  - Primary clock source for all PLLs that generate the clocks for the CPU, Bus, and high-speed interfaces.
  - This clock source can be bypassed by the user, and replaced with another external clock source.
- **32KHz XTAL oscillator**
  - Primary clock source for RTC as well as low-speed clock source for CCM/SRC/GPC.

16.3.1.1 Bypass configuration (24MHz XTAL oscillator)

If it is desired to drive the chip with an external clock source, then it should be connected to XTALI and OSC_24M_CTRL[BYPASS_EN] should be set to 1. XTALO should be left externally floating.

16.3.2 RC Oscillators

The XTALOSC is supported by RC Oscillators (RCOSC). This chip has four RCOSC:

- **48MHz RC oscillator**
  - Generates the 24MHz clock source for the chip during start-up when the external 24MHz crystal is not ready.
  - Alternative 24MHz clock source in low power mode when the crystal oscillator is turned off, or in system which does not have any crystal oscillator.
- **32KHz RC oscillator**
  - 32KHz clock source for the chip during start-up when the external 32KHz crystal is not ready.
  - Alternative 32KHz clock source when the external 32KHz crystal oscillator is not stable, or in system which does not have any crystal oscillator.
- **16MHz RC oscillator**
  - Clock source in low power mode.
- **400MHz RC oscillator**
  - Clock source during chip boot up before PLL is enabled or in low-power mode when PLL is turned off.

NOTE

- The switch from external 32KHz XTALOSC to internal 32KHz RCOSC is controlled by hardware and occurs automatically when the system detects a loss of 32KHz crystal clock.
- To properly switch between 24MHz XTAL and 48MHz internal RC, ensure the PLL is powered down before the switch. After switching the clock, power up PLL.

16.3.3 Analog IP (AI) Interface

The chip has various analog IP and components that are controlled via an AI interface. The AI control registers are used to indirectly program the analog components on the AI bus. The following table shows the AI interface registers relative to their respective analog components and power domains.

Power Domain	Analog Component	AI Registers
SOC2PLL	SYS_PLL1 (1G)	VDDSOC2PLL_AI_CTRL_1G
	AUDIO_PLL	VDDSOC2PLL_AI_WDATA_1G
	VIDEO_PLL	VDDSOC2PLL_AI_RDATA_1G
		VDDSOC2PLL_AI_CTRL_AUDIO
		VDDSOC2PLL_AI_WDATA_AUDIO
		VDDSOC2PLL_AI_RDATA_AUDIO
		VDDSOC2PLL_AI_CTRL_VIDEO
		VDDSOC2PLL_AI_WDATA_VIDEO
		VDDSOC2PLL_AI_RDATA_VIDEO
SOC	PHY LDO	VDDSOC_AI_CTRL
		VDDSOC_AI_WDATA
		VDDSOC_AI_RDATA
		PMU_LDO_PLL
LPSR	Bandgap	VDDLPSR_AI_CTRL
	Tempsensor	VDDLPSR_AI_WDATA
	RCOSC_400M	VDDLPSR_AI_RDATA_REFTOP
		PMU_REF_CTRL
		VDDLPSR_AI400M_CTRL
		VDDLPSR_AI400M_WDATA
		VDDLPSR_AI400M_RDATA
		VDDLPSR_AI_RDATA_TMPSNS

Follow the steps below to perform register accesses through the AI interface.

Steps to perform a write operation of an analog component's AI interface:

1. Write *AI_CTRL register
   - Set RWB value to 0
   - Set ADDR value to the analog component's relative AI control register to be accessed
2. Write *AI_WDATA
   - Set Data[31:0] value to the analog component's relative AI control register value to be written
3. Write *CTRL IP Toggle

- Set TOGGLE value to 1 in the bit position for the respective analog component. The toggle will initiate the write sequence.

Steps to perform a read operation of an analog component's AI interface:

1. Write *AI_CTRL register
   - Set RWB value to 1
   - Set ADDR value to the analog component's relative AI control register to be accessed
2. Write *CTRL IP Toggle
   - Set TOGGLE value to 1 in the bit position for the respective analog component. The toggle will initiate the read sequence
3. Read *CTRL
   - Poll this register until the respective analog component's busy bit is low, indicating the read transaction has completed.
4. Read *AI_RDATA
   - Read Data[31:0]. The contents of the Read Data register is the value of the analog component's respective AI register's contents.

