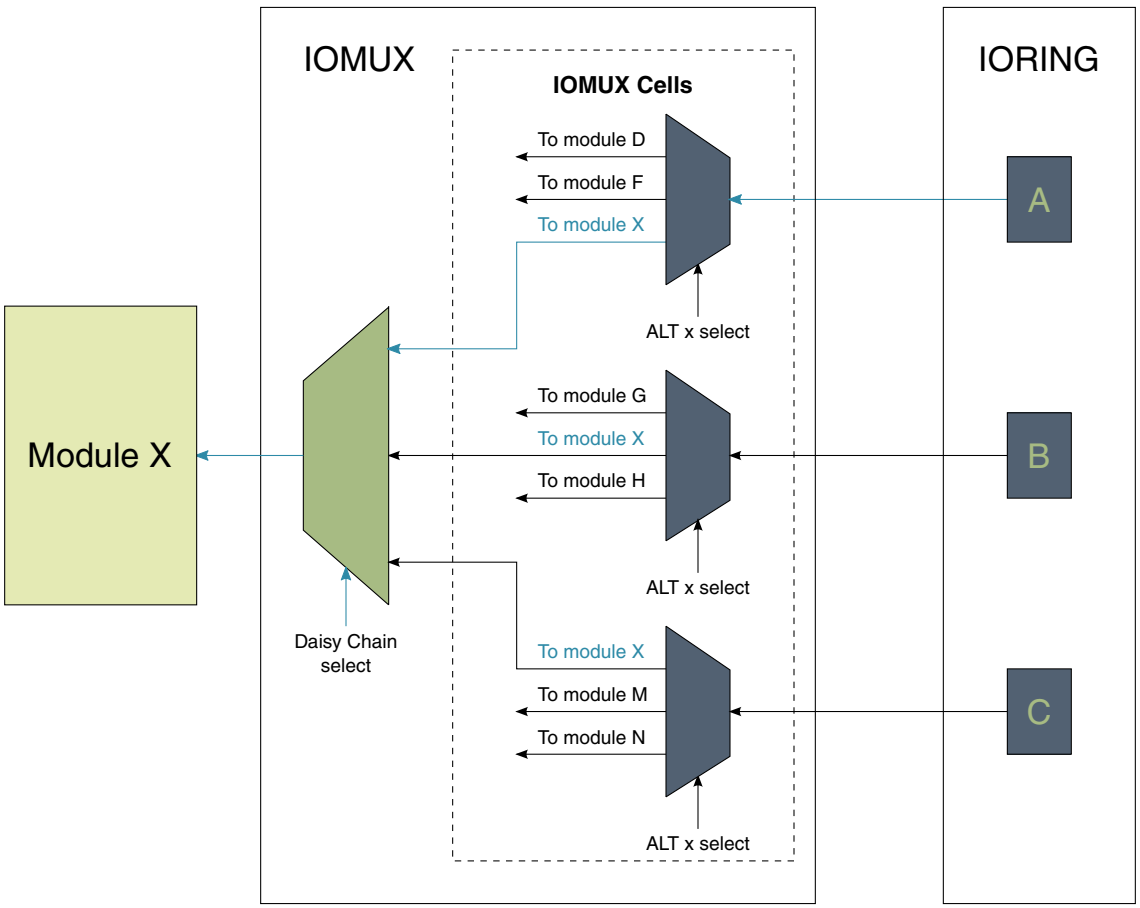

Figure 12-3. Daisy chain illustration

12.3.4 Clocks

The table found here describes the clock sources for IOMUXC. Please see Clock Controller Module (CCM) chapter for clock setting, configuration and gating information.

Table 12-2. IOMUXC Clocks

Clock Name	Description
ipg_clk	Peripheral clock
ipg_clk_s	Peripheral access clock

12.4 Memory Map and register definition

This section includes the IOMUXC module memory map and detailed descriptions of all registers.

12.4.1 IOMUXC SNVS GPR register descriptions

12.4.1.1 iomuxc_snvs_gpr memory map

IOMUXC_SNVS_GPR base address: 40C9_8000h

Offset	Register	Width (In bits)	Access	Reset value
0h - 7Ch	GPR0 General Purpose Register (GPR0 - GPR31)	32	RW	0000_0000h

Field	Function
31-30 DWP_LOCK	Domain write protection lock Once DWP_LOCK bit i is set the write to DWP bit i will be blocked. 00b - Neither of DWP bits is locked 01b - The lower DWP bit is locked 10b - The higher DWP bit is locked 11b - Both DWP bits are locked
29-28 DWP	Domain write protection These 2 bits determine which core is forbidden to change CM4_INIT_VTOR_HIGH field. When bit 0 is set, CM7 is forbidden. When bit 1 is set, CM4 is forbidden. 00b - Both cores are allowed 01b - CM7 is forbidden 10b - CM4 is forbidden 11b - Both cores are forbidden
27-16	Reserved

Table continues on the next page...

Field	Function
—	
15-0 CM4_INIT_VTOR_HIGH	CM4 Vector table offset value higher bits out of reset The VTOR sets the offset of the vector table base address from memory address 0x00000000. This field contains bits 31:16 of CM4 VTOR. **NOTE:** When user uses HAB authenticated or encrypted boot function, NXP strongly suggest user to set the default value (ROM entry address) into INIT_VTOR register and lock the default value.

12.4.5.6.4 Fields

Field	Function
31-30 DWP_LOCK	Domain write protection lock Once DWP_LOCK bit i is set the write to DWP bit i will be blocked. 00b - Neither of DWP bits is locked 01b - The lower DWP bit is locked 10b - The higher DWP bit is locked 11b - Both DWP bits are locked
29-28 DWP	Domain write protection These 2 bits determine which core is forbidden to change bits 15:0. When bit 0 is set, CM7 is forbidden. When bit 1 is set, CM4 is forbidden. 00b - Both cores are allowed 01b - CM7 is forbidden 10b - CM4 is forbidden 11b - Both cores are forbidden
27-16 —	Reserved
15-4 —	Reserved
3 ENET_EVENT0IN_SEL	ENET ENET_1588_EVENT0_IN source select 0: ENET_1588_EVENT0_IN input is from pad 1: ENET_1588_EVENT0_IN input is from GPT2 COMPARE1 output
2	ENET master timer source select

Table continues on the next page...

Field	Function
ENET_TIME_SEL	IEEE 1588 master counter value is used when IEEE 1588 circuitry for ENET is in slave mode. 0: master counter value is from ENET1G module 1: master counter value is from ENET_QOS module
1 ENET_REF_CLK_DIR	ENET_REF_CLK direction control This bitfield controls the direction of ENET_REF_CLK. ENET_REF_CLK is the 50MHz RMII clock. It should be set together with the corresponding IOMUXC SW_MUX_CTL_PAD_xx SION bit so that ENET1_CLK_ROOT can provide 50MHz RMII clock to both ENET and board. 0: ENET_REF_CLK is input 1: ENET_REF_CLK is output driven by ENET1_CLK_ROOT
0 ENET_TX_CLK_SEL	ENET TX_CLK select This bit should always be set to 1 to use the 25MHz MII clock 0: Not supported 1: ENET TX_CLK is from pad

15-5 —	Reserved
4 ENET1G_EVENT0IN_SEL	ENET1G ENET_1588_EVENT0_IN source select 0: ENET_1588_EVENT0_IN input is from pad 1 ENET_1588_EVENT0_IN input is from GPT2_COMPARE2 output

Table continues on the next page...

Field	Function
3 ENET1G_TIME_SEL	ENET1G master timer source select IEEE 1588 master counter value is used when IEEE 1588 circuitry for ENET1G is in slave mode. 0: master counter value is from ENET module 1: master counter value is from ENET_QOS module
2 ENET1G_RGMII_EN	ENET1G RGMII TX clock output enable Set this bit to enable ENET1G RGMII TX clock output on TX_CLK_IO pad. It should be set in RGMII mode, and be cleared in MII mode as in MII mode TX_CLK_IO is input.
1 ENET1G_REF_CLK_DIR	ENET1G_REF_CLK direction control This bitfield controls the direction of ENET1G_REF_CLK. ENET1G_REF_CLK is the 50MHz RMII clock. It should be set together with the corresponding IOMUXC SW_MUX_CTL_PAD_xx SION bit so that ENET1_CLK_ROOT can provide 50MHz RMII clock to both ENET and board. 0: ENET1G_REF_CLK is input 1: ENET1G_REF_CLK is output driven by ENET2_CLK_ROOT
0 ENET1G_TX_CLK_SEL	ENET1G TX_CLK select This bit should be set to 1 in MII mode to use the 25MHz TX clock. This bit should be set to 0 in RGMII mode to use ENET2_CLK_ROOT as the 125MHZ TX clock. 0 ENET1G TX_CLK is driven by ENET2_CLK_ROOT 1: ENET1G TX_CLK is from pad

7	ENET_QOS ENET_1588_EVENT0_IN source select 0: ENET_1588_EVENT0_IN input is from pad

Table continues on the next page...

Field	Function
ENET_QOS_EVENT0IN_SEL	1: ENET_1588_EVENT0_IN input is from GPT3_COMPARE1 output
6 ENET_QOS_CLKGEN_EN	ENET_QOS clock generator enable The ENET_QOS clock generator provides ENET_QOS TX/RX clocks according to the PHY interface type and speed. Set this bit to enable the clock generator. It's required by all the three modes. In RGMII mode, ENET_QOS_CLK_ROOT is the source of TX clock and will drive ENET_QOS TX_CLK pad given ENET_QOS_RGMII_EN is set. In MII mode, the TX clock is input from TX_CLK. In RMII mode, the TX clock is input from REF_CLK.
5-3 ENET_QOS_INTF_SEL	ENET_QOS PHY Interface Select Selects the PHY interface of the MAC. This config is sampled only during ENET_QOS reset assertion, and it is ignored after that. User can assert ENET_QOS reset via ENET_QOS software reset bit. 000: MII 001: RGMII 100: RMII
2 ENET_QOS_TIME_SEL	ENET_QOS master timer source select IEEE 1588 master counter value is used when IEEE 1588 circuitry for ENET_QOS is in slave mode. 0: master counter value is from ENET module 1 master counter value is from ENET_1G module
1 ENET_QOS_RGMII_EN	ENET_QOS RGMII TX clock output enable Set this bit to enable ENET_QOS RGMII TX clock output on TX_CLK pad. It should be set in RGMII mode, and be cleared in MII mode as in MII mode TX_CLK is input.
0 ENET_QOS_REF_CLK_DIR	ENET_QOS_REF_CLK direction control This bitfield controls the direction of ENET_QOS_REF_CLK. ENET_QOS_REF_CLK is the 50MHz RMII clock. It should be set together with the corresponding IOMUXC SW_MUX_CTL_PAD_xx SION bit so that ENET1_CLK_ROOT can provide 50MHz RMII clock to both ENET and board. 0: ENET_QOS_REF_CLK is input 1 ENET_QOS_REF_CLK is output driven by ENET_QOS_CLK_ROOT

24-21 GPIO_DISP1_NASRC	GPIO_DISP_B1 IO bank compensation codes 4-bit NMOS compensation codes or 4-bit PMOS compensation codes selected by GPIO_DISP1_SELECT_NASRC.
20 GPIO_DISP1_COMPOK	GPIO_DISP_B1 IO bank compensation OK flag It can be high only in the Normal mode and when a new measured code is available.
19-15 —	Reserved
14 GPIO_DISP1_SUPLYDET_LATCH	GPIO_DISP_B1 IO bank power supply mode latch enable Supply detector cell is used to detect the IO supply range and set IO to 3V3 supply mode or 1V8 supply mode according to the detection. Setting this bit will latch the current detect result.
13 GPIO_DISP1_REFGEN_SLEEP	GPIO_DISP_B1 IO bank reference voltage generator cell sleep enable Reference voltage generator cell provides reference voltages to the IO bank. When this bit is high, it puts the reference voltage generator cell in sleep mode to reduce the static power consumption.
12 GPIO_DISP1_SELECT_NASRC	GPIO_DISP1_NASRC selection 0: Show the 4-bit PMOS compensation codes in GPIO_DISP1_NASRC field 1: Show the 4-bit NMOS compensation codes in GPIO_DISP1_NASRC field
11-8 GPIO_DISP1_RASRCN	GPIO_DISP_B1 IO bank's 4-bit NMOS compensation codes from core These codes are used in compensation Read mode when COMPEN, COMPTQ, FREEZE, FASTFRZ_EN is high, high, low, low.
7-4 GPIO_DISP1_RASRCP	GPIO_DISP_B1 IO bank's 4-bit PMOS compensation codes from core These codes are used in compensation Read mode when COMPEN, COMPTQ, FREEZE, FASTFRZ_EN is high, high, low, low.
3 GPIO_DISP1_FASTFRZ_EN	Compensation code fast freeze When COMPEN, COMPTQ, FREEZE, FASTFRZ_EN is low, low, low, high, compensation cell Fast Freeze mode is enabled. Fast Freeze mode is activated on signal rising edge. The compensation cell delivers a refreshed compensation code, at a comparatively lesser delay after signal falling edge than the delay of Freeze mode.
2 GPIO_DISP1_COMPEN	COMPEN and COMPTQ control the operating modes of the compensation cell

Table continues on the next page...

<table>
<tr><th>Field</th><th>Function</th></tr>
<tr><td></td><td>Normal Mode: In this mode, the macro cell constantly tracks the PVT condition of the chip and generates an 8-bit digital code. This 8-bit code is referred to as f(PVT) and it represents current PVT state. In Normal mode, the internal reference current generators are active and power consumption is higher than that in all the other modes.

Freeze mode: This mode is used where the current consumption is to be kept low. In this mode, all the internal blocks are switched off to reduce the static power consumption. Internal latches keep the code, which is calculated before the cell enters the Freeze mode.

Fast Freeze mode: This mode is used to freeze the digital compensation codes, when the data is transferred from the compensated IOs on a chip to an external device during Burst mode. This ensures signal integrity and eliminates the jitter caused due to modification in IO driver strength. In this mode, the current consumption is comparable to consumption in the Normal mode.

Read Mode: In this mode, it is possible to force the digital codes from the chip core logic. The bandgap, measurement block, and comparator blocks are switched off to reduce static power consumption to minimum value.

Fixed Code mode: The digital code is forced to a fixed value, obtained at typical PVT conditions and represents typical bit patterns. The bandgap, measurement, and other blocks are switched off to reduce static power consumption to minimum value.

11-8 GPIO_SD2_RASRCN	GPIO_SD_B2 IO bank's 4-bit NMOS compensation codes from core These codes are used in compensation Read mode when COMPEN, COMPTQ, FREEZE, FASTFRZ_EN is high, high, low, low.
7-4 GPIO_SD2_RASRCP	GPIO_SD_B2 IO bank's 4-bit PMOS compensation codes from core These codes are used in compensation Read mode when COMPEN, COMPTQ, FREEZE, FASTFRZ_EN is high, high, low, low.
3 GPIO_SD2_FASTFRZ_EN	Compensation code fast freeze When COMPEN, COMPTQ, FREEZE, FASTFRZ_EN is low, low, low, high, compensation cell Fast Freeze mode is enabled. Fast Freeze mode is activated on signal rising edge. The compensation cell delivers a refreshed compensation code, at a comparatively lesser delay after signal falling edge than the delay of Freeze mode.
2 GPIO_SD2_COMPEN	COMPEN and COMPTQ control the operating modes of the compensation cell Normal Mode: In this mode, the macro cell constantly tracks the PVT condition of the chip and generates an 8-bit digital code. This 8-bit code is referred to as f(PVT) and it represents current PVT state. In Normal mode, the internal reference current generators are active and power consumption is higher than that in all the other modes. Freeze mode: This mode is used where the current consumption is to be kept low. In this mode, all the internal blocks are switched off to reduce the static power consumption. Internal latches keep the code, which is calculated before the cell enters the Freeze mode. Fast Freeze mode: This mode is used to freeze the digital compensation codes, when the data is transferred from the compensated IOs on a chip to an external device during Burst mode. This ensures signal integrity and eliminates the jitter caused due to modification in IO driver strength. In this mode, the current consumption is comparable to consumption in the Normal mode. Read Mode: In this mode, it is possible to force the digital codes from the chip core logic. The bandgap, measurement block, and comparator blocks are switched off to reduce static power consumption to minimum value.

Table continues on the next page...

<table>
<tr><th>Field</th><th>Function</th></tr>
<tr><td></td><td>Fixed Code mode: The digital code is forced to a fixed value, obtained at typical PVT conditions and represents typical bit patterns. The bandgap, measurement, and other blocks are switched off to reduce static power consumption to minimum value.

12.4.6.211.4 Fields

Field	Function
31-30 DWP_LOCK	Domain write protection lock Once DWP_LOCK bit i is set the write to DWP bit i will be blocked. 00b - Neither of DWP bits is locked 01b - The lower DWP bit is locked 10b - The higher DWP bit is locked 11b - Both DWP bits are locked
29-28 DWP	Domain write protection These 2 bits determine which core is forbidden to change bits 6:0. When bit 0 is set, CM7 is forbidden. When bit 1 is set, CM4 is forbidden. 00b - Both cores are allowed 01b - CM7 is forbidden 10b - CM4 is forbidden 11b - Both cores are forbidden
27-5 —	- Reserved
4	Open Drain Field

Table continues on the next page...

Field	Function
ODE	If set to 1, the output driver drives only logic 0. The drain of the internal transistor is open. It means that logic 1 has to be driven by an external component. This option is essential if connection between the pad and an external component is bi-directional. If ODE = 0, then the output driver drives logic 1 and logic 0. Select one out of next values for pad: GPIO_AD_01 0b - Disabled 1b - Enabled
3 PUS	Pull Up / Down Config. Field Select one out of next values for pad: GPIO_AD_01 0b - Weak pull down 1b - Weak pull up
2 PUE	Pull / Keep Select Field Select one out of next values for pad: GPIO_AD_01 0b - Pull Disable 1b - Pull Enable
1 DSE	Drive Strength Field Select one out of next values for pad: GPIO_AD_01 0b - normal drive strength 1b - high drive strength
0 SRE	Slew Rate Field Select one out of next values for pad: GPIO_AD_01 0b - Fast Slew Rate 1b - Slow Slew Rate

12.4.6.224.4 Fields

Field	Function
31-30 DWP_LOCK	Domain write protection lock Once DWP_LOCK bit i is set the write to DWP bit i will be blocked. 00b - Neither of DWP bits is locked 01b - The lower DWP bit is locked 10b - The higher DWP bit is locked 11b - Both DWP bits are locked
29-28 DWP	Domain write protection These 2 bits determine which core is forbidden to change bits 6:0. When bit 0 is set, CM7 is forbidden. When bit 1 is set, CM4 is forbidden. 00b - Both cores are allowed 01b - CM7 is forbidden 10b - CM4 is forbidden 11b - Both cores are forbidden
27-5 —	- Reserved
4 ODE	Open Drain Field If set to 1, the output driver drives only logic 0. The drain of the internal transistor is open. It means that logic 1 has to be driven by an external component. This option is essential if connection between the pad and an external component is bi-directional. If ODE = 0, then the output driver drives logic 1 and logic 0. Select one out of next values for pad: GPIO_AD_14 0b - Disabled 1b - Enabled
3 PUS	Pull Up / Down Config. Field Select one out of next values for pad: GPIO_AD_14 0b - Weak pull down 1b - Weak pull up
2 PUE	Pull / Keep Select Field Select one out of next values for pad: GPIO_AD_14

12.4.6.237.4 Fields

Field	Function
31-30 DWP_LOCK	Domain write protection lock Once DWP_LOCK bit i is set the write to DWP bit i will be blocked. 00b - Neither of DWP bits is locked 01b - The lower DWP bit is locked 10b - The higher DWP bit is locked 11b - Both DWP bits are locked
29-28 DWP	Domain write protection These 2 bits determine which core is forbidden to change bits 6:0. When bit 0 is set, CM7 is forbidden. When bit 1 is set, CM4 is forbidden. 00b - Both cores are allowed 01b - CM7 is forbidden 10b - CM4 is forbidden 11b - Both cores are forbidden
27-5 —	- Reserved
4 ODE	Open Drain Field If set to 1, the output driver drives only logic 0. The drain of the internal transistor is open. It means that logic 1 has to be driven by an external component. This option is essential if connection between the pad and an external component is bi-directional. If ODE = 0, then the output driver drives logic 1 and logic 0. Select one out of next values for pad: GPIO_AD_27 0b - Disabled 1b - Enabled
3 PUS	Pull Up / Down Config. Field Select one out of next values for pad: GPIO_AD_27 0b - Weak pull down 1b - Weak pull up
2 PUE	Pull / Keep Select Field Select one out of next values for pad: GPIO_AD_27 0b - Pull Disable 1b - Pull Enable
1 DSE	Drive Strength Field Select one out of next values for pad: GPIO_AD_27 0b - normal drive strength 1b - high drive strength
0 SRE	Slew Rate Field Select one out of next values for pad: GPIO_AD_27 0b - Fast Slew Rate 1b - Slow Slew Rate

Field	Function
31-30 DWP_LOCK	Domain write protection lock Once DWP_LOCK bit i is set the write to DWP bit i will be blocked. 00b - Neither of DWP bits is locked 01b - The lower DWP bit is locked 10b - The higher DWP bit is locked 11b - Both DWP bits are locked
29-28 DWP	Domain write protection These 2 bits determine which core is forbidden to change bits 6:0. When bit 0 is set, CM7 is forbidden. When bit 1 is set, CM4 is forbidden. 00b - Both cores are allowed 01b - CM7 is forbidden 10b - CM4 is forbidden 11b - Both cores are forbidden
27-5 —	- Reserved
4	Open Drain Field

Table continues on the next page...

Field	Function
ODE	If set to 1, the output driver drives only logic 0. The drain of the internal transistor is open. It means that logic 1 has to be driven by an external component. This option is essential if connection between the pad and an external component is bi-directional. If ODE = 0, then the output driver drives logic 1 and logic 0. Select one out of next values for pad: GPIO_DISP_B2_13 0b - Disabled 1b - Enabled
3 PUS	Pull Up / Down Config. Field Select one out of next values for pad: GPIO_DISP_B2_13 0b - Weak pull down 1b - Weak pull up
2 PUE	Pull / Keep Select Field Select one out of next values for pad: GPIO_DISP_B2_13 0b - Pull Disable 1b - Pull Enable
1 DSE	Drive Strength Field Select one out of next values for pad: GPIO_DISP_B2_13 0b - normal drive strength 1b - high drive strength
0 SRE	Slew Rate Field Select one out of next values for pad: GPIO_DISP_B2_13 0b - Fast Slew Rate 1b - Slow Slew Rate

Chapter 13
General Purpose Input/Output (GPIO)

13.1 Chip-specific GPIO information

Table 13-1. Reference links to related information

Topic	Related module(s)	Reference
System memory map	-	System Memory Map
Clocking	CCM	Clock Management Clock Control Module (CCM)
Power management	PMU	Power Management Power Management Unit
Signal multiplexing	IOMUX	External Signals and Pin Multiplexing IOMUX
Interrupts, DMA Events and XBAR Assignments	-	Interrupts, DMA Events and XBAR Assignments

GPIO_MUX2_IOn and GPIO_MUX3_IOn signals can be routed to the standard GPIO modules (GPIO2 and GPIO3), or they can be routed to high speed GPIO modules (CM7_GPIO2 and CM7_GPIO3). By default, all of the GPIO_MUX2 and GPIO_MUX3 signals route to the standard GPIO2 and GPIO3 modules. To use high speed GPIOs, the IOMUXC_GPR40 - IOMUC_GPR43 registers must be reconfigured to route the desired signals to the CM7_GPIO2 and/or CM7_GPIO3 modules.

When LPSRMIX master is accessing GPIO13, XB will hold WAKEUPMIX master requests to any AIPS4 peripheral until current LPSRMIX master access is completed. Because GPIO13 access is based on 32 K clock as it’s in SNVS domain to save power, these WAKEUPMIX master requests could be held for over 31µs.

13.2 Overview

The General-Purpose Input/Output (GPIO) peripheral provides dedicated general-purpose pins that can be configured as either inputs or outputs.

When configured as an output, it is possible to write to an internal register to control the state driven on the output pin. When configured as an input, it is possible to detect the state of the input by reading the state of an internal register. In addition, the GPIO peripheral can produce CORE interrupts.

13.2.1 Block Diagram

The GPIO subsystem contains multiple GPIO blocks, which can generate and control up to 32 signals for general purpose.

The block diagram for the GPIO block is provided below.

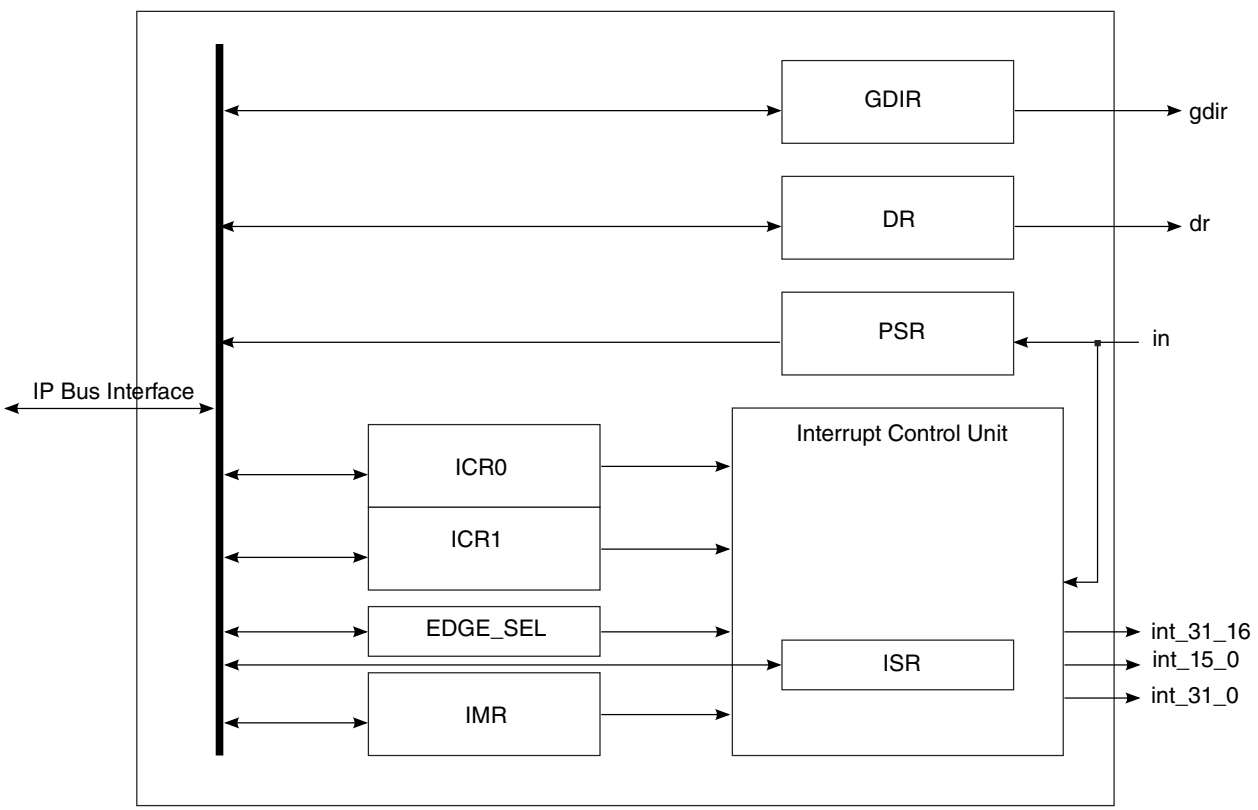

Figure 13-1. GPIO Block Diagram

13.2.2 Features

The GPIO includes the following features:

- General purpose input/output logic capabilities:
  - Drives specific data to output using the data register (DR)
  - Controls the direction of the signal using the GPIO direction register (GDIR)
  - Enables the core to sample the status of the corresponding inputs by reading the pad sample register (PSR).
- GPIO interrupt capabilities:
  - Supports 32 interrupts
  - Identifies interrupt edges
  - Generates three active-high interrupts to the SoC interrupt controller

13.3 Functional Description

The GPIO is one of the blocks controlling the IOMUX of the chip.

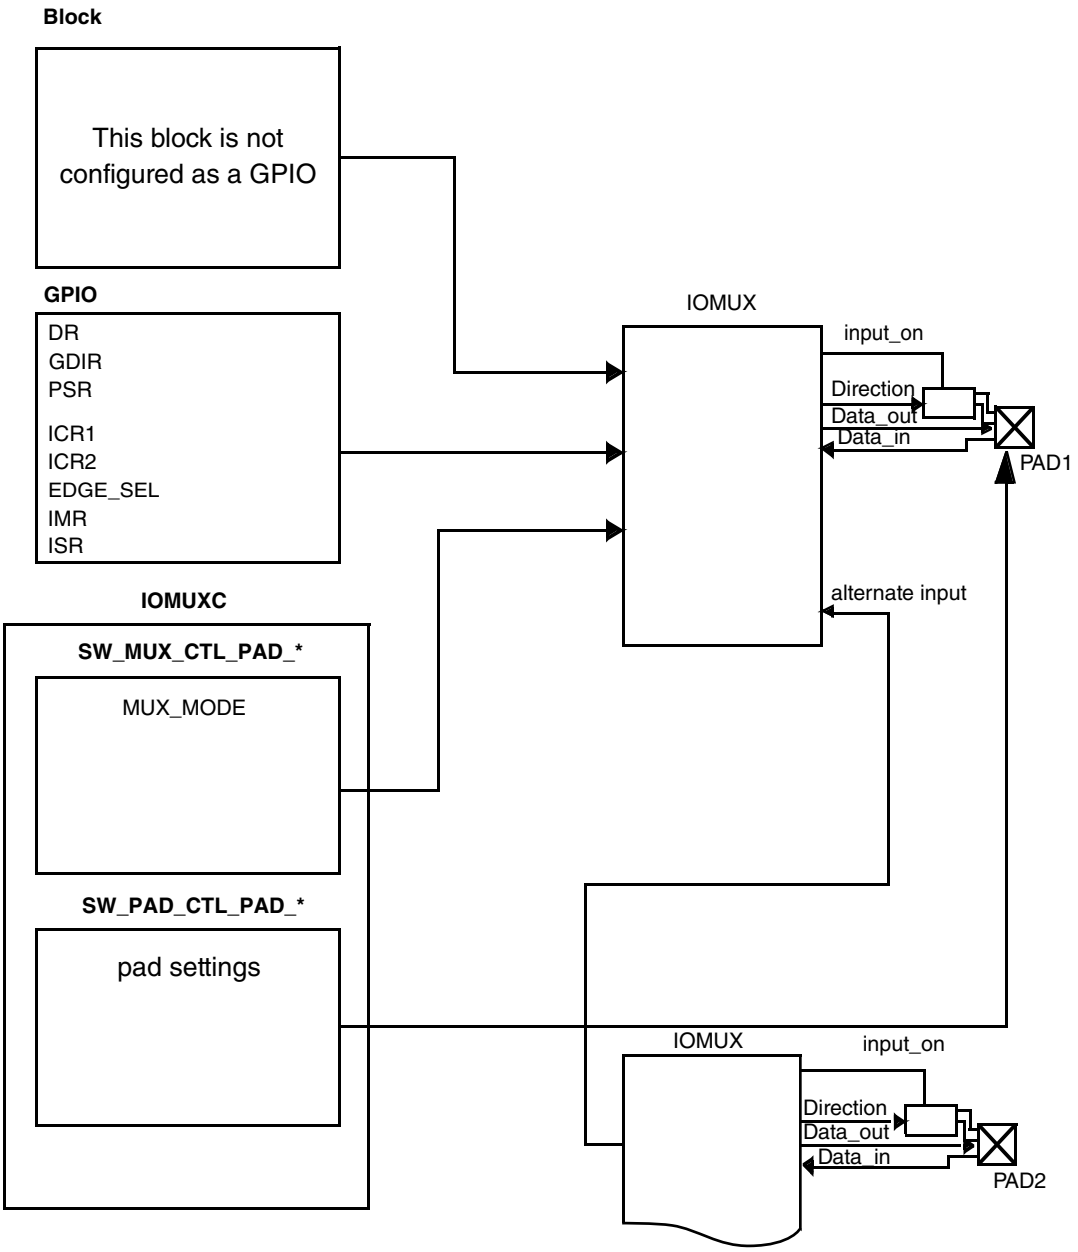

Figure 13-2. Chip IOMUX Scheme

A GPIO signal can operate as a general-purpose input/output when the IOMUX is set to GPIO mode. Each GPIO signal may be independently configured as either an input or an output using the GPIO direction register (GDIR).

When configured as an output (GDIR[GDIR] = 1), the value in the data bit in the GPIO data register (DR) is driven on the corresponding GPIO line. When a signal is configured as an input (GDIR[GDIR] = 0), the state of the input can be read from the corresponding PSR[PSR] bit.

The GPIO functionality is provided through eight registers, an edge-detect circuit, and interrupt generation logic.

The eight registers are:

- Data register (DR)
- GPIO direction register (GDIR)
- Pad sample register (PSR)
- Interrupt control registers (ICR1, ICR2)
- Edge select register (EDGE_SEL)
- Interrupt mask register (IMR)
- Interrupt status register (ISR)

The above registers are described in detail in the Register section.

Each GPIO input has a dedicated edge-detect circuit which can be configured through software to detect rising edges, falling edges, logic low-levels or logic high-levels on the input signals. The outputs of the edge detect circuits are optionally masked by setting the corresponding bit in the interrupt mask register (IMR). These qualified outputs are OR'ed together to generate two one-bit interrupt lines:

- Combined interrupt indication for GPIOx signals 0 - 15
- Combined interrupt indication for GPIOx signals 16 - 31

The GPIO edge detection is described further in Interrupt Control Unit.

13.3.1 GPIO pad structure

The functional diagram for the GPIO pad is provided below.

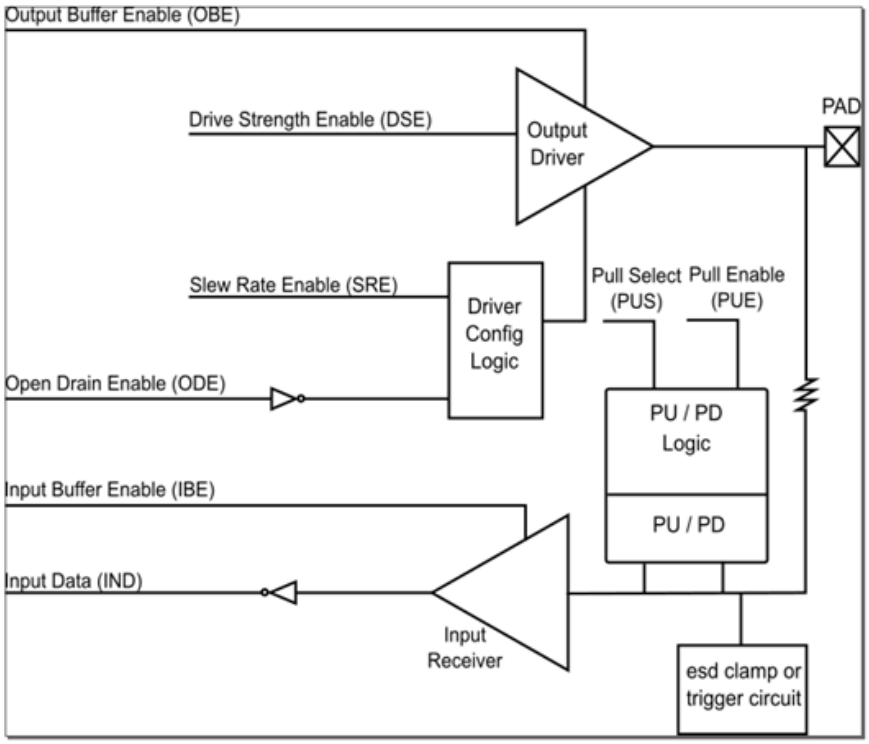

Figure 13-3. GPIO pad functional diagram

13.3.2 Interrupt Control Unit

In addition to the general-purpose input/output function, the edge-detect logic in the GPIO peripheral reflects whether a transition has occurred on a given GPIO signal that is configured as an input (GDIR[GDIR] = 0). The interrupt control registers (ICR1 and ICR2) may be used to independently configure the interrupt condition of each input signal (low-to-high transition, high-to-low transition, low, or high). For information about ICR1 and ICR2 settings, see the Register section.

The interrupt control unit is built of 32 interrupt control subunits, where each subunit handles a single interrupt line.

13.3.3 Clocks

The following table describes the clock sources for GPIO. Please see the CCM for clock setting, configuration and gating information.

Table 13-2. GPIO Clocks

Clock name	Description
ipg_clk_s	Peripheral access clock

13.4 External Signals

The following table describes the external signals of GPIO.

Table 13-3. GPIO External Signals

Signal	Description
IOn	GPIO Signal

13.5 Application Information

13.5.1 GPIO Read Mode

The programming sequence for reading input signals should be as follows:

1. Configure IOMUX to select GPIO mode (via IOMUX Controller (IOMUXC)).
2. Configure GPIO direction register to input (GDIR[GDIR] = 0b).
3. Read value from data register/pad status register.

A pseudocode description to read [input3:input0] values is as follows:

```
// SET INPUTS TO GPIO MODE.
write sw_mux_ctl_<input0>_<input1>_<input2>_<input3>, 32'h00000000
// SET GDIR TO INPUT.
write GDIR[31:4,input3_bit, input2_bit, input1_bit, input0_bit,] 32'hxxxxxxx0
// READ INPUT VALUE FROM DR.
read DR
// READ INPUT VALUE FROM PSR.
read PSR
```

NOTE

While the GPIO direction is set to input (GDIR[GDIR] = 0), a read access to DR does not return DR data. Instead, it returns the PSR data, which is the corresponding input signal value.

13.5.2 GPIO Write Mode

The programming sequence for driving output signals should be as follows:

1. Configure IOMUX to select GPIO mode (via IOMUXC). If needed, enable SION to read the loopback pad value through PSR.

2. Configure GPIO direction register to output (GDIR[GDIR] = 1b).
3. Write value to data register (DR).

A pseudocode description to drive 4'b0101 on [output3:output0] is as follows:

```
// SET PADS TO GPIO MODE VIA IOMUX.
write sw_mux_ctl_pad_<output[0-3]>.mux_mode, <GPIO_MUX_MODE>
// Enable loopback to capture pad value into PSR in output mode
write sw_mux_ctl_pad_<output[0-3]>.sion, 1
// SET GDIR=1 TO OUTPUT BITS.
write GDIR[31:4,output3_bit,output2_bit, output1_bit, output0_bit,] 32'hxxxxxxxF
// WRITE OUTPUT VALUE=4'b0101 TO DR.
write DR, 32'hxxxxxxx5
// READ OUTPUT VALUE FROM PSR ONLY.
read_cmp PSR, 32'hxxxxxxx5
```

13.6 Memory Map/Register Definition

This section includes the memory map and descriptions of all registers.

13.6.1 GPIO register descriptions

There are eight 32-bit GPIO registers. All registers are accessible from the IP interface. Only 32-bit access is supported.

The GPIO memory map is shown in the following table.

13.6.1.1 GPIO memory map

CM7_GPIO2 base address: 4200_8000h

CM7_GPIO3 base address: 4200_C000h

GPIO1 base address: 4012_C000h

GPIO2 base address: 4013_0000h

GPIO3 base address: 4013_4000h

GPIO4 base address: 4013_8000h

GPIO5 base address: 4013_C000h

GPIO6 base address: 4014_0000h

GPIO7 base address: 40C5_C000h

GPIO8 base address: 40C6_0000h

GPIO9 base address: 40C6_4000h

GPIO10 base address: 40C6_8000h

GPIO11 base address: 40C6_C000h

GPIO12 base address: 40C7_0000h

GPIO13 base address: 40CA_0000h

Offset	Register	Width (In bits)	Access	Reset value
0h	GPIO data register (DR)	32	RW	0000_0000h
4h	GPIO direction register (GDIR)	32	RW	0000_0000h
8h	GPIO pad status register (PSR)	32	R	0000_0000h
Ch	GPIO interrupt configuration register1 (ICR1)	32	RW	0000_0000h
10h	GPIO interrupt configuration register2 (ICR2)	32	RW	0000_0000h
14h	GPIO interrupt mask register (IMR)	32	RW	0000_0000h
18h	GPIO interrupt status register (ISR)	32	RW	0000_0000h
1Ch	GPIO edge select register (EDGE_SEL)	32	RW	0000_0000h
84h	GPIO data register SET (DR_SET)	32	W	0000_0000h
88h	GPIO data register CLEAR (DR_CLEAR)	32	W	0000_0000h
8Ch	GPIO data register TOGGLE (DR_TOGGLE)	32	W	0000_0000h

13.6.1.2 GPIO data register (DR)

13.6.1.2.1 Offset

Register	Offset
DR	0h

13.6.1.2.2 Function

The 32-bit DR register stores data that is ready to be driven to the output lines. If the IOMUXC is in GPIO mode and a given GPIO direction bit is set, then the corresponding DR bit is driven to the output. If a given GPIO direction bit is cleared, then a read of DR register reflects the value of the corresponding signal. Two wait states are required in read access for synchronization.

The results of a read of a DR bit depends on the IOMUXC input mode settings and the corresponding GDIR bit as follows:

- If GDIR[*n*] is set and IOMUXC input mode is GPIO, then reading DR[*n*] returns the contents of DR[*n*].
- If GDIR[*n*] is cleared and IOMUXC input mode is GPIO, then reading DR[*n*] returns the corresponding input signal's value.
- If GDIR[*n*] is set and IOMUXC input mode is not GPIO, then reading DR[*n*] returns the contents of DR[*n*].
- If GDIR[*n*] is cleared and IOMUXC input mode is not GPIO, then reading DR[*n*] always returns zero.

13.6.1.2.3 Diagram

R W	DR															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

13.6.1.2.4 Fields

Field	Function
31-0 DR	DR data bits This register defines the value of the GPIO output when the signal is configured as an output (GDIR[n]=1). Writes to this register are stored in a register. Reading DR register returns the value stored in the register if the signal is configured as an output (GDIR[n]=1), or the input signal's value if configured as an input (GDIR[n]=0). **NOTE:** The IOMUXC must be configured to GPIO mode for the DR register value to connect with the signal. Reading the data register with the input path disabled always returns a zero value.