NOTE

Varying IP will have a corresponding identical toggle bit

NOTE

For PLL operations, follow the PLL enable sequence first.

16.4 External Signals

The table found here describes the external signals of XTALOSC:

Table 16-2. XTALOSC External Signals

Signal	Description	Pad	Mode	Direction
RTC_XTALI	Real-time clock crystal oscillator input	RTC_XTALI	No muxing	I
RTC_XTALO	Real-time clock crystal oscillator output	RTC_XTALO	No muxing	O
XTALI	Crystal oscillator input signal	XTALI	No muxing	I
XTALO	Crystal oscillator output signal	XTALO	No muxing	O

16.5 Memory Map and register definition

This section includes the module memory map and detailed descriptions of all registers.

NOTE

For related IPS Domain Slot control, please see IPS Domain Registers in Power Management Unit (PMU) chapter.

16.5.1 OSC register descriptions

16.5.1.1 OSC memory map

osc base address: 40C8_4000h

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)
10	48MHz RCOSC Control Register (OSC_48M_CTRL)	32	RW	0179_01F2
20	24MHz OSC Control Register (OSC_24M_CTRL)	32	RW	0000_0080
40	400MHz RCOSC Control0 Register (OSC_400M_CTRL0)	32	RW	0000_0000
50	400MHz RCOSC Control1 Register (OSC_400M_CTRL1)	32	RW	0000_0001
60	400MHz RCOSC Control2 Register (OSC_400M_CTRL2)	32	RW	0000_0000
C0	16MHz RCOSC Control Register (OSC_16M_CTRL)	32	RW	0000_0007

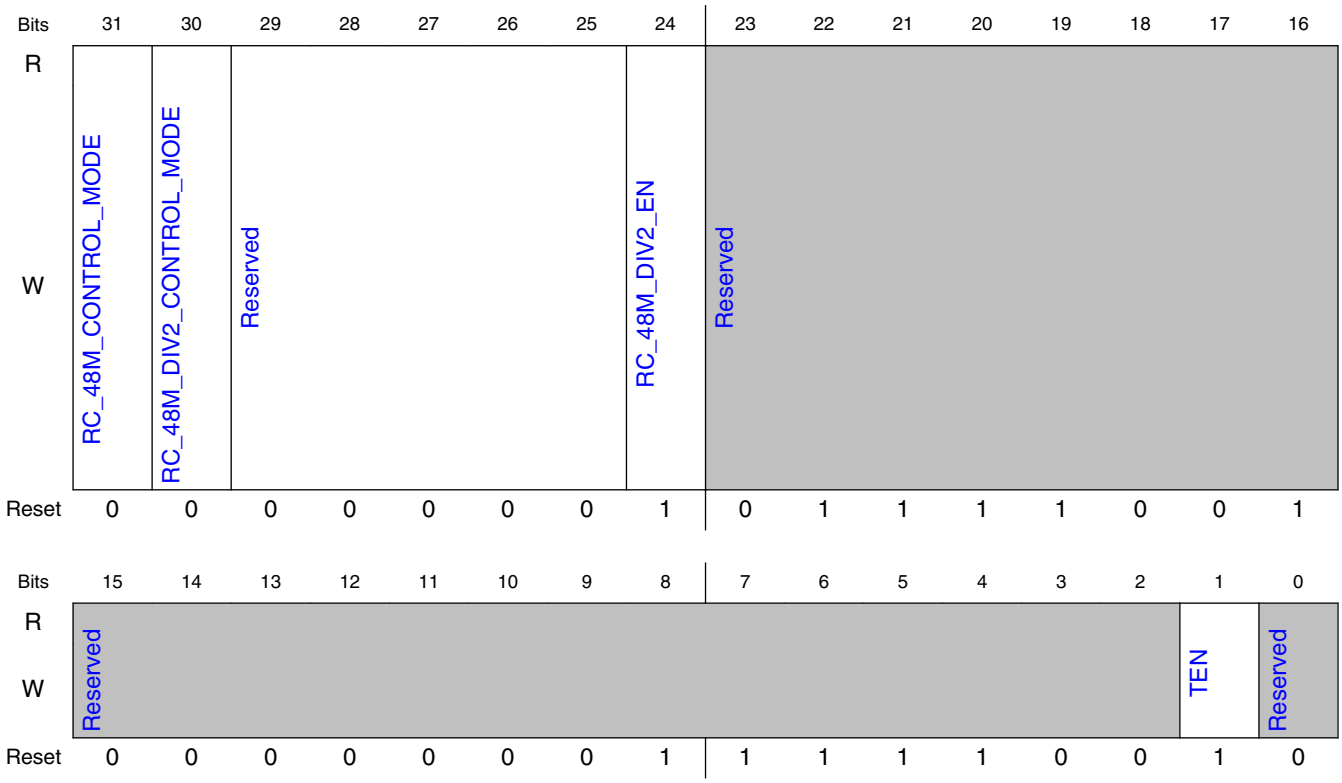
16.5.1.2 48MHzRCOSC Control Register (OSC_48M_CTRL)