13.6.1.3 GPIO direction register (GDIR)

13.6.1.3.1 Offset

Register	Offset
GDIR	4h

13.6.1.3.2 Function

The GDIR register functions as direction control when the IOMUXC is in GPIO mode. Each bit specifies the direction of a one-bit signal. The mapping of each DIR bit to a corresponding SoC signal is determined by the SoC's pin assignment and the IOMUX table. For more details consult the IOMUXC chapter.

13.6.1.3.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	GDIR															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	GDIR															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

13.6.1.3.4 Fields

Field	Function
31-0 GDIR	GPIO direction bits Bit n of this register defines the direction of the GPIO[n] signal. **NOTE:** The GDIR register affects only the direction of the I/O signal when the corresponding bit in the IOMUXC is configured for GPIO. 0b - GPIO is configured as input. 1b - GPIO is configured as output.

13.6.1.4 GPIO pad status register (PSR)

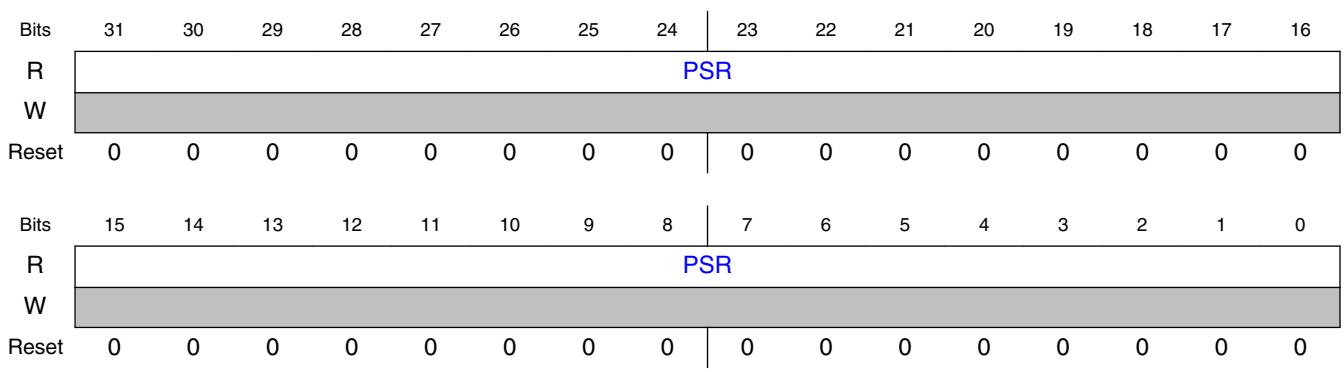
13.6.1.4.1 Offset

Register	Offset
PSR	8h

13.6.1.4.2 Function

The PSR register is a read-only register. Each bit stores the value of the corresponding input signal (as configured in the IOMUX). This register is clocked with the ipg_clk_s clock, meaning that the input signal is sampled only when accessing this location. Two wait states are required any time this register is accessed for synchronization.

13.6.1.4.3 Diagram



13.6.1.4.4 Fields

Field	Function
31-0 PSR	GPIO pad status bits Reading the PSR register returns the state of the corresponding input signal. **NOTE:** The IOMUXC must be configured to GPIO mode for the PSR register to reflect the state of the corresponding signal.

13.6.1.5 GPIO interrupt configuration register1 (ICR1)

13.6.1.5.1 Offset

Register	Offset
ICR1	Ch

13.6.1.5.2 Function

The ICR1 register contains 16 two-bit fields, where each field specifies the interrupt configuration for a different input signal.

13.6.1.5.3 Diagram

Field	Function
ICR13	This bit field controls the active condition of the interrupt function for GPIO interrupt 13. 00b - Interrupt 13 is low-level sensitive. 01b - Interrupt 13 is high-level sensitive. 10b - Interrupt 13 is rising-edge sensitive. 11b - Interrupt 13 is falling-edge sensitive.
25-24	Interrupt configuration field for GPIO interrupt 12
ICR12	This bit field controls the active condition of the interrupt function for GPIO interrupt 12. 00b - Interrupt 12 is low-level sensitive. 01b - Interrupt 12 is high-level sensitive. 10b - Interrupt 12 is rising-edge sensitive. 11b - Interrupt 12 is falling-edge sensitive.
23-22	Interrupt configuration field for GPIO interrupt 11
ICR11	This bit field controls the active condition of the interrupt function for GPIO interrupt 11. 00b - Interrupt 11 is low-level sensitive. 01b - Interrupt 11 is high-level sensitive. 10b - Interrupt 11 is rising-edge sensitive. 11b - Interrupt 11 is falling-edge sensitive.
21-20	Interrupt configuration field for GPIO interrupt 10
ICR10	This bit field controls the active condition of the interrupt function for GPIO interrupt 10. 00b - Interrupt 10 is low-level sensitive. 01b - Interrupt 10 is high-level sensitive. 10b - Interrupt 10 is rising-edge sensitive. 11b - Interrupt 10 is falling-edge sensitive.
19-18	Interrupt configuration field for GPIO interrupt 9
ICR9	This bit field controls the active condition of the interrupt function for GPIO interrupt 9. 00b - Interrupt 9 is low-level sensitive. 01b - Interrupt 9 is high-level sensitive. 10b - Interrupt 9 is rising-edge sensitive. 11b - Interrupt 9 is falling-edge sensitive.
17-16	Interrupt configuration field for GPIO interrupt 8
ICR8	This bit field controls the active condition of the interrupt function for GPIO interrupt 8. 00b - Interrupt 8 is low-level sensitive. 01b - Interrupt 8 is high-level sensitive. 10b - Interrupt 8 is rising-edge sensitive. 11b - Interrupt 8 is falling-edge sensitive.
15-14	Interrupt configuration field for GPIO interrupt 7
ICR7	This bit field controls the active condition of the interrupt function for GPIO interrupt 7. 00b - Interrupt 7 is low-level sensitive. 01b - Interrupt 7 is high-level sensitive. 10b - Interrupt 7 is rising-edge sensitive. 11b - Interrupt 7 is falling-edge sensitive.
13-12	Interrupt configuration field for GPIO interrupt 6
ICR6	This bit field controls the active condition of the interrupt function for GPIO interrupt 6. 00b - Interrupt 6 is low-level sensitive. 01b - Interrupt 6 is high-level sensitive. 10b - Interrupt 6 is rising-edge sensitive. 11b - Interrupt 6 is falling-edge sensitive.

Table continues on the next page...

Field	Function
11-10 ICR5	Interrupt configuration field for GPIO interrupt 5 This bit field controls the active condition of the interrupt function for GPIO interrupt 5. 00b - Interrupt 5 is low-level sensitive. 01b - Interrupt 5 is high-level sensitive. 10b - Interrupt 5 is rising-edge sensitive. 11b - Interrupt 5 is falling-edge sensitive.
9-8 ICR4	Interrupt configuration field for GPIO interrupt 4 This bit field controls the active condition of the interrupt function for GPIO interrupt 4. 00b - Interrupt 4 is low-level sensitive. 01b - Interrupt 4 is high-level sensitive. 10b - Interrupt 4 is rising-edge sensitive. 11b - Interrupt 4 is falling-edge sensitive.
7-6 ICR3	Interrupt configuration field for GPIO interrupt 3 This bit field controls the active condition of the interrupt function for GPIO interrupt 3. 00b - Interrupt 3 is low-level sensitive. 01b - Interrupt 3 is high-level sensitive. 10b - Interrupt 3 is rising-edge sensitive. 11b - Interrupt 3 is falling-edge sensitive.
5-4 ICR2	Interrupt configuration field for GPIO interrupt 2 This bit field controls the active condition of the interrupt function for GPIO interrupt 2. 00b - Interrupt 2 is low-level sensitive. 01b - Interrupt 2 is high-level sensitive. 10b - Interrupt 2 is rising-edge sensitive. 11b - Interrupt 2 is falling-edge sensitive.
3-2 ICR1	Interrupt configuration field for GPIO interrupt 1 This bit field controls the active condition of the interrupt function for GPIO interrupt 1. 00b - Interrupt 1 is low-level sensitive. 01b - Interrupt 1 is high-level sensitive. 10b - Interrupt 1 is rising-edge sensitive. 11b - Interrupt 1 is falling-edge sensitive.
1-0 ICR0	Interrupt configuration field for GPIO interrupt 0 This bit field controls the active condition of the interrupt function for GPIO interrupt 0. 00b - Interrupt 0 is low-level sensitive. 01b - Interrupt 0 is high-level sensitive. 10b - Interrupt 0 is rising-edge sensitive. 11b - Interrupt 0 is falling-edge sensitive.

13.6.1.6 GPIO interrupt configuration register2 (ICR2)

13.6.1.6.1 Offset

Register	Offset
ICR2	10h

13.6.1.6.2 Function

The ICR2 register contains 16 two-bit fields, where each field specifies the interrupt configuration for a different input signal.

13.6.1.6.3 Diagram

13.6.1.6.4 Fields

Field	Function
31-30 ICR31	Interrupt configuration field for GPIO interrupt 31 This bit field controls the active condition of the interrupt function for GPIO interrupt 31. 00b - Interrupt 31 is low-level sensitive. 01b - Interrupt 31 is high-level sensitive. 10b - Interrupt 31 is rising-edge sensitive. 11b - Interrupt 31 is falling-edge sensitive.
29-28 ICR30	Interrupt configuration field for GPIO interrupt 30 This bit field controls the active condition of the interrupt function for GPIO interrupt 30. 00b - Interrupt 30 is low-level sensitive. 01b - Interrupt 30 is high-level sensitive. 10b - Interrupt 30 is rising-edge sensitive. 11b - Interrupt 30 is falling-edge sensitive.
27-26 ICR29	Interrupt configuration field for GPIO interrupt 29 This bit field controls the active condition of the interrupt function for GPIO interrupt 29. 00b - Interrupt 29 is low-level sensitive. 01b - Interrupt 29 is high-level sensitive. 10b - Interrupt 29 is rising-edge sensitive. 11b - Interrupt 29 is falling-edge sensitive.
25-24 ICR28	Interrupt configuration field for GPIO interrupt 28 This bit field controls the active condition of the interrupt function for GPIO interrupt 28. 00b - Interrupt 28 is low-level sensitive. 01b - Interrupt 28 is high-level sensitive.

Table continues on the next page...

Field	Function
	10b - Interrupt 28 is rising-edge sensitive. 11b - Interrupt 28 is falling-edge sensitive.
23-22 ICR27	Interrupt configuration field for GPIO interrupt 27 This bit field controls the active condition of the interrupt function for GPIO interrupt 27. 00b - Interrupt 27 is low-level sensitive. 01b - Interrupt 27 is high-level sensitive. 10b - Interrupt 27 is rising-edge sensitive. 11b - Interrupt 27 is falling-edge sensitive.
21-20 ICR26	Interrupt configuration field for GPIO interrupt 26 This bit field controls the active condition of the interrupt function for GPIO interrupt 26. 00b - Interrupt 26 is low-level sensitive. 01b - Interrupt 26 is high-level sensitive. 10b - Interrupt 26 is rising-edge sensitive. 11b - Interrupt 26 is falling-edge sensitive.
19-18 ICR25	Interrupt configuration field for GPIO interrupt 25 This bit field controls the active condition of the interrupt function for GPIO interrupt 25. 00b - Interrupt 25 is low-level sensitive. 01b - Interrupt 25 is high-level sensitive. 10b - Interrupt 25 is rising-edge sensitive. 11b - Interrupt 25 is falling-edge sensitive.
17-16 ICR24	Interrupt configuration field for GPIO interrupt 24 This bit field controls the active condition of the interrupt function for GPIO interrupt 24. 00b - Interrupt 24 is low-level sensitive. 01b - Interrupt 24 is high-level sensitive. 10b - Interrupt 24 is rising-edge sensitive. 11b - Interrupt 24 is falling-edge sensitive.
15-14 ICR23	Interrupt configuration field for GPIO interrupt 23 This bit field controls the active condition of the interrupt function for GPIO interrupt 23. 00b - Interrupt 23 is low-level sensitive. 01b - Interrupt 23 is high-level sensitive. 10b - Interrupt 23 is rising-edge sensitive. 11b - Interrupt 23 is falling-edge sensitive.
13-12 ICR22	Interrupt configuration field for GPIO interrupt 22 This bit field controls the active condition of the interrupt function for GPIO interrupt 22. 00b - Interrupt 22 is low-level sensitive. 01b - Interrupt 22 is high-level sensitive. 10b - Interrupt 22 is rising-edge sensitive. 11b - Interrupt 22 is falling-edge sensitive.
11-10 ICR21	Interrupt configuration field for GPIO interrupt 21 This bit field controls the active condition of the interrupt function for GPIO interrupt 21. 00b - Interrupt 21 is low-level sensitive. 01b - Interrupt 21 is high-level sensitive. 10b - Interrupt 21 is rising-edge sensitive. 11b - Interrupt 21 is falling-edge sensitive.
9-8 ICR20	Interrupt configuration field for GPIO interrupt 20 This bit field controls the active condition of the interrupt function for GPIO interrupt 20.

Table continues on the next page...

Field	Function
	00b - Interrupt 20 is low-level sensitive. 01b - Interrupt 20 is high-level sensitive. 10b - Interrupt 20 is rising-edge sensitive. 11b - Interrupt 20 is falling-edge sensitive.
7-6 ICR19	Interrupt configuration field for GPIO interrupt 19 This bit field controls the active condition of the interrupt function for GPIO interrupt 19. 00b - Interrupt 19 is low-level sensitive. 01b - Interrupt 19 is high-level sensitive. 10b - Interrupt 19 is rising-edge sensitive. 11b - Interrupt 19 is falling-edge sensitive.
5-4 ICR18	Interrupt configuration field for GPIO interrupt 18 This bit field controls the active condition of the interrupt function for GPIO interrupt 18. 00b - Interrupt 18 is low-level sensitive. 01b - Interrupt 18 is high-level sensitive. 10b - Interrupt 18 is rising-edge sensitive. 11b - Interrupt 18 is falling-edge sensitive.
3-2 ICR17	Interrupt configuration field for GPIO interrupt 17 This bit field controls the active condition of the interrupt function for GPIO interrupt 17. 00b - Interrupt 17 is low-level sensitive. 01b - Interrupt 17 is high-level sensitive. 10b - Interrupt 17 is rising-edge sensitive. 11b - Interrupt 17 is falling-edge sensitive.
1-0 ICR16	Interrupt configuration field for GPIO interrupt 16 This bit field controls the active condition of the interrupt function for GPIO interrupt 16. 00b - Interrupt 16 is low-level sensitive. 01b - Interrupt 16 is high-level sensitive. 10b - Interrupt 16 is rising-edge sensitive. 11b - Interrupt 16 is falling-edge sensitive.

13.6.1.7 GPIO interrupt mask register (IMR)

13.6.1.7.1 Offset

Register	Offset
IMR	14h

13.6.1.7.2 Function

The IMR register contains masking bits for each interrupt line.

13.6.1.7.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	IMR															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	IMR															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

13.6.1.7.4 Fields

Field	Function
31-0 IMR	Interrupt Mask bits This register is used to enable or disable the interrupt function on each of the 32 GPIO signals. Bit IMR[n] (n=0...31) controls interrupt n as follows: 0b - Interrupt n is disabled. 1b - Interrupt n is enabled.

13.6.1.8 GPIO interrupt status register (ISR)

13.6.1.8.1 Offset

Register	Offset
ISR	18h

13.6.1.8.2 Function

The ISR register functions as an interrupt status indicator. Each bit indicates whether an interrupt condition has been met for the corresponding input signal. When an interrupt condition is met (as determined by the corresponding interrupt condition register field), the corresponding bit in this register is set. Two wait states are required in read access for synchronization. One wait state is required for reset.

13.6.1.8.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	ISR															
W	W1C															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	ISR															
W	W1C															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

13.6.1.8.4 Fields

Field	Function
31-0	Interrupt status bits
ISR	Bit n of this register is asserted (active high) when the active condition (as determined by the corresponding ICR bit) is detected on the GPIO input and is waiting for service. The value of this register is independent of the value in IMR register. When the active condition has been detected, the corresponding bit remains set until cleared by software. Status flags are cleared by writing a 1 to the corresponding bit position.

13.6.1.9 GPIO edge select register (EDGE_SEL)

13.6.1.9.1 Offset

Register	Offset
EDGE_SEL	1Ch

13.6.1.9.2 Function

The EDGE_SEL register may be used to override the ICR registers' configuration. If the GPIO_EDGE_SEL bit is set, then a rising edge or falling edge in the corresponding signal generates an interrupt. This register provides backward compatibility. On reset all bits are cleared (ICR is not overridden).

13.6.1.9.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	GPIO_EDGE_SEL

Chapter 14
Clock and Power Management

14.1 Introduction

This chip targets many applications with power requirements that include low power consumption, long battery life, always-on capability, instant-on capability, and doesn't require active cooling. To meet these requirements, the chip design focuses on reducing current consumption, while simultaneously enabling the maximum level of peak performance, and also a balanced level of sustained performance. The chip architecture uses a wide range of power-management techniques, used in combination, for system design flexibility.

This chapter describes these architecture details as a high-level clock and power management overview of the chip. This overview chapter covers:

- Structural components of the power and clock management systems
- Clock generation and distribution system
- Power generation and distribution system
- Power mode definition
- Power and clock and management techniques supported.

NOTE

All numerical values in this chapter are either typical values or used as an example. Please see the datasheet for accurate values.

14.2 Components of Clock and Power Management

The centralized clock generation, power generation and distribution are implemented by the following blocks:

Table 14-1. Clock and Power Components

IP Module	Description
Crystal OSC (XTALOSC)	The XTALOSC includes a 24 MHz and 32 kHz oscillators. The 24MHz crystal oscillator is the primary clock source for all the PLLs, and clock generation for the CPU and high-speed interfaces. The 32KHz crystal oscillator is the primary clock source for the RTC as well as the low-speed clock source for CCM/SRC/GPC. See the Crystal Oscillator (XTALOSC) chapter for details of the XTALOSC block.
PLLs and PFDs	The PLLs and their associated PFDs generate the clocks with various frequencies required to feed the CCM clock generator that supplies the different functional blocks. See the PLL and PFD section in Clock Controller Module (CCM) for information on the PLL and PFD architecture, functional description and programming model.
Clock Control Module (CCM)	The CCM module provides control for clock generation, division, distribution, synchronization, and coarse-level gating. See Clock Controller Module (CCM) for information on the CCM architecture, functional description and programming model.
Low Power Clock Gating (LPCG)	The LPCG distributes the clocks to all blocks in the SoC and handles automated clock gating and block level software-controllable clock gating. See Clock Controller Module (CCM) for information on the LPCG architecture and functional description.
General Power Controller (GPC)	This module controls the power state of the SoC. The GPC handles the power gating under low power modes and also manages the power up / power down sequences. See the General Power Controller (GPC) chapter for information on the GPC architecture, functional description and programming model.
Power Management Unit (PMU)	This module generates the internal power supplies distributed to the entire SoC. See the Power Management Unit (PMU) chapter for information on the PMU architecture, functional description, and programming model.
System Reset Controller (SRC)	This module generates the reset signals to all the modules in the SoC. The SRC will appropriately assert reset signals for power transitions, entry, and exit. See the System Reset Controller (SRC) chapter for information on the SRC architecture, functional description and programming model.
Power Gating and Memory Controller (PGMC)	This module is a power management component, which controls the power gating of power domains and memory low power mode. See Power Gating and Memory Controller (PGMC) chapter for information on PGMC architecture, functional description, and programming model.
DCDC Converter (DCDC)	This module generates the power supply for chip's core logic. See DCDC converter (DCDC) chapter for information on functional description, and programming model.

Together, the modules listed above provide enhanced power-management features with the centralized control for the clock, reset, and power-management signals on the SoC.

14.3 Power Management

The power management design on the chip satisfies many use cases that depend on a key balance of performance and low-power consumption. In order to meet these criteria, the system power management needs to be dynamic and flexible. This is accomplished on a multi-core system by utilizing a power scheme that considers each CPU domain, and arbitrates the appropriate power mode configuration to satisfy the needs of both CPUs, and the system as a whole. The following are additional features supported by the power management architecture:

- Programmable power mode transition rules
- Independent operation mode for individual CPU cores
- Intelligent clock and power management for multi-core architecture
- Unified power management interface (UPI) for all on-chip resources, including clock, power, reset, and peripherals

A high-level view of the power management controllers and connections is shown below:

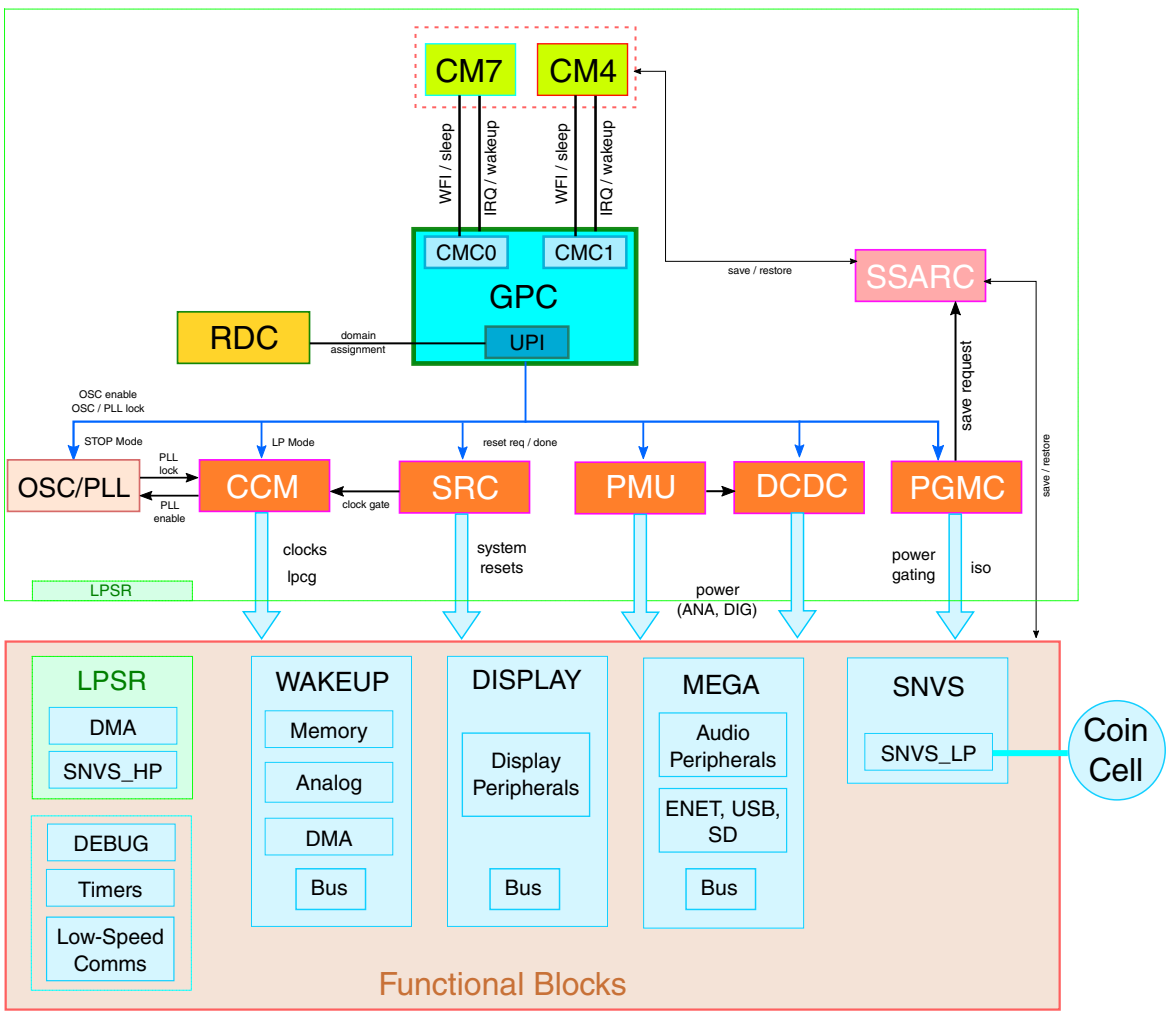

Figure 14-1. Power Management Block Diagram

14.3.1 Resources and Chip Domains

The chip is divided into resources and domains. Resources are controlled by resource controllers. Domains are grouped by central bus controllers and crossbars. Some domains reside within larger domains, which may have power dependencies. For illustrative representation of the power domains and bus configurations, please see the Power Management Block Diagram and the System Bus Diagram. The Resource types and Chip Domains are listed in the tables below:

Table 14-2. Resources

Resource	Description
CPU Platforms	The processor and associated on-platform peripherals that support the complex. The CPU Platforms supported on this chip are the CM7 and the CM4 platforms.
System Controllers	The System Controllers are the associated peripherals that control or define the power management resources for the chip. These modules include GPC, PMU, CCM, SRC, SSARC, PGMC, and RDC.
Functional blocks	The functional blocks are comprised of all the other peripherals, other than System Controllers. These modules include external memory controllers, timers, high-speed and low-speed peripherals, audio and video peripherals, connectivity, and others.

Table 14-3. Chip Domains

Domain	Description
CM7	The Cortex-M7 core and platform, which includes FlexRAM (TCM) and GPIO2-3.
CM4	The Cortex-M4 core and platform, which includes LMEM (TCM).
WAKEUP	The WAKEUP Domain contains the memory controllers and analog on the chip. The CM7 platform (incl JTAGC and debug components) also reside within WAKEUP, but the CM7 functions as it's own domain. The specific modules in WAKEUP include: EWM, WDOG1-3, eDMA, DMAMUX0 (WAKEUP), ACMP1-4, LPADC1-2, ADC_ETC, DAC, XBAR1-3, KPP, IOMUXC, IOMUXC_GPR, GPIO1-6, LPUART1-10, MTR, FLEXCAN1-2 (CANFD), QDC1-4, PIT1, AOI1-2, GPT1-6, TMR1-4, FlexPWM1-4, LPI2C1-4, LPSPI1-4, FlexIO1-2, EMVSIM1-2, FlexSP1-2, SEMC, MECC1-2, XECC (XECC_FLEXSPI1-2, XECC_SEMC), IEE.
MEGA	Contains the connectivity peripherals and audio peripherals. The specific modules include: ENET1G, ENET, ENET QoS, uSDHC, USB, CAAM, ASRC, MQS, SAI1-3, SPDIF.
DISPLAY	The DISPLAY Domain contains the display and graphics peripherals on the chip. The specific modules include: GPU2D, PXP, eLCDIF, LCDIFv2, CSI, MIPI_CSI2, MIPI_DSI, VIDEO_MUX (incl DCIC1,2)
LPSR	The LPSR Domain contains the System Control blocks and associated peripherals. The CM4 platform and portions of SNVS (SNVS_LP) also reside within LPSR, but function as their own domains. The specific modules of LPSR include: GPC, PGMC, DCDC, SRC, SSARC, PMU (ANADIG), TEMPSENSE, XTALOSC, CCM, OCOTP, SNVS_HP, KEYMGR, WDOG (CM4), IOMUXC_SNVS, IOMUXC_LPSR, MU, XRDC2_D0, XRDC2_D1 (CM4, CM7), RDC, SEMA4, SEMA42, eDMA, DMAMUX1 (LPSR), GPIO7-12, PDM, SAI4, PIT2, LPUART11-12, LPSPI5-6, LPI2C5-6, FLEXCAN3 (CANFD)

Table continues on the next page...

Table 14-3. Chip Domains (continued)

Domain	Description
SNVS	The SNVS Domain contains SNVS_LP, which connects to a coin cell or non-interruptible power source. This domain also contains IOMUXC_SNVS, SRAM, and GPIO13.

14.3.2 Power Management Unit (PMU)

The PMU has the following components integrated for power management:

- DCDC
  - Generates the core power supply
  - Supports dynamic voltage scaling
- LDOs
  - Internal logic power supply
- Power Switches for sophisticated power mode management

The typical power architecture of the chip is shown below. The use case illustrated shows the whole system working with a single 3.3V power supply and a coin cell. This is the power system configuration of traditional MCU. Depending on the application, other power supply schemes may be used, including bypassing the DCDC converter and using an external voltage regulator or PMIC.

NOTE

The on-chip DCDC converter is suitable for consumer and industrial applications up to the rated temperature specified in their respective market datasheets. For automotive applications, please check the automotive datasheet or consult with your NXP representative for appropriate power supply requirements.

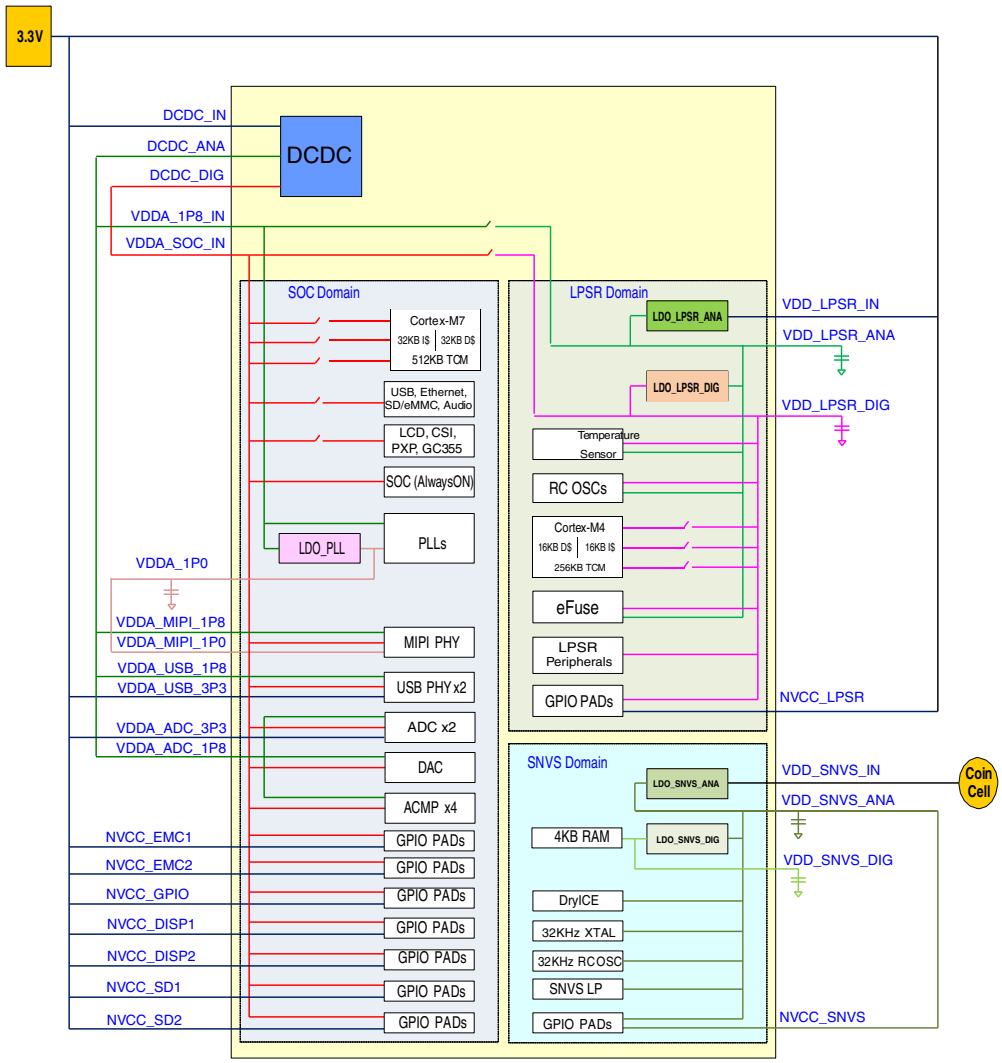

Figure 14-2. Power Architecture

14.3.3 Body Biasing (BB)

Forward Body Biasing (FBB) and Reverse Body Biasing (RBB) are implemented for performance boost and power reduction. The list and figure below define the power domains that support BB.

- FBB is implemented in the CM7 platform in order to achieve higher performance.
- RBB is implemented in the LPSR domain to reduce power consumption in LPSR mode.
- RBB is implemented in the SoC to reduce power consumption in low-power modes.

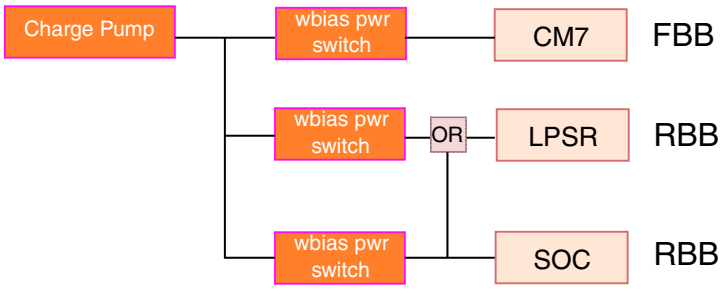

Figure 14-3. Supported Body Biasing

NOTE

Software must ensure that FBB and RBB are not enabled simultaneously. Only one of them can be used at a time.

14.3.4 Power Modes

The chip resources abide by CPU or system-level power modes, depending on their resource assignment. Resources are assigned to one of four categories, which are defined below.

Table 14-4. Resources Categories

Category	Description
Private	A resource that are fully owned and controlled by one CPU platform. These resources can be controlled by hardware and software.
Shared	A resource that is shared by more than one CPU platform. These resources are limited by the other CPU power state. Software must take into regard, shared resources, since they are limited by other CPU power states. If a shared resource supports Setpoint control, then it is recommended that the resource is under Setpoint control, rather than CPU platform control.
Public	A resource that is managed at the system-level, which is not owned and controlled by any of the CPU platforms. These resources can only be controlled by hardware.
Unassigned	A resource that is not assigned as private, shared, or public. This is the default state of a resource after reset.

Resources can be assigned to different CPU domains by the RDC. If one CPU wants to put the chip into a power mode, it must arbitrate with the other CPU to ensure the appropriate power state is chosen for shared resources. Depending on the resource type, varying power control mechanisms are followed. Private and Shared resources follow the power modes defined by the CPU (CPU mode). Public resources are configured by system-level settings (Setpoint mode).

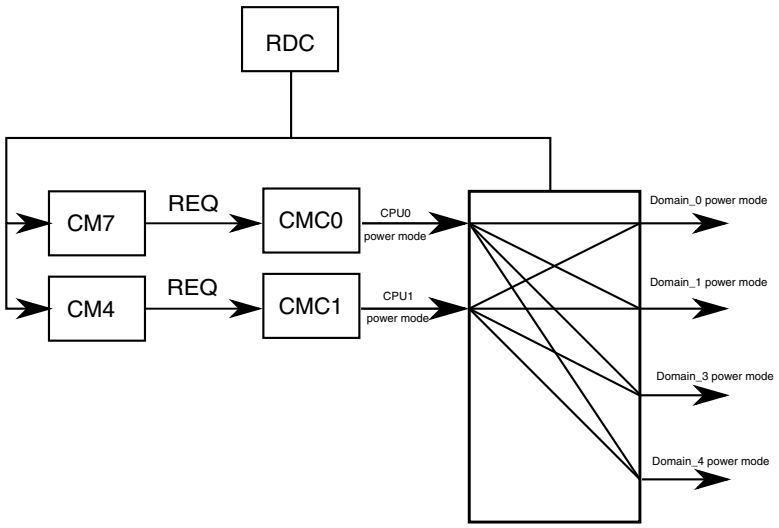

Figure 14-4. Domain Assignment

14.3.4.1 CPU Mode

The CPU platforms both support the same power states that are defined as CPU modes. The CPU Modes are detailed below.

Table 14-5. CPU Mode

CPU Mode	Description
RUN	The CPU is active and running.
WAIT	The CPU is in the WFI state. The CPU core and L1 cache are clock gated, TCM and peripheral can still be alive. The chip can wakeup from this mode from IRQ with a very short latency.
STOP	The CPU is in the WFI state. The CPU core, L1 cache, TCM, and it's private peripherals are all clock gated. The chip requires a longer time to wakeup from this mode.
SUSPEND	The CPU core and L1 cache are power gated (except the M4 cache). The TCM is in retention mode. SUSPEND mode consumes the least amount of power, while keeping parts of the the system alive. But the chip requires a much longer time to wakeup from this mode.

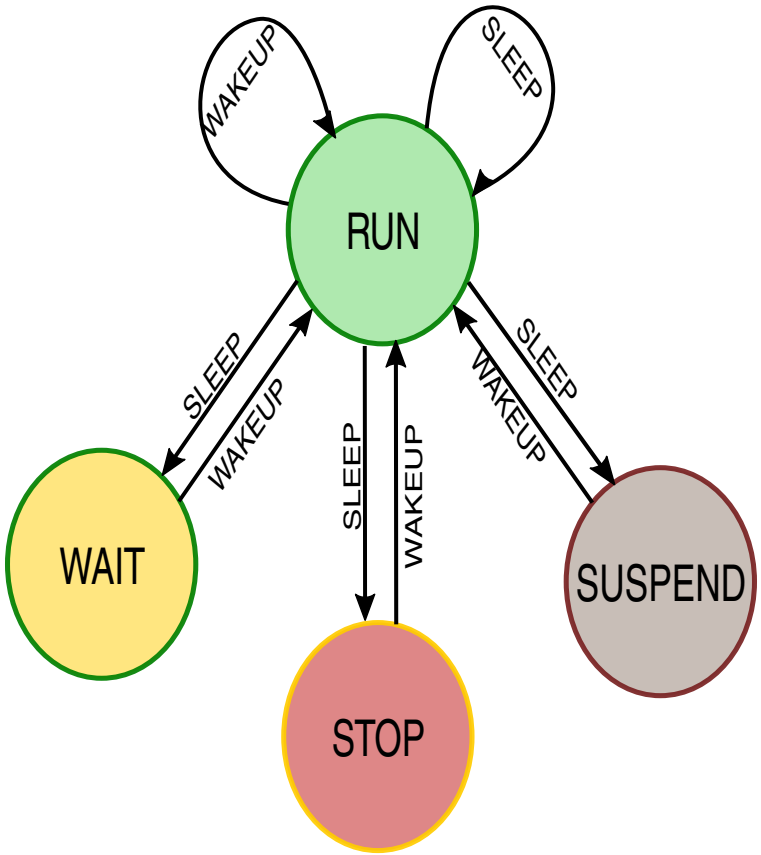

Figure 14-5. CPU Modes

For the modules / resources outside (public) of the CPU platform domain, the power is managed by Setpoint mode. There are up to 16 Setpoints supported. In each Setpoint, the state of the modules is configurable. The power mode of the chip is a combination of the Setpoint and CPU mode. Please refer to the specific System Controller blocks / modules for more information on their specific configuration options for Setpoint mode.

14.3.4.1.1 Memory Power Connection

A few of the power connections that exist in this chip are shown below:

- M7 Cache and TCM memory:
  - M7 core and memory peripheral logics are on the same power domain, which are on/off together
  - When operating, memory array is supplied from VDD_SOC_IN
  - Supported modes
    - M7 on, cache and TCM on
    - M7 off, cache off, TCM off
  - No access to TCM memory when M7 core is power gated
- M4 Cache & TCM memory:
  - Supported modes

- M4 on, cache and TCM on
- M4 off, cache and TCM on
- M4 off, cache on, TCM off

- OCRAM memories:
  - Controller and memory peripheral logics are on the same power domain, which are always on when VDD_SOC_IN is there
  - It will only be off when then entire SOC domain is off

14.3.4.2 Setpoint Mode

Setpoints are preconfigured power states (up to 16) that are defined within the System Controller resources. Resources that aren't owned by either CPU, follow Setpoint mode to define the system-level settings for clocking, power, BB, and reset. Please see the respective System Controller chapters for more details on the specifc controls supported by Setpoint mode.

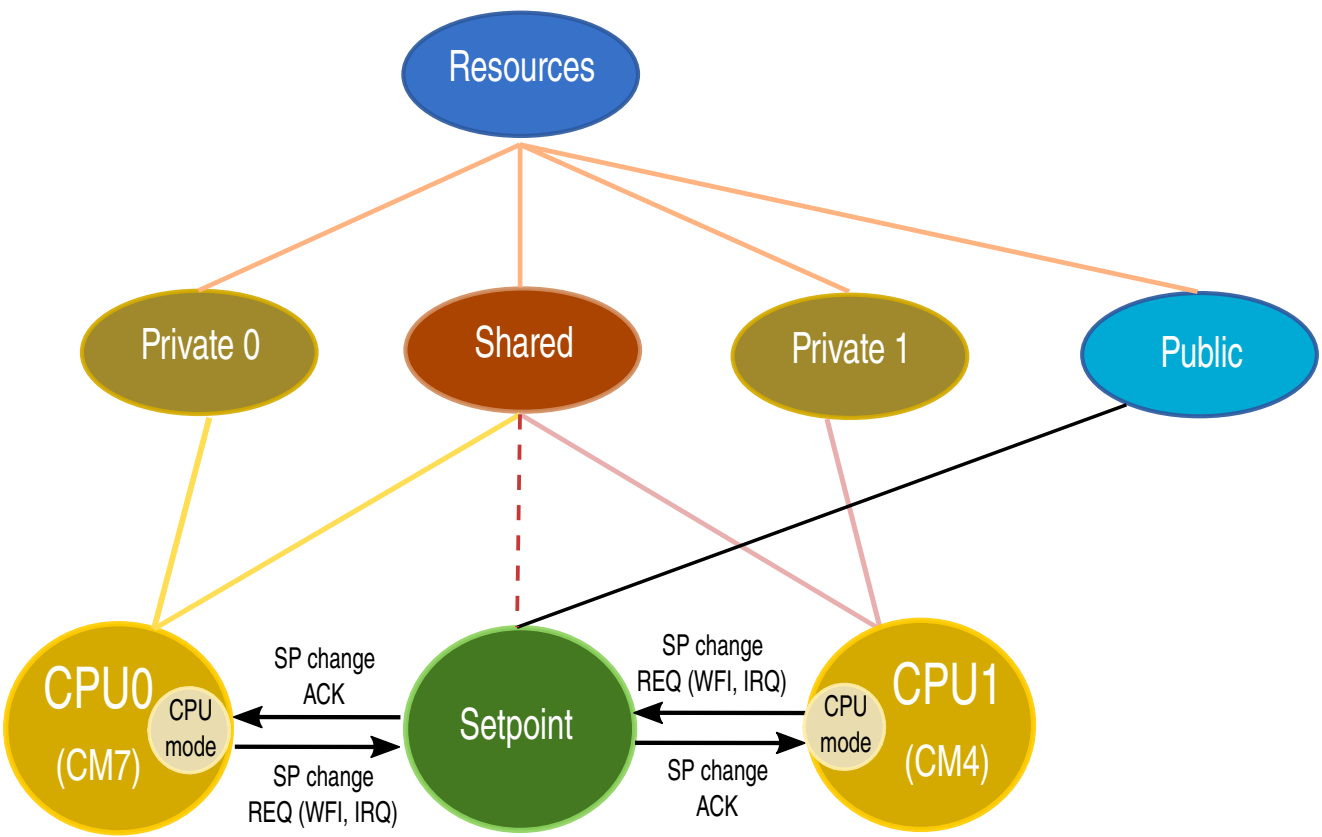

Figure 14-6. Setpoint Mode

14.3.4.2.1 Setpoint Arbitration

The power mode of the CPU platforms is independent of the other. But the shared resources must have a target Setpoint and a lookup table of allowed Setpoints for each CPU mode transition. The GPC will arbitrate between the target Setpoint, and allowed Setpoints, in order to determine the appropriate and accepted Setpoint setting. The lookup tables in GPC are a 16x16 bit table, that work for one domain. If more than one Setpoint is allowed, control logic first checks if any Setpoints match the request from CM7 or CM4. If both match, the selection is done, and based on priority of CPUs. If none match, logic will compare priority of Setpoints, and select the high-priority Setpoint. If the priority is the same, Setpoint in the biggest value will be selected.

14.3.4.3 Standby Mode

Standby mode is the third low-power mode, besides CPU mode and Setpoint mode. Standby mode is related to the state of both CPU platforms, and has a much shorter transition time than Setpoint. The GPC SBC state machine starts when CMC sends a standby request. It looks at all CMC standby statuses, and if any CPU platform is not in sleep mode, this standby request will be refused. CPU mode and Setpoint transition can't be broken by a wakeup event once it starts. A key benefit of Standby mode, is the Standby transition can be broken after any step completes, due to a wakeup requirement.

14.3.5 Power Sequence

The software flow for low-power entry and exit are listed below.

NOTE

The power flow assumes all resource assignments are complete after reset

1. CPU decides to enter any low power mode according its current loading
2. Software handshaking: set ipg_stop/doze in IOMUXC_GPR register; polling corresponding ips_stop_ack
   - Note: DMA/ENET (bus masters) should complete the handshake first, then flash/memories (bus slaves)
3. Set CPU target mode and system target/allowed setpoint in GPC registers
4. WFI/WFE
   - CPU mode transition stage: SSARC restore database; clock/power of CPU private resources are shut off
   - Setpoint transition stage: clock/power of public resource are shut off
   - System enter target low power state and waiting for wakeup event

5. Wakeup event comes
    - Setpoint transition stage: power recover, then clock recover for public resources
    - CPU transition stage: power recover, then clock recover for CPU private resources; SSARC recover database
    - CPU wakeup when core clock is recovered
6. CPU enter wakeup event ISR and recover the field before entering low power state

Please see GPC for a detailed sequence.

14.4 Clock Generation

The clock system is designed to provide a scalable, powerful, and easy-to-use clock solution.

14.4.1 Overview

The overall clock system for the chip is shown in the diagram below.

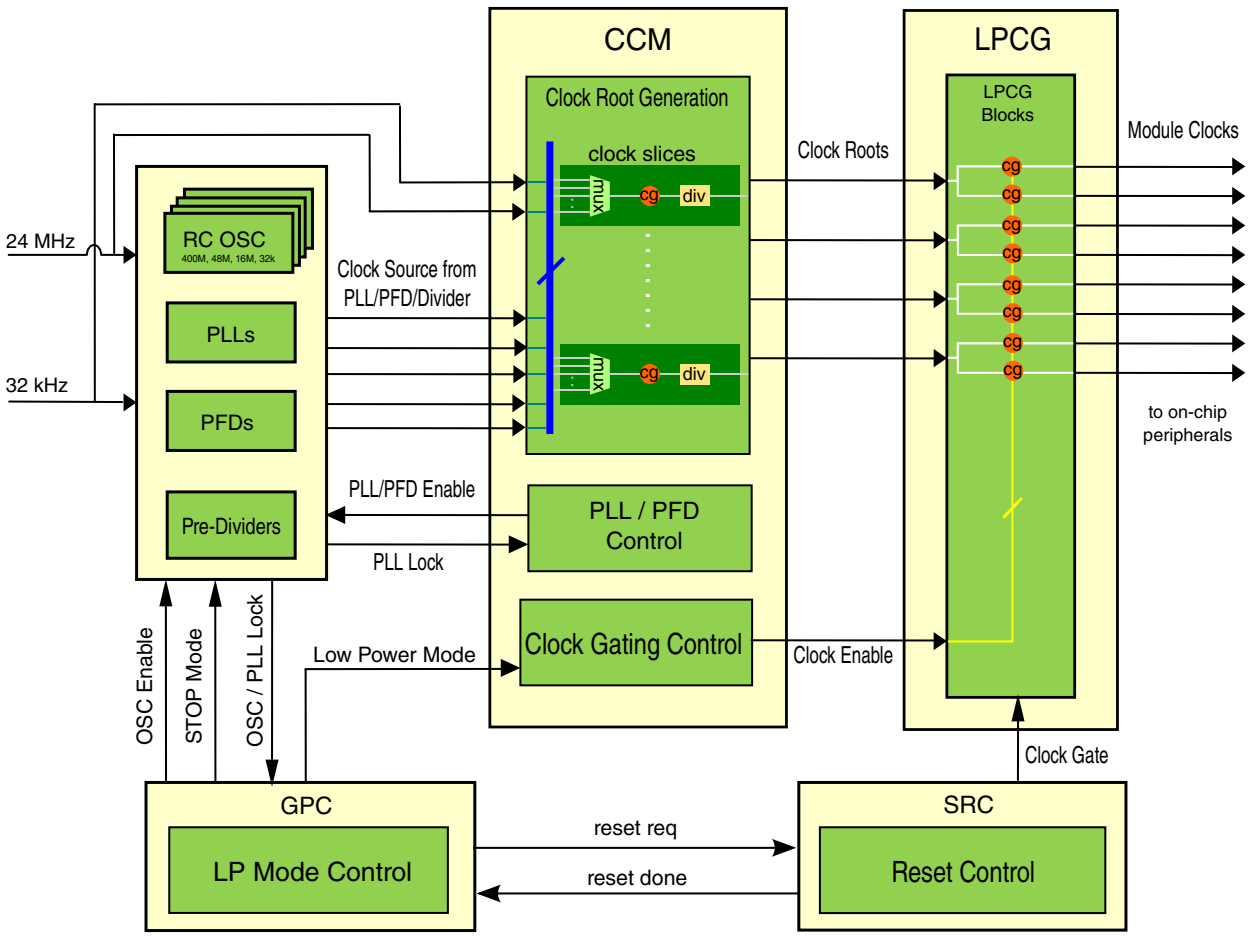

Figure 14-7. Clock System

The OSCs, PLLs, PFDs and Pre-Dividers generate the clock sources with fixed or variable frequency. The clock sources feed the clock root generation logic inside CCM, which generates numerous clock roots required for core, bus, and peripheral blocks. These clock roots are branched to each module through the LPCG logic, which contains the clock gating cells for each clock. Control signals for the LPCGs are in CCM (clock enable signal). Some of the clocks need to be gated off during reset, because of this, the SRC module will also send clock gate signals to the LPCG.

In low power mode, GPC will drive the low power mode state signal to CCM, then CCM will enable clock gating based on the configuration. At the same time, CCM may also deassert enable signals for PLLs and PFDs, so these modules can power off during low power modes. When the chip enters STOP mode, CCM may deassert the OSC enable signal to shut off the OSC, it may also assert the STOP mode signal to set OSC to low power mode.

The detailed functional description for each block will be described in the following sections.

14.4.2 Oscillator

This chip has two crystal oscillators and four RC oscillators:

Table 14-6. Oscillators

Oscillator	Description
24 MHz Crystal Oscillator (24M XTALOSC)	The primary clock source for all PLLs to generate the clocks for CPU, bus, and high-speed interfaces
32 kHz Crystal Oscillator (32K XTALOSC)	The primary clock source for RTC as well as low-power clock source for CCM, SRC, and GPC. The typical frequency is 32.768KHz.
48 MHz RC Oscillator (48M RCOSC)	Generates the 24 MHz clock source for the chip during startup, before the 24MHz crystal oscillator is ready. The 48M RCOSC can also be used as an alternative 24 MHz clock source in low power mode, when the crystal oscillator is turned off, or in a system that doesn't have a crystal oscillator.
32 kHz RC Oscillator (32K RCOSC)	The 32 kHz clock source for the chip during startup when 32 kHz crystal is not ready. It can also be used as alternative 32 kHz clock source when the external 32 kHz crystal oscillator is not stable, or in system which does not have any crystal oscillator. The switch from external 32 kHz to internal 32 kHz RC is controlled by hardware, and it happens automatically when the system detects a loss of the 32 kHz crystal clock.
16 MHz RC Oscillator (16M RCOSC)	The clock source in low power mode.
400 MHz RC Oscillator (400M RCOSC)	The clock source during chip boot up, before PLLs are enabled, or in low-power mode when the PLLs are turned off.

See Crystal Oscillator (XTALOSC) chapter for functional description details and the programming model on these blocks.

14.4.3 PLL and PFD

The PLLs are used in the chip to generate the high speed clocks required by the modules in SoC. A few PLLs are equipped with Phase Fractional Dividers (PFDs) in order to generate additional frequencies. The following PLLs are used in this chip:

Table 14-7. PLLs

PLL	Description	Spread Spectrum	Configurable
ARM_PLL	The ARM_PLL is used to generate the clock for the Arm Cortex-M7 platform. It is a programmable integer-frequency multiplier PLL, capable of an output frequency over 1 GHz.	-	Yes
SYS_PLL1	An AVPLL that is used primarily by the ENET module. It has a dedicated frequency of 1GHz.	Yes	1 GHz

Table continues on the next page...

Table 14-7. PLLs (continued)

PLL	Description	Spread Spectrum	Configurable
SYS_PLL2	The SYS_PLL2 main output clock has a dedicated frequency of 528MHz, but has several configurable PFDs.	Yes	528 MHz
SYS_PLL3	The SYS_PLL3 main output clock has a dedicated frequency of 480MHz, but has several configurable PFDs.	-	480 MHz
AUDIO_PLL	An AVPLL used to generate reference clocks, mainly for serial audio interfaces, and external audio codecs. This fractional multiplier PLL provides a low-jitter and high precision audio clock with standardized audio frequencies. The PLL's oscillator frequency range is from 650MHz to 1300MHz, and the frequency resolution is better than 1Hz.	Yes	Yes
VIDEO_PLL	An AVPLL used to generate reference clocks, mainly for display and video interfaces. This fractional multiplier PLL provides a low-jitter and high-precision video clock at standardized video frequencies. The PLL's oscillator frequency range is from 650MHz to 1300MHz, and the frequency resolution is better than 1Hz.	Yes	Yes

NOTE

Please see the datasheet for all supported maximum PLL frequencies

The following PLLs also feature the following dedicated dividers, which provides fixed frequencies for system usage:

- SYS_PLL1_DIV2: dedicated 500MHz clock
- SYS_PLL1_DIV5: dedicated 200MHz clock
- SYS_PLL3_DIV2: dedicated 240MHz clock

Each PLL can use one of the following clock sources as it's reference clock:

- Primary Option: 24 MHz clock from 24 MHz oscillator (XTAL)
- Secondary Option: 24 MHz clock from 48 MHz RCOSC (divided by 2)

Only the AUDIO_PLL and VIDEO_PLL have the capability to spread spectrum the generated signal. They do not require exact/constant frequency, and can be changed as a part of dynamic frequency scaling procedure and/or can be spread-spectrum modulated.

The main output clocks for the System PLLs (SYS_PLLx_CLK) are not configurable, but their PFDs are. Each PFD works independently by interpolating the VCO of the PLL to which it is connected. It effectively takes the PLL VCO frequency and produces 18/N x Fvco at it's output where N ranges from 12 to 35. PFD is a completely digital design with no analog components or feedback loops. The frequency switch time is much faster than a PLL because keeping the base PLL locked and changing the integer N only

changes the logical combination of the interpolated outputs of the VCO. Note that the PFD not only enables faster frequency changes than a PLL, but also allows the configuration to be safely changed "on-the-fly" without going through the output clock disabling/enabling process.

The basic logical connections for the PLLs, PFDs and Dividers is shown in the diagram below:

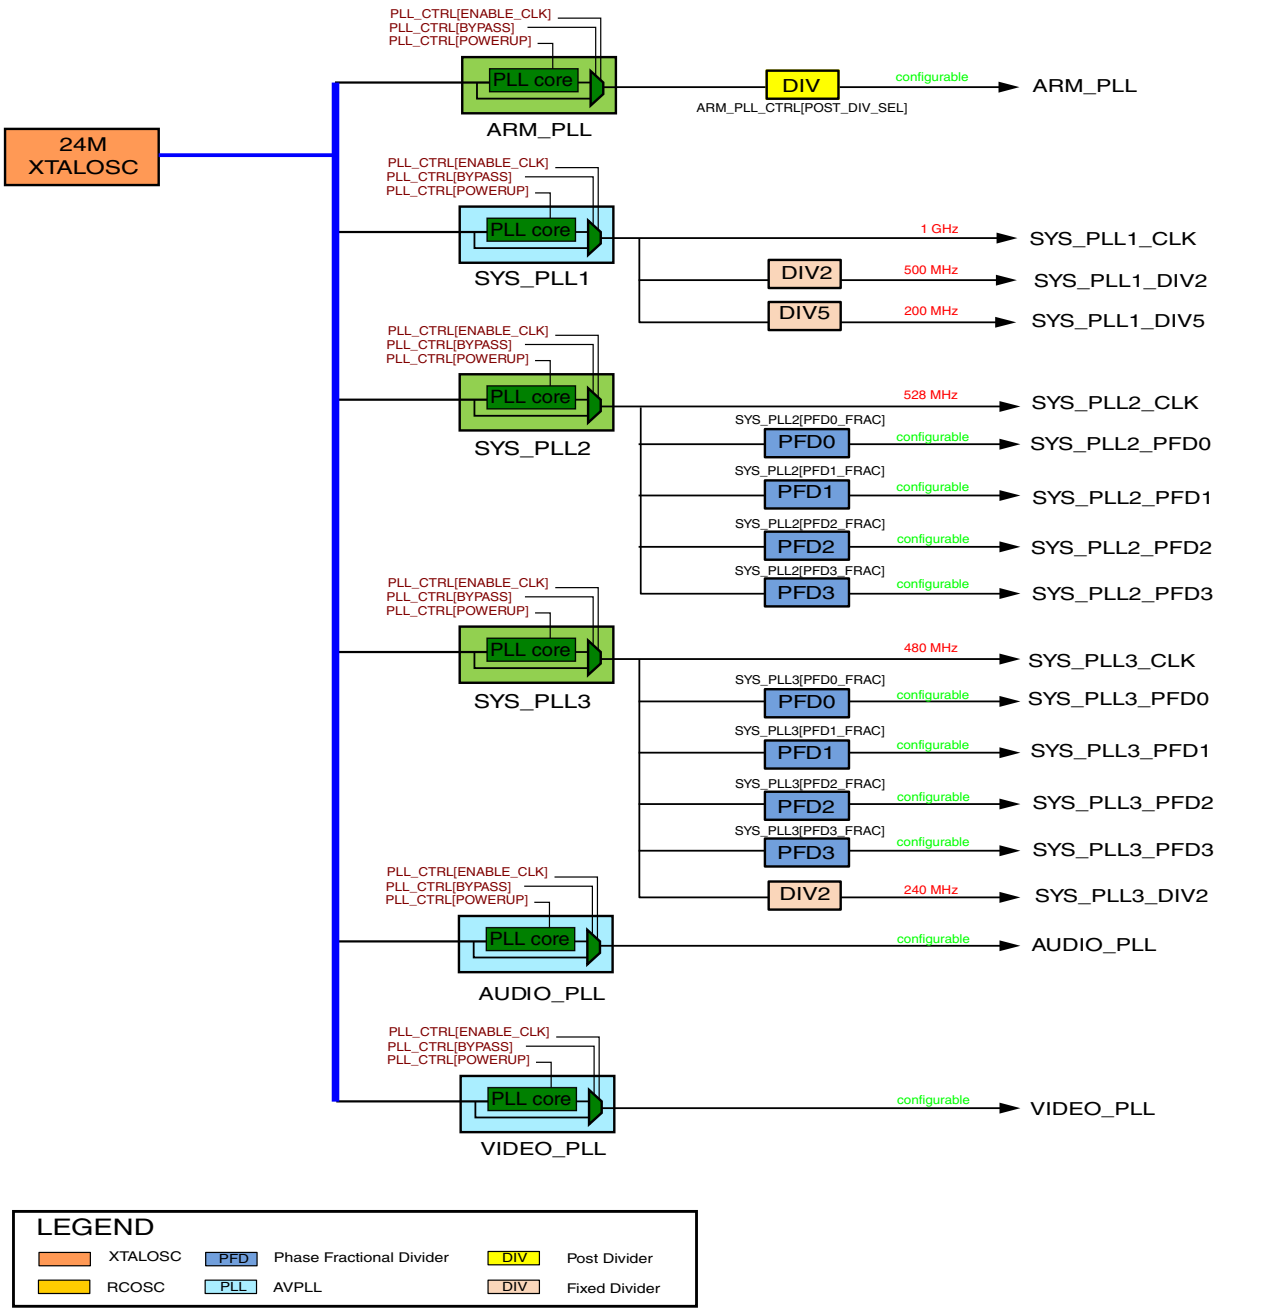

Figure 14-8. PLL and PFD

PLL configuration and control functions are accessible via individual PLL and PFD configuration and status registers. Each PLL has a dedicated configuration register. Software can directly enable / disable the PLL, or change it's clock frequency. In addition to the register interface, each PLL also has a dedicated ENABLE input, and a LOCK

output, to support the PLL disable / enable control from CCM. The CCM block contains the detailed descriptions of the memory mapped registers, and control functions of the clock generation sub-module. Please see CCM for more information.

14.4.4 Clock Root Generation

Clock generation in the CCM creates clock roots for on-chip peripherals. Each clock root will have a dedicated clock slice. It takes the clock source from Oscillators, PLL/PFD or Pre-Dividers, and generate the clock root with required frequency.

The CCM can manage on-chip peripheral clocks by controlling the low power clock gating cells (LPCGs) before the clock roots enter the peripherals.

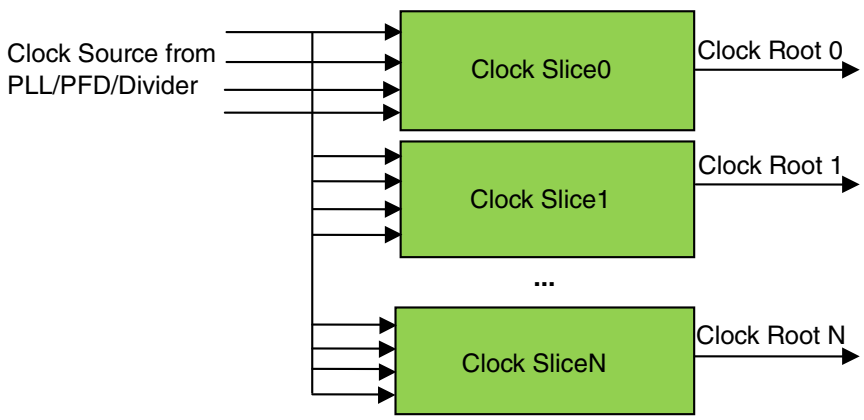

Figure 14-9. Clock Root Generation from Clock Slice

The LPCGs are implemented to control peripheral functions, and there could be several LPCGs for each functions in a peripheral.

For details on the programming model, please refer to CCM Memory Map/Register Definition.

14.4.5 Low Power Clock Gating (LPCG)

The clock roots generated inside CCM are distributed to the entire SoC through LPCG. The LPCG block receives the root clocks from CCM and splits them to clock branches for each functional block. The clock branches are individually gated clocks.

The LPCG can be programmed directly or controlled by CPU Low-Power Mode (CPULPM) according to the low-power signal from GPC. The settings for LPCG in CPULPM are defined by a 3-bit clock dependent level setting in the LPCGx_DOMAIN register. The configuration of the LPCGx_DOMAIN[LEVELn] settings are as follows:

- 3b’000: The clock source is not needed in any mode, and can be turned off
- 3’b001: The clock source is needed in RUN mode, but not needed in WAIT or STOP mode
- 3’b010: The clock source is needed in RUN and WAIT mode, but not needed in STOP mode
- 3’b011: The clock source is needed in RUN, WAIT, and STOP mode
- 3’b100: The clock source is always on in any mode (including SUSPEND)
- Others: Reserved

Chapter 15
Clock Controller Module (CCM)

15.1 Chip-specific CCM information

Table 15-1. Reference links to related information

Topic	Related module(s)	Reference
System memory map	-	System Memory Map
Clocking	CCM	Clock Management Clock Control Module (CCM)
Power management	PMU	Power Management Power Management Unit
Signal multiplexing	IOMUX	External Signals and Pin Multiplexing IOMUX
Interrupts, DMA Events and XBAR Assignments	-	Interrupts, DMA Events and XBAR Assignments

NOTE

- SYS_PLL1 has a fixed frequency of 1GHz and is primarily used by the ENET modules
- SYS_PLL2 has a fixed frequency of 528MHz
- SYS_PLL3 has a fixed frequency of 480MHz

15.2 Overview

The Clock Control Module (CCM) manages the on-chip module clocks. The oscillators, PLLs, and Phase Fractional Dividers (PFD) will generate clock sources with fixed or variable frequencies.

15.2.1 Block diagram

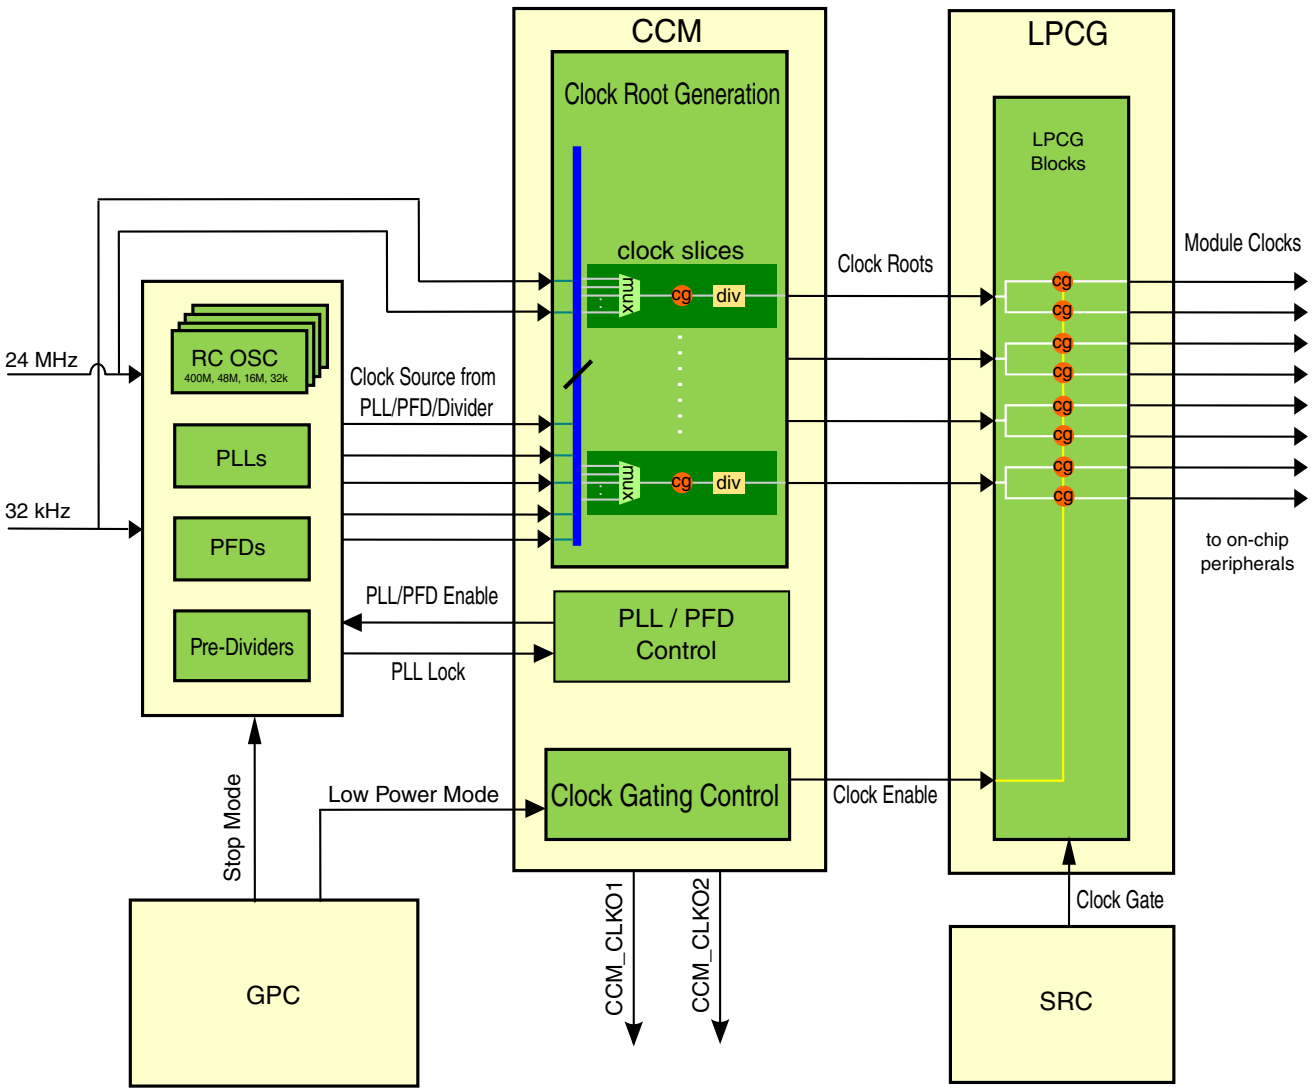

Figure 15-1. CCM block diagram

The clock root generation logic inside CCM will generate various clock roots required for core, bus, and peripheral blocks. These clock roots will be delivered to each module through LPCG, which contains the clock gating logic for each clock.

The control signal for LPCGs in CCM will be the source for clock enable signals. Since some of the clocks need to be gated off during the reset, the System Reset Controller (SRC) will also send clock gate signals to the LPCG.

In low power mode, the General Power Controller (GPC) will drive the low power mode state signal to CCM, and CCM will enable clock gating based on the configuration. At the same time, CCM may also de-assert enable signals for PLLs, so these modules can be powered off during the low power mode.

15.2.2 Features

The CCM includes the following features:

- Clock Root
  - Supports 8 clock sources for each clock root
  - 8-bit divider supports up to divide by 256 in each clock root
  - Each clock root can be shutdown by software
  - 4-bit fractional divide (numerator and denominator)
  - 16 preset clock root Setpoints transitions on power mode change
- Clock Group
  - Synchronous clock group where each clock can change on-the-fly
  - Clock group can be shutdown by software
  - 16 preset clock group Setpoint transitions on power mode change
- Peripheral clocks can be auto gated according to CPU platform, software, or system power mode
- PLLs and oscillators can be auto shutdown according to CPU platform, software, or system power mode
- Access control schemes:
  - Each component can be protected independently
  - Independent setting for user, privileged, secure, non-secure
  - Whitelist that can control Domain Mode access
  - Access control setting can be locked independently

15.3 System Clocks

The table found here shows the CCM output clocks' system-level connectivity.

Table 15-2. System Clocks Table

Module	Module Clock	Clock Root	LPCG Enable (LPCGx_DIRECT[ON])
ACMPn	acmp1_fast_clk	ACMP_CLK_ROOT	clk_enable_acmp1 (LPCG58)
	acmp1_ipg_clk	BUS_CLK_ROOT	clk_enable_acmp1 (LPCG58)
	acmp1_ipg_clk_s	BUS_CLK_ROOT	clk_enable_acmp1 (LPCG58)

15.5 Functional description

The following sections describe the functionality of CCM:

- Clock Source
- Clock Root
- Clock Gate
- Clock Group
- General Purpose Registers (GPR)

15.5.1 CCM Modes

CCM functional blocks support the following modes:

- Unassigned Mode
- Domain Mode
- CPU Low Power Mode (CPULPM)
- Setpoint Mode

NOTE

In any of the modes, every register in any Domain is readable. But write access will be restricted for protection.

15.5.1.1 Unassigned Mode

If a clock is not assigned to Domain or Setpoint Mode or CPU Low Power Mode, it automatically assumes Unassigned Mode. After reset, all clock sources, clock roots, clock gates, and clock groups remain in Unassigned Mode.

In Unassigned Mode, Domain access control scheme is disabled, but access control is still active.

Clock Source

In Unassigned Mode, clock source setting comes from OSCPLLn_DIRECT registers (PLL/OSC is required to function in GPC mode). These register can only be accessed in Unassigned Mode if access authentication is passed. They have no effect in CPULPM or Setpoint Mode and are not writable in these modes.

Clock Root

In this mode, the clock root setting comes from the CLOCK_ROOTn_CONTROL registers. These registers can only be accessed in Unassigned Mode if access authentication is passed.

Clock Group

In Unassigned Mode, the clock group setting comes from CLOCK_GROUPn_CONTROLregisters. These registers can be modified from any domain in Unassigned Mode after passing access authentication.

Clock Gate (LPCG)

For this mode, the clock gate setting comes from the LPCGn_DIRECT registers. These register can only be accessed in Unassigned Mode if access authentication is passed. They cannot be modified or will not have any effect in CPULPM or Setpoint Mode.

15.5.1.2 Domain Mode

In Domain Mode, domain access control is enabled.

Clock Source

In this mode, clock source setting comes from OSCPLLn_DIRECT register. This register can only be accessed if access authentication is passed and access comes from domain in Whitelist. This register have no effect in CPU Low Power Mode and Setpoint Mode and is not writable.

Clock Root

In this mode, the Domain based authentication is activated and only domains on the Whitelist can change the value of the CLOCK_ROOTn_CONTROL register.

Clock Group

In this mode, the clock group setting comes from CLOCK_GROUPn_CONTROL. Since Domain based authentication is active in this mode, only the domains available on the Whitelist can modify these registers.

Clock Gate (LPCG)

For this mode, the clock gate setting come from the LPCGn_DIRECT register. This register can only be accessed in if access authentication is passed and access comes from domain in Whitelist. This register cannot be modified or will not have any effect in CPU Low Power Mode or Setpoint Mode.

NOTE

The Domain setting register can be written from any domain in Unassigned Mode, but need to pass access authentication.

15.5.1.3 CPU Low Power Mode (CPULPM)

The CPU Low power Mode will control the OSC/PLL/LPCG according to the low power signal from the GPC.

Clock Source

In this mode, there are 3-bit fields in OSCPLLn_DOMAIN register, which helps select the clock source dependency level for each CPU platform. The valid values are as follows:

- 0: This clock source is not needed in any mode
- 1: This clock source is needed in RUN mode, but not needed in WAIT, STOP mode
- 2: This clock source is needed in RUN and WAIT mode, but not needed in STOP mode
- 3: This clock source is needed in RUN, WAIT and STOP mode
- 4: this clock source is needed in RUN, WAIT, STOP and SUSPEND mode

Clock Root

Clock Root does not support this mode.

Clock Group

Clock Group does not support this mode.

Clock Gate (LPCG)

There are 3-bit clock dependent levels setting for each CPU platform in the register LPCGn_DOMAIN. The valid values are the same as the values shown for clock source.

The clock gate calculates whether the clock is dependent for each CPU platform and if not required, it will be shut down.

15.5.1.4 Setpoint Mode

Clock Source

The Setpoint registers define 16 work points of clock source using 16 bits for system work modes through OSCPLLn_SETPOINT registers.

As the system work mode transitions from one Setpoint to another, the clock source will look up the corresponding value and source the clock according to the response on the request from General Power Controller (GPC).

Clock Root

For clock roots running in this mode, the CLOCK_ROOTn_CONTROL register does not affect the clock root, and all the write access will be blocked.

The Setpoint registers define 16 work points of clock roots using 16 bits for system work modes. As the system work mode transition from one Setpoint to another, the clock root will look up corresponding value and changes the clock root setting to the value requested by GPC.

Please refer to CLOCK_ROOTn_SETPOINTm register to see which clock roots support Setpoints.

Speed Grade:

In Setpoints, speed grade information needs to be provided for clock root channel through CLOCK_ROOTn_SETPOINTm. The clock channel uses this information to determine whether to change the clock setting before or after a change in system supply voltage. A smaller grade value refers to faster clock speed.

Speed grade is being used by Setpoint logic to determine whether the clock is transitioning up or down between a Setpoint transition. Setpoint logic handles relationship between other components, such as power control. Each Setpoint setting is associated with a speed grade setting. A smaller speed grade value indicates higher speed. For example, the value of 0 refers to the fastest clock and the value of 15 refers to the slowest clock. For Setpoint setting with same speed, speed grade relation can be any or higher, lower or equal.

Clock Group

In this mode, the CLOCK_GROUPn_CONTROL registers do not affect the clock group and all write access is blocked.

The Setpoint registers define 16 work points of clock channel for system work modes. As the system work mode transition from one Setpoint to another, clock group will look up the corresponding value and change the clock group setting to the corresponding value requested from GPC.

In Setpoints, speed grade information needs to be provided for clock root channel through CLOCK_ROOTn_SETPOINTm.

Clock Gate (LPCG)

The Setpoint registers define 16 work points of clock gate for system work modes. As the system work mode transition from one Setpoint to another, clock gate will look up corresponding value and change the clock gate setting to the corresponding value requested from GPC.

In Setpoint Mode, the Domain setting register will not affect clock source, and all write access is blocked.

NOTE

These registers can only be changed in Unassigned Mode after passing access authentication.

After the clock channel, source, root, or gate is assigned to Setpoint Mode, the registers cannot be changed by application. If application needs to change the Setpoint value, the clock channel should be switched to Unassigned Mode.

15.5.2 Clock Sources

Clock roots are generated from various clock sources, which can be either oscillators or PLLs. Clock sources are implemented to control PLLs and oscillators by automatically turning them OFF or ON on system low power actions.

The following table shows the clock sources and the associated control registers.

Table 15-3. Clock Sources

Control Register	Clock Source	Typical PFD value	Description
OSCPLL0	OSC_RC_16M	-	16MHz RC OSC Output
OSCPLL1	OSC_RC_48M	-	48MHz RC OSC Output
OSCPLL2	OSC_RC_48M_DIV2	-	48MHz divided by 2 clock output
OSCPLL3	OSC_RC_400M	-	400MHz RC OSC output
OSCPLL4	OSC_24M	-	VCO (Not connected to the clock tree)
OSCPLL5	OSC_24M_CLK	-	24MHz main output clock
OSCPLL6	ARM_PLL	-	VCO (Not connected to the clock tree)
OSCPLL7	ARM_PLL_CLK	4	ARM PLL main output clock
OSCPLL8	SYS_PLL2	-	VCO (Not connected to the clock tree)
OSCPLL9	SYS_PLL2_CLK	1	System PLL2 main output clock
OSCPLL10	SYS_PLL2_PFD0	27	System PLL2 PFD0 clock
OSCPLL11	SYS_PLL2_PFD1	16	System PLL2 PFD1 clock

Table continues on the next page...

Table 15-3. Clock Sources (continued)

Control Register	Clock Source	Typical PFD value	Description
OSCPLL12	SYS_PLL2_PFD2	24	System PLL2 PFD2 clock
OSCPLL13	SYS_PLL2_PFD3	32	System PLL2 PFD3 clock
OSCPLL14	SYS_PLL3	-	VCO (Not connected to the clock tree)
OSCPLL15	SYS_PLL3_CLK	1	System PLL3 main output
OSCPLL16	SYS_PLL3_DIV2	2	System PLL3 divided by 2 clock
OSCPLL17	SYS_PLL3_PFD0	13	System PLL3 PFD0 clock
OSCPLL18	SYS_PLL3_PFD1	17	System PLL3 PFD1 clock
OSCPLL19	SYS_PLL3_PFD2	32	System PLL3 PFD2 clock
OSCPLL20	SYS_PLL3_PFD3	24	System PLL3 PFD3 clock
OSCPLL21	SYS_PLL1	-	VCO (Not connected to the clock tree)
OSCPLL22	SYS_PLL1_CLK	1	System PLL1 main clock output
OSCPLL23	SYS_PLL1_DIV2	2	System PLL1 divided by 2 clock
OSCPLL24	SYS_PLL1_DIV5	5	System PLL1 divided by 5 clock
OSCPLL25	AUDIO_PLL	-	VCO (Not connected to the clock tree)
OSCPLL26	AUDIO_PLL_CLK	-	Audio PLL main clock
OSCPLL27	VIDEO_PLL	-	VCO (Not connected to the clock tree)
OSCPLL28	VIDEO_PLL_CLK	-	Video PLL main clock output

NOTE

The clock source calculates whether the clock is required for each CPU domain. If clock source is not needed for any domain, clock will be shutdown.

The typical PDF value for AUDIO_PLL_CLK and VIDEO_PLL_CLK depends on the user application.

15.5.3 Clock Root

CCM clock root generation contains multiple clock root channels. All clock roots are asynchronous, even when all the clock root setting are the same.

All clock channel contains an 8-to-1 MUX, and an 8-bit divider. The clock MUX selects 1 clock out of 8 clock inputs. The 8-bit divider can divide selected clock by up to 256. The clock output of the clock channel can be gated off.

The clock root channel setting can be changed from any value to any value, and at any time. It is also possible to change the clock setting when the clock root channel is gating off. If more than one setting is changed at the same time, internal logic will use a

procedure to change the setting. The procedure will make sure the clock output is not faster than the current clock root setting or target clock root setting. If the application does care about the clock during transition, software will need to change the setting one field at a time. This typically happens when a clock must be faster than the given frequency. In this case, the application needs to change each field one at a time and wait for the field to take effect before changing the next field.

Although a clock root channel is designed to be able to switch clocks regardless of clock input status. When the current selected clock input is off, the application needs to avoid changing the clock MUX after the clock input is turned on. This will lead to unstable behavior for the clock root and loading peripherals (peripherals driven by a clock). To avoid this scenario, the application can either switch the clock MUX before turning on the clock input, or wait until the clock input is stable before changing the MUX option.

The clock root channels have 3 working modes, Unassigned Mode, Domain Mode, and Setpoint Mode. Unassigned Mode is an implicit mode, if a clock channel is not assigned to Domain or Setpoint Mode, it defaults to Unassigned Mode. After reset, all clock root channels are in Unassigned Mode.

All registers are readable for any Domain in any mode, but write access are restricted. In Unassigned Mode, Domain access control scheme is disabled, but access control is still active. In Unassigned Mode and Domain Mode, the clock root setting comes from the CLOCK_ROOTn_CONTROL register. This register can be written from any Domain in Unassigned Mode, but needs to pass access authentication.

In Domain control Mode, Domain based authentication is activate and only the Domain on the Whitelist can change the value of CLOCK_ROOTn_CONTROL register. In Setpoint Mode, this register does not affect the clock root, and all write access will be blocked. CLOCK_ROOTn_SETPOINT registers define 16 work points of the clock channel for system work modes. As system work mode transitions from one Setpoint to another, the clock root will look up the corresponding value and will change the clock root setting to the value requested from GPC. These registers can only be changed in Unassigned Mode, after passing access authentication.

After the clock channel is assigned to Setpoint Mode, CLOCK_ROOTn_SETPOINT registers cannot be changed by the application. If the application needs to change the Setpoint value, Unassigned Mode needs to be switched to, before doing any modification. In Setpoints, speed grade information needs to be provided for the clock root channel.

The table below shows the Clock roots and the associated control registers.

UD, NM and OD represent Under-drive, Nominal, and Over-drive frequencies.

If 'SP' is blank, Setpoint is present, and if 'SP' is N, Setpoint is not present.

If 'Frac' is blank, Fraction is present, and if 'Frac' is N, Fraction is not present.

NOTE

The frequency values of the cores are dependent on the part configuration. Please see the datasheet for supported core frequencies.

15.5.4 Clock Gate

Before a clock root goes to on-chip peripherals, the clock roots go through the Low Power Clock Gates (LPCG). These LPCGs are implemented to perform automatic clock gating when a domain enters or leaves low-power states. LPCGs are implemented to control peripheral functions. Different LPCGs could interface different clocks of the same peripheral.

Clock gates implements four modes: Unassigned Mode, Domain Mode, CPU Low Power Mode, and Setpoint Mode. Unassigned Mode is an implicit mode. If a clock gate is not assigned to Domain, Setpoint Mode or CPU Low Power Mode, the default mode is Unassigned Mode. After reset, all clock gates work in Unassigned Mode. All registers are readable for any domain in any mode, but write access is restricted for protection. In Unassigned Mode, Domain access control scheme is disabled, but access control is still active.

In Unassigned Mode, clock gate settings come from LPCGn_DIRECT registers. Application can only change clock gate status by accessing LPCGn_DIRECT registers. These can only be accessed in Unassigned Mode if access authentication was passed. LPCGn_DIRECT registers have no effect and are not writable in CPULPM or Setpoint Mode.

In Domain Mode, the clock gate setting come from the LPCGn_DIRECT register. This register can only be accessed in if access authentication is passed and access comes from domain in Whitelist.

In CPULPM, there are 3-bit clock dependent level settings for each CPU platform in the LPCGx_DOMAIN registers. The bigger the 3-bit value is, the stronger the clock dependency. Valid values are as follows:

- 0: This clock is not needed in any mode
- 1: This clock is needed in RUN mode, but not needed in WAIT, STOP mode
- 2: This clock is needed in RUN and WAIT mode, but not needed in STOP mode
- 3: This clock is needed in RUN, WAIT and STOP mode
- 4: This clock is always on in any mode (including SUSPEND)

NOTE

The clock gates calculate whether the clock is dependent for each CPU Domain. If clock is not needed for any domain, the clock will be shutdown. The Domain setting register can be written from any domain in Unassigned Mode, but needs to pass access authentication. In Domain control Mode, the Domain setting register is locked and not changeable. If the application needs to change the Domain setting, it should switch the clock gate back into Unassigned Mode. In Setpoint

Mode, the Domain register does not affect the clock gate, and all write accesses are blocked.