This register is used to control the 48MHz RC oscillator.

16.5.1.2.1 Offset

Register	Offset
OSC_48M_CTRL	10h

16.5.1.2.2 Diagram



16.5.1.2.3 Fields

Field	Description
31 RC_48M_CONTROL_MODE	48MHzRCOSC Control Mode This field selects between GPC mode and Software mode 0 - Software mode (default) 1 - GPC mode (Setpoint)
30 RC_48M_DIV2_CONTROL_MODE	RCOSC_48M_DIV2 Control Mode This field selects between GPC mode and Software mode 0 - Software mode (default) 1 - GPC mode (Setpoint)
29-25 —	Always set to zero
24 RC_48M_DIV2_EN	RCOSC_48M_DIV2 Enable This field enables/disables the 24MHz clock sourced from 48MHz RCOSC 0 - Disable 1 - Enable
23-2	Reserved

Table continues on the next page...

Field	Description
—	
1 TEN	48MHzRCOSC Enable This field powers up or powers down the 48MHz RCOSC 0 - Power down 1 - Power up
0 —	Reserved

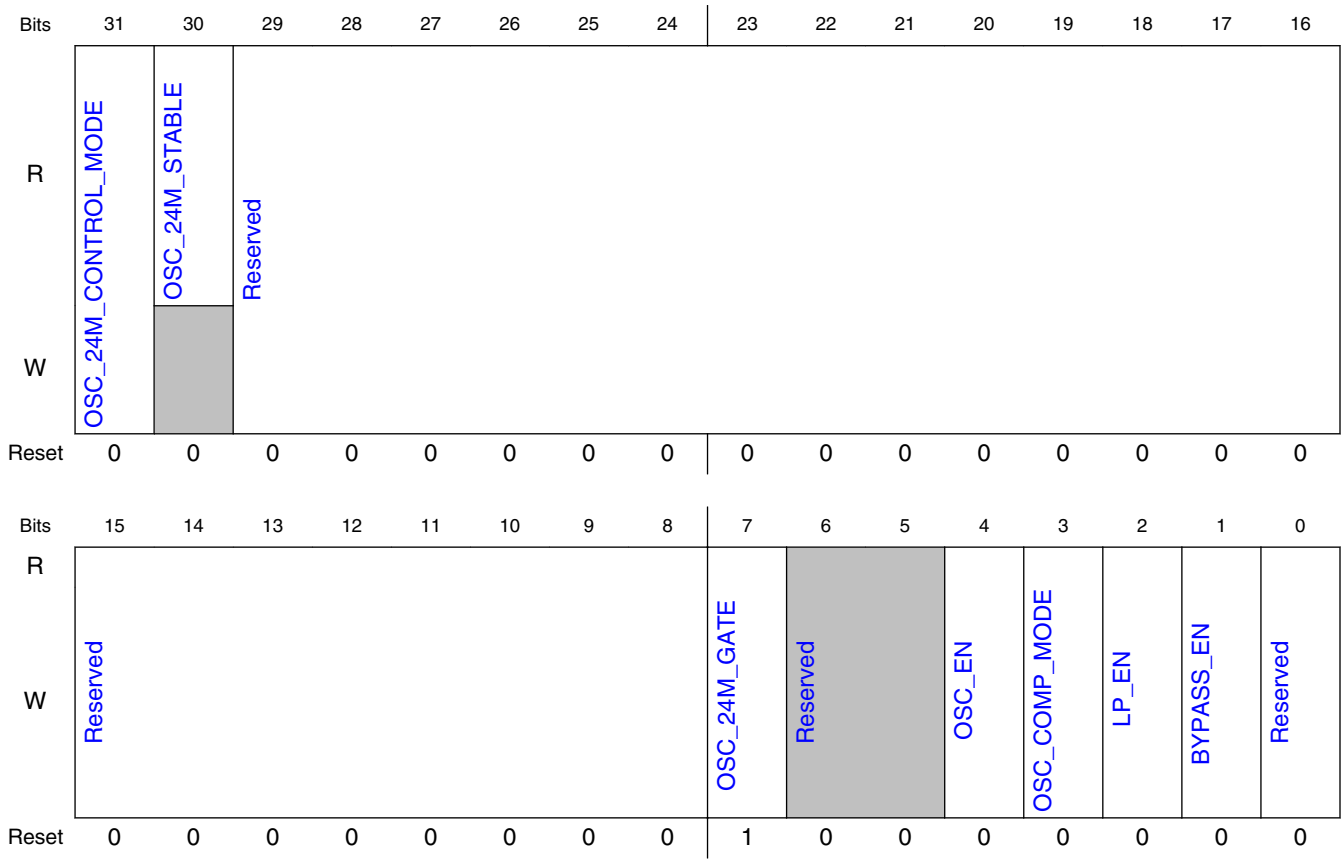
16.5.1.3 24MHz OSC Control Register (OSC_24M_CTRL)

This register is used to control the 24MHz Oscillator.

16.5.1.3.1 Offset

Register	Offset
OSC_24M_CTRL	20h

16.5.1.3.2 Diagram



16.5.1.3.3 Fields

Field	Description
31 OSC_24M_CONTROL_MODE	24MHz OSC Control Mode This field selects between GPC mode and Software mode 0 - Software mode (default) 1 - GPC mode (Setpoint)
30 OSC_24M_STABLE	24MHz OSC Stable This field indicates whether 24MHzOSC is stable (24MHz OSC will not be stable the time it is enabled) 0 - Not Stable 1 - Stable
29-8 —	Always set to zero
7 OSC_24M_GATE	24MHz OSC Gate Control This field gates the 24MHz OSC output for saving power 0 - Not Gated

Table continues on the next page...