The Setpoint registers define 16 work points of the clock gates by 16 register bits for system work modes. As the work modes transition from one Setpoint to another, the clock gate will look up corresponding value and will gate the clock according to the value requested by GPC. These registers can only be changed in Unassigned Mode, after passing access authentication. After the clock gate is assigned to Setpoint Mode, Setpoint registers cannot be changed by the application. If the application needs to change Setpoint value, the clock gate must be switched to Unassigned Mode as a first step.

15.5.5 Clock Group

Clock group creates a divided clock for a secondary clock input or a peripheral. The generated clock is synchronized to its parent clock. Each group contains a 4-bit clock divider which can divide up to 16. There is an 8-bit reset divider on clock divider. Clock divider will be synchronized on reset divider overflow. Reset divider and clock divider should be set in same write operation.

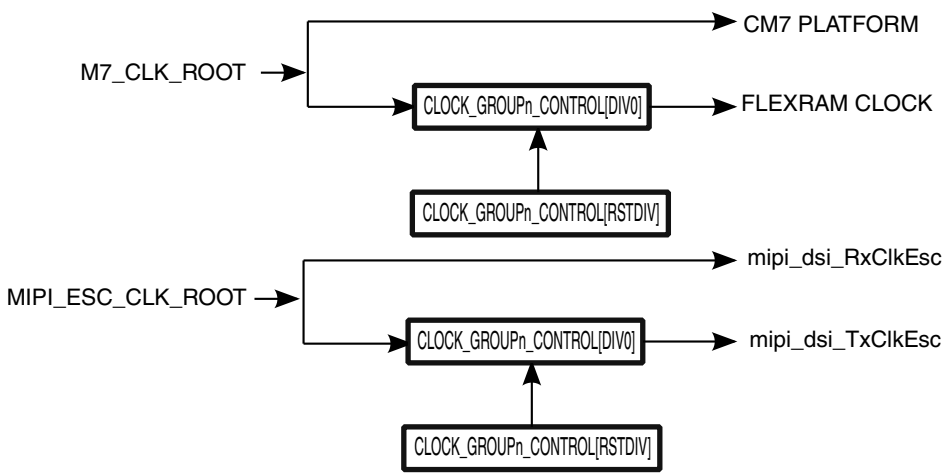
There are 2 clock groups in this chip as shown in the table below. Flexram clock group generates flexram AXI port clock, and the mipi_esc clock group generates mipi esc clock.

Each clock supports a 4-bit divider, which can divide down by 16. In a clock group, a restart cycle needs to be set. This restart cycle value should be a common multiple of all dividers in the clock group.

NOTE

If the wrong restart cycle value is set, the group behaviour will become unpredictable and the clocks cannot be recovered even after writing the correct value.

Each clock group contains a Manage counter. The figure below shows the manage counter and the group controls.



The clock group setting can be changed from any value to another value at any time. It can also be changed while the clock group is gated OFF. The clock group will update the setting on restart counter overflow. However, the clock group will take a few cycles to complete the action due to synchronous signal generation.

The clock groups can work in all modes.

The following table lists the clock groups.

Control Register	Clock Group
CLOCK_GROUP0	flexram_clk_group
CLOCK_GROUP1	mipi_esc_clk_group

15.5.6 Clock Observe

The clock observe slices are used to observe on-chip clocks or signals. Each observe channel contains a 512-to-1 MUX, an inverter, and an 8-bit divider. The clock MUX selects one observe signal out of 512 inputs. The 8-bit divider can divide the selected clock by up to 256. The inverter is selectable by software. If any of the settings change, the logic will be automatically reset. However, if the settings remain unchanged, a reset can be forced by writing "1" to OBSERVEn_CONTROL[RESET]. The table below shows the target signal, selection index, and the slice number. The target signal can be observed at associated slice number when the corresponding index is selected via OBSERVEn_CONTROL[SELECT].

NOTE

The observe functionality is for debug purposes only, and the accuracy is not guaranteed. Use of this field should be limited to room temperature, and frequency limited to less than 400 MHz.

Observe slice can measure frequency on selected signals or clocks. Each time an observe signal selection changes, all measurement data will be reset, and the measurement will restart. During measurement, the register value may change, and read from registers may not be valid. To get the measurement result, software must turn OFF the observe slice before the measurement results are read. For frequency measurements, a 32KHz clock is used as a time reference. The 32KHz clock is divided down to 64Hz resolution. The measurement unit records the maximum and minimum value that has occurred. The observe signal can be directly read from the OBSERVEn_STATUS0 register. The clock root channels have 2 work modes: unassigned mode and domain mode. In both modes, the clock root setting comes from the OBSERVEn_CONTROL register. In unassigned mode, this register can be written from any domain, but it needs to pass access authentication. In domain mode, the domain based authentication is activated, and only the domains listed in the Whitelist can change the value of the OBSERVEn_CONTROL register.

NOTE

The observe functionality is for debug purposes only, and the accuracy is not guaranteed. Use of this field should be limited to room temperature, and frequency limited to less than 400 MHz.

15.5.7 General Purpose Registers (GPR)

The general purpose registers provide miscellaneous controls and data saving functions. The GPRs are divided in two regions - shared and private region.

In shared region, all CPU domains access the same registers. If any CPU updates the value in the shared region, all the other CPU domains can read out the new value. The registers have an access control bit field to protect it from being changed unexpectedly.

In private region, each CPU domain has its own register. A CPU domain can only access registers belonging to itself. Since all the registers share the same address, a CPU domain will not have access to registers belonging to another CPU domain.

Shared registers have 2 work modes, Unassigned Mode and Domain Mode. Private registers work in Unassigned Mode only. Whitelist is ignored by private registers. Unassigned Mode is an implicit mode, if a shared register is not assigned to Domain Mode, the default mode is Unassigned Mode. After reset, all registers work in Unassigned Mode.

All registers are readable for any domain in any mode, but write access is restricted for protection. In Unassigned Mode, Domain access control scheme is disabled, but access control is still active.

Type	GPR	Position	Width	Description
Shared	0	0	4	Setpoint LPCG response time. This value need be set when Setpoint controlled LPCG is controlling a clock slower than 16MHz. The value need be no less than the multiple number of the slowest clock to 16M cycle.
Private	0	0	4	Domain LPCG response time. This value need be set when CPU domain low power controlled LPCG is controlling a clock slower than 16MHz. The value need be no less than the multiple number of the slowest clock to 16M cycle.

NOTE

A larger response time will lead to Low power Mode and Setpoint transition penalty time.

15.5.8 Reset

The reset of CCM will be released along with system early reset and clocks are provided during system reset. For each power domain, early reset of the power domain in which that clock group and clock gate reside, will be fed for correct power up and reset flow.

15.6 External Signals

The table below shows the external signals associated with CCM block.

Table 15-6. External Signals

External Signal	Description
CCM_CLKO1	Clock output 1 for off-chip devices
CCM_CLKO2	Clock output 2 for off-chip devices
CCM_ENET_REF_CLK_25M	ENET Reference Clock

15.7 Analog IP (AI) Interface

The chip has various analog IP and components that are controlled via an AI interface. The AI interface provides a bridge to access the control registers within the analog IP and their respective components. The following table shows the AI interface registers relative to their respective analog components and power domains.

Table 15-7. AI registers

Domain	Analog Component	AI Registers
SOC2PLL	SYS_PLL1 (1G)	VDDSOC2PLL_AI_CTRL_1G
	AUDIO_PLL	VDDSOC2PLL_AI_WDATA_1G
	VIDEO_PLL	VDDSOC2PLL_AI_RDATA_1G
		VDDSOC2PLL_AI_CTRL_AUDIO
		VDDSOC2PLL_AI_WDATA_AUDIO
		VDDSOC2PLL_AI_RDATA_AUDIO
		VDDSOC2PLL_AI_CTRL_VIDEO
		VDDSOC2PLL_AI_WDATA_VIDEO
		VDDSOC2PLL_AI_RDATA_VIDEO
SOC	PHY LDO	VDDSOC_AI_CTRL
		VDDSOC_AI_WDATA
		VDDSOC_AI_RDATA
		PMU_LDO_PLL
LPSR	Bandgap	VDDLPSR_AI_CTRL
	RCOSC_400M	VDDLPSR_AI_WDATA
	Tempsensor	VDDLPSR_AI_RDATA_REFTOP
		PMU_REF_CTRL
		VDDLPSR_AI400M_CTRL

Table continues on the next page...

Table 15-7. AI registers (continued)

Domain	Analog Component	AI Registers
		VDDLPSR_AI400M_WDATA
		VDDLPSR_AI400M_RDATA
		VDDLPSR_AI_RDATA_TMPSNS

The following recommendations outline how to perform register accesses through the AI interface.

Steps to perform a write operation of an analog component's AI interface:

1. Write *AI_CTRL register
   - RWB value is 0
   - ADDRESS value is the analog component's relative AI control register to be accessed.
2. Write *AI_WDATA
   - Data[31:0] value is the analog component's relative AI control register value to be written
3. Write *CTRL IP Toggle
   - Toggle the TOGGLE bit in the bit position for the respective analog component. The toggle will initiate the write sequence.

Steps to perform a read operation of an analog component's AI interface:

1. Write *AI_CTRL register
   - RWB value is 1
   - ADDRESS value is the analog component's relative AI control register to be accessed.
2. Write *CTRL IP Toggle
   - Toggle the TOGGLE bit in the bit position for the respective analog component. The toggle will initiate the read sequence.
3. Read *CTRL
   - Poll this register until the respective analog component's busy bit is low, indicating the read transaction has completed.
4. Read *AI_RDATA
   - Read Data[31:0]. The contents of the Read Data register is the value of the analog component's respective AI register's contents.

NOTE

- For PLL operations, follow the PLL enable sequence first.
- Varying IP will have a corresponding identical toggle bit

Example: To open the bandgap, the following steps have to be made:

1. Perform the write on CTRL0
    - Set REFTOP_PWD value to 0
2. Wait 100us
3. Perform the write on CTRL0
    - Set REFTOP_SELFBIASOFF value to 1

15.8 Programming Guidelines

The Clock Controller Module contains the following Fractional and Integer PLLs:

- Fractional PLLs:
    - SYS_PLL1
    - AUDIO PLL
    - VIDEO PLL
- Integer PLLs:
    - SYS_PLL2
    - SYS_PLL3
    - ARM PLL

The PLLs can work in either GPC mode or Software mode (default). In GPC mode, GPC is the master and drives all the slaves and the users can configure the Setpoint registers. In Software mode, the users can configure all the registers.

The equations given below help to calculate the output frequency for PLLs based on the mode (Software or GPC) and type of PLL (Fractional or Integer).

- During Software mode (default):
    - For Fractional PLLs (SYS_PLL1, AUDIO_PLL, VIDEO_PLL):
        - Output frequency = Fref * (CTRL0[DIV_SELECT] + (NUMERATOR[NUM]/DENOMINATOR[DENOM]))
        - **NOTE**

          The range limitation for NUMERATOR[NUM]/ DENOMINATOR[DENOM] restricts to -1 to +1.

    - For Integer PLLs (SYS_PLL2, SYS_PLL3, ARM_PLL):
        - Output frequency = Fref * MFI
- During GPC mode:
    - For Fractional PLLs (SYS_PLL1, AUDIO_PLL, VIDEO_PLL):
        - Output frequency = Fref * (SYS_PLLx_DIV_SELECT[DIV_SELECT] + (SYS_PLLx_NUMERATOR[NUM]/ SYS_PLLx_DENOMINATOR[DENOM]))
    - For Integer PLLs (SYS_PLL2, SYS_PLL3, ARM_PLL):
        - Output frequency = Fref * MFI

Fref is the PLL Reference Frequency sourced from 24MHz.

NOTE

For SYS_PLL2 and SYS_PLL3, MFI is a fixed value of 22 and 20 respectively.

For ARM_PLL, MFI is equivalent to (ARM_PLL_CTRL[DIV_SELECT]/2)/ ARM_PLL_CTRL[POST_DIV_SELECT].

15.8.1 Spread Spectrum Parameters

The SYS_PLL1, SYS_PLL2, AUDIO_PLL, VIDEO_PLL and the related PFDs support spread spectrum (down spread). The equations given below help to calculate spread spectrum range, and modulation frequency based on the mode (Software or GPC) and type of PLL (Fractional or Integer).

- During Software mode (default):
  - For Fractional PLLs (SYS_PLL1, AUDIO_PLL, VIDEO_PLL):
    - Spread spectrum range = Fref * SPREAD_SPECTRUM[STOP]/ DENOMINATOR[DENOM]
    - Modulation frequency = Fref * SPREAD_SPECTRUM[STEP]/ (2*SPREAD_SPECTRUM[STOP])
  - For Integer PLL (SYS_PLL2):
    - Spread spectrum range = Fref * SYS_PLL2_SS[STOP]/ SYS_PLL2_MFD[MFD]
    - Modulation frequency= Fref * SYS_PLL2_SS[STEP]/ (SYS_PLL2_SS[STOP] *2)
- During GPC mode:
  - For Fractional PLLs (SYS_PLL1, AUDIO_PLL, VIDEO_PLL):
    - Spread spectrum range = Fref * SYS_PLLx_SS[STOP]/ SYS_PLLx_DENOMINATOR[DENOM]
    - Modulation frequency = Fref * SYS_PLLx_SS[STEP]/ (2*SYS_PLLx_SS[STOP])
  - For Integer PLL (SYS_PLL2):
    - Spread spectrum range = Fref * SYS_PLL2_SS[STOP]/ SYS_PLL2_MFD[MFD]
    - Modulation frequency= Fref * SYS_PLL2_SS[STEP]/ (SYS_PLL2_SS[STOP] *2)

Fref is the PLL Reference Frequency sourced from 24MHz.

The spread range indicates how much frequency the PLL will sweep down. For example, a spread range of 6MHz would mean that the PLL will sweep from 'Target_frequency' to 'Target_Frequency - 6MHz' and sweep back.

15.8.2 PLL Enable Sequence

The following sequence has to be followed to enable ARM_PLL, SYS_PLL2 and SYS_PLL3. The PLLs should be powered down and output should be disabled before beginning the sequence.

1. Enable PHY_LDO by setting Analog Control Register CTRL0 [LINREG_EN]. It is recommended to set LinReg output voltage = 1V [LINREG_OUTPUT_TRG] and enable LinReg current limit [LINREG_ILIMIT_EN]. This must be done via ANALOG IP interface. Please read chapter ANALOG IP Interface in RM.
2. Wait at least 100 us.
3. Enable the reference voltage by setting PMU_REF_CTRL[EN_PLL_VOL_REF_BUFFER].
4. Configure the PLL registers such as xx_DIV_SELECT/xx_MFN/xx_MFD/xx_SS described in the PLL Register Descriptions section.
5. Enable the internal LDO (ARM_PLL does not have internal LDO and this step is skipped.
6. Wait at least 30 us for LDO stability (ARM_PLL does not have internal LDO and this step is skipped).
7. Power up the PLL by enabling xx_PLL_CTRL[POWERUP] and assertxx_PLL_CTRL[HOLD_RING_OFF].
8. When the PLL lock time is halfway through, de-assert the xx_PLL_CTRL[HOLD_RING_OFF].
9. Wait till the PLL lock time is complete. This can be monitored through the xx_PLL_CTRL[xx_PLL_STABLE] bit.
10. Enable clock output through xx_PLL_CTRL[ENABLE_CLK].

The following sequence has to be followed for SYS_PLL1, AUDIO_PLL and VIDEO_PLL:

1. Enable PHY_LDO by setting Analog Control Register CTRL0 [LINREG_EN]. It is recommended to set LinReg output voltage = 1V [LINREG_OUTPUT_TRG] and enable LinReg current limit [LINREG_ILIMIT_EN]. This must be done via ANALOG IP interface. Please read chapter ANALOG IP Interface in RM.
2. Wait at least 100 µs.
3. Enable the reference voltage by setting PMU_REF_CTRL[EN_PLL_VOL_REF_BUFFER].

4. Bypass PLL by asserting BYPASS bit in Fractional PLL Control Register (CTRL0). This must be done via ANALOG IP interface. Please read chapter ANALOG IP Interface in RM There are separate registers for access SYS_PLL1 (VDDSOC2PLL_AI_CTRL_1G), AUDIO_PLL (VDDSOC2PLL_AI_CTRL_AUDIO) and VIDEO_PLL(VDDSOC2PLL_AI_CTRL_VIDEO).
5. Enable PLL clock output by setting SYS_PLL1_CTRL[ENABLE_CLK], PLL_AUDIO_CTRL[ENABLE_CLK] or PLL_VIDEO_CTRL[ENABLE_CLK].
6. Configure the PLL registers Fractional PLL Control Register (CTRL0) [POST_DIV_SEL], Fractional PLL Control Register (CTRL0)[DIV_SELECT], Fractional PLL Numerator Control Register (NUMERATOR)[NUM], Fractional PLL Denominator Control Register(DENOMINATOR)[DENOM], Fractional PLL Spread Spectrum Control Register(SPREAD_SPECTRUM)[STOP/STEP] [ENABLE]. This must be done via ANALOG IP interface. Please read chapter ANALOG IP Interface in RM. SYS_PLL1 is fixed PLL, so Fractional PLL Spread Spectrum Control Register(SPREAD_SPECTRUM) can be only configured.
7. Enable the internal LDO by setting Fractional PLL Control Register (CTRL0) [PLL_REG_EN] via ANALOG IP Interface.
8. When the PLL lock time is halfway through, de-assert the Fractional PLL Control Register (CTRL0) [HOLD_RING_OFF] via ANALOG IP interface.
9. Wait till the PLL lock time is complete. This can be monitored through the xx_PLL_CTRL[xx_PLL_STABLE] bit.
10. Disable PLL gate by deasserting SYS_PLL1_CTRL[SYS_PLL1_GATE], PLL_AUDIO_CTRL[PLL_AUDIO_GATE] or PLL_VIDEO_CTRL[PLL_VIDEO_GATE].
11. Disable PLL bypass by deasserting Fractional PLL Control Register (CTRL0) [BYPASS] via ANALOG IP Interface.

NOTE

- In order to avoid unstable clocks that might alter the PFD's state machine, all PFDs are required to be clock-gated when the PLL is not locked.
- PFD's input can be changed on-the fly, while PLL's input cannot be changed on-the-fly (except for MFN).
- The initialization for software and GPC modes is handled by Setpoints automatically.

15.9 Memory Map and register definition

This section includes the CCM module memory map and detailed descriptions of all registers.

NOTE

For related IPS Domain Slot control, please see IPS Domain Registers in Power Management Unit (PMU) chapter.

15.9.1 CCM register descriptions

15.9.1.1 CCM memory map

CCM base address: 40CC_0000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Clock root control (CLOCK_ROOT0_CONTROL)	32	RW	0000_0000h

15.9.1.2 Clock root control (CLOCK_ROOT0_CONTROL - CLOCK_ROOT78_CONTROL)

15.9.1.2.1 Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

For a = 0 to 78:

Register	Offset	Description
CLOCK_ROOTa_CONTROL	0h + (a × 80h)	Clock root control
CLOCK_ROOTa_CONTROL_SET	4h + (a × 80h)	Writing 1 to a bit in this register ensures that the corresponding bit in CLOCK_ROOTa_CONTROL is 1

Table continues on the next page...

Register	Offset	Description
CLOCK_ROOTa_CONTROL_CLR	8h + (a × 80h)	Writing 1 to a bit in this register ensures that the corresponding bit in CLOCK_ROOTa_CONTROL is 0
CLOCK_ROOTa_CONTROL_TOG	Ch + (a × 80h)	Writing 1 to a bit in this register inverts the value of the corresponding bit in CLOCK_ROOTa_CONTROL

15.9.1.2.2 Function

This register controls clock root generation.

15.9.1.2.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15.9.1.2.4 Fields

Field	Function
31-25 —	Reserved
24 OFF	OFF Shutdown clock root 0b - Turn on clock 1b - Turn off clock
23-16 —	Reserved
15-11 —	Reserved
10-8 MUX	Clock multiplexer Select clock from 8 clock sources.
7-0 DIV	Clock divider Divider selected clock by DIV + 1.

15.9.1.3 Clock root working status (CLOCK_ROOT0_STATUS0 - CLOCK_ROOT78_STATUS0)

15.9.1.3.1 Offset

For a = 0 to 78:

Register	Offset
CLOCK_ROOTa_STATUS0	20h + (a × 80h)

15.9.1.3.2 Function

This register shows current clock root running status.

15.9.1.3.4 Fields

Field	Function
31 CHANGING	Internal updating in clock root Indication for clock root logic is internal updating. This status is combination of UPDATE_FORWARD, UPDATE_REVERSE, and SLICE_BUSY. 0b - Clock Status is not updating currently

Table continues on the next page...

Field	Function
	1b - Clock generation logic is updating currently
30 UPDATE_REVERSE	Internal status synchronization from clock generation logic Indication for internal status synchronizing to clock generation logic. 0b - Synchronization not in process 1b - Synchronization in process
29 UPDATE_FORWARD	Internal status synchronization to clock generation logic Indication for clock status is synchronizing for clock root. 0b - Synchronization not in process 1b - Synchronization in process
28 SLICE_BUSY	Internal updating in generation logic Indication for clock generation logic is applying new setting. 0b - Clock generation logic is not busy 1b - Clock generation logic is applying the new setting
27 POWERDOWN	Current clock root POWERDOWN setting Current running state of POWERDOWN field for clock root. 0b - Clock root is running 1b - Clock root is Powered Down
26-25 —	Reserved
24 OFF	Current clock root OFF setting Current running state of OFF field for clock root. 0b - Clock is running 1b - Clock is disabled/off
23-16 —	Reserved
15-11 —	Reserved
10-8 MUX	Current clock root MUX setting Current running state of MUX field for clock root.
7-0 DIV	Current clock root DIV setting Current running state of DIV field for clock root.

15.9.1.4 Clock root low power status (CLOCK_ROOT0_STATUS1 - CLOCK_ROOT78_STATUS1)

15.9.1.4.1 Offset

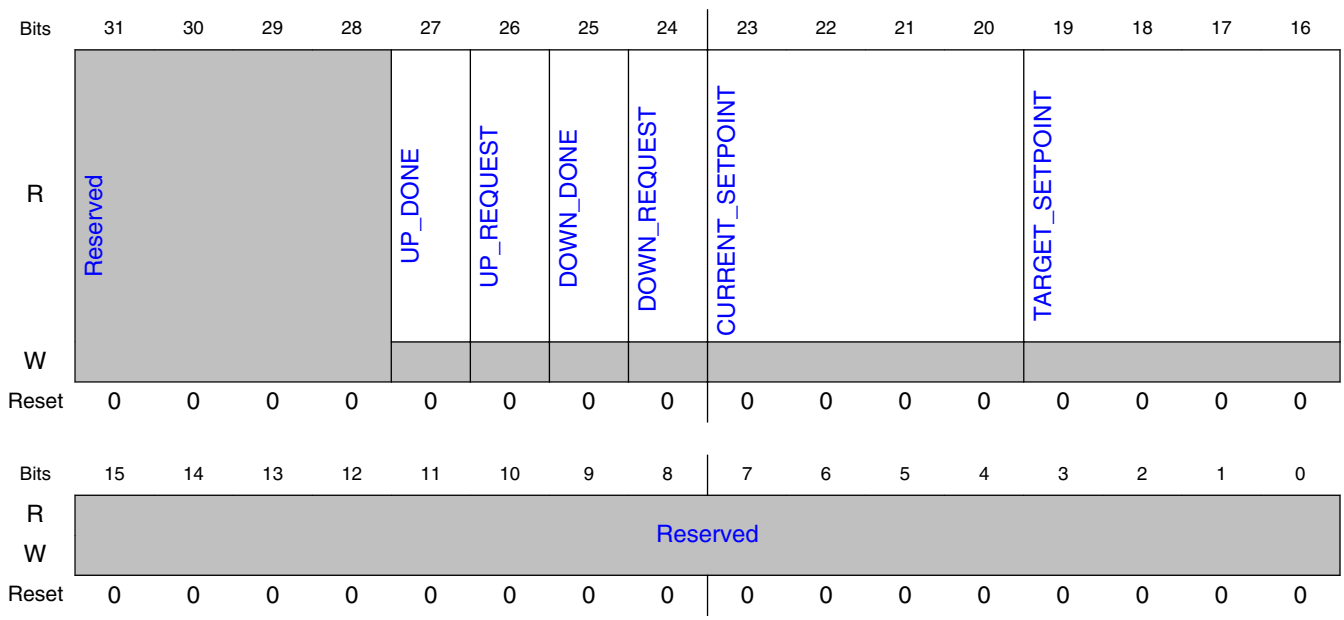
For a = 0 to 78:

Register	Offset
CLOCK_ROOTa_STATUS1	24h + (a × 80h)

15.9.1.4.2 Function

This register shows low power status of clock root.

15.9.1.4.3 Diagram



15.9.1.4.4 Fields

Field	Function
31-28 —	Reserved
27 UP_DONE	Clock frequency increase finish Handshake signal with GPC status indicating frequency increase finish. 0b - Frequency increase not completed 1b - Frequency increase completed
26 UP_REQUEST	Clock frequency increase request Handshake signal with GPC status indicating frequency increase is requesting. 0b - Frequency increase not requested 1b - Frequency increase requested
25 DOWN_DONE	Clock frequency decrease finish Handshake signal with GPC status indicating frequency decrease finish.

Table continues on the next page...

Field	Function
	0b - Frequency decrease not completed 1b - Frequency decrease completed
24 DOWN_REQUEST	Clock frequency decrease request Handshake signal with GPC status indicating frequency decrease is requesting. 0b - Frequency decrease not requested 1b - Frequency decrease requested
23-20 CURRENT_SETPOINT	Current Setpoint This is the Setpoint value the Soc is current working in.
19-16 TARGET_SETPOINT	Target Setpoint This is the Setpoint value the SoC will switch to
15-0 —	Reserved

15.9.1.5 Clock root configuration (CLOCK_ROOT0_CONFIG - CLOCK_ROOT78_CONFIG)

15.9.1.5.1 Offset

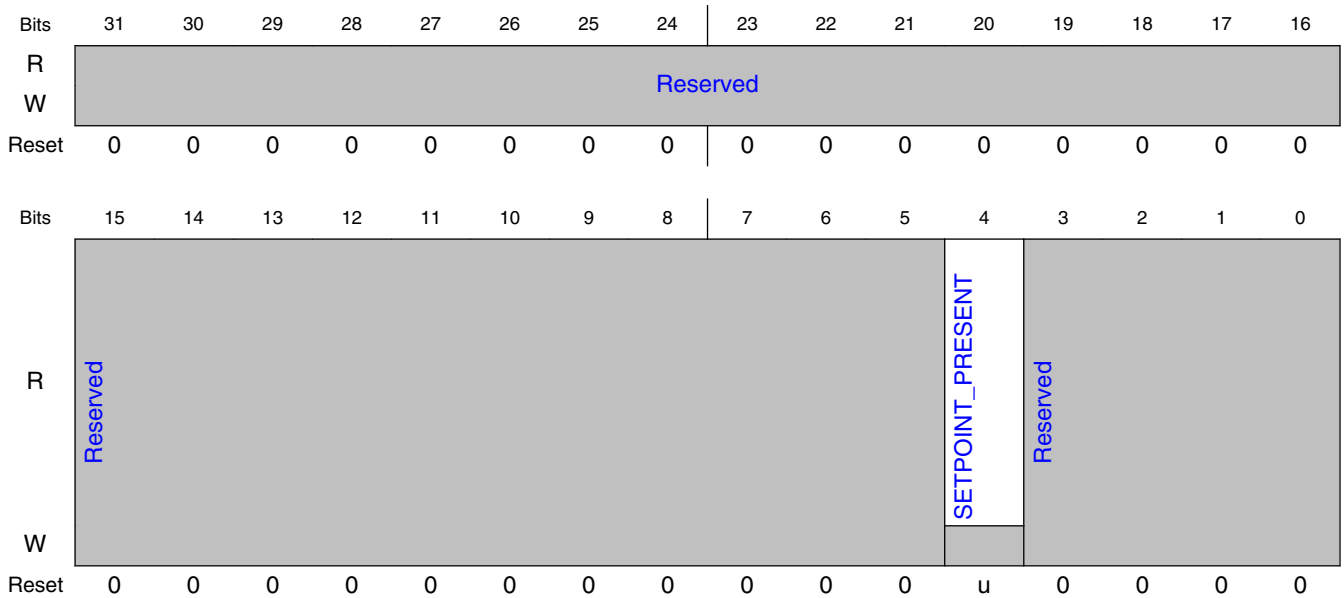
For a = 0 to 78:

Register	Offset
CLOCK_ROOTa_CONFIG	2Ch + (a × 80h)

15.9.1.5.2 Function

This register shows integration parameters

15.9.1.5.3 Diagram



15.9.1.5.4 Fields

Field	Function
31-5 —	Reserved
4 SETPOINT_PRESENT	Setpoint present This bit indicate whether this clock root implement Setpoint control scheme. 0b - Setpoint is not implemented. 1b - Setpoint is implemented.
3-0 —	Reserved

15.9.1.6 Clock root access control (CLOCK_ROOT0_AUTHEN - CLOCK_ROOT78_AUTHEN)

15.9.1.6.1 Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

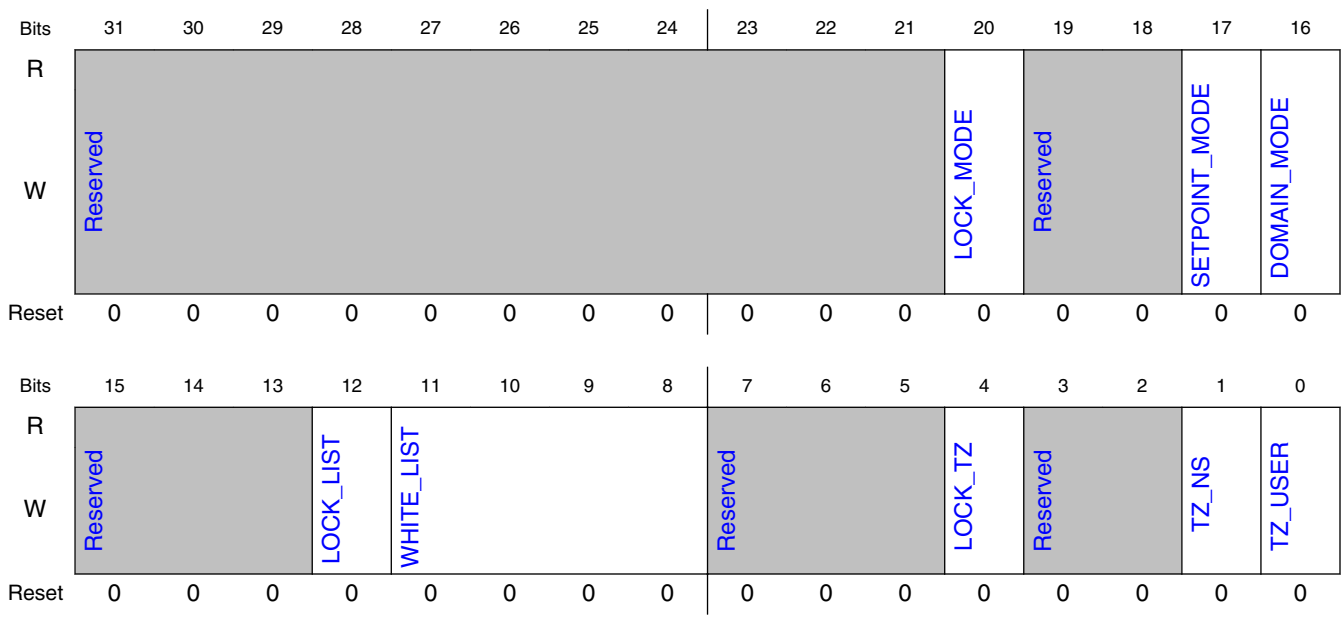
For a = 0 to 78:

Register	Offset	Description
CLOCK_ROOTa_AUTHEN	30h + (a × 80h)	Clock root access control
CLOCK_ROOTa_AUTHEN_SET	34h + (a × 80h)	Writing 1 to a bit in this register ensures that the corresponding bit in CLOCK_ROOTa_AUTHEN is 1
CLOCK_ROOTa_AUTHEN_CLR	38h + (a × 80h)	Writing 1 to a bit in this register ensures that the corresponding bit in CLOCK_ROOTa_AUTHEN is 0
CLOCK_ROOTa_AUTHEN_TOG	3Ch + (a × 80h)	Writing 1 to a bit in this register inverts the value of the corresponding bit in CLOCK_ROOTa_AUTHEN

15.9.1.6.2 Function

This register that manages clock root access control.

15.9.1.6.3 Diagram



15.9.1.6.4 Fields

Field	Function
31-21 —	Reserved
20 LOCK_MODE	Lock low power and access mode This bit lock low power and access control mode. When this bit is set, bits 16-20 cannot be changed. Once this bit is set, it cannot be cleared, until next system reset. 0b - MODE is not locked 1b - MODE is locked

Table continues on the next page...

Field	Function
19-18 —	Reserved
17 SETPOINT_MODE	Low power and access control by Setpoint Clock root works in Setpoint controlled Mode 0b - Clock does NOT work in Setpoint Mode 1b - Clock works in Setpoint Mode
16 DOMAIN_MODE	Low power and access control by domain Clock root works in domain controlled mode 0b - Clock does NOT work in Domain Mode 1b - Clock works in Domain Mode
15-13 —	Reserved
12 LOCK_LIST	Lock Whitelist This bit lock Whitelist. When this bit is set, CLOCK_ROOTx_AUTHEN[WHITE_LIST] cannot be changed. Once this bit is set, it cannot be cleared, until next system reset. 0b - Whitelist is not locked 1b - Whitelist is locked
11-8 WHITE_LIST	Whitelist Domains that on the Whitelist can change this clock root. Each field in this field represent for one domain. Bit8~Bit11 represent for DOMAIN0~DOMAIN3 respectively. 0000b - This domain is NOT allowed to change clock 0001b - This domain is allowed to change clock
7-5 —	Reserved
4 LOCK_TZ	Lock TZ_USER and TZ_NS When this bit is set, TZ_USER and TZ_NS cannot be changed. Once this bit is set, it cannot be cleared, until next system reset. 0b - Not locked 1b - Locked
3-2 —	Reserved
1 TZ_NS	Non-secure access This clock root can be changed when CPU is in Non-secure mode. 0b - Cannot be changed in Non-secure mode 1b - Can be changed in Non-secure mode
0 TZ_USER	User access This clock root can be changed when CPU is in user mode (in CMx core). 0b - Clock cannot be changed in user mode 1b - Clock can be changed in user mode

15.9.1.7 Setpoint setting (CLOCK_ROOT0_SETPOINT0 - CLOCK_ROOT78_SETPOINT15)

15.9.1.7.1 Offset

Register	Offset
CLOCK_ROOT0_SETPOINT0	40h
CLOCK_ROOT0_SETPOINT1	44h
CLOCK_ROOT0_SETPOINT2	48h
CLOCK_ROOT0_SETPOINT3	4Ch
CLOCK_ROOT0_SETPOINT4	50h
CLOCK_ROOT0_SETPOINT5	54h
CLOCK_ROOT0_SETPOINT6	58h
CLOCK_ROOT0_SETPOINT7	5Ch
CLOCK_ROOT0_SETPOINT8	60h
CLOCK_ROOT0_SETPOINT9	64h
CLOCK_ROOT0_SETPOINT10	68h
CLOCK_ROOT0_SETPOINT11	6Ch
CLOCK_ROOT0_SETPOINT12	70h
CLOCK_ROOT0_SETPOINT13	74h
CLOCK_ROOT0_SETPOINT14	78h
CLOCK_ROOT0_SETPOINT15	7Ch
CLOCK_ROOT1_SETPOINT0	C0h
CLOCK_ROOT1_SETPOINT1	C4h
CLOCK_ROOT1_SETPOINT2	C8h
CLOCK_ROOT1_SETPOINT3	CCh
CLOCK_ROOT1_SETPOINT4	D0h
CLOCK_ROOT1_SETPOINT5	D4h
CLOCK_ROOT1_SETPOINT6	D8h

Table continues on the next page...

Register	Offset
CLOCK_ROOT78_SETPOINT15	277Ch

15.9.1.7.2 Function

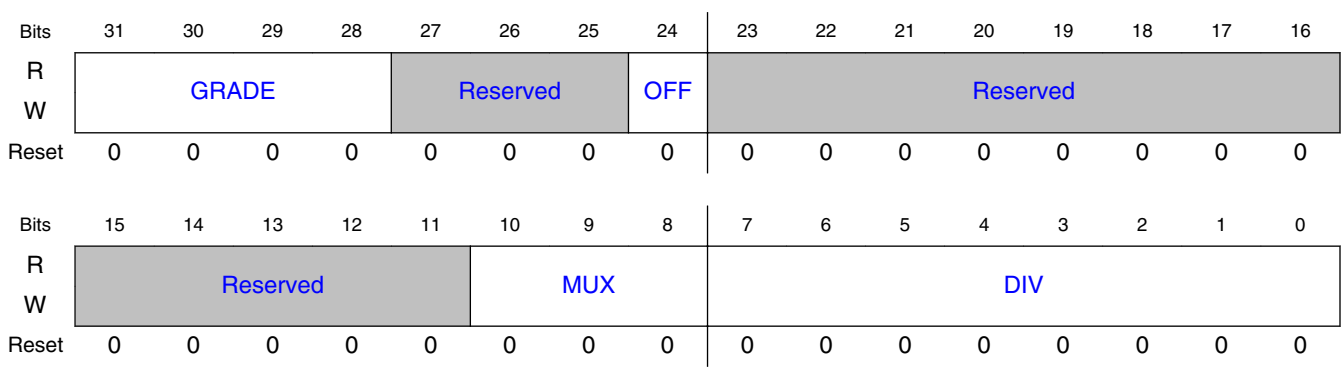
These registers define 16 clock root setting which will take effect when the system switches to a corresponding Setpoint.

These 16 registers provide clock root generation settings for the Setpoint. Corresponding settings will be automatically loaded when system low power mode transition takes place.

The following clock roots support Setpoints:

- M7_CLK_ROOT
- M4_CLK_ROOT
- BUS_CLK_ROOT
- BUS_LPSR_CLK_ROOT
- SEMC_CLK_ROOT
- FLEXSPI1_CLK_ROOT
- FLEXSPI2_CLK_ROOT
- CCM_CLK01_CLK_ROOT
- CCM_CLKO2_CLK_ROOT

15.9.1.7.3 Diagram



15.9.1.7.4 Fields

Field	Function
31-28	Grade

Table continues on the next page...

Field	Function
GRADE	Indicate speed grade for each Setpoint setting. This value MUST be set to make Setpoint work properly. Values will be used CCM internally to determine clock frequency relation ship between Setpoint settings and generate proper sequence. Smaller value means higher clock speed.
27-25 —	Reserved
24 OFF	OFF OFF value in Setpoint 0b - ON 1b - OFF
23-11 —	Reserved
10-8 MUX	Clock multiplexer MUX value in Setpoint.
7-0 DIV	Clock divider DIV value in Setpoint.

15.9.1.8 Clock group control (CLOCK_GROUP0_CONTROL - CLOCK_GROUP1_CONTROL)

15.9.1.8.1 Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

For a = 0 to 1:

Register	Offset	Description
CLOCK_GROUPa_CONTROL	4000h + (a × 80h)	Clock group control
CLOCK_GROUPa_CONTROL_SET	4004h + (a × 80h)	Writing 1 to a bit in this register ensures that the corresponding bit in CLOCK_GROUPa_CONTROL is 1
CLOCK_GROUPa_CONTROL_CLR	4008h + (a × 80h)	Writing 1 to a bit in this register ensures that the corresponding bit in CLOCK_GROUPa_CONTROL is 0
CLOCK_GROUPa_CONTROL_TOG	400Ch + (a × 80h)	Writing 1 to a bit in this register inverts the value of the corresponding bit in CLOCK_GROUPa_CONTROL

15.9.1.8.2 Function

This register controls synchronous clock group clocks generation.

15.9.1.8.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	Reserved							OFF	RSTDIV							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	Reserved												DIV0			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

15.9.1.8.4 Fields

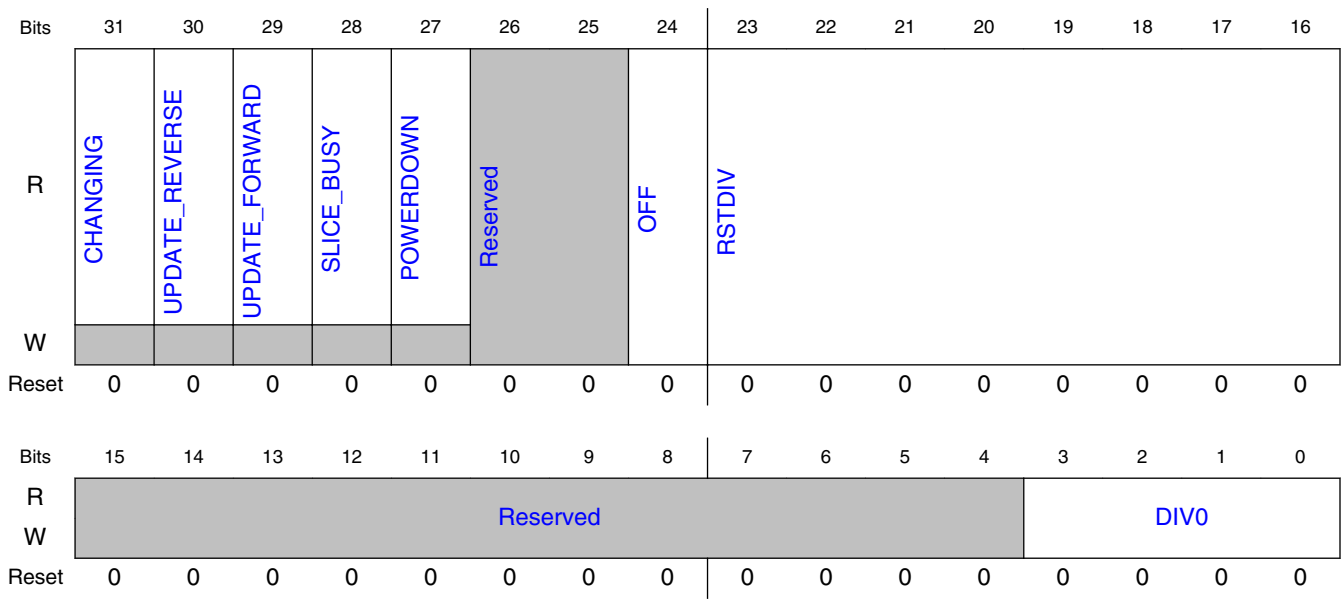
Field	Function
31-25 —	Reserved
24 OFF	OFF Shutdown all clocks in clock group 0b - Clock is running 1b - Turn off clock
23-16 RSTDIV	Clock group global restart count Clock group will restart when this divider overflows. This field must be common multiple of all dividers.
15-4 —	Reserved
3-0 DIV0	Clock divider0 Divider clock root by DIV0 + 1.

15.9.1.9 Clock group working status (CLOCK_GROUP0_STATUS0 - CLOCK_GROUP1_STATUS0)

15.9.1.9.1 Offset

Register	Offset
CLOCK_GROUP0_STATUS0	4020h
CLOCK_GROUP1_STATUS0	40A0h

15.9.1.9.2 Diagram



15.9.1.9.3 Fields

Field	Function
31 CHANGING	Internal updating in clock group Indication for clock group logic is internal updating. This status is combination of UPDATE_FORWARD, UPDATE_REVERSE, and SLICE_BUSY. 0b - Clock root is not updating currently 1b - Clock root logic is updating currently
30 UPDATE_REVERSE	Internal status synchronization from clock generation logic Indication for internal status synchronizing to clock generation logic. 0b - Synchronization not in process 1b - Synchronization in process
29 UPDATE_FORWARD	Internal status synchronization to clock generation logic Indication for clock status is synchronizing fro clock generation logic. 0b - Synchronization not in process 1b - Synchronization in process

Table continues on the next page...

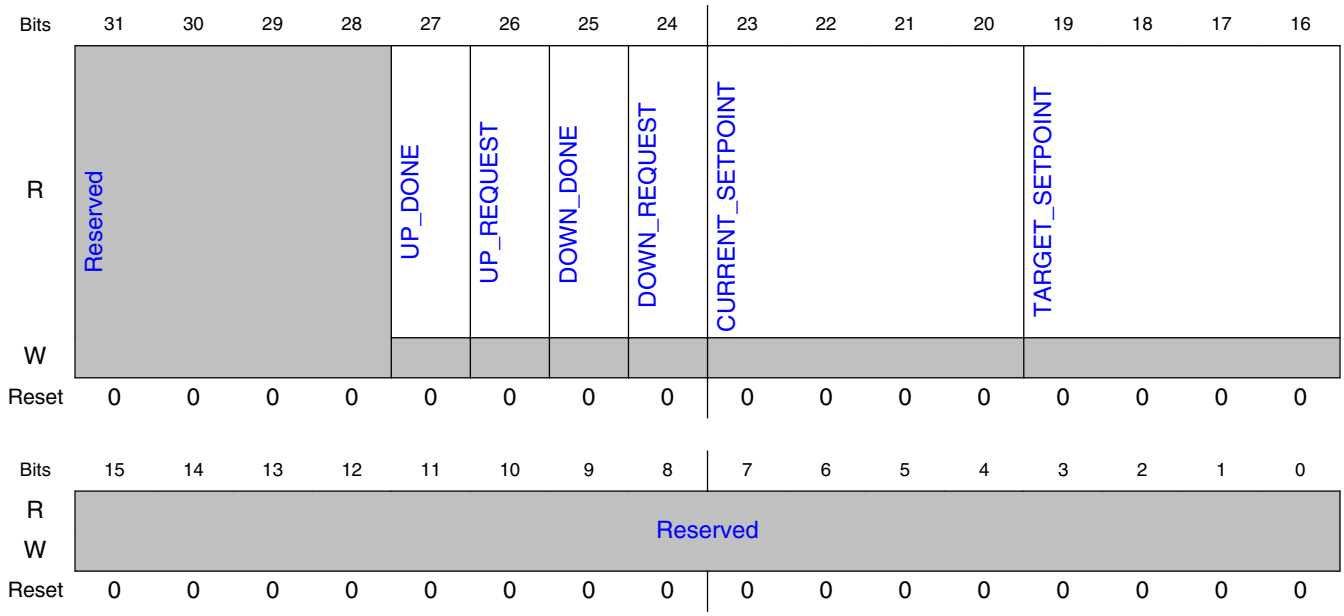
Field	Function
28 SLICE_BUSY	Internal updating in generation logic Indication for clock generation logic is applying new setting. 0b - Clock generation logic is not busy 1b - Clock generation logic is applying the new setting
27 POWERDOWN	Current clock root POWERDOWN setting Current running state of POWERDOWN field for clock root. 0b - Clock root is running 1b - Clock root is Powered Down
26-25 —	Reserved
24 OFF	OFF Current running state of OFF field for clock group. 0b - Clock is running. 1b - Turn off clock.
23-16 RSTDIV	Clock divider Current running state of RSTDIV field for clock group.
15-4 —	Reserved
3-0 DIV0	Clock divider Current running state of DIV0 field for clock group.

15.9.1.10 Clock group low power/extend status (CLOCK_GROUP0_STATUS1 - CLOCK_GROUP1_STATUS1)

15.9.1.10.1 Offset

Register	Offset
CLOCK_GROUP0_STATUS1	4024h
CLOCK_GROUP1_STATUS1	40A4h

15.9.1.10.2 Diagram



15.9.1.10.3 Fields

Field	Function
31-28 —	Reserved
27 UP_DONE	Clock frequency increase complete Handshake signal with GPC status indicating frequency increase is complete. 0b - Handshake signal with GPC status indicating frequency increase is not complete 1b - Handshake signal with GPC status indicating frequency increase is complete
26 UP_REQUEST	Clock frequency increase request Handshake signal with GPC status indicating frequency increase is requested. 0b - No handshake signal is not requested 1b - Handshake signal with GPC status indicating frequency increase is requested
25 DOWN_DONE	Clock frequency decrease complete Handshake signal with GPC status indicating frequency decrease is complete. 0b - Handshake signal with GPC status indicating frequency decrease is not complete 1b - Handshake signal with GPC status indicating frequency decrease is complete
24 DOWN_REQUEST	Clock frequency decrease request 0b - No handshake signal is not requested 1b - Handshake signal with GPC status indicating frequency decrease is requested
23-20 CURRENT_SETPOINT	Current Setpoint This is the Setpoint value the Soc is current working in
19-16	Next Setpoint to change to This is the Setpoint value the SoC will switch to

Table continues on the next page...

Field	Function
TARGET_SETPOINT	
15-0 —	Reserved

15.9.1.11 Clock group configuration (CLOCK_GROUP0_CONFIG - CLOCK_GROUP1_CONFIG)

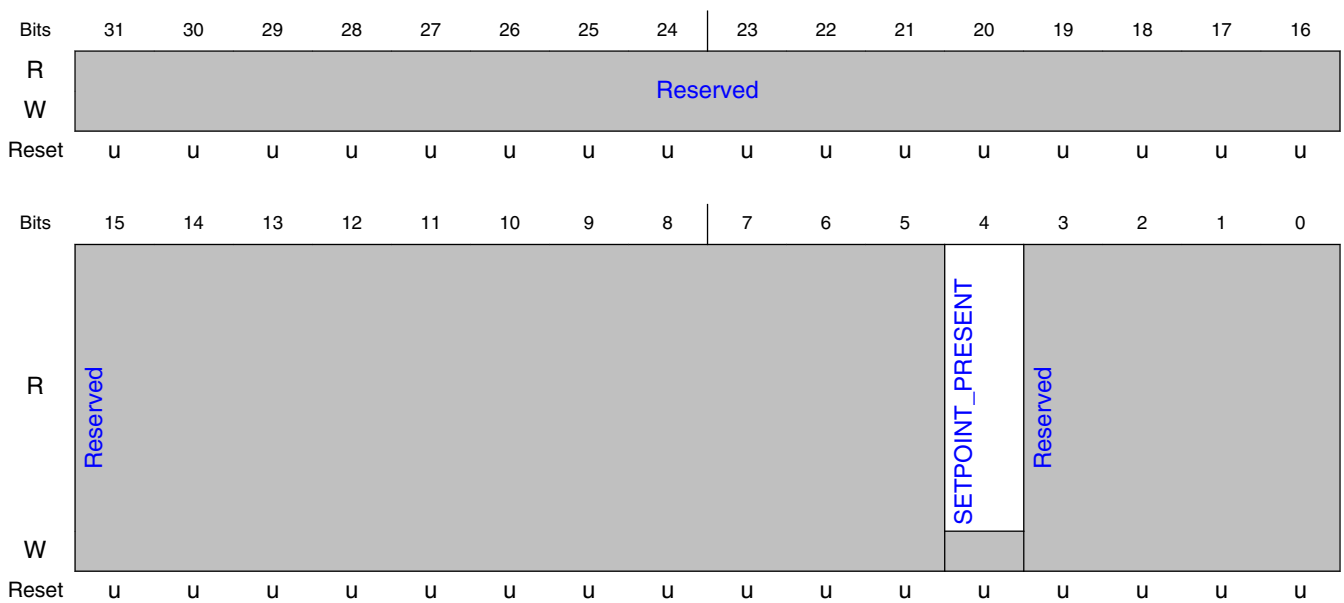
15.9.1.11.1 Offset

Register	Offset
CLOCK_GROUP0_CONFIG	402Ch
CLOCK_GROUP1_CONFIG	40ACh

15.9.1.11.2 Function

This register shows integration parameters.

15.9.1.11.3 Diagram



15.9.1.11.4 Fields

Field	Function
31-5 —	Reserved
4 SETPOINT_PRESENT	Setpoint present This bit indicate whether this clock root implement Setpoint control scheme. 0b - Setpoint is not implemented. 1b - Setpoint is implemented.
3-0 —	Reserved

15.9.1.12 Clock group access control (CLOCK_GROUP0_AUTHEN - CLOCK_GROUP1_AUTHEN)

15.9.1.12.1 Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

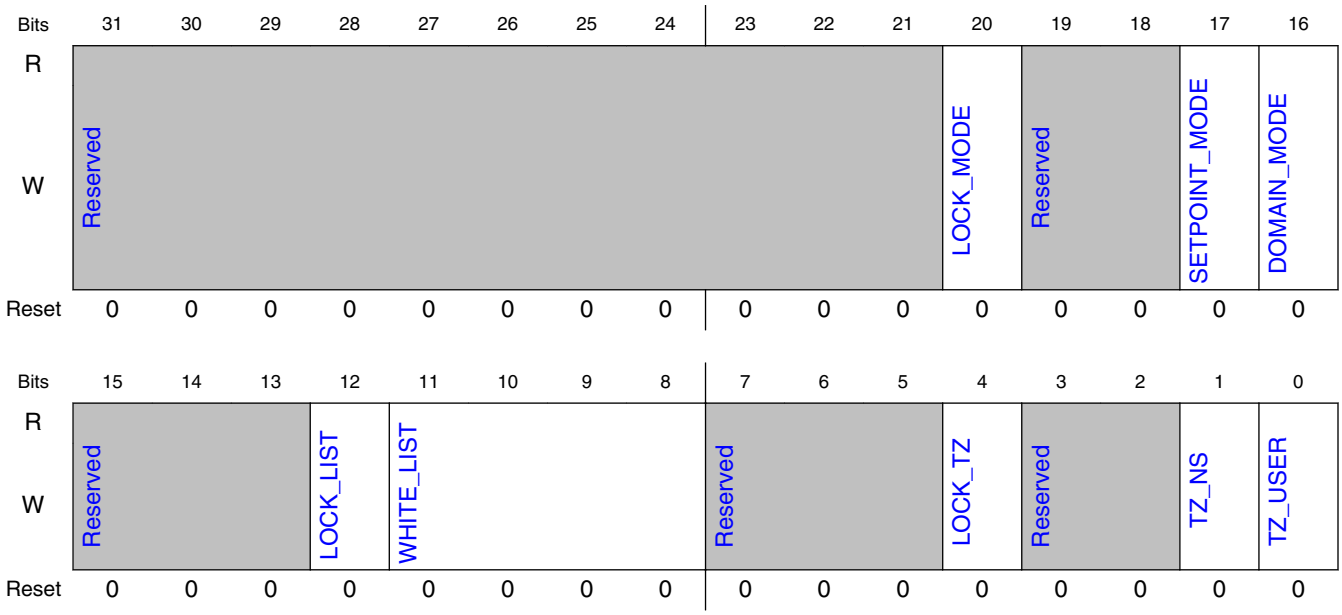
For a = 0 to 1:

Register	Offset	Description
CLOCK_GROUPa_AUTHEN	4030h + (a × 80h)	Clock group access control
CLOCK_GROUPa_AUTHEN_SET	4034h + (a × 80h)	Writing 1 to a bit in this register ensures that the corresponding bit in CLOCK_GROUPa_AUTHEN is 1
CLOCK_GROUPa_AUTHEN_CLR	4038h + (a × 80h)	Writing 1 to a bit in this register ensures that the corresponding bit in CLOCK_GROUPa_AUTHEN is 0
CLOCK_GROUPa_AUTHEN_TOG	403Ch + (a × 80h)	Writing 1 to a bit in this register inverts the value of the corresponding bit in CLOCK_GROUPa_AUTHEN

15.9.1.12.2 Function

This register manages clock group access control.

15.9.1.12.3 Diagram



15.9.1.12.4 Fields

Field	Function
31-21 —	Reserved
20 LOCK_MODE	Lock low power and access mode This bit lock low power and access control mode. When this bit is set, bits 16-20 cannot be changed. Once this bit is set, it cannot be cleared, until next system reset. 0b - MODE is not locked. 1b - MODE is locked.
19-18 —	Reserved
17 SETPOINT_MODE	Low power and access control by Setpoint Clock group works in Setpoint controlled Mode.
16 DOMAIN_MODE	Low power and access control by domain Clock group works in Domain controlled Mode. 0b - Clock does not work in Domain Mode. 1b - Clock works in Domain Mode.
15-13 —	Reserved
12 LOCK_LIST	Lock Whitelist This bit lock Whitelist. When this bit is set, CLOCK_GROUPx_AUTHEN[WHITE_LIST] cannot be changed. Once this bit is set, it cannot be cleared, until next system reset. 0b - Whitelist is not locked.

Table continues on the next page...

Field	Function
	1b - Whitelist is locked.
11-8 WHITE_LIST	Whitelist Domains that on the Whitelist can change this clock root. Each field in this field represent for one domain. Bit8~Bit11 represent for DOMAIN0~DOMAIN3 respectively.
7-5 —	Reserved
4 LOCK_TZ	Lock TZ_USER and TZ_NS When this bit is set, TZ_USER and TZ_NS cannot be changed. Once this bit is set, it cannot be cleared, until next system reset. 0b - Not locked. 1b - Locked.
3-2 —	Reserved
1 TZ_NS	Non-secure access This clock root can be changed when CPU is in Non-secure mode. 0b - Cannot be changed in Non-secure mode. 1b - Can be changed in Non-secure mode.
0 TZ_USER	User access This clock group can be changed when CPU is in user mode (in CMx core). 0b - Clock cannot be changed in user mode. 1b - Clock can be changed in user mode.

15.9.1.13 Setpoint setting (CLOCK_GROUP0_SETPOINT0 - CLOCK_GROUP1_SETPOINT15)

15.9.1.13.1 Offset

For a = 0 to 1; c = 0 to 15:

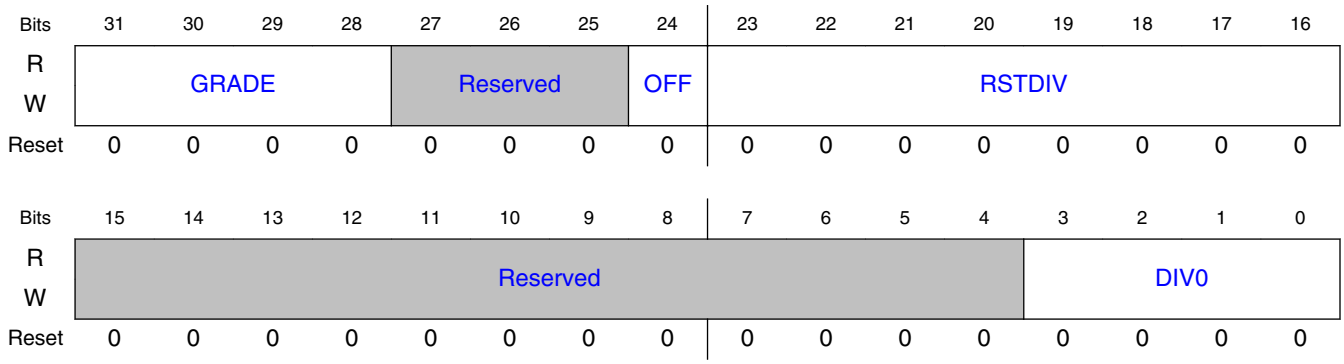
Register	Offset
CLOCK_GROUPa_SETPOINTc	4040h + (a × 80h) + (c × 4h)

15.9.1.13.2 Function

Register that provide clock root generation setting for Setpoint.

Corresponding setting will be automatically loaded when system low power mode shift.

15.9.1.13.3 Diagram



15.9.1.13.4 Fields

Field	Function
31-28 GRADE	Grade Indicate speed grade for each Setpoint setting. This value MUST be set to make Setpoint work properly. Values will be used CCM internally to determine clock frequency relation ship between Setpoint settings and generate proper sequence. Smaller value means higher clock speed.
27-25 —	Reserved
24 OFF	OFF Shutdown all locks in clock group. 0b - Clock is running. 1b - Turn off clock.
23-16 RSTDIV	Clock group global restart count Clock group will restart when this divider overflows. This field must be common multiple of all dividers.
15-4 —	Reserved
3-0 DIV0	Clock divider Divider selected clock by DIV + 1. 0000b - Direct output. 0001b - Divide by 2. 0010b - Divide by 3. 0011b - Divide by 4. 1111b - Divide by 16.

15.9.1.14 General Purpose Register (GPR_SHARED0 - GPR_SHARED7)

15.9.1.14.1 Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

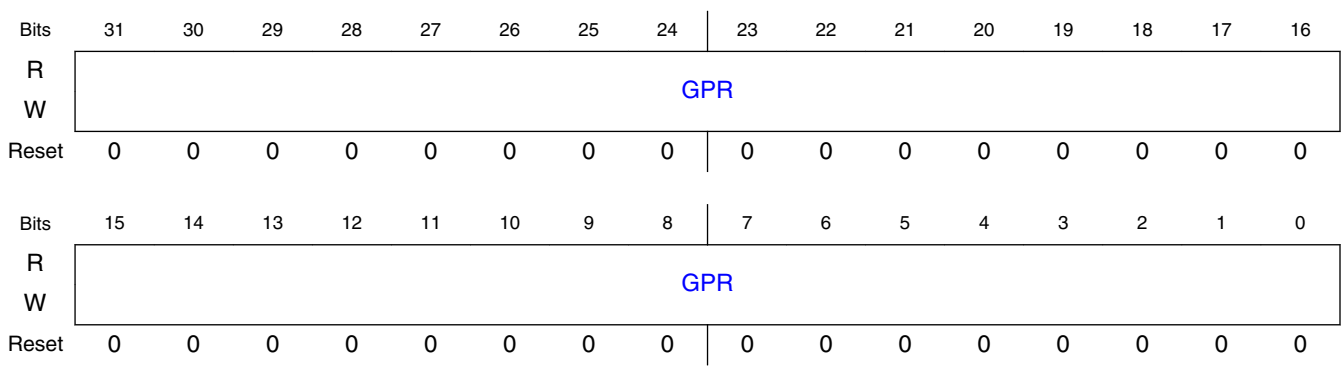
For a = 0 to 7:

Register	Offset	Description
GPR_SHAREDa	4800h + (a × 20h)	General Purpose Register
GPR_SHAREDa_SET	4804h + (a × 20h)	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_SHAREDa is 1
GPR_SHAREDa_CLR	4808h + (a × 20h)	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_SHAREDa is 0
GPR_SHAREDa_TOG	480Ch + (a × 20h)	Writing 1 to a bit in this register inverts the value of the corresponding bit in GPR_SHAREDa

15.9.1.14.2 Function

These registers do not have any dedicated functions. They can be set by the user

15.9.1.14.3 Diagram



15.9.1.14.4 Fields

Field	Function
31-0 GPR	GP register This register is shared for all CPU domains.

15.9.1.15 GPR access control (GPR_SHARED0_AUTHEN - GPR_SHARED7_AUTHEN)

15.9.1.15.1 Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

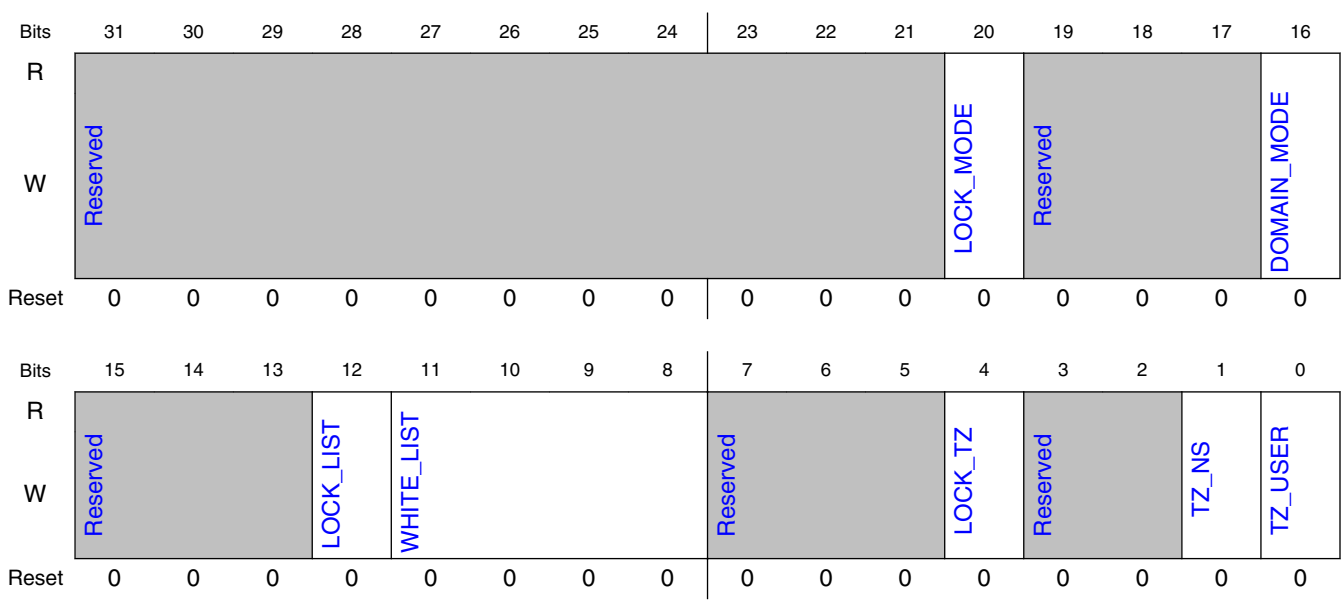
For a = 0 to 7:

Register	Offset	Description
GPR_SHAREDa_AUTHEN	4810h + (a × 20h)	GPR access control
GPR_SHAREDa_AUTHEN_SET	4814h + (a × 20h)	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_SHAREDa_AUTHEN is 1
GPR_SHAREDa_AUTHEN_CLR	4818h + (a × 20h)	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_SHAREDa_AUTHEN is 0
GPR_SHAREDa_AUTHEN_TOG	481Ch + (a × 20h)	Writing 1 to a bit in this register inverts the value of the corresponding bit in GPR_SHAREDa_AUTHEN

15.9.1.15.2 Function

This register manages GPR access control.

15.9.1.15.3 Diagram



15.9.1.15.4 Fields

Field	Function
31-21 —	Reserved
20 LOCK_MODE	Lock low power and access mode This bit lock low power and access control mode. When this bit is set, bits 16-20 cannot be changed. Once this bit is set, it cannot be cleared, until next system reset. 0b - MODE is not locked. 1b - MODE is locked.
19-17 —	Reserved
16 DOMAIN_MODE	Low power and access control by domain Register works in Domain controlled Mode. 0b - Clock does NOT work in Domain Mode. 1b - Clock works in Domain Mode.
15-13 —	Reserved
12 LOCK_LIST	Lock Whitelist This bit lock Whitelist. When this bit is set, GPR_SHAREDx_AUTHEN[WHITE_LIST] cannot be changed. Once this bit is set, it cannot be cleared, until next system reset. 0b - Whitelist is not locked. 1b - Whitelist is locked.
11-8 WHITE_LIST	Whitelist Domains that on the Whitelist can change this register. Each field in this field represent for one domain. Bit8~Bit11 represent for DOMAIN0~DOMAIN3 respectively. 0000b - This domain is NOT allowed to change clock. 0001b - This domain is allowed to change clock.
7-5 —	Reserved
4 LOCK_TZ	Lock TZ_USER and TZ_NS When this bit is set, TZ_USER and TZ_NS cannot be changed. Once this bit is set, it cannot be cleared, until next system reset. 0b - Not locked. 1b - Locked.
3-2 —	Reserved
1 TZ_NS	Non-secure access This register can be changed when CPU is in Non-secure mode. 0b - Cannot be changed in Non-secure mode. 1b - Can be changed in Non-secure mode.
0 TZ_USER	User access This register can be changed when CPU is in user mode (in CMx core). 0b - Clock cannot be changed in user mode. 1b - Clock can be changed in user mode.

15.9.1.16 General Purpose Register (GPR_PRIVATE1 - GPR_PRIVATE7)

15.9.1.16.1 Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

For a = 1 to 7:

Register	Offset	Description
GPR_PRIVATEa	4C00h + (a × 20h)	General Purpose Register
GPR_PRIVATEa_SET	4C04h + (a × 20h)	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_PRIVATEa is 1
GPR_PRIVATEa_CLR	4C08h + (a × 20h)	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_PRIVATEa is 0
GPR_PRIVATEa_TOG	4C0Ch + (a × 20h)	Writing 1 to a bit in this register inverts the value of the corresponding bit in GPR_PRIVATEa

15.9.1.16.2 Function

These registers is general purpose register.

15.9.1.16.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	GPR															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	GPR															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

15.9.1.16.4 Fields

Field	Function
31-0 GPR	GP register General purpose register. This register has dedicate bits for each domain.

Field	Function
	Bit 0: Override CM7 core clk enable 1. CM7 core clk is always enabled 2. CM7 core clk is gated by CM7 SLEEPING

15.9.1.17 GPR access control (GPR_PRIVATE1_AUTHEN - GPR_PRIVATE7_AUTHEN)

15.9.1.17.1 Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

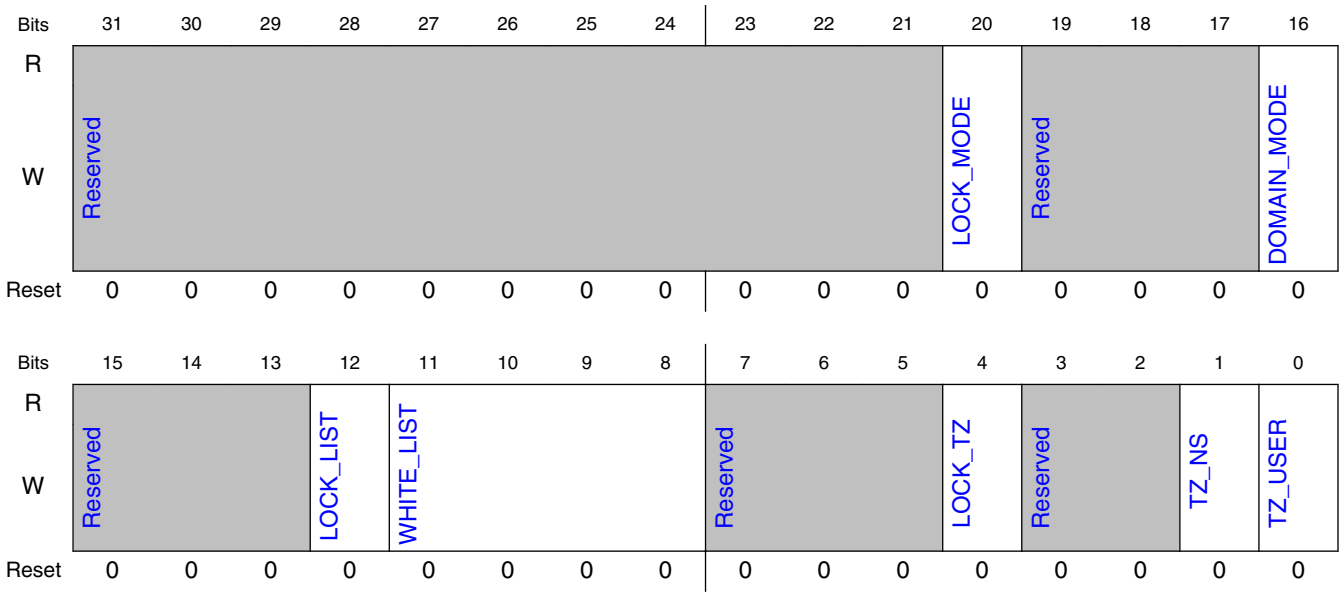
For a = 1 to 7:

Register	Offset	Description
GPR_PRIVATEa_AUTHEN	4C10h + (a × 20h)	GPR access control
GPR_PRIVATEa_AUTHEN_SET	4C14h + (a × 20h)	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_PRIVATEa_AUTHEN is 1
GPR_PRIVATEa_AUTHEN_CLR	4C18h + (a × 20h)	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_PRIVATEa_AUTHEN is 0
GPR_PRIVATEa_AUTHEN_TOG	4C1Ch + (a × 20h)	Writing 1 to a bit in this register inverts the value of the corresponding bit in GPR_PRIVATEa_AUTHEN

15.9.1.17.2 Function

This register that manages clock root access control.

15.9.1.17.3 Diagram



15.9.1.17.4 Fields

Field	Function
31-21 —	Reserved
20 LOCK_MODE	Lock low power and access mode This bit lock low power and access control mode. When this bit is set, bits 16-20 cannot be changed. Once this bit is set, it cannot be cleared, until next system reset. 0b - MODE is not locked. 1b - MODE is locked.
19-17 —	Reserved
16 DOMAIN_MODE	Low power and access control by Domain Register works in Domain controlled Mode. 0b - Clock does NOT work in Domain Mode. 1b - Clock works in Domain Mode.
15-13 —	Reserved
12 LOCK_LIST	Lock Whitelist This bit lock Whitelist. When this bit is set, GPR_PRIVATEx_AUTHEN[WHITE_LIST] cannot be changed. Once this bit is set, it cannot be cleared, until next system reset. 0b - Whitelist is not locked. 1b - Whitelist is locked.
11-8 WHITE_LIST	Whitelist Domains that on the Whitelist can change this register. Each field in this field represent for one domain. Bit8~Bit11 represent for DOMAIN0~DOMAIN3 respectively.

Table continues on the next page...

Field	Function
	0000b - This domain is NOT allowed to change clock. 0001b - This domain is allowed to change clock.
7-5 —	Reserved
4 LOCK_TZ	Lock TZ_USER and TZ_NS When this bit is set, TZ_USER and TZ_NS cannot be changed. Once this bit is set, it cannot be cleared, until next system reset. 0b - Not locked. 1b - Locked.
3-2 —	Reserved
1 TZ_NS	Non-secure access This register can be changed when CPU is in Non-secure mode. 0b - Cannot be changed in Non-secure mode. 1b - Can be changed in Non-secure mode.
0 TZ_USER	User access This register can be changed when CPU is in user mode (in CMx core). 0b - Clock cannot be changed in user mode. 1b - Clock can be changed in user mode.

15.9.1.18 Clock source direct control (OSCPLL0_DIRECT - OSCPLL28_DIRECT)

15.9.1.18.1 Offset

For a = 0 to 28:

Register	Offset
OSCPLLa_DIRECT	5000h + (a × 20h)

15.9.1.18.2 Function

This register controls clock source on and off when clock source works in Unassigned Mode and Domain Mode.

15.9.1.18.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	Reserved															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R W	Reserved															ON
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

15.9.1.18.4 Fields

Field	Function
31-1 —	Reserved
0 ON	turn on clock source This bit controls clock source. 0b - OSCPLL is OFF 1b - OSCPLL is ON

15.9.1.19 Clock source domain control (OSCPLL0_DOMAIN - OSCPLL28_DOMAIN)

15.9.1.19.1 Offset

For a = 0 to 28:

Register	Offset
OSCPLLa_DOMAIN	5004h + (a × 20h)

15.9.1.19.2 Function

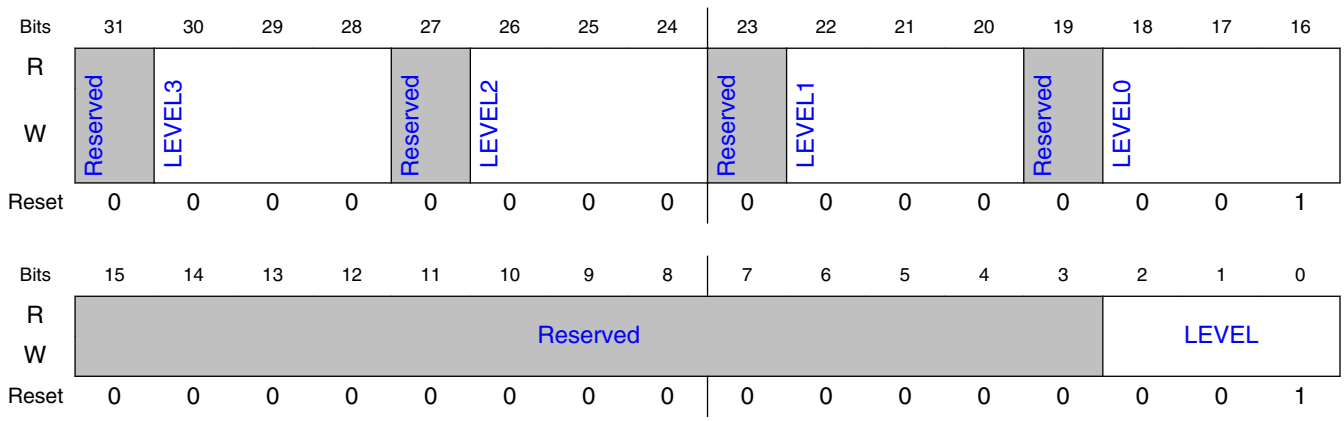
This register controls clock source on and off when Clock source works in CPU Low Power Mode.

During CPULPM mode, write to bit field OSCPLLn_DOMAIN[LEVEL], and during Unassigned mode, write to OSCPLLn_DOMAIN[LEVELx], where x = 0,1,2 or 3. See the table below for more details.

Table 15-8. CCM Mode and access types

CCM Mode/ Access	Unassigned Mode		CPU Low Power Mode		Other Modes	
	Read	Write	Read	Write	Read	Write
LEVEL	Y	N	Y	Y	Y	N
LEVEL0	Y	Y	Y	N	Y	N
LEVEL1	Y	Y	Y	N	Y	N
LEVEL2	Y	Y	Y	N	Y	N
LEVEL3	Y	Y	Y	N	Y	N

15.9.1.19.3 Diagram



15.9.1.19.4 Fields

Field	Function
31 —	Reserved
30-28 LEVEL3	Depend level Depend level of this clock source for DOMAIN3. 000b - This clock source is not needed in any mode, and can be turned off 001b - This clock source is needed in RUN mode, but not needed in WAIT, STOP mode 010b - This clock source is needed in RUN and WAIT mode, but not needed in STOP mode 011b - This clock source is needed in RUN, WAIT and STOP mode 100b - This clock source is always on in any mode (including SUSPEND) 101b,110b,111b - Reserved
27 —	Reserved

Table continues on the next page...

Field	Function
26-24 LEVEL2	Depend level Depend level of this clock source for DOMAIN2. 000b - This clock source is not needed in any mode, and can be turned off 001b - This clock source is needed in RUN mode, but not needed in WAIT, STOP mode 010b - This clock source is needed in RUN and WAIT mode, but not needed in STOP mode 011b - This clock source is needed in RUN, WAIT and STOP mode 100b - This clock source is always on in any mode (including SUSPEND) 101b,110b,111b - Reserved
23 —	Reserved
22-20 LEVEL1	Depend level Depend level of this clock source for DOMAIN1. 000b - This clock source is not needed in any mode, and can be turned off 001b - This clock source is needed in RUN mode, but not needed in WAIT, STOP mode 010b - This clock source is needed in RUN and WAIT mode, but not needed in STOP mode 011b - This clock source is needed in RUN, WAIT and STOP mode 100b - This clock source is always on in any mode (including SUSPEND) 101b,110b,111b - Reserved
19 —	Reserved
18-16 LEVEL0	Dependence level Dependence level of this clock source for DOMAIN0 000b - This clock source is not needed in any mode, and can be turned off 001b - This clock source is needed in RUN mode, but not needed in WAIT, STOP mode 010b - This clock source is needed in RUN and WAIT mode, but not needed in STOP mode 011b - This clock source is needed in RUN, WAIT and STOP mode 100b - This clock source is always on in any mode (including SUSPEND) 101b,110b,111b - Reserved
15-3 —	Reserved
2-0 LEVEL	Current dependence level Dependence level of this clock source for the current accessing domain 000b - This clock source is not needed in any mode, and can be turned off 001b - This clock source is needed in RUN mode, but not needed in WAIT, STOP mode 010b - This clock source is needed in RUN and WAIT mode, but not needed in STOP mode 011b - This clock source is needed in RUN, WAIT and STOP mode 100b - This clock source is always on in any mode (including SUSPEND) 101b,110b,111b - Reserved

15.9.1.20 Clock source Setpoint setting (OSCPLL0_SETPOINT - OSCPLL28_SETPOINT)

15.9.1.20.1 Offset

For a = 0 to 28:

Register	Offset
OSCPLLa_SETPOINT	5008h + (a × 20h)

15.9.1.20.2 Function

This register defines 16 Setpoint values when clock source works in Setpoint Mode.

15.9.1.20.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	STANDBY															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	SETPOINT															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

15.9.1.20.4 Fields

Field	Function
31-16 STANDBY	Standby This field defines 16 Setpoint standby values. Bit0~Bit15 hold value for Setpoint 0~16 standby respectively. A bitfield value of 0 implies the OSC or PLL will be shutdown during standby. A bitfield value of 1 represent OSC or PLL will keep Setpoint setting during standby.
15-0 SETPOINT	Setpoint This field defines 16 Setpoint values. Bit0~Bit15 hold value for Setpoint 0~16 respectively. A bitfield value of 0 implies OSC or PLL will be shutdown in this Setpoint. A bitfield value of 1 implies OSC or PLL will be turn on in this Setpoint.

15.9.1.21 Clock source working status (OSCPLL0_STATUS0 - OSCPLL28_STATUS0)

15.9.1.21.1 Offset

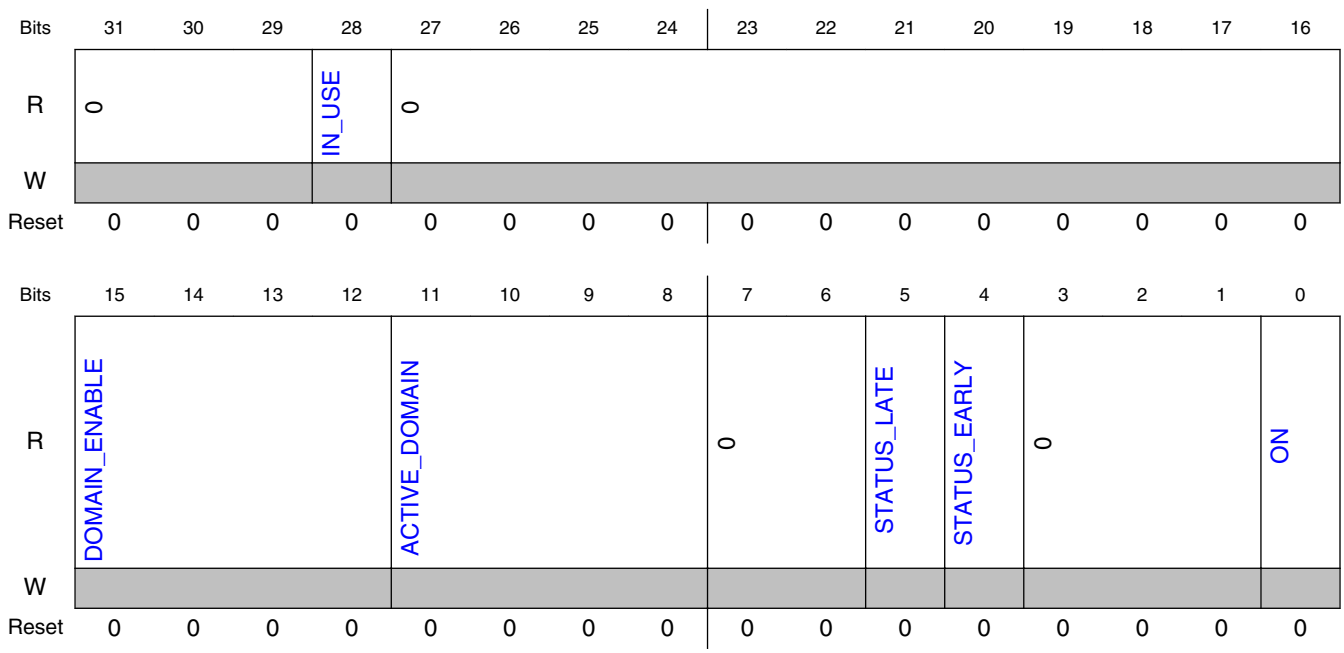
For a = 0 to 28:

Register	Offset
OSCPLLa_STATUS0	5010h + (a × 20h)

15.9.1.21.2 Function

This register shows current clock source running status.

15.9.1.21.3 Diagram



15.9.1.21.4 Fields

Field	Function
31-29 —	Reserved
28 IN_USE	In use This status bit indicates whether the clock source is being used by active clock roots 0b - Clock source is not being used by clock roots 1b - Clock source is being used by clock roots
27-16 —	Reserved
15-12 DOMAIN_ENABLE	Enable status from each domain Enable status from domains, each bit represent one domain. 0000b - No domain request 0001b - Request from Domain0

Table continues on the next page...