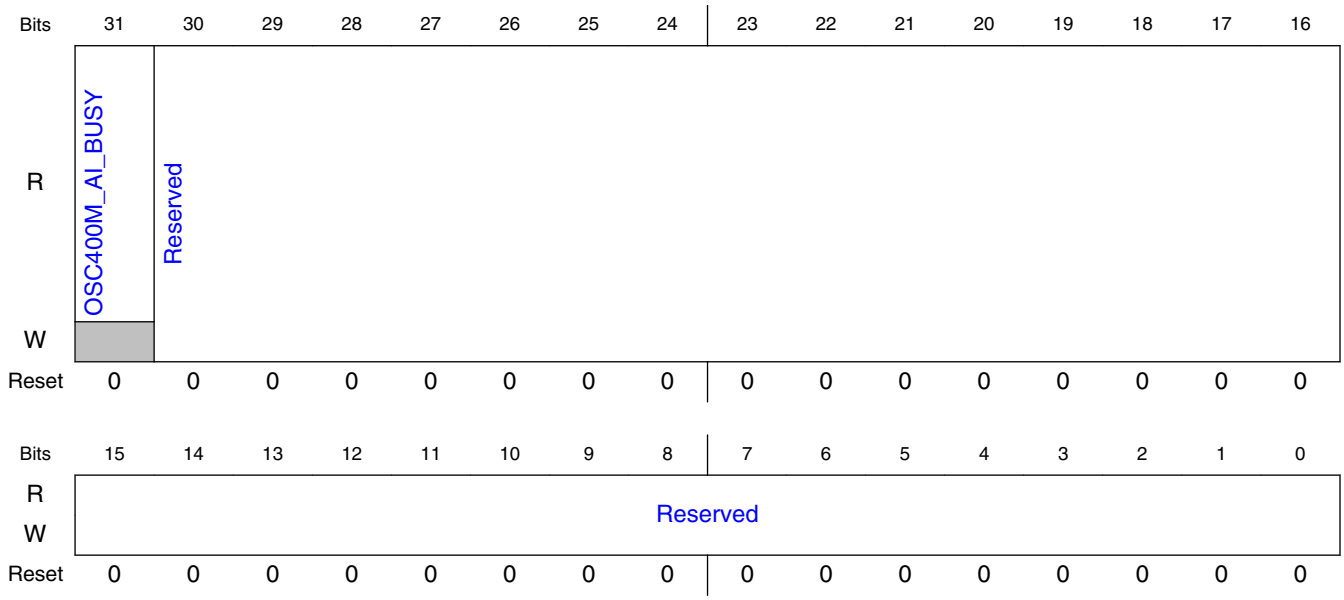
Field	Description
	1 - Gated
6-5 —	Reserved
4 OSC_EN	24MHzOSC Enable This field enables the 24MHz XTALOSC 0 - Disable 1 - Enable
3 OSC_COMP_MODE	24MHz OSC Comparator Mode This field selects the ac-coupling comparator operation-mode 0 - Single-ended mode (default) 1 - Differential mode (test mode)
2 LP_EN	24MH OSC Low-Power Mode Enable 0 - High Gain mode (HP) 1 - Low-power mode (LP)
1 BYPASS_EN	24MHz OSC Bypass Enable Enable signal for external bypass clock (mostly connect to XTAL directly in SOC level). Users can use this filed to enable an external source of XTAL. 0 - Disable 1 - Enable
0 -	Reserved

16.5.1.4 400MHz RCOSC Control0 Register (OSC_400M_CTRL0)

16.5.1.4.1 Offset

Register	Offset
OSC_400M_CTRL0	40h

16.5.1.4.2 Diagram



16.5.1.4.3 Fields

Field	Description
31 OSC400M_AI_BUSY	400MHz OSC AI BUSY This field is associated with AI busy monitor function in AI bus. Please see 'Analog IP (AI) Interface' topic for more details.
30-0 —	Always set to zero