Field	Function
	0010b - Request from Domain1 0011b - Request from Domain0 and Domain1 0100b - Request from Domain2 0101b - Request from Domain0 and Domain2 0110b - Request from Domain1 and Domain2 0111b - Request from Domain0, Domain1 and Domain 2 1000b - Request from Domain3 1001b - Request from Domain0 and Domain3 1010b - Request from Domain1 and Domain3 1011b - Request from Domain2 and Domain3 1100b - Request from Domain0, Domain 1, and Domain3 1101b - Request from Domain0, Domain 2, and Domain3 1110b - Request from Domain1, Domain 2, and Domain3 1111b - Request from all domains
11-8 ACTIVE_DOMAIN	Domains that own this clock source Domains that own this clock source according to Whitelist. 0000b - Clock not owned by any domain 0001b - Clock owned by Domain0 0010b - Clock owned by Domain1 0011b - Clock owned by Domain0 and Domain1 0100b - Clock owned by Domain2 0101b - Clock owned by Domain0 and Domain2 0110b - Clock owned by Domain1 and Domain2 0111b - Clock owned by Domain0, Domain1 and Domain 2 1000b - Clock owned by Domain3 1001b - Clock owned by Domain0 and Domain3 1010b - Clock owned by Domain1 and Domain3 1011b - Clock owned by Domain2 and Domain3 1100b - Clock owned by Domain0, Domain 1, and Domain3 1101b - Clock owned by Domain0, Domain 2, and Domain3 1110b - Clock owned by Domain1, Domain 2, and Domain3 1111b - Clock owned by all domains
7-6 —	Reserved
5 STATUS_LATE	Clock source ready This status bit indicating clock source is ready to use. 0b - Clock source is not ready to use 1b - Clock source is ready to use
4 STATUS_EARLY	Clock source active This status bit indicating clock source is active. 0b - Clock source is not active 1b - Clock source is active
3-1 —	Reserved
0 ON	Clock source current state Clock source running status 0b - Clock source is OFF 1b - Clock source is ON

15.9.1.22 Clock source low power status (OSCPLL0_STATUS1 - OSCPLL28_STATUS1)

15.9.1.22.1 Offset

For a = 0 to 28:

Register	Offset
OSCPLLa_STATUS1	5014h + (a × 20h)

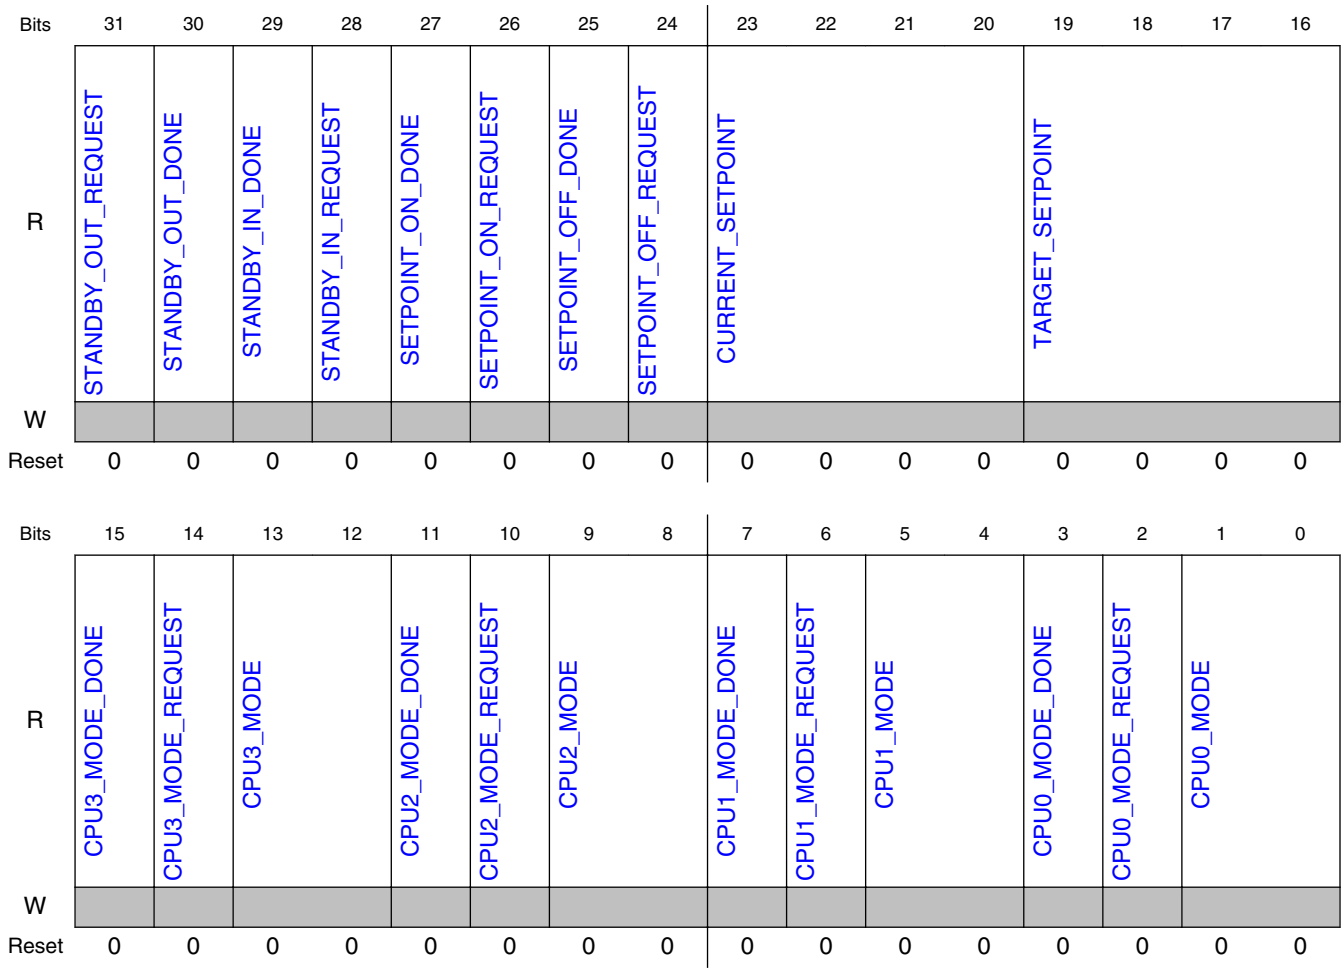
15.9.1.22.2 Function

This register shows low power status of clock source.

NOTE

The CPU0-3 references are to the CPU domain assignment, not the number of supported CPU platforms. Each CPU platform can be assigned to any domain, including the same domain.

15.9.1.22.3 Diagram



15.9.1.22.4 Fields

Field	Function
31 STANDBY_OUT_REQUEST	Clock gate turn on request from GPC standby Status bit indication clock gate is requested to turned on from GPC. 0b - No request 1b - Clock gate requested to be turned on
30 STANDBY_OUT_DONE	Clock gate turn on finish from GPC standby Status bit indication clock gate is requested to turned on from GPC. 0b - Request to turn on Clock gate is not complete 1b - Request to turn on Clock gate is complete
29 STANDBY_IN_DONE	Clock source turn off finish from GPC standby Status bit indication clock source is turned off according to GPC request. 0b - Clock source is not turned off 1b - Clock source is turned off
28	Clock gate turn off request from GPC standby

Table continues on the next page...

Field	Function
STANDBY_IN_REQUEST	Status bit indication clock gate is requested to turned off from GPC. 0b - No request 1b - Clock gate requested to be turned off
27 SETPOINT_ON_DONE	Clock gate turn on finish from GPC Setpoint Status bit indication clock gate is requested to turned on from GPC. 0b - No request 1b - Request to turn on clock gate
26 SETPOINT_ON_REQUEST	Clock gate turn on request from GPC Setpoint Status bit indication clock gate is requested to turned on from GPC. 0b - No request 1b - Clock gate requested to be turned on
25 SETPOINT_OFF_DONE	Clock source turn off finish from GPC Setpoint Status bit indication clock source is turned off according to GPC request. 0b - Clock source is not turned off 1b - Clock source is turned off
24 SETPOINT_OFF_REQUEST	Clock gate turn off request from GPC Setpoint Status bit indication clock gate is requested to turned off from GPC. 0b - No request 1b - Clock gate requested to be turned off
23-20 CURRENT_SETPOINT	Current Setpoint This is the Setpoint value the Soc is current working in
19-16 TARGET_SETPOINT	Next Setpoint to change to This is the Setpoint value the SoC will switch to
15 CPU3_MODE_DONE	Domain3 Low Power Mode task done Domain3 response signal status to GPC to indicate clock was gated-off if needed to enter Low Power Mode 0b - Clock is not gated 1b - Clock is gated-off
14 CPU3_MODE_REQUEST	Domain3 request enter Low Power Mode Domain3 request signal status to enter Low Power Mode 0b - No request 1b - Request from domain to enter Low Power Mode
13-12 CPU3_MODE	Domain3 Low Power Mode Domain3 will enter in Low Power Mode. 00b - Run 01b - Wait 10b - Stop 11b - Suspend
11 CPU2_MODE_DONE	Domain2 Low Power Mode task done Domain2 response signal status to GPC to indicate clock was gate-off if needed to enter Low Power Mode 0b - Clock is not gated 1b - Clock is gated-off
10	Domain2 request enter Low Power Mode Domain2 request signal status to enter Low Power Mode

Table continues on the next page...

Field	Function
CPU2_MODE_REQUEST	0b - No request 1b - Request from domain to enter Low Power Mode
9-8 CPU2_MODE	Domain2 Low Power Mode Domain2 will enter in Low Power Mode. 00b - Run 01b - Wait 10b - Stop 11b - Suspend
7 CPU1_MODE_DONE	Domain1 Low Power Mode task done Domain1 response signal status to GPC to indicate clock was gated-off if needed to enter Low Power Mode 0b - Clock is not gated 1b - Clock is gated-off
6 CPU1_MODE_REQUEST	Domain1 request enter Low Power Mode Domain1 request signal status to enter Low Power Mode 0b - No request 1b - Request from domain to enter Low Power Mode
5-4 CPU1_MODE	Domain1 Low Power Mode Domain1 will enter in Low Power Mode 00b - Run 01b - Wait 10b - Stop 11b - Suspend
3 CPU0_MODE_DONE	Domain0 Low Power Mode task done Domain0 response signal status to GPC to indicate clock was gate-off if needed to enter Low Power Mode 0b - Clock is not gated 1b - Clock is gated-off
2 CPU0_MODE_REQUEST	Domain0 request enter Low Power Mode Domain0 request signal status to enter Low Power Mode 0b - No request 1b - Request from domain to enter Low Power Mode
1-0 CPU0_MODE	Domain0 Low Power Mode Domain0 will enter in Low Power Mode 00b - Run 01b - Wait 10b - Stop 11b - Suspend

15.9.1.23 Clock source configuration (OSCPLL0_CONFIG - OSCPLL28_CONFIG)

15.9.1.23.1 Offset

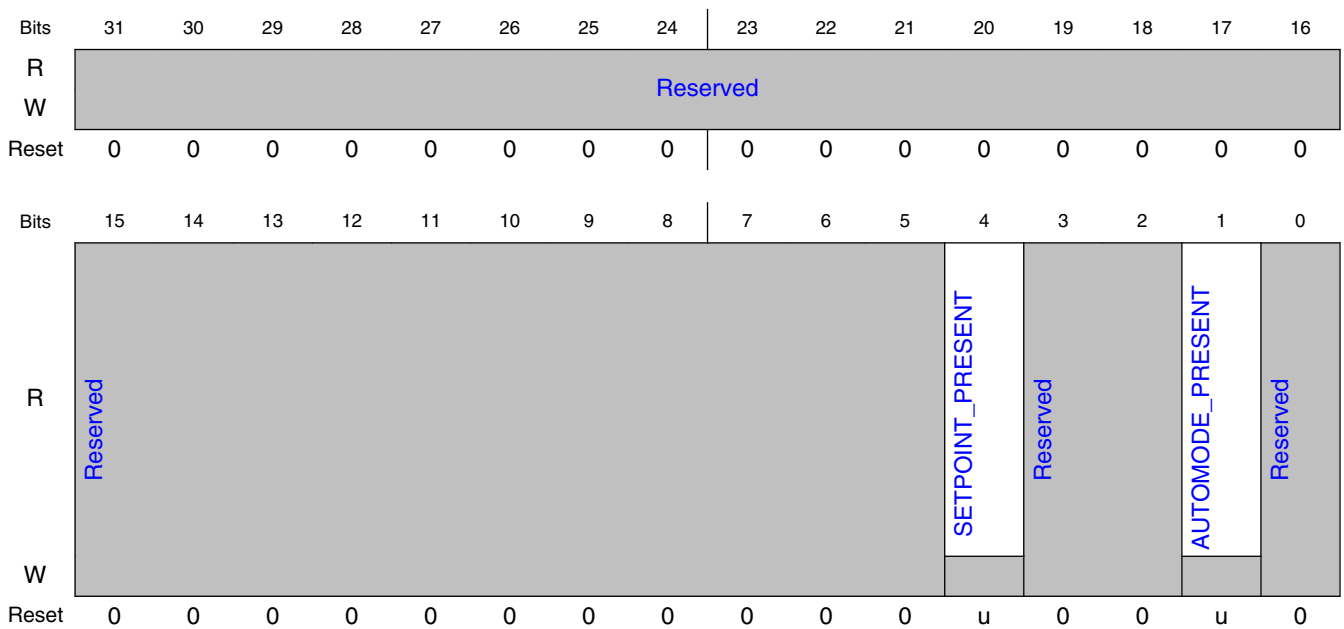
For a = 0 to 28:

Register	Offset
OSCPLLa_CONFIG	5018h + (a × 20h)

15.9.1.23.2 Function

This register shows integration parameters.

15.9.1.23.3 Diagram



15.9.1.23.4 Fields

Field	Function
31-5 —	Reserved
4 SETPOINT_PRESENT	Setpoint present This bit indicate whether this clock source implement Setpoint control scheme. 0b - Setpoint is not implemented. 1b - Setpoint is implemented.
3-2 —	Reserved
1 AUTOMODE_PRESENT	Automode Present 0b - Not present 1b - Present
0	Reserved

Field	Function
—	

15.9.1.24 Clock source access control (OSCPLL0_AUTHEN - OSCPLL28_AUTHEN)

15.9.1.24.1 Offset

For a = 0 to 28:

Register	Offset
OSCPLLa_AUTHEN	501Ch + (a × 20h)

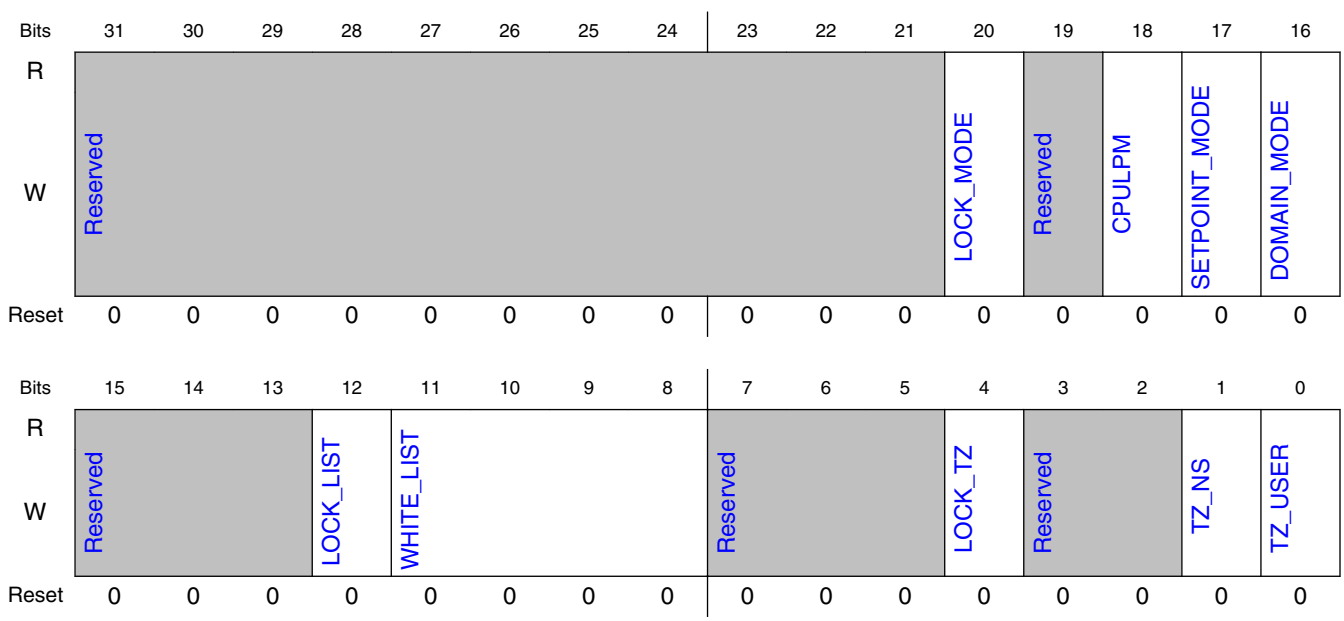
15.9.1.24.2 Function

This register that manages clock source access control.

NOTE

SETPOINT_MODE, DOMAIN_MODE, and CPULPM cannot be set to '1' at the same time.

15.9.1.24.3 Diagram



15.9.1.24.4 Fields

Field	Function
31-21 —	Reserved
20 LOCK_MODE	Lock low power and access mode This bit lock low power and access control mode. When this bit is set, bits 16-20 cannot be changed. Once this bit is set, it cannot be cleared, until next system reset. 0b - MODE is not locked. 1b - MODE is locked.
19 —	Reserved
18 CPULPM	CPU Low Power Mode PLL works in CPU Low Power Mode 0b - PLL does not function in Low power Mode 1b - PLL functions in Low Power Mode
17 SETPOINT_MODE	LPCG works in Setpoint controlled Mode. Clock source works in Setpoint controlled Mode.
16 DOMAIN_MODE	Low power and access control by domain Clock source works in Domain controlled Mode. 0b - Clock does not work in Domain Mode. 1b - Clock works in Domain Mode.
15-13 —	Reserved
12 LOCK_LIST	Lock Whitelist This bit lock Whitelist. When this bit is set, OSCPLLx_AUTHEN[WHITE_LIST] cannot be changed. Once this bit is set, it cannot be cleared, until next system reset. 0b - Whitelist is not locked. 1b - Whitelist is locked.
11-8 WHITE_LIST	Whitelist Domains that on the Whitelist can change this clock source. Each field in this field represent for one domain. Bit8~Bit11 represent for DOMAIN0~DOMAIN3 respectively.
7-5 —	Reserved
4 LOCK_TZ	Lock TZ_USER and TZ_NS When this bit is set, TZ_USER and TZ_NS cannot be changed. Once this bit is set, it cannot be cleared, until next system reset. 0b - Not locked. 1b - Locked.
3-2 —	Reserved
1 TZ_NS	Non-secure access This clock source can be changed when CPU is in Non-secure mode. 0b - Cannot be changed in Non-secure mode.

Table continues on the next page...

Field	Function
	1b - Can be changed in Non-secure mode.
0 TZ_USER	User access This clock source can be changed when CPU is in user mode (in CMx core). 0b - Clock cannot be changed in user mode. 1b - Clock can be changed in user mode.

15.9.1.25 LPCG direct control (LPCG0_DIRECT - LPCG137_DIRECT)

15.9.1.25.1 Offset

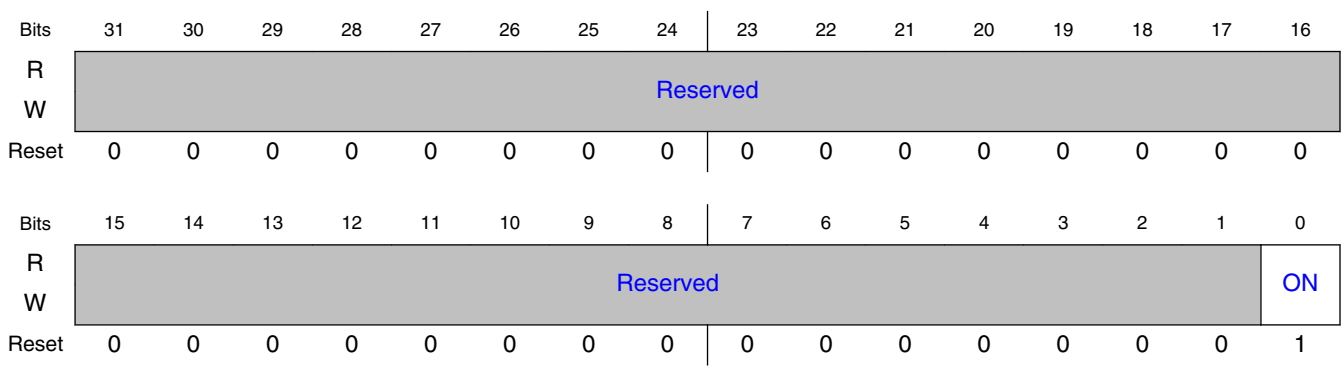
For a = 0 to 137:

Register	Offset
LPCGa_DIRECT	6000h + (a × 20h)

15.9.1.25.2 Function

This register controls LPCG on and off when LPCG works in Unassigned Mode and Domain Mode.

15.9.1.25.3 Diagram



15.9.1.25.4 Fields

Field	Function
31-1 —	Reserved

Table continues on the next page...

Field	Function
0 ON	LPCG on This bit controls LPCG. 0b - LPCG is OFF. 1b - LPCG is ON.

15.9.1.26 LPCG domain control (LPCG0_DOMAIN - LPCG137_DOMAIN)

15.9.1.26.1 Offset

For a = 0 to 137:

Register	Offset
LPCGa_DOMAIN	6004h + (a × 20h)

15.9.1.26.2 Function

This register controls LPCG on and off when LPCG works in CPU Low Power Mode.

During CPULPM mode, write to bit field LPCGn_DOMAIN[LEVEL], and during Unassigned mode, write to LPCGn_DOMAIN[LEVELx], where x = 0,1,2 or 3. See the table below for more details.

Table 15-9. CCM Mode and access types

CCM Mode/ Access	Unassigned Mode		CPU Low Power Mode		Other Modes	
	Read	Write	Read	Write	Read	Write
LEVEL	Y	N	Y	Y	Y	N
LEVEL0	Y	Y	Y	N	Y	N
LEVEL1	Y	Y	Y	N	Y	N
LEVEL2	Y	Y	Y	N	Y	N
LEVEL3	Y	Y	Y	N	Y	N

18-16 LEVEL0	Depend level Depend level of this LPCG for DOMAIN0. 000b - This clock source is not needed in any mode, and can be turned off 001b - This clock source is needed in RUN mode, but not needed in WAIT, STOP mode 010b - This clock source is needed in RUN and WAIT mode, but not needed in STOP mode 011b - This clock source is needed in RUN, WAIT and STOP mode 100b - This clock source is always on in any mode (including SUSPEND) 101b,110b,111b - Reserved
15-3 —	Reserved
2-0 LEVEL	Current dependence level Dependence level of this clock source for the current accessing domain 000b - This clock source is not needed in any mode, and can be turned off 001b - This clock source is needed in RUN mode, but not needed in WAIT, STOP mode 010b - This clock source is needed in RUN and WAIT mode, but not needed in STOP mode 011b - This clock source is needed in RUN, WAIT and STOP mode 100b - This clock source is always on in any mode (including SUSPEND) 101b,110b,111b - Reserved

15.9.1.27 LPCG working status (LPCG0_STATUS0 - LPCG137_STATUS0)

15.9.1.27.1 Offset

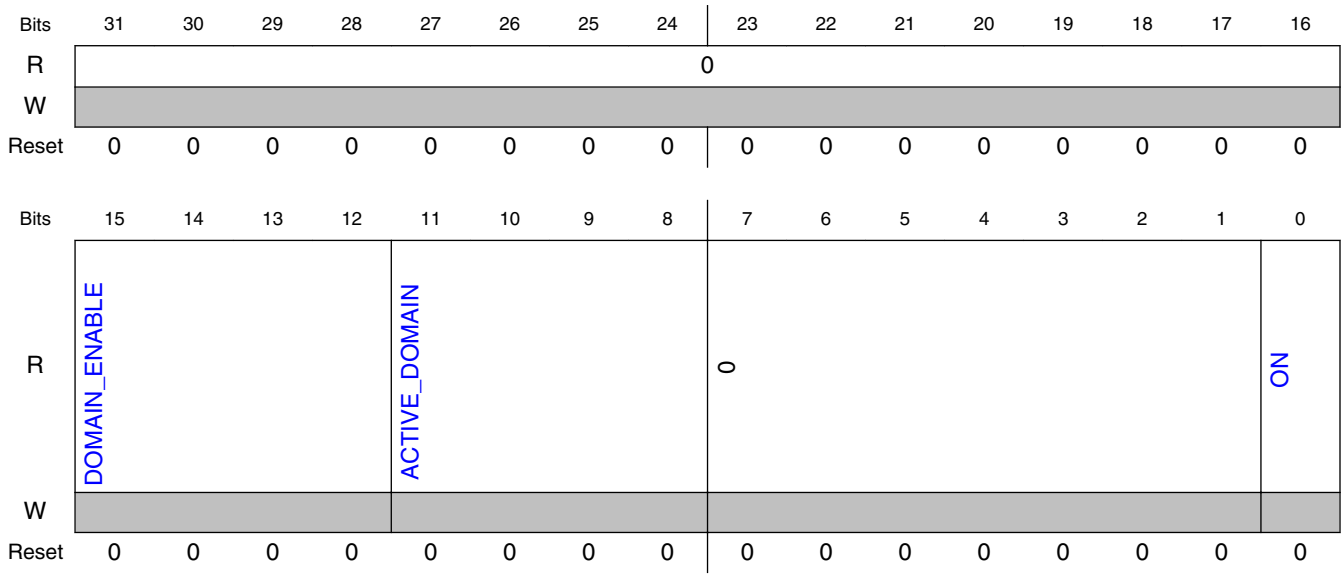
For a = 0 to 137:

Register	Offset
LPCGa_STATUS0	6010h + (a × 20h)

15.9.1.27.2 Function

This register shows current LPCG running status.

15.9.1.27.3 Diagram



15.9.1.27.4 Fields

Field	Function
31-16 —	Reserved
15-12 DOMAIN_ENABLE	Enable status from each domain Enable status from domains, each bit represent one domain. 0000b - No domain request 0001b - Request from Domain0 0010b - Request from Domain1 0011b - Request from Domain0 and Domain1 0100b - Request from Domain2 0101b - Request from Domain0 and Domain2 0110b - Request from Domain1 and Domain2 0111b - Request from Domain0, Domain1 and Domain 2 1000b - Request from Domain3 1001b - Request from Domain0 and Domain3 1010b - Request from Domain1 and Domain3 1011b - Request from Domain2 and Domain3 1100b - Request from Domain0, Domain 1, and Domain3 1101b - Request from Domain0, Domain 2, and Domain3 1110b - Request from Domain1, Domain 2, and Domain3 1111b - Request from all domains
11-8 ACTIVE_DOMAIN	Domains that own this clock gate Domains that own this clock gate according to Whitelist. 0000b - Clock not owned by any domain 0001b - Clock owned by Domain0 0010b - Clock owned by Domain1 0011b - Clock owned by Domain0 and Domain1 0100b - Clock owned by Domain2

Table continues on the next page...

Field	Function
	0101b - Clock owned by Domain0 and Domain2 0110b - Clock owned by Domain1 and Domain2 0111b - Clock owned by Domain0, Domain1 and Domain 2 1000b - Clock owned by Domain3 1001b - Clock owned by Domain0 and Domain3 1010b - Clock owned by Domain1 and Domain3 1011b - Clock owned by Domain2 and Domain3 1100b - Clock owned by Domain0, Domain 1, and Domain3 1101b - Clock owned by Domain0, Domain 2, and Domain3 1110b - Clock owned by Domain1, Domain 2, and Domain3 1111b - Clock owned by all domains
7-1 —	Reserved
0 ON	LPCG current state LPCG running status. 0b - LPCG is OFF. 1b - LPCG is ON.

15.9.1.28 LPCG low power status (LPCG0_STATUS1 - LPCG137_STATUS1)

15.9.1.28.1 Offset

For a = 0 to 137:

Register	Offset
LPCGa_STATUS1	6014h + (a × 20h)

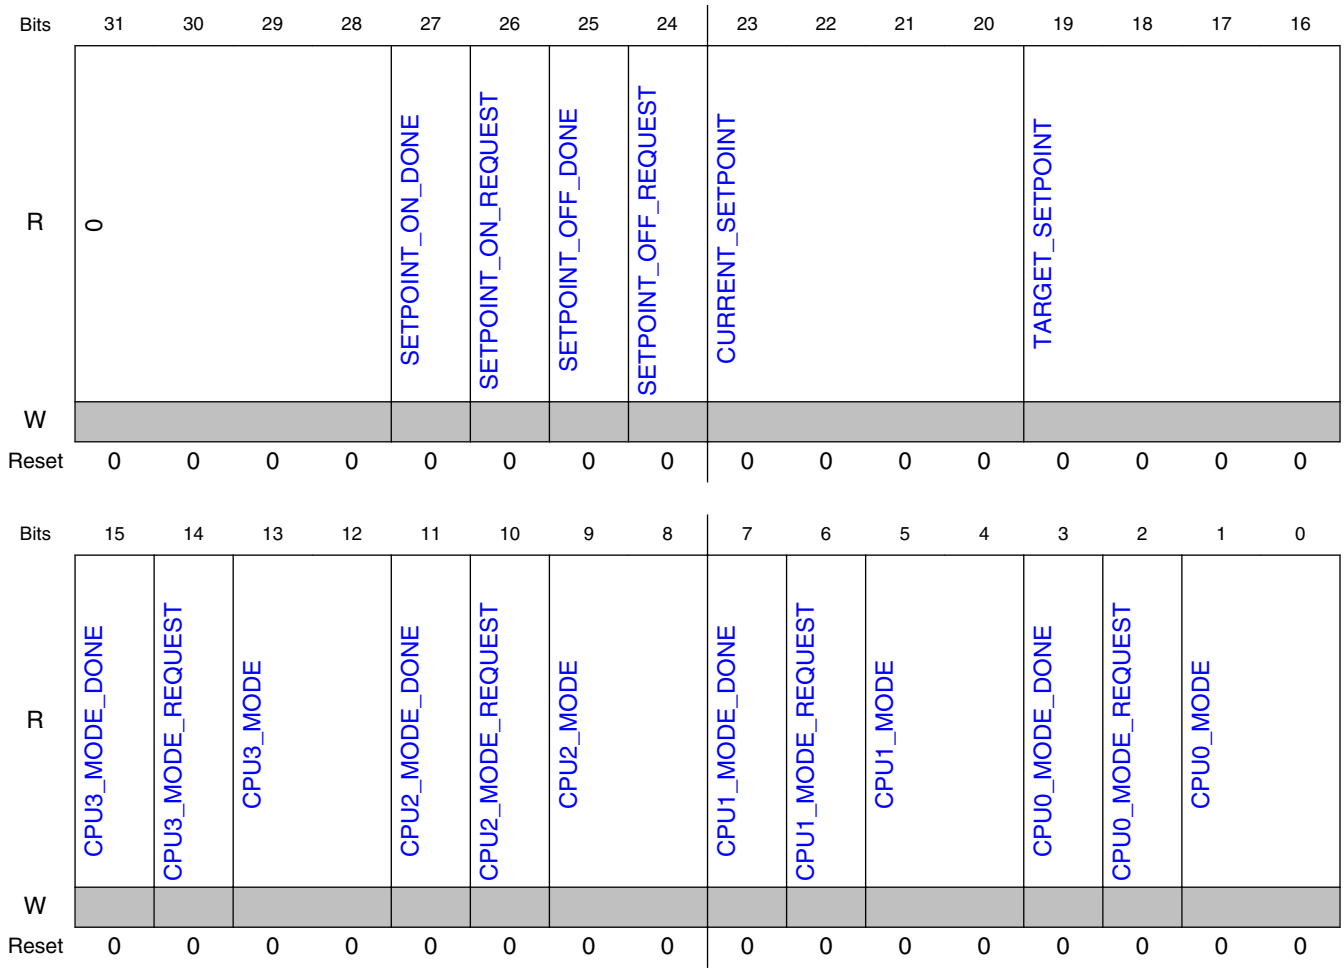
15.9.1.28.2 Function

This register shows low power status of LPCG.

NOTE

The CPU0-3 references are to the CPU domain assignment, not the number of supported CPU platforms. Each CPU platform can be assigned to any domain, including the same domain.

15.9.1.28.3 Diagram



15.9.1.28.4 Fields

Field	Function
31-28 —	Reserved
27 SETPOINT_ON_DONE	Clock gate turn on finish from GPC Setpoint Status bit indication clock gate is turned on according to GPC request. 0b - Clock gate is not turned on 1b - Clock gate is turned on
26 SETPOINT_ON_REQUEST	Clock gate turn on request from GPC Setpoint Status bit indication clock gate is requested to turned on from GPC. 0b - No request 1b - Clock gate requested to be turned on
25 SETPOINT_OFF_DONE	Clock gate turn off finish from GPC Setpoint Status bit indication clock gate is turned off according to GPC request. 0b - Clock gate is not turned off

Table continues on the next page...

Field	Function
	1b - Clock gate is turned off
24 SETPOINT_OFF_REQUEST	Clock gate turn off request from GPC Setpoint Status bit indication clock gate is requested to turned off from GPC. 0b - No request 1b - Clock gate requested to be turned off
23-20 CURRENT_SETPOINT	Current Setpoint This is the Setpoint value the Soc is current working in
19-16 TARGET_SETPOINT	Next Setpoint to change to This is the Setpoint value the SoC will switch to
15 CPU3_MODE_DONE	Domain3 Low Power Mode task done Domain3 response signal status to GPC to indicate clock was gate-off if needed to enter Low Power Mode 0b - Clock is not gated 1b - Clock is gated-off
14 CPU3_MODE_REQUEST	Domain3 request enter Low Power Mode Domain3 request signal status to enter Low Power Mode 0b - No request 1b - Request from domain to enter Low Power Mode
13-12 CPU3_MODE	Domain3 Low Power Mode Domain3 will enter in Low Power Mode. 00b - Run 01b - Wait 10b - Stop 11b - Suspend
11 CPU2_MODE_DONE	Domain2 Low Power Mode task done Domain2 response signal status to GPC to indicate clock was gate-off if needed to enter Low Power Mode 0b - Clock is not gated 1b - Clock is gated-off
10 CPU2_MODE_REQUEST	Domain2 request enter Low Power Mode Domain2 request signal status to enter Low Power Mode 0b - No request 1b - Request from domain to enter Low Power Mode
9-8 CPU2_MODE	Domain2 Low Power Mode Domain2 will enter in Low Power Mode 00b - Run 01b - Wait 10b - Stop 11b - Suspend
7 CPU1_MODE_DONE	Domain1 Low Power Mode task done Domain1 response signal status to GPC to indicate clock was gate-off if needed to enter Low Power Mode 0b - Clock is not gated 1b - Clock is gated-off
6	Domain1 request enter Low Power Mode

Table continues on the next page...

Field	Function
CPU1_MODE_REQUEST	Domain1 request signal status to enter Low Power Mode 0b - No request 1b - Request from domain to enter Low Power Mode
5-4 CPU1_MODE	Domain1 Low Power Mode Domain1 will enter in Low Power Mode 00b - Run 01b - Wait 10b - Stop 11b - Suspend
3 CPU0_MODE_DONE	Domain0 Low Power Mode task done Domain0 response signal status to GPC to indicate clock was gate-off to enter Low Power Mode 0b - Clock is not gated 1b - Clock is gated-off
2 CPU0_MODE_REQUEST	Domain0 request enter Low Power Mode Domain0 request signal status to enter Low Power Mode 0b - No request 1b - Request from domain to enter Low Power Mode
1-0 CPU0_MODE	Domain0 Low Power Mode Domain0 will enter in Low Power Mode 00b - Run 01b - Wait 10b - Stop 11b - Suspend

15.9.1.29 LPCG configuration (LPCG0_CONFIG - LPCG137_CONFIG)

15.9.1.29.1 Offset

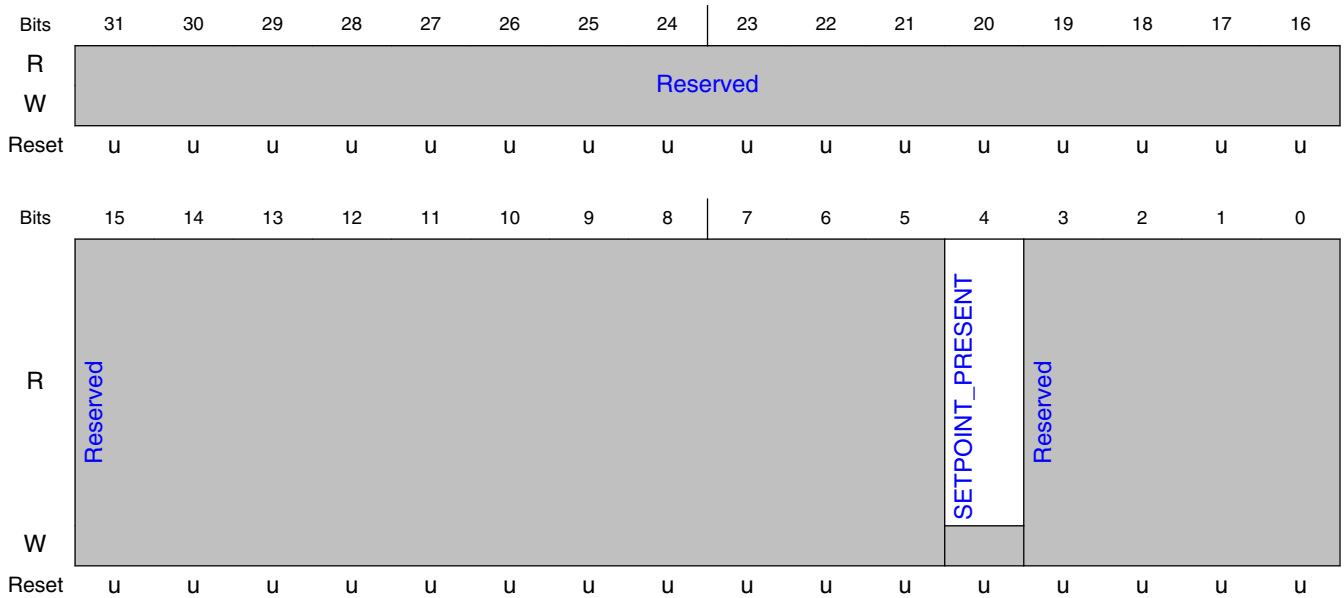
For a = 0 to 137:

Register	Offset
LPCGa_CONFIG	6018h + (a × 20h)

15.9.1.29.2 Function

This register shows integration parameters.

15.9.1.29.3 Diagram



15.9.1.29.4 Fields

Field	Function
31-5 —	Reserved
4 SETPOINT_PRESENT	Setpoint present This bit indicate whether this clock root implement Setpoint control scheme. 0b - Setpoint is not implemented. 1b - Setpoint is implemented.
3-0 —	Reserved

15.9.1.30 LPCG access control (LPCG0_AUTHEN - LPCG137_AUTHEN)

15.9.1.30.1 Offset

For a = 0 to 137:

Register	Offset
LPCGa_AUTHEN	601Ch + (a × 20h)

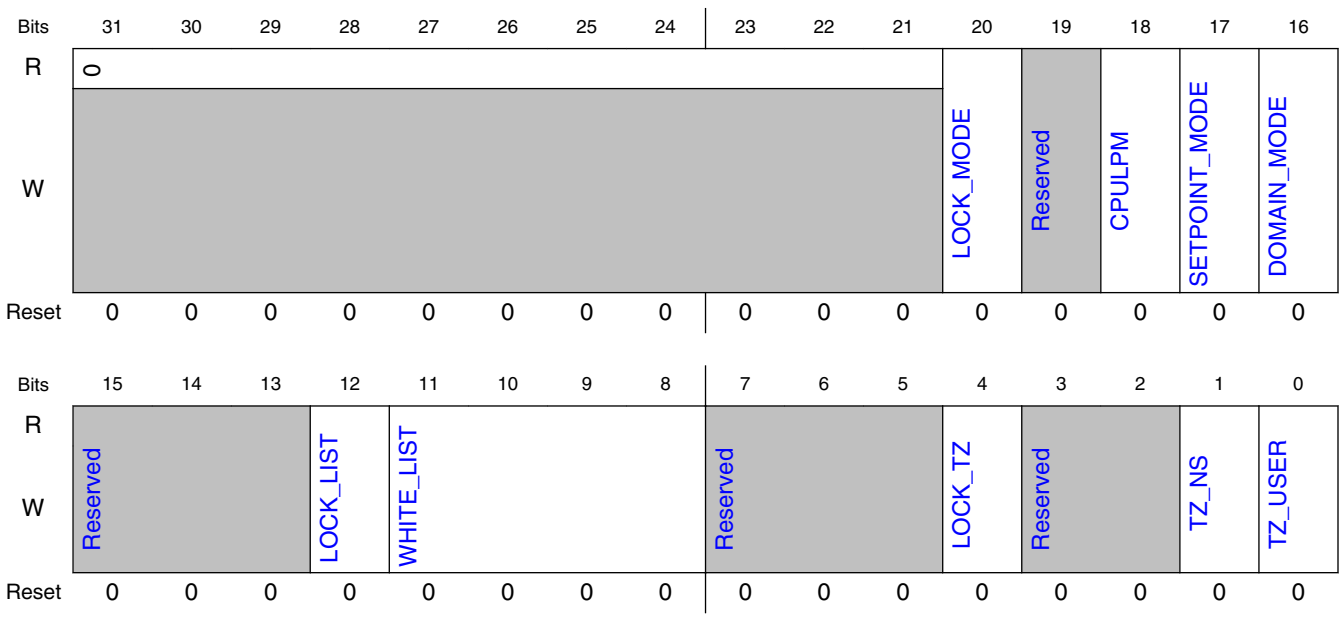
15.9.1.30.2 Function

This register that manages LPCG access control.

NOTE

SETPOINT_MODE, DOMAIN_MODE, and CPULPM cannot be set to '1' at the same time.

15.9.1.30.3 Diagram



15.9.1.30.4 Fields

Field	Function
31-21 —	Reserved
20 LOCK_MODE	Lock low power and access mode This bit lock low power and access control mode. When this bit is set, bits 16-20 cannot be changed. Once this bit is set, it cannot be cleared, until next system reset. 0b - MODE is not locked. 1b - MODE is locked.
19 —	Reserved
18 CPULPM	CPU Low Power Mode LPCG works in CPU Low Power Mode 0b - LPCG is not functioning in Low power Mode 1b - LPCG is functioning in Low Power Mode

Table continues on the next page...

Field	Function
17 SETPOINT_MODE	Low power and access control by Setpoint 0b - LPCG is not functioning in Setpoint controlled Mode 1b - LPCG is functioning in Setpoint controlled Mode
16 DOMAIN_MODE	Low power and access control by domain LPCG works in Domain controlled Mode. 0b - Clock does not work in Domain Mode 1b - Clock works in Domain Mode
15-13 —	Reserved
12 LOCK_LIST	Lock Whitelist This bit lock Whitelist. When this bit is set, LPCGx_AUTHEN[WHITE_LIST] cannot be changed. Once this bit is set, it cannot be cleared, until next system reset. 0b - Whitelist is not locked. 1b - Whitelist is locked.
11-8 WHITE_LIST	Whitelist Domains that on the Whitelist can change this clock root. Each field in this field represent for one domain. Bit8~Bit11 represent for DOMAIN0~DOMAIN3 respectively.
7-5 —	Reserved
4 LOCK_TZ	Lock TZ_USER AND TZ_NS When this bit is set, TZ_USER and TZ_NS cannot be changed. Once this bit is set, it cannot be cleared, until next system reset. 0b - Not locked. 1b - Locked.
3-2 —	Reserved
1 TZ_NS	Non-secure access This LPCG can be changed when CPU is in Non-secure mode. 0b - Cannot be changed in Non-secure mode. 1b - Can be changed in Non-secure mode.
0 TZ_USER	User access This LPCG can be changed when CPU is in user mode (in CMx core). 0b - LPCG cannot be changed in user mode. 1b - LPCG can be changed in user mode.

15.9.1.31 LPCG Setpoint setting (LPCG2_SETPOINT - LPCG48_SETPOINT)

15.9.1.31.1 Offset

Register	Offset
LPCG2_SETPOINT	6048h
LPCG3_SETPOINT	6068h
LPCG4_SETPOINT	6088h
LPCG5_SETPOINT	60A8h
LPCG6_SETPOINT	60C8h
LPCG7_SETPOINT	60E8h

15.9.2.2 Observe control (OBSERVE0_CONTROL - OBSERVE5_CONTROL)

Register that control observe.

15.9.2.2.1 Offset

For a = 0 to 5:

Register	Offset	Description
OBSERVEa_CONTROL	0h + (a × 80h)	Observe control
OBSERVEa_CONTROL_SET	4h + (a × 80h)	Writing a 1 to a bit in this register sets the corresponding bit in OBSERVEa_CONTROL
OBSERVEa_CONTROL_CLR	8h + (a × 80h)	Writing a 1 to a bit in this register clears the corresponding bit in OBSERVEa_CONTROL
OBSERVEa_CONTROL_TOG	Ch + (a × 80h)	Writing a 1 to a bit in this register toggles the corresponding bit in OBSERVEa_CONTROL

15.9.2.4 Observe access control (OBSERVE0_AUTHEN - OBSERVE5_AUTHEN)

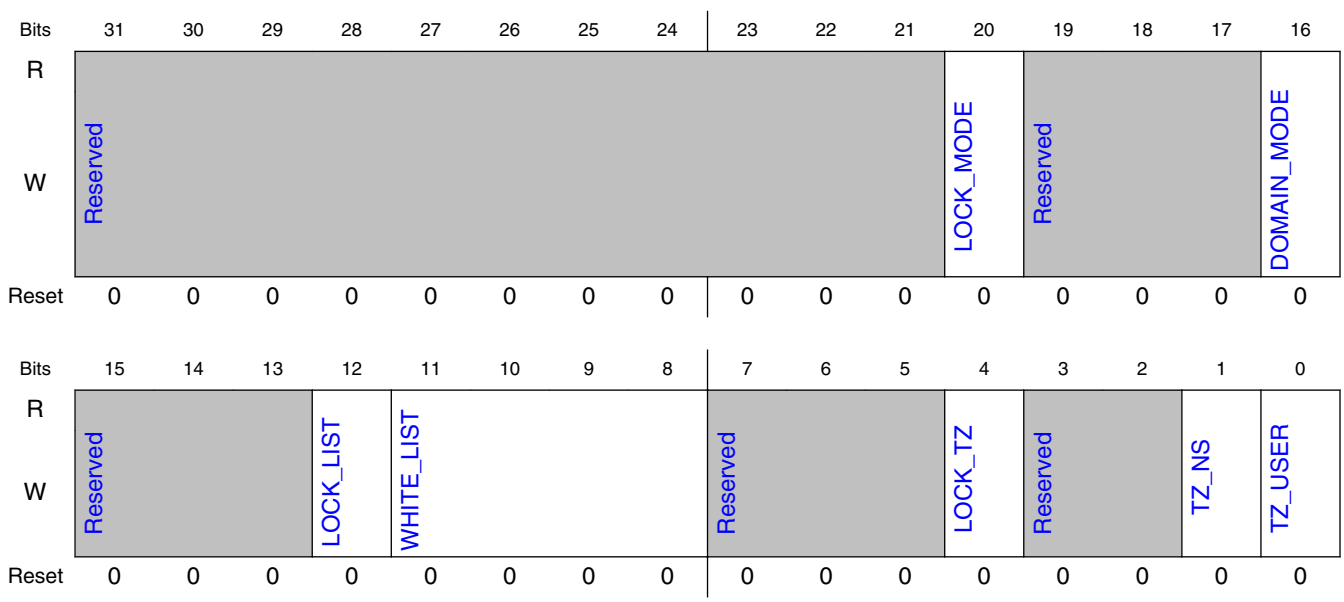
This register that manages observe access control.

15.9.2.4.1 Offset

For a = 0 to 5:

Register	Offset	Description
OBSERVEa_AUTHEN	30h + (a × 80h)	Observe access control
OBSERVEa_AUTHEN_SET	34h + (a × 80h)	Writing a 1 to a bit in this register sets the corresponding bit in OBSERVEa_AUTHEN
OBSERVEa_AUTHEN_CLR	38h + (a × 80h)	Writing a 1 to a bit in this register clears the corresponding bit in OBSERVEa_AUTHEN
OBSERVEa_AUTHEN_TOG	3Ch + (a × 80h)	Writing a 1 to a bit in this register toggles the corresponding bit in OBSERVEa_AUTHEN

15.9.2.4.2 Diagram



15.9.2.4.3 Fields

Field	Description
31-21 —	Reserved

Table continues on the next page...

Field	Description
20 LOCK_MODE	Lock low power and access mode This bit lock low power and access control mode. When this bit is set, DOMAIN_MODE cannot change. Once this bit is set, it cannot be cleared, until next system reset. 0 - MODE is not locked. 1 - MODE is locked.
19-17 —	Reserved
16 DOMAIN_MODE	Low power and access control by domain Observe works in domain controlled mode. 0 - Clock does not work in domain mode. 1 - Clock works in domain mode.
15-13 —	Reserved
12 LOCK_LIST	Lock white list This bit lock white list. When this bit is set, WHITE_LIST cannot be changed. Once this bit is set, it cannot be cleared, until next system reset. 0 - White list is not locked. 1 - White list is locked.
11-8 WHITE_LIST	White list Domains that on the white list can change this observe. Each field in this field represent for one domain. Bit8~Bit12 represent for DOMAIN0~DOMAIN3 respectively. 0000 - No domain can change. 0001 - Domain 0 can change. 0010 - Domain 1 can change. 0011 - Domain 0 and domain 1 can change. 0100 - Domain 2 can change. 1111 - All domain can change.
7-5 —	Reserved
4 LOCK_TZ	Lock TZ_USER and TZ_NS When this bit is set, TZ_USER and TZ_NS cannot be changed. Once this bit is set, it cannot be cleared, until next system reset. 0 - Not locked. 1 - Locked.
3-2 —	Reserved
1 TZ_NS	Non-secure access This observe can be changed when CPU is in Non-secure mode. 0 - Cannot be changed in Non-secure mode. 1 - Can be changed in Non-secure mode.

Table continues on the next page...

Field	Description
0 TZ_USER	User access This observe can be changed when CPU is in user mode. 0 - Clock cannot be changed in user mode. 1 - Clock can be changed in user mode.

15.9.2.5 Current frequency detected (OBSERVE0_FREQUENCY_CURRENT - OBSERVE5_FREQUENCY_CURRENT)

This register shows the current frequency detected since last update or reset. After the measurement begins, wait for 20ms before reading this register.

NOTE

Frequency related measurement requires 32K crystal clock.

15.9.2.5.1 Offset

Register	Offset
OBSERVE0_FREQUENCY_CURRENT	40h
OBSERVE1_FREQUENCY_CURRENT	C0h
OBSERVE2_FREQUENCY_CURRENT	140h
OBSERVE3_FREQUENCY_CURRENT	1C0h
OBSERVE4_FREQUENCY_CURRENT	240h
OBSERVE5_FREQUENCY_CURRENT	2C0h

15.9.2.5.2 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15.9.2.5.3 Fields

Field	Description
31-0 FREQUENCY	Frequency Current frequency of observed signal in Hz.

15.9.2.6 Minimum frequency detected (OBSERVE0_FREQUENCY_MIN - OBSERVE5_FREQUENCY_MIN)

This register shows the minimum frequency detected since last update or reset. After the measurement begins, wait for 20ms before reading this register.

15.9.2.6.1 Offset

Register	Offset
OBSERVE0_FREQUENCY_MIN	44h
OBSERVE1_FREQUENCY_MIN	C4h
OBSERVE2_FREQUENCY_MIN	144h
OBSERVE3_FREQUENCY_MIN	1C4h
OBSERVE4_FREQUENCY_MIN	244h
OBSERVE5_FREQUENCY_MIN	2C4h

15.9.2.6.3 Fields

Field	Description
31-0 FREQUENCY	Frequency Minimum frequency of observed signal in Hz.

15.9.2.7 Maximum frequency detected (OBSERVE0_FREQUENCY_MAX - OBSERVE5_FREQUENCY_MAX)

This register shows the maximum frequency detected since last update or reset. After the measurement begins, wait for 20ms before reading this register.

15.9.2.7.1 Offset

Register	Offset
OBSERVE0_FREQUENCY_MAX	48h
OBSERVE1_FREQUENCY_MAX	C8h
OBSERVE2_FREQUENCY_MAX	148h
OBSERVE3_FREQUENCY_MAX	1C8h
OBSERVE4_FREQUENCY_MAX	248h
OBSERVE5_FREQUENCY_MAX	2C8h

15.9.2.7.2 Diagram

15.9.4.2 ARM_PLL_CTRL_REGISTER (ARM_PLL_CTRL)

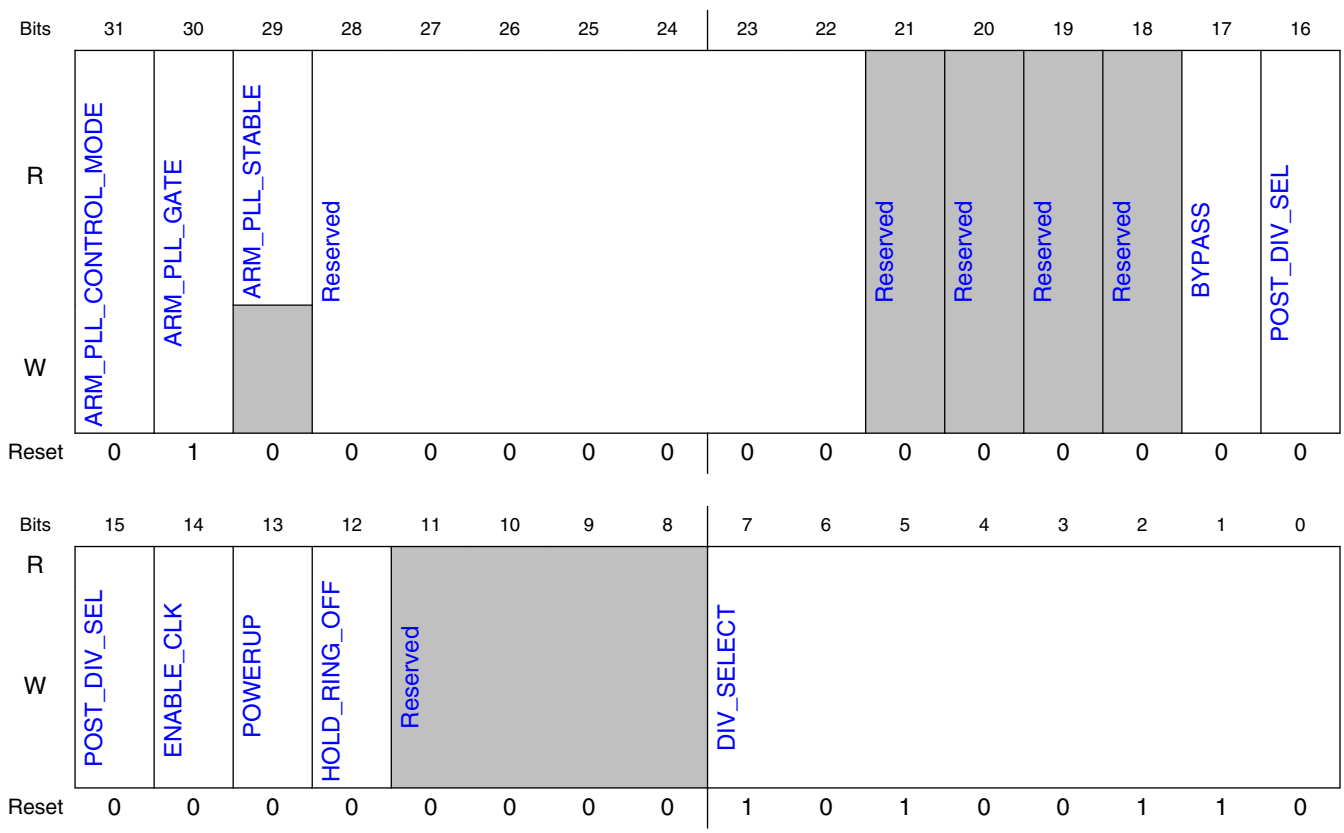
ARM_PLL control register

The control register provides control for the ARM PLL.

15.9.4.2.1 Offset

Register	Offset
ARM_PLL_CTRL	200h

15.9.4.2.2 Diagram



15.9.4.2.3 Fields

Field	Description
31 ARM_PLL_CONTROL_MODE	pll_arm_control_mode Enable mode 0 - Software Mode (Default) 1 - GPC Mode
30 ARM_PLL_GATE	ARM_PLL_GATE default value is 1'b1 0 - Clock is not gated 1 - Clock is gated
29 ARM_PLL_STABLE	ARM_PLL_STABLE The stable indicate bit. Normally in Software mode, after the power up and enable sequence for arm pll, arm pll will not be in stable state immediately. This bit is used by software to monitor the locking status for arm pll. GPC mode do not need to take care of this bit. Hardware will handle it automatically. 0 - ARM PLL is not stable 1 - ARM PLL is stable
28-22 —	Always set to zero (0). Always set to zero (0).
21 —	Reserved
20 —	Reserved
19 —	Reserved
18 —	Reserved
17 BYPASS	Bypass the pll. Bypass the pll enable bit. This bit could be used to bypass the PLL output to the source of reference clock 0 - Function mode 1 - Bypass Mode
16-15 POST_DIV_SEL	POST_DIV_SEL 00 - Divide by 2 01 - Divide by 4 10 - Divide by 8 11 - Divide by 1
14 ENABLE_CLK	Enable the clock output. Please refer to PLL Enable Sequence for more details on how to use this bit during the PLL enablement. 0 - Disable the clock 1 - Enable the clock
13	Powers up the PLL.

Table continues on the next page...

Field	Description
POWERUP	Please refer to PLL Enable Sequence for more details on how to use this bit during the PLL enablement. 0 - Power down the PLL 1 - Power Up the PLL
12 HOLD_RING_OFF	PLL Start up initialization This field should be set to 1 every time during PLL lock, and cleared after a certain delay. Please refer to PLL Enable Sequence for more details on how to use this bit during the PLL enablement. 0 - Normal operation 1 - Initialize PLL start up
11-8 —	Reserved
7-0 DIV_SELECT	DIV_SELECT This field controls the pll loop divider. Valid range for divider value: 104-208. Fout = Fin * div_select/2.0

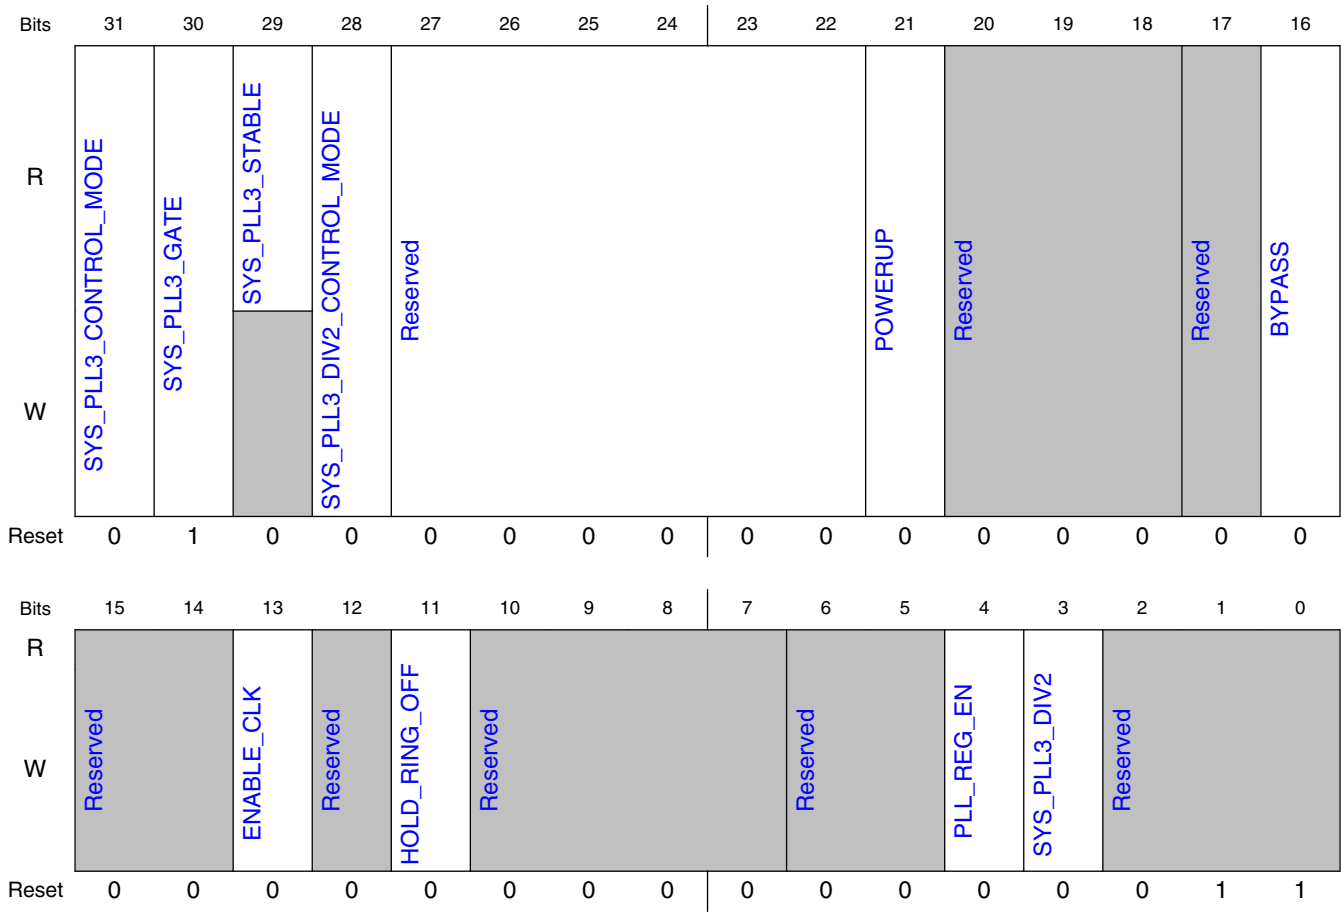
15.9.4.3 SYS_PLL3_CTRL_REGISTER (SYS_PLL3_CTRL)

The control register provides control for the 480 PLL.

15.9.4.3.1 Offset

Register	Offset
SYS_PLL3_CTRL	210h

15.9.4.3.2 Diagram



15.9.4.3.3 Fields

Field	Description
31 SYS_PLL3_CONTROL_MODE	SYS_PLL3_control_mode Enable mode 0 - Software Mode (Default) 1 - GPC Mode
30 SYS_PLL3_GATE	SYS_PLL3_GATE default value is 1'b1 0 - Clock is not gated 1 - Clock is gated
29 SYS_PLL3_STABLE	SYS_PLL3_STABLE The stable indicate bit. Normally in Software mode, after the power up and enable sequence for SYS_PLL3, arm pll will not be in stable state immediately. This bit is used by software to monitor the locking status for SYS_PLL3.
28	SYS_PLL3_DIV2_CONTROL_MODE

Table continues on the next page...

Field	Description
SYS_PLL3_DIV2_CONTROL_MODE	Enable mode 0 - Software Mode (Default) 1 - GPC Mode
27-22 —	Always set to zero (0). Always set to zero (0).
21 POWERUP	Powers up the PLL. Please refer to PLL Enable Sequence for more details on how to use this bit during the PLL enablement. 0 - Power down the PLL 1 - Power Up the PLL
20-18 —	Reserved
17 —	Reserved
16 BYPASS	BYPASS Bypass the pll enable bit. This bit could be used to bypass the PLL output to the source of reference clock 0 - Function mode 1 - Bypass Mode
15-14 —	Reserved
13 ENABLE_CLK	Enable the clock output. Please refer to PLL Enable Sequence for more details on how to use this bit during the PLL enablement. 0 - Disable the clock 1 - Enable the clock
12 —	Reserved
11 HOLD_RING_OFF	PLL Start up initialization This field should be set to 1 every time during PLL lock, and cleared after a certain delay. Please refer to PLL Enable Sequence for more details on how to use this bit during the PLL enablement. 0 - Normal operation 1 - Initialize PLL start up
10-7 —	Reserved
6-5 —	Reserved
4 PLL_REG_EN	Enable Internal PLL Regulator Please refer to PLL Enable Sequence for more details on how to use this bit during the PLL enablement.
3 SYS_PLL3_DIV2	SYS PLL3 DIV2 gate Enable SYS_PLL3_DIV2 clock which is sourced from SYS_PLL3 0 : disable

Table continues on the next page...

Field	Description
	1 : enable
2-0 —	Reserved

15.9.4.4 SYS_PLL3_UPDATE_REGISTER (SYS_PLL3_UPDATE)

The control register provides control for the 480 PLL.

15.9.4.4.1 Offset

Register	Offset
SYS_PLL3_UPDATE	220h

15.9.4.4.2 Diagram

6 PFD1_CONTROL_MODE	pfd1_control_mode Enable mode 0 - Software Mode (Default) 1 - GPC Mode
5 PFD0_CONTROL_MODE	pfd0_control_mode Enable mode 0 - Software Mode (Default) 1 - GPC Mode
4 PFD3_UPDATE	PFD3_UPDATE PFD update This bit is used to update the pfd value. Toggle it will make the update function.
3 PFD2_UPDATE	PFD2_OVERRIDE PFD update This bit is used to update the pfd value. Toggle it will make the update function.
2 PFD1_UPDATE	PFD1_OVERRIDE PFD update This bit is used to update the pfd value. Toggle it will make the update function.
1 PFD0_UPDATE	PFD0_OVERRIDE PFD update This bit is used to update the pfd value. Toggle it will make the update function.
0 —	Reserved

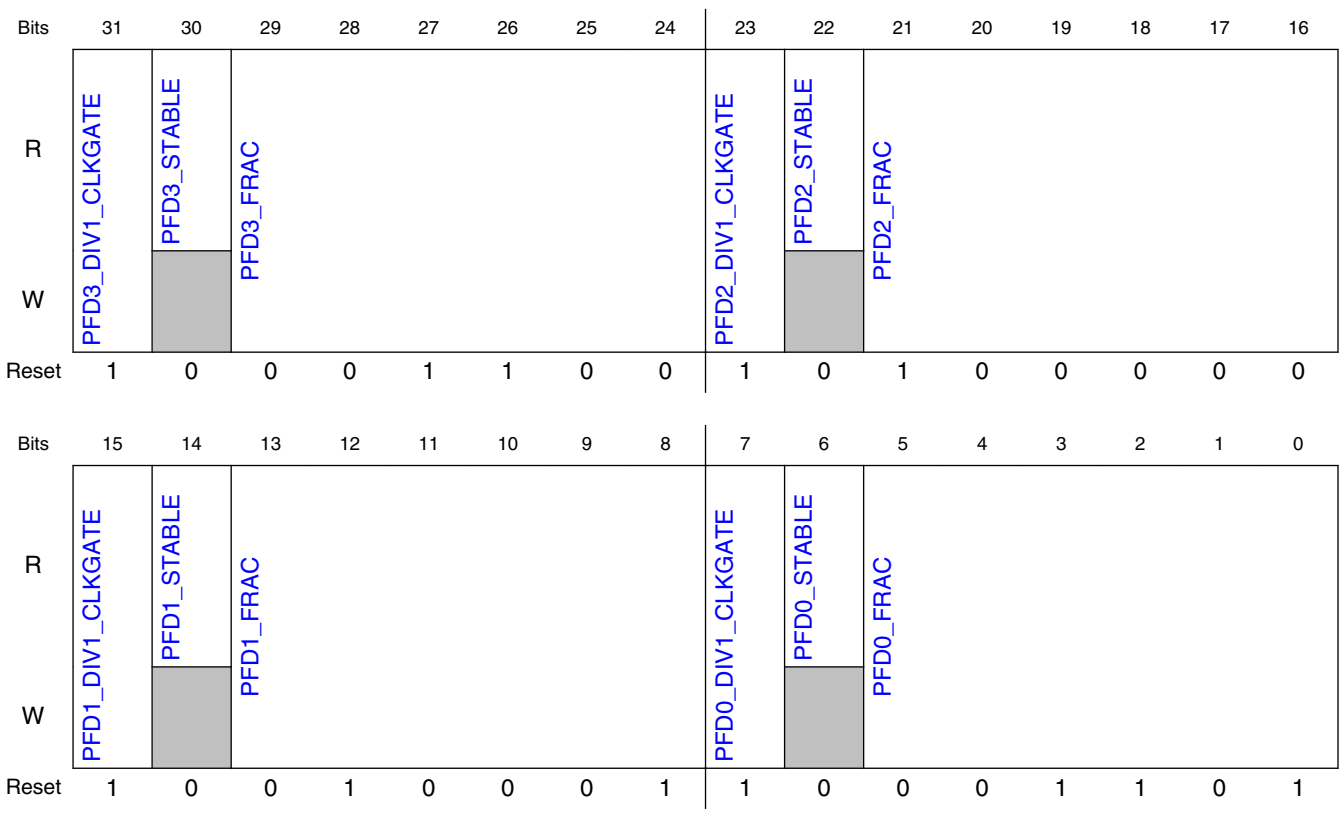
15.9.4.5 SYS_PLL3_PFD_REGISTER (SYS_PLL3_PFD)

This register contains the numerator of SYS PLL3 fractional loop divider.

15.9.4.5.1 Offset

Register	Offset
SYS_PLL3_PFD	230h

15.9.4.5.2 Diagram



15.9.4.5.3 Fields

Field	Description
31 PFD3_DIV1_CLKGATE	PFD3_DIV1_CLKGATE 0 - ref_pfd3 fractional divider clock is enabled 1 - Fractional divider clock (reference ref_pfd3) is off (power savings)
30 PFD3_STABLE	PFD3_STABLE This read-only bitfield is for DIAGNOSTIC PURPOSES ONLY since the fractional divider should become stable quickly enough that this field will never need to be used by either device driver or application code. The value inverts when the new programmed fractional divide value has taken effect. Read this bit, program the new value, and when this bit inverts, the phase divider clock output is stable. Note that the value will not invert when the fractional divider is taken out of or placed into clock-gated state.

Table continues on the next page...

Field	Description
29-24 PFD3_FRAC	PFD3_FRAC This field controls the fractional divide value. The resulting frequency shall be 480*18/PFD3_FRAC where PFD3_FRAC is in the range 13-35. **NOTE:** The PFD value can be set to 12, however the lowest recommended setting for PFD is 13.
23 PFD2_DIV1_CLKGATE	PFD2_DIV1_CLKGATE 0 - ref_pfd2 fractional divider clock is enabled 1 - Fractional divider clock (reference ref_pfd2) is off (power savings)
22 PFD2_STABLE	PFD2_STABLE This read-only bitfield is for DIAGNOSTIC PURPOSES ONLY since the fractional divider should become stable quickly enough that this field will never need to be used by either device driver or application code. The value inverts when the new programmed fractional divide value has taken effect. Read this bit, program the new value, and when this bit inverts, the phase divider clock output is stable. Note that the value will not invert when the fractional divider is taken out of or placed into clock-gated state.
21-16 PFD2_FRAC	PFD2_FRAC This field controls the fractional divide value. The resulting frequency shall be 480*18/PFD2_FRAC where PFD2_FRAC is in the range 13-35.
15 PFD1_DIV1_CLKGATE	PFD1_DIV1_CLKGATE 0 - ref_pfd1 fractional divider clock is enabled 1 - Fractional divider clock (reference ref_pfd1) is off (power savings)
14 PFD1_STABLE	PFD1_STABLE This read-only bitfield is for DIAGNOSTIC PURPOSES ONLY since the fractional divider should become stable quickly enough that this field will never need to be used by either device driver or application code. The value inverts when the new programmed fractional divide value has taken effect. Read this bit, program the new value, and when this bit inverts, the phase divider clock output is stable. Note that the value will not invert when the fractional divider is taken out of or placed into clock-gated state.
13-8 PFD1_FRAC	PFD1_FRAC This field controls the fractional divide value. The resulting frequency shall be 480*18/PFD1_FRAC where PFD1_FRAC is in the range 13-35.
7 PFD0_DIV1_CLKGATE	PFD0_DIV1_CLKGATE 0 - ref_pfd0 fractional divider clock is enabled 1 - Fractional divider clock (reference ref_pfd0) is off (power savings
6 PFD0_STABLE	PFD0_STABLE This read-only bitfield is for DIAGNOSTIC PURPOSES ONLY since the fractional divider should become stable quickly enough that this field will never need to be used by either device driver or application code. The value inverts when the new programmed fractional divide value has taken effect. Read this bit, program the new value, and when this bit inverts, the phase divider clock output is stable. Note that the value will not invert when the fractional divider is taken out of or placed into clock-gated state.
5-0 PFD0_FRAC	PFD0_FRAC This field controls the fractional divide value. The resulting frequency shall be 480*18/PFD0_FRAC where PFD0_FRAC is in the range 13-35.

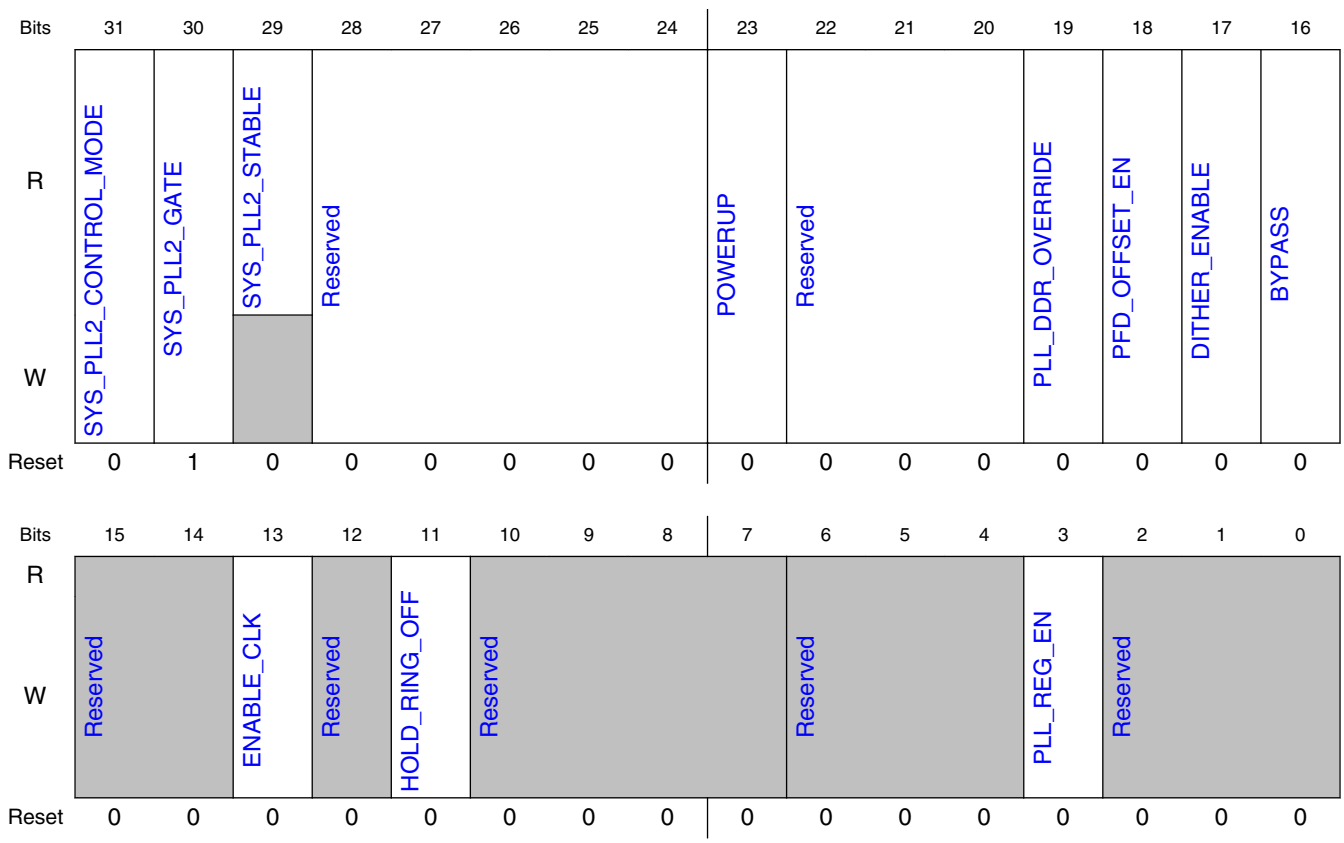
15.9.4.6 SYS_PLL2_CTRL_REGISTER (SYS_PLL2_CTRL)

The control register provides control for the SYS_PLL2

15.9.4.6.1 Offset

Register	Offset
SYS_PLL2_CTRL	240h

15.9.4.6.2 Diagram



15.9.4.6.3 Fields

Field	Description
31 SYS_PLL2_CONTROL_MODE	SYS_PLL2_control_mode SYS_PLL2 has two mode to for enable. One is software mode, the other is GPC mode(Setpoint). 0 - Software Mode (Default)

Table continues on the next page...

Field	Description
	1 - GPC Mode
30 SYS_PLL2_GATE	SYS_PLL2_GATE default value is 1'b1 0 - Clock is not gated 1 - Clock is gated
29 SYS_PLL2_STABLE	SYS_PLL2_STABLE The stable indicate bit. Normally in Software mode, after the power up and enable sequence for SYS_PLL2, ARM_PLL will not be in stable state immediately. This bit is used by software to monitor the locking status for SYS_PLL2.
28-24 —	Always set to zero (0). Always set to zero (0).
23 POWERUP	Powers up the PLL. Please refer to PLL Enable Sequence for more details on how to use this bit during the PLL enablement. 0 - Power down the PLL 1 - Power Up the PLL
22-20 —	Always set to zero (0). Always set to zero (0).
19 PLL_DDR_OVERRIDE	PLL_DDR_OVERRIDE The OVERRIDE bit allows the clock control module to automatically override portions of the register. PLL_DDR_OVERRIDE = 0x0: ENABLE_CLK bits and the POWERDOWN bit controlled by this register. PLL_DDR_OVERRIDE = 0x1: CCM based hardware bits override the ENABLE_CLK bits and the POWERDOWN bit in this register.
18 PFD_OFFSET_EN	PFD_OFFSET_EN Enables an offset in the phase frequency detector.
17 DITHER_ENABLE	DITHER_ENABLE Enables dither in the fractional modulator calculation. 0 - Disable Dither 1 - Enable Dither
16 BYPASS	Bypass the pll. Control bit to Bypass the pll to the reference clock 0 - Function mode 1 - Bypass Mode
15-14 —	Reserved
13 ENABLE_CLK	Enable the clock output. Enable the clock output. 0 - Disable the clock 1 - Enable the clock
12 —	Reserved

Table continues on the next page...

Field	Description
11 HOLD_RING_OFF	PLL Start up initialization This field should be set to 1 every time during PLL lock, and cleared after a certain delay. Please refer to PLL Enable Sequence for more details on how to use this bit during the PLL enablement. 0 - Normal operation 1 - Initialize PLL start up
10-7 —	Reserved
6-4 —	Reserved
3 PLL_REG_EN	Enable Internal PLL Regulator Please refer to PLL Enable Sequence for more details on how to use this bit during the PLL enablement.
2-0 —	Reserved

15.9.4.7 SYS_PLL2_UPDATE_REGISTER (SYS_PLL2_UPDATE)

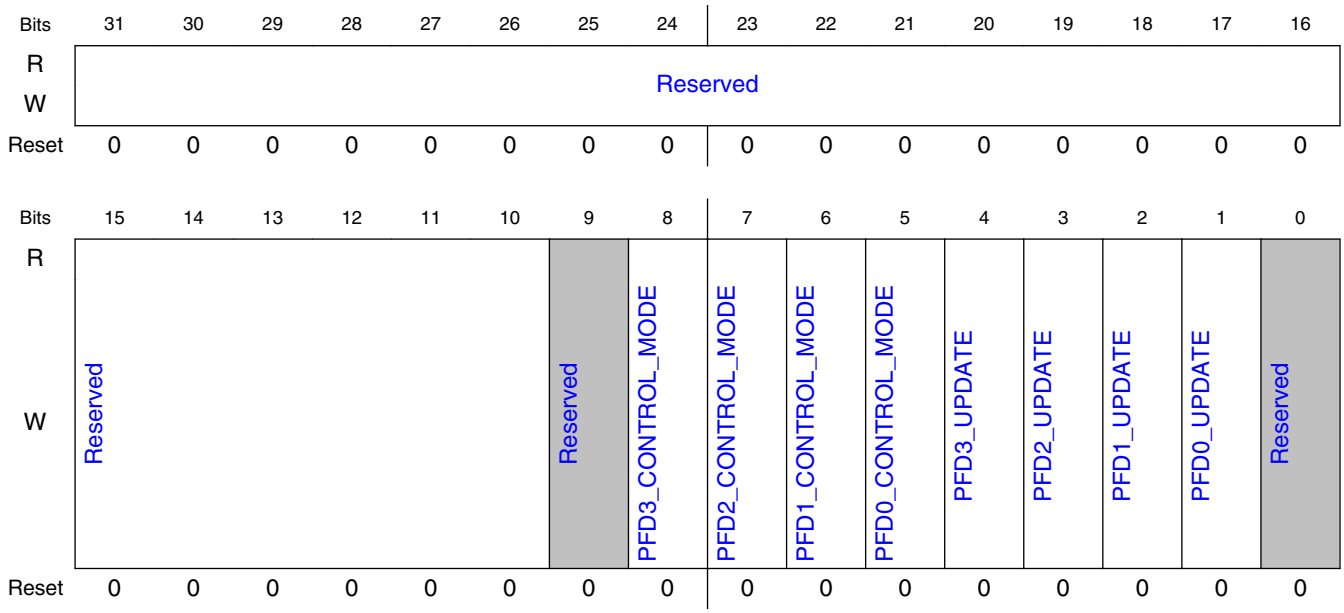
SYS_PLL2 PFD control register

The control register provides control for the 528 PLL.

15.9.4.7.1 Offset

Register	Offset
SYS_PLL2_UPDATE	250h

15.9.4.7.2 Diagram



15.9.4.7.3 Fields

Field	Description
31-10 —	Always set to zero (0). Always set to zero (0).
9 —	Reserved
8 PFD3_CONTROL_MODE	pfd3_control_mode Enable mode 0 - Software Mode (Default) 1 - GPC Mode
7 PFD2_CONTROL_MODE	pfd2_control_mode Enable mode 0 - Software Mode (Default) 1 - GPC Mode
6 PFD1_CONTROL_MODE	pfd1_control_mode Enable mode 0 - Software Mode (Default) 1 - GPC Mode
5 PFD0_CONTROL_MODE	pfd0_control_mode Enable mode 0 - Software Mode (Default)

Table continues on the next page...

Field	Description
	1 - GPC Mode
4 PFD3_UPDATE	PFD3_UPDATE PFD update This bit is used to update the pfd value. Toggle it will make the update function.
3 PFD2_UPDATE	PFD2_UPDATE PFD update This bit is used to update the pfd value. Toggle it will make the update function.
2 PFD1_UPDATE	PFD1_UPDATE PFD update This bit is used to update the pfd value. Toggle it will make the update function.
1 PFD0_UPDATE	PFD0_UPDATE PFD update This bit is used to update the pfd value. Toggle it will make the update function.
0 —	Reserved

15.9.4.8 SYS_PLL2_SS_REGISTER (SYS_PLL2_SS)

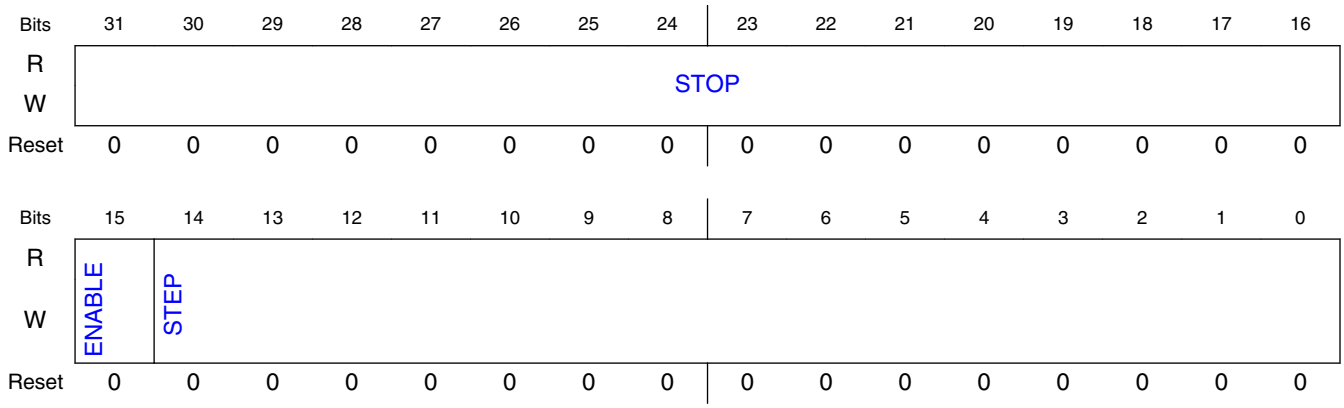
This register contains the SYS PLL2 spread spectrum controls

Refer to Spread Spectrum Parameters for more details.

15.9.4.8.1 Offset

Register	Offset
SYS_PLL2_SS	260h

15.9.4.8.2 Diagram



15.9.4.8.3 Fields

Field	Description
31-16 STOP	STOP Frequency change = stop/MFD*24MHz.
15 ENABLE	ENABLE This bit enables the spread spectrum modulation 0 - Disable Spread Spectrum. In this setting, the values for STEP and STOP are ignored 1 - Enable Spread Spectrum
14-0 STEP	STEP The max frequency change = step/MFD*24MHz.

15.9.4.9 SYS_PLL2_PFD_REGISTER (SYS_PLL2_PFD)

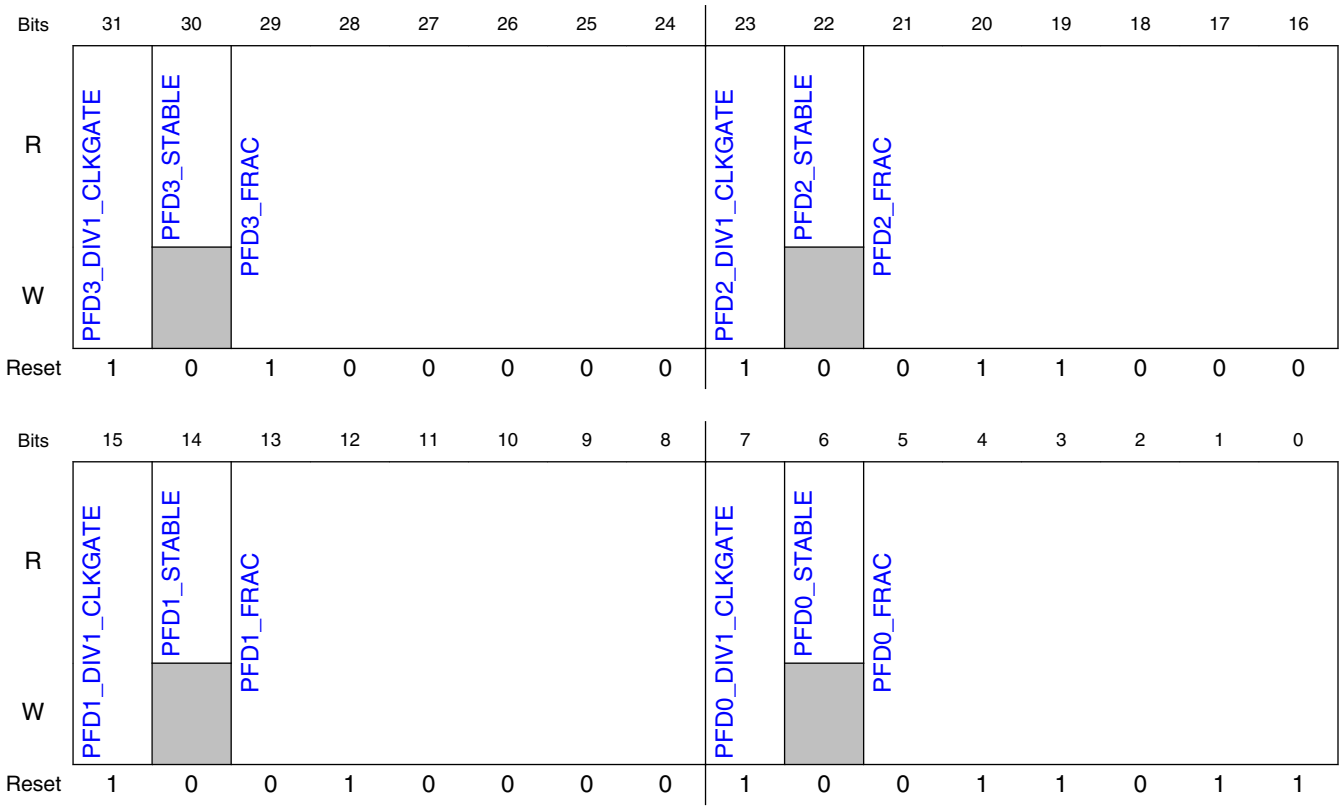
SYS_PLL2 fractional loop divider

This register contains the numerator of DDR PLL fractional loop divider.

15.9.4.9.1 Offset

Register	Offset
SYS_PLL2_PFD	270h

15.9.4.9.2 Diagram



15.9.4.9.3 Fields

Field	Description
31 PFD3_DIV1_CLKGATE	PFD3_DIV1_CLKGATE If set to 1, the 3rd fractional divider clock (reference ref_pfd3) is off (power savings). 0: ref_pfd3 fractional divider clock is enabled.
30 PFD3_STABLE	PFD3_STABLE This read-only bitfield is for DIAGNOSTIC PURPOSES ONLY since the fractional divider should become stable quickly enough that this field will never need to be used by either device driver or application code. The value inverts when the new programmed fractional divide value has taken effect. Read this bit, program the new value, and when this bit inverts, the phase divider clock output is stable. Note that the value will not invert when the fractional divider is taken out of or placed into clock-gated state.
29-24 PFD3_FRAC	PFD3_FRAC This field controls the fractional divide value. The resulting frequency shall be 528*18/PFD3_FRAC where PFD3_FRAC is in the range 13-35.
23 PFD2_DIV1_CLKGATE	PFD2_DIV1_CLKGATE If set to 1, the 2 fractional divider clock (reference ref_pfd2) is off (power savings). 0: ref_pfd2 fractional divider clock is enabled.
22 PFD2_STABLE	PFD2_STABLE

Table continues on the next page...

Field	Description
	This read-only bitfield is for DIAGNOSTIC PURPOSES ONLY since the fractional divider should become stable quickly enough that this field will never need to be used by either device driver or application code. The value inverts when the new programmed fractional divide value has taken effect. Read this bit, program the new value, and when this bit inverts, the phase divider clock output is stable. Note that the value will not invert when the fractional divider is taken out of or placed into clock-gated state.
21-16 PFD2_FRAC	PFD2_FRAC This field controls the fractional divide value. The resulting frequency shall be 528*18/PFD2_FRAC where PFD2_FRAC is in the range 13-35.
15 PFD1_DIV1_CLKGATE	PFD1_DIV1_CLKGATE If set to 1, the 1 fractional divider clock (reference ref_pfd1) is off (power savings). 0: ref_pfd1 fractional divider clock is enabled.
14 PFD1_STABLE	PFD1_STABLE This read-only bitfield is for DIAGNOSTIC PURPOSES ONLY since the fractional divider should become stable quickly enough that this field will never need to be used by either device driver or application code. The value inverts when the new programmed fractional divide value has taken effect. Read this bit, program the new value, and when this bit inverts, the phase divider clock output is stable. Note that the value will not invert when the fractional divider is taken out of or placed into clock-gated state.
13-8 PFD1_FRAC	PFD1_FRAC This field controls the fractional divide value. The resulting frequency shall be 528*18/PFD1_FRAC where PFD1_FRAC is in the range 13-35.
7 PFD0_DIV1_CLKGATE	PFD0_DIV1_CLKGATE If set to 1, the 0 fractional divider clock (reference ref_pfd0) is off (power savings). 0: ref_pfd0 fractional divider clock is enabled.
6 PFD0_STABLE	PFD0_STABLE This read-only bitfield is for DIAGNOSTIC PURPOSES ONLY since the fractional divider should become stable quickly enough that this field will never need to be used by either device driver or application code. The value inverts when the new programmed fractional divide value has taken effect. Read this bit, program the new value, and when this bit inverts, the phase divider clock output is stable. Note that the value will not invert when the fractional divider is taken out of or placed into clock-gated state.
5-0 PFD0_FRAC	PFD0_FRAC This field controls the fractional divide value. The resulting frequency shall be 528*18/PFD0_FRAC where PFD0_FRAC is in the range 13-35.

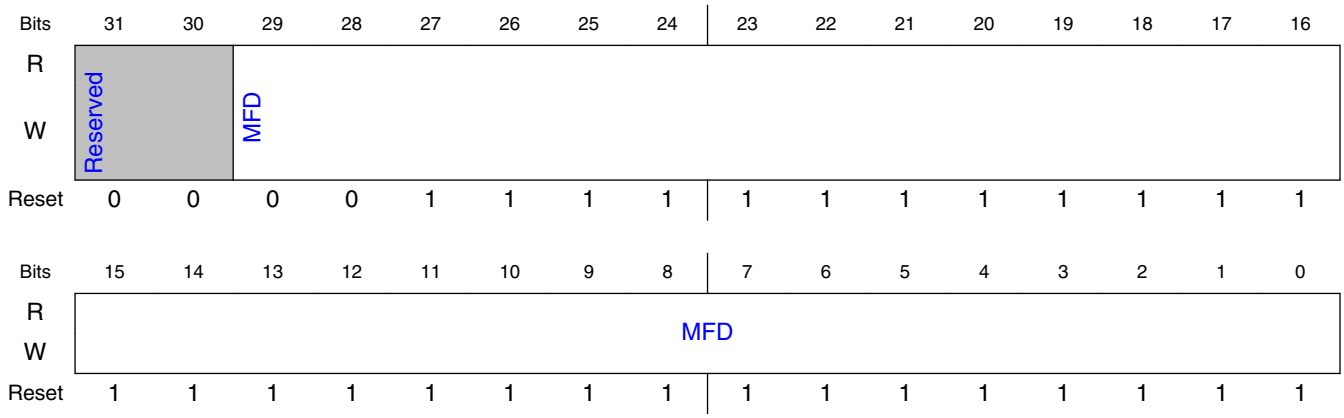
15.9.4.10 SYS_PLL2_MFD_REGISTER (SYS_PLL2_MFD)

Spread Spectrum Frequency Range is calculated as follows: Range = (STOP/MFD) * Fref

15.9.4.10.1 Offset

Register	Offset
SYS_PLL2_MFD	2A0h

15.9.4.10.2 Diagram



15.9.4.10.3 Fields

Field	Description
31-30 —	Reserved
29-0 MFD	Denominator Refer to Programming Guidelines for more details.

15.9.4.11 SYS_PLL1_SS_REGISTER (SYS_PLL1_SS)

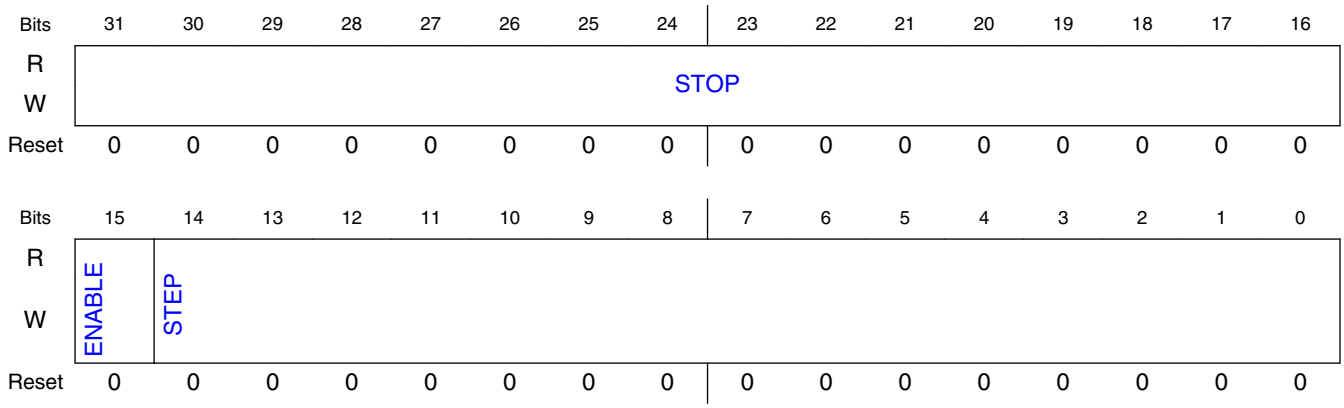
This register contains the 1G PLL spread spectrum controls

Refer to Spread Spectrum Parameters for more details.

15.9.4.11.1 Offset

Register	Offset
SYS_PLL1_SS	2B0h

15.9.4.11.2 Diagram



15.9.4.11.3 Fields

Field	Description
31-16 STOP	STOP Frequency change = stop/MFD*24MHz.
15 ENABLE	ENABLE This bit enables the spread spectrum modulation 0 - Disable Spread Spectrum. In this setting, the values for STEP and STOP are ignored 1 - Enable Spread Spectrum
14-0 STEP	STEP The max frequency change = step/MFD*24MHz.

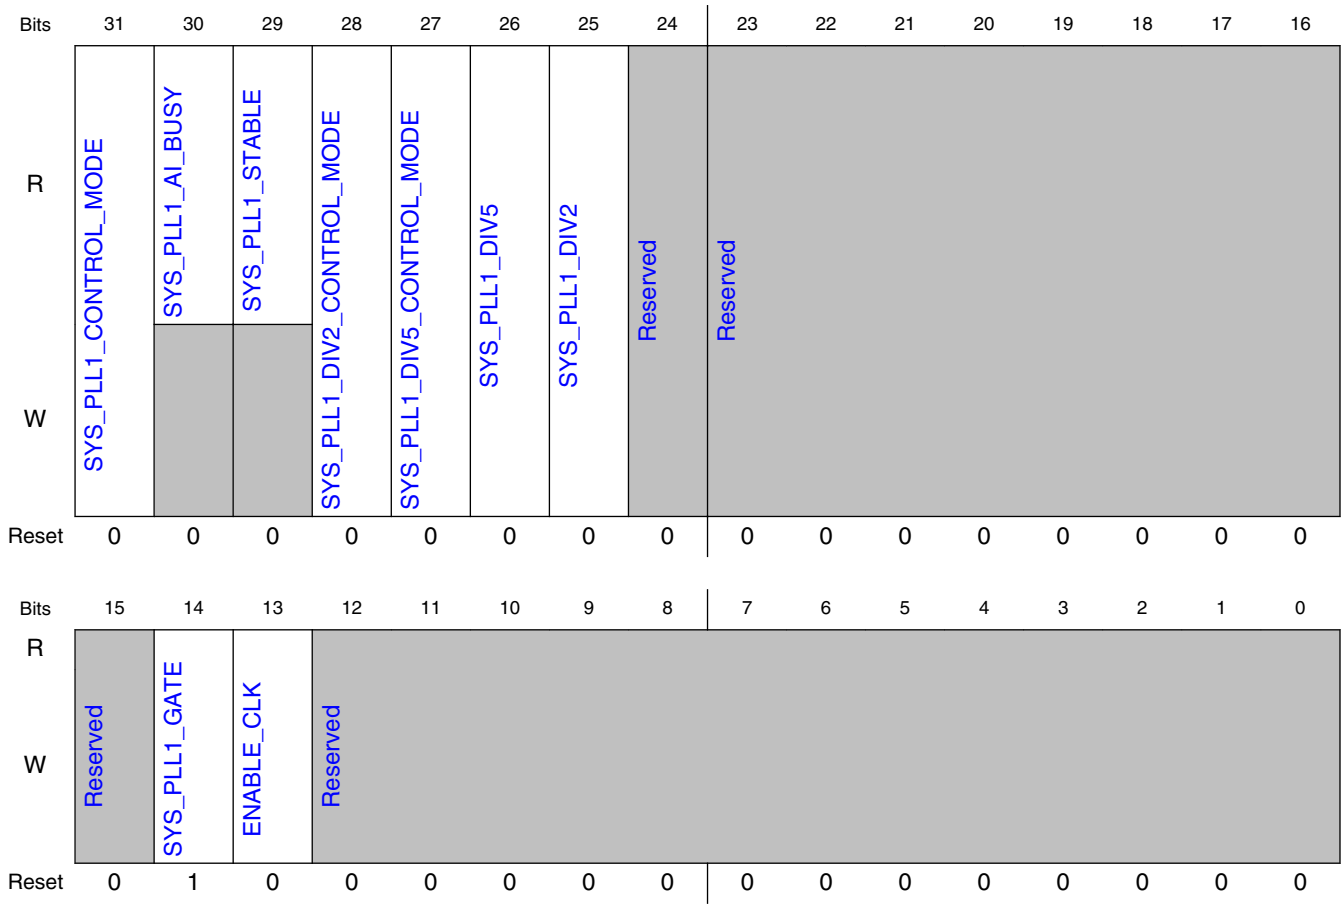
15.9.4.12 SYS_PLL1_CTRL_REGISTER (SYS_PLL1_CTRL)

The control register provides control for the 1G PLL.

15.9.4.12.1 Offset

Register	Offset
SYS_PLL1_CTRL	2C0h

15.9.4.12.2 Diagram



15.9.4.12.3 Fields

Field	Description
31 SYS_PLL1_CONTROL_MODE	SYS_PLL1_CONTROL_MODE Enable mode 0 - Software Mode (Default) 1 - GPC Mode
30 SYS_PLL1_AI_BUSY	SYS_PLL1_AI_BUSY For this AI bridge register field, this bit is used along with AI bus. Function is for AI busy monitor. There will be a detail description on how to use it. For debug purpose. Reserved.
29 SYS_PLL1_STABLE	SYS_PLL1_STABLE SYS_PLL1_STABLE Normally in Software mode, after the power up and enable sequence for pll, arm pll will not be in stable state immediately. This bit is used by software to monitor the locking status for pll. GPC mode do not need to take care of this bit. Hardware will handle it automatically.
28	SYS_PLL1_DIV2_CONTROL_MODE

Table continues on the next page...

Field	Description
SYS_PLL1_DIV2_CONTROL_MODE	Enable mode 0 - Software Mode (Default) 1 - GPC Mode
27 SYS_PLL1_DIV5_CONTROL_MODE	SYS_PLL1_DIV5_CONTROL_MODE Enable mode 0 - Software Mode (Default) 1 - GPC Mode
26 SYS_PLL1_DIV5	SYS_PLL1_DIV5 SYS_PLL1_DIV5 The PLL 1g has the source which is DIV5 by the actual frequency of PLL 1G, this bit control of the enable of this divider.
25 SYS_PLL1_DIV2	SYS_PLL1_DIV2 The PLL 1g has the source which is DIV2 by the actual frequency of PLL 1G, this bit control of the enable of this divider.
24 —	Reserved
23-15 —	Reserved
14 SYS_PLL1_GATE	SYS_PLL1_GATE SYS_PLL1_GATE There is a gate in top level to gate the pll output for power saving purpose,this field it to control this gate. 0 - No gate 1 - Gate the output
13 ENABLE_CLK	ENABLE_CLK Enable the clock output. This field is used to align the software mode and GPC mode. The usage of this bit is to describe the last PLL mode(enable or disable) before entering GPC mode. User need to make sure the pll state is matching first Setpoint will be entered.
12-0 —	Reserved

15.9.4.13 SYS_PLL1_DENOMINATOR_REGISTER (SYS_PLL1_DENOMINATOR)

As this AI interface PLL is used both in Software mode and GPC mode. This field is an entry to GPC mode for the corresponding field.

Output frequency=Fref*(MFI+MFN/MFD)

29-0 DENOM	DENOM As this is AI interface PLL, there will be two modes support for this PLL, software mode and GPC mode. And this file is providing the entry to the corresponding field in GPC mode.

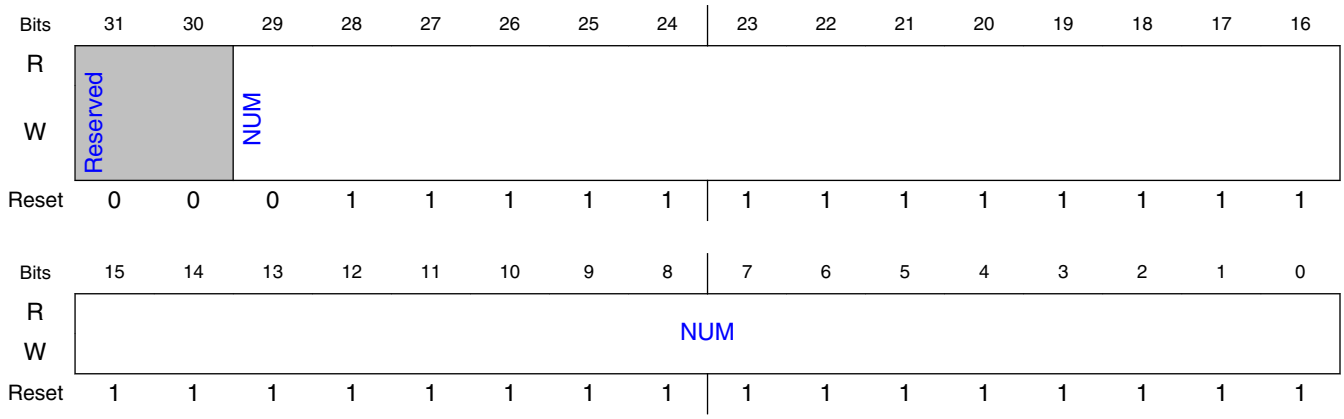
15.9.4.24 PLL_VIDEO_NUMERATOR_REGISTER (PLL_VIDEO_NUMERATOR)

As this AI interface PLL is used both in Software mode and GPC mode. This field is an entry to GPC mode for the corresponding field.

15.9.4.24.1 Offset

Register	Offset
PLL_VIDEO_NUMERATOR	380h

15.9.4.24.2 Diagram



15.9.4.24.3 Fields

Field	Description
31-30 —	Reserved
29-0 NUM	NUM As this is AI interface PLL, there will be two modes support for this PLL, software mode and GPC mode. And this file is providing the entry to the corresponding field in GPC mode.

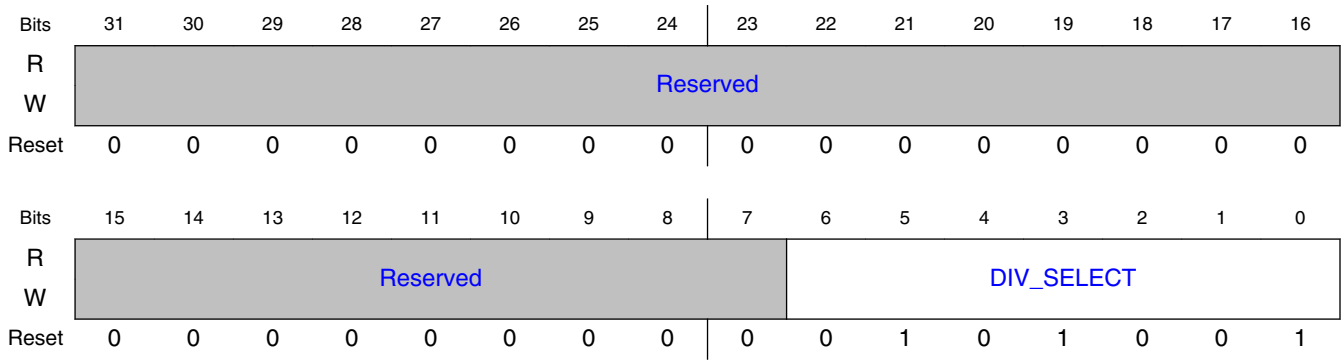
15.9.4.25 PLL_VIDEO_DIV_SELECT_REGISTER (PLL_VIDEO_DIV_SELECT)

As this AI interface PLL is used both in Software mode and GPC mode. This field is an entry to GPC mode for the corresponding field.

15.9.4.25.1 Offset

Register	Offset
PLL_VIDEO_DIV_SELECT	390h

15.9.4.25.2 Diagram



15.9.4.25.3 Fields

Field	Description
31-7 —	Reserved
6-0 DIV_SELECT	DIV_SELECT As this is AI interface PLL, there will be two modes support for this PLL, software mode and GPC mode. And this file is providing the entry to the corresponding field in GPC mode.

15.9.5 Fractional PLL register descriptions

NOTE

The CCM Fractional PLL registers are accessed through the Analog IP (AI) Interface.

15.9.5.1 FRACTIONAL_PLL memory map

frac_pll base address: 40C8_4000h

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)
0	Fractional PLL Control Register (CTRL0)	32	RW	0000_0000
4	Fractional PLL Control Register (CTRL0_SET)	32	RW	0000_0000
8	Fractional PLL Control Register (CTRL0_CLR)	32	RW	0000_0000

Table continues on the next page...

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)
C	Fractional PLL Control Register (CTRL0_TOG)	32	RW	0000_0000
10	Fractional PLL Spread Spectrum Control Register (SPREAD_SPECTRUM)	32	RW	0000_0000
14	Fractional PLL Spread Spectrum Control Register (SPREAD_SPECTRUM_SET)	32	RW	0000_0000
18	Fractional PLL Spread Spectrum Control Register (SPREAD_SPECTRUM_CLR)	32	RW	0000_0000
1C	Fractional PLL Spread Spectrum Control Register (SPREAD_SPECTRUM_TOG)	32	RW	0000_0000
20	Fractional PLL Numerator Control Register (NUMERATOR)	32	RW	0000_0000
24	Fractional PLL Numerator Control Register (NUMERATOR_SET)	32	RW	0000_0000
28	Fractional PLL Numerator Control Register (NUMERATOR_CLR)	32	RW	0000_0000
2C	Fractional PLL Numerator Control Register (NUMERATOR_TOG)	32	RW	0000_0000
30	Fractional PLL Denominator Control Register (DENOMINATOR)	32	RW	0000_0000
34	Fractional PLL Denominator Control Register (DENOMINATOR_SET)	32	RW	0000_0000
38	Fractional PLL Denominator Control Register (DENOMINATOR_CLR)	32	RW	0000_0000
3C	Fractional PLL Denominator Control Register (DENOMINATOR_TOG)	32	RW	0000_0000

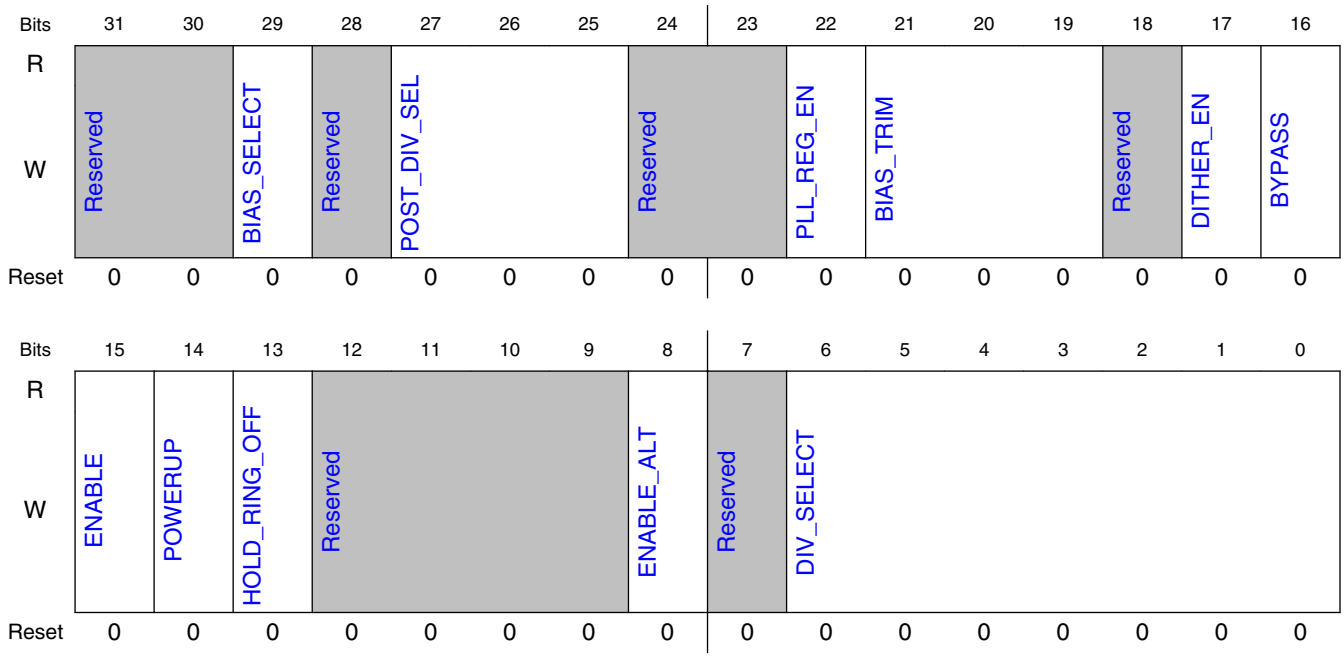
15.9.5.2 Fractional PLL Control Register (CTRL0)

This register contains fractional pll control registers.

15.9.5.2.1 Offset

Register	Offset	Description
CTRL0	0h	Fractional PLL Control Register
CTRL0_SET	4h	Writing a 1 to a bit in this register sets the corresponding bit in CTRL0
CTRL0_CLR	8h	Writing a 1 to a bit in this register clears the corresponding bit in CTRL0
CTRL0_TOG	Ch	Writing a 1 to a bit in this register toggles the corresponding bit in CTRL0

15.9.5.2.2 Diagram



15.9.5.2.3 Fields

Field	Description
31-30 —	Reserved
29 BIAS_SELECT	BIAS_SELECT Selects which input bias current is expected by the PLL. 0 - Used in SoCs with a bias current of 10uA 1 - Used in SoCs with a bias current of 2uA
28 —	Reserved
27-25 POST_DIV_SEL	Post Divide Select Fractional PLL Post Divider Select (glitchless clock mux) 000 - Divide by 1 001 - Divide by 2 010 - Divide by 4 011 - Divide by 8 100 - Divide by 16 101 - Divide by 32
24-23 —	Reserved

Table continues on the next page...

Field	Description
22 PLL_REG_EN	PLL_REG_EN Enables the internal PLL regulator.
21-19 BIAS_TRIM	BIAS_TRIM Not currently used.
18 —	Reserved
17 DITHER_EN	DITHER_EN Enables dither in the fractional modulator calculation. 0 - Disable Dither 1 - Enable Dither
16 BYPASS	BYPASS Byapss the PLL. Output is the PLL reference clock source 0 - No Bypass 1 - Bypass the PLL
15 ENABLE	ENABLE 0 - Disable the clock output 1 - Enable the clock output
14 POWERUP	POWERUP 0 - Power down the PLL 1 - Power Up the PLL
13 HOLD_RING_OFF	PLL Start up initialization This field should be set to 1 every time during PLL lock, and cleared after a certain delay. 0 - Normal operation 1 - Initialize PLL start up
12-9 —	Reserved
8 ENABLE_ALT	ENABLE_ALT 0 - Disable the alternate clock output 1 - Enable the alternate clock output which is the output of the post_divider, and cannot be bypassed
7 —	Reserved
6-0 DIV_SELECT	DIV_SELECT This field controls the pll loop divider. Valid range for DIV_SELECT divider value: 27-54 decimal.

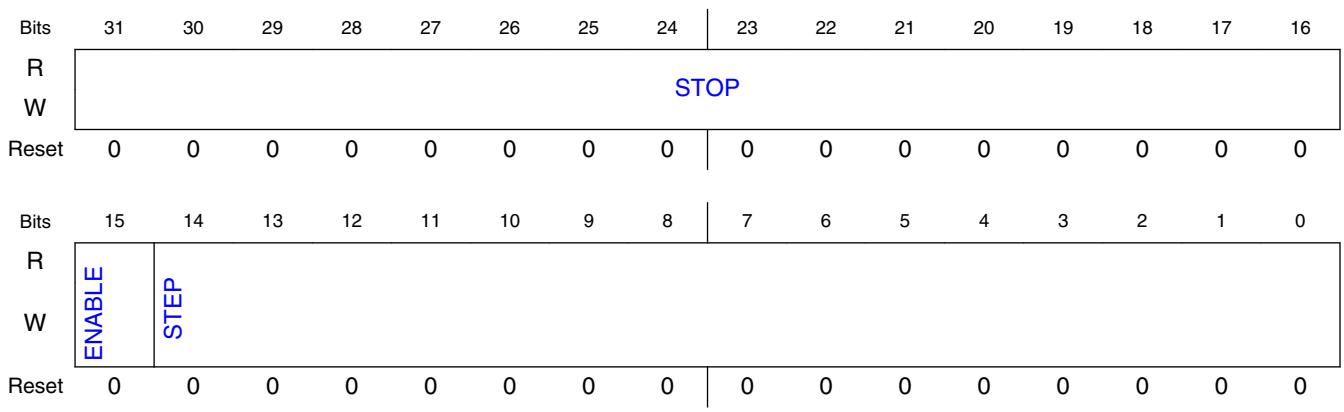
15.9.5.3 Fractional PLL Spread Spectrum Control Register (SPREAD_SPECTRUM)

This register contains fractional pll spread spectrum control registers.

15.9.5.3.1 Offset

Register	Offset	Description
SPREAD_SPECTRUM	10h	Fractional PLL Spread Spectrum Control Register
SPREAD_SPECTRUM_SET	14h	Writing a 1 to a bit in this register sets the corresponding bit in SPREAD_SPECTRUM
SPREAD_SPECTRUM_CLR	18h	Writing a 1 to a bit in this register clears the corresponding bit in SPREAD_SPECTRUM
SPREAD_SPECTRUM_TOG	1Ch	Writing a 1 to a bit in this register toggles the corresponding bit in SPREAD_SPECTRUM

15.9.5.3.2 Diagram



15.9.5.3.3 Fields

Field	Description
31-16	Stop
STOP	Spread Spectrum Stop Register. Frequency change = step/MFD*24MHz.
15	Enable
ENABLE	This bit enables the spread spectrum modulation.
14-0	Step
STEP	Spread Spectrum Step The max frequency change = stop/MFD*24MHz.

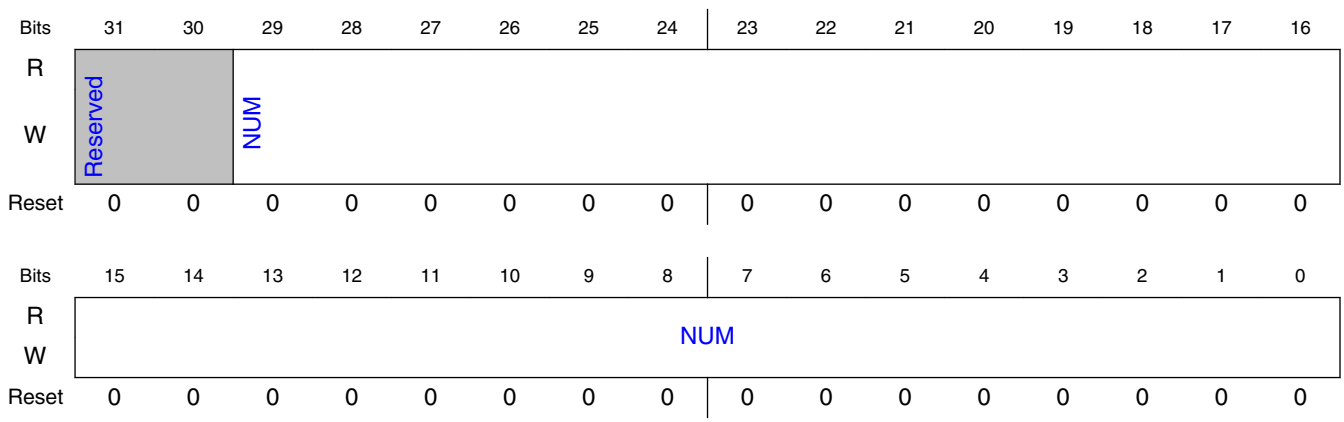
15.9.5.4 Fractional PLL Numerator Control Register (NUMERATOR)

This register contains fractional pll numerator control registers.

15.9.5.4.1 Offset

Register	Offset	Description
NUMERATOR	20h	Fractional PLL Numerator Control Register
NUMERATOR_SET	24h	Writing a 1 to a bit in this register sets the corresponding bit in NUMERATOR
NUMERATOR_CLR	28h	Writing a 1 to a bit in this register clears the corresponding bit in NUMERATOR
NUMERATOR_TOG	2Ch	Writing a 1 to a bit in this register toggles the corresponding bit in NUMERATOR

15.9.5.4.2 Diagram



15.9.5.4.3 Fields

Field	Description
31-30 —	Reserved
29-0 NUM	Numerator Numerator of PLL Fractional Loop Divider. Signed number.

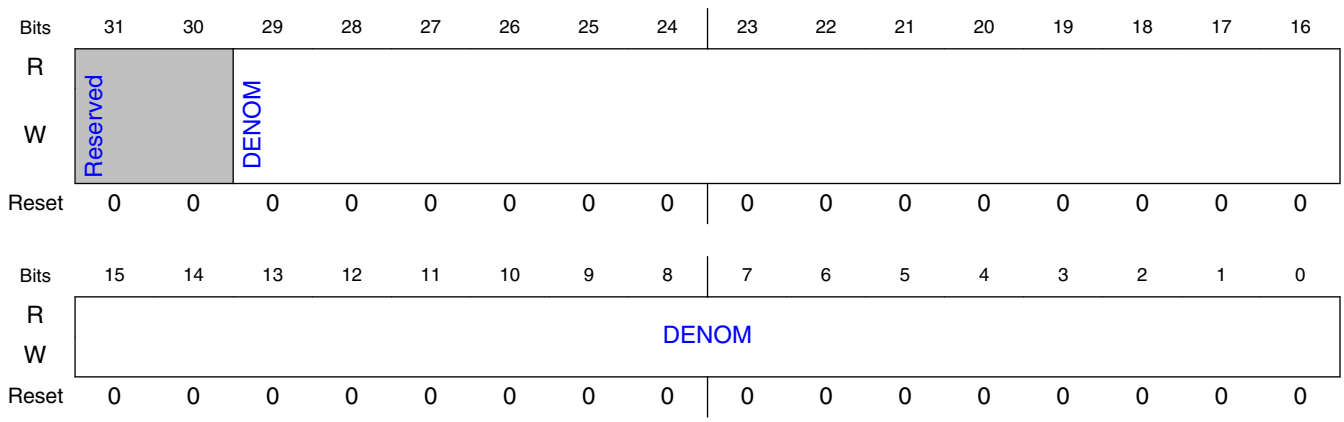
15.9.5.5 Fractional PLL Denominator Control Register (DENOMINATOR)

This register contains fractional pll denominator control registers.

15.9.5.5.1 Offset

Register	Offset	Description
DENOMINATOR	30h	Fractional PLL Denominator Control Register
DENOMINATOR_SET	34h	Writing a 1 to a bit in this register sets the corresponding bit in DENOMINATOR
DENOMINATOR_CLR	38h	Writing a 1 to a bit in this register clears the corresponding bit in DENOMINATOR
DENOMINATOR_TOG	3Ch	Writing a 1 to a bit in this register toggles the corresponding bit in DENOMINATOR

15.9.5.5.2 Diagram



15.9.5.5.3 Fields

Field	Description
31-30 —	Reserved
29-0 DENOM	Denominator Denominator of Fractional Loop Divider. Unsigned number.

Chapter 16
Crystal Oscillator (XTALOSC)

16.1 Chip-specific XTALOSC information

Table 16-1. Reference links to related information

Topic	Related module(s)	Reference
System memory map	-	System Memory Map
Clocking	CCM	Clock Management Clock Control Module (CCM)
Power management	PMU	Power Management Power Management Unit
Signal multiplexing	IOMUX	External Signals and Pin Multiplexing IOMUX
Interrupts, DMA Events and XBAR Assignments	-	Interrupts, DMA Events and XBAR Assignments

16.2 Overview

This block details the function and control of the oscillators on the chip.

This chip contains two Crystal Oscillators for clock generation - 24MHz, and 32KHz. In addition, it also contains four RC oscillators - 48MHz, 32KHz, 16MHz, and 400MHz.

16.2.1 Block Diagram

The Crystal Oscillator block diagram is shown below.

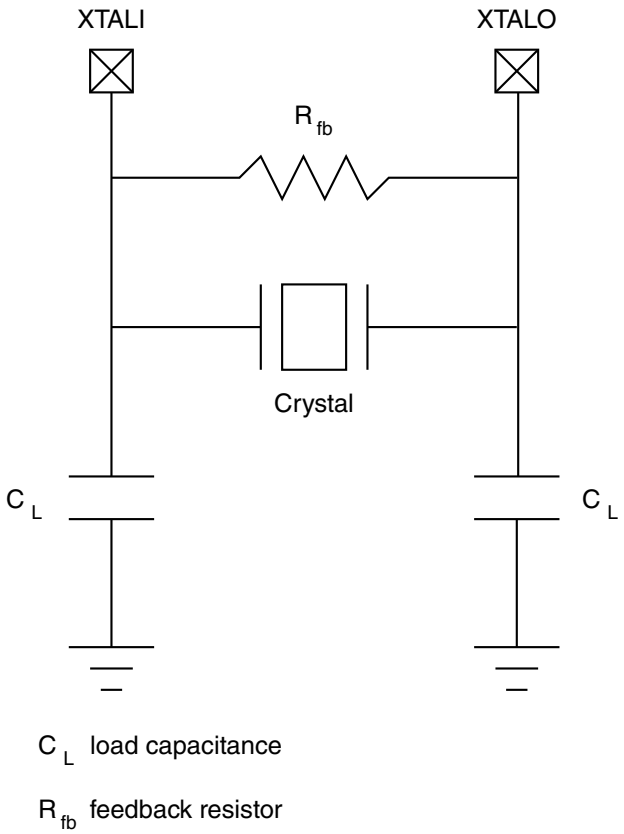


Figure 16-1. Block diagram

The Rfb resistor is used in high gain mode. It is not used in low power mode.

16.3 Functional Description

This section details the oscillator clock sources to the chip.

16.3.1 Crystal Oscillators

The XTALOSC has two external crystal oscillators:

- **24MHz XTAL oscillator**