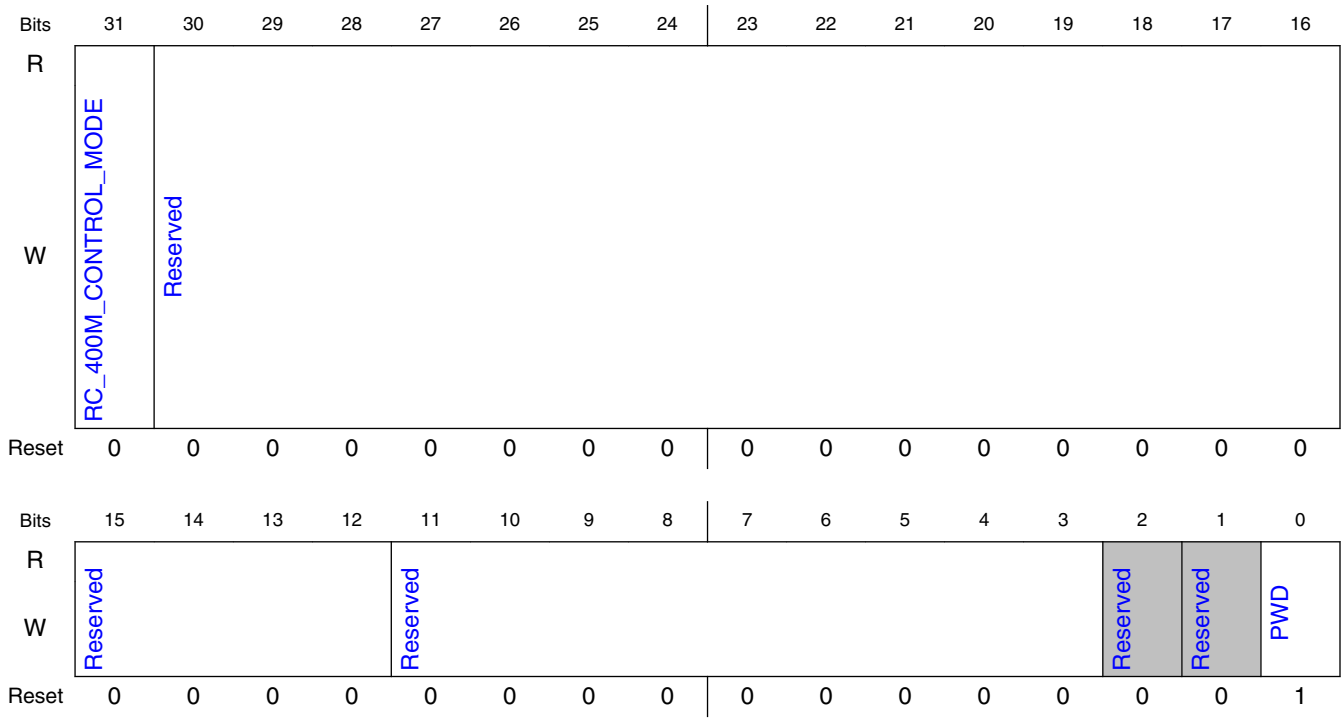
16.5.1.5 400MHz RCOSC Control1 Register (OSC_400M_CTRL1)

This register provides the controls for clock gate, power down, and 400MHz RCOSC mode selects.

16.5.1.5.1 Offset

Register	Offset
OSC_400M_CTRL1	50h

16.5.1.5.2 Diagram



16.5.1.5.3 Fields

Field	Description
31 RC_400M_CONTROL_MODE	rc_400m_control_mode This field selects between GPC mode and Software mode 0 - Software mode (default) 1 - GPC mode (Setpoint)
30-12 —	Always set to zero
11-3 —	Always set to zero
2 —	Reserved
1	Reserved
0 PWD	Power down control for 400MHz RCOSC 400MHz RCOSC can be powered down directly with this bit. There is no need to follow AI bus sequence 0 - No Power down 1 - Power down

16.5.1.6 400MHz RCOSC Control2 Register (OSC_400M_CTRL2)

This register provides the OSC tune value and clock enable control used for HW mode.

16.5.1.6.1 Offset

Register	Offset
OSC_400M_CTRL2	60h

16.5.1.6.2 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	OSC_TUNE_VAL								Reserved							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	Reserved	Reserved			Reserved	TUNE_BYP	Reserved		Reserved							ENABLE_CLK
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

16.5.1.6.3 Fields

Field	Description
31-24 OSC_TUNE_VAL	Oscillator Tune Value These bits determine the frequency of oscillator when tuning is not enabled. Frequency varies with PVT. 0 - Lowest frequency 255 - Highest frequency
23-15 —	Always set to zero
14-12 —	Always set to zero
11 —	Always set to zero

Table continues on the next page...

Field	Description
10 TUNE_BYP	Bypass tuning logic 0 - Use the output of tuning logic to run the oscillator 1 - Bypass the tuning logic and use the programmed OSC_TUNE_VAL to run the oscillator
9-8 —	Always set to zero
7-1 —	Always set to zero
0 ENABLE_CLK	Clock enable This bit is used for the switching between Software mode and GPC mode. ENABLE_CLK is to indicate the GPC mode, the last Software mode RC400M state. It must be programed correspondingly. 0 - Clock is disabled before entering GPC mode 1 - Clock is enabled before entering GPC mode

16.5.1.7 16MHz RCOSC Control Register (OSC_16M_CTRL)

This register is used to control the 16MHz RC oscillator.

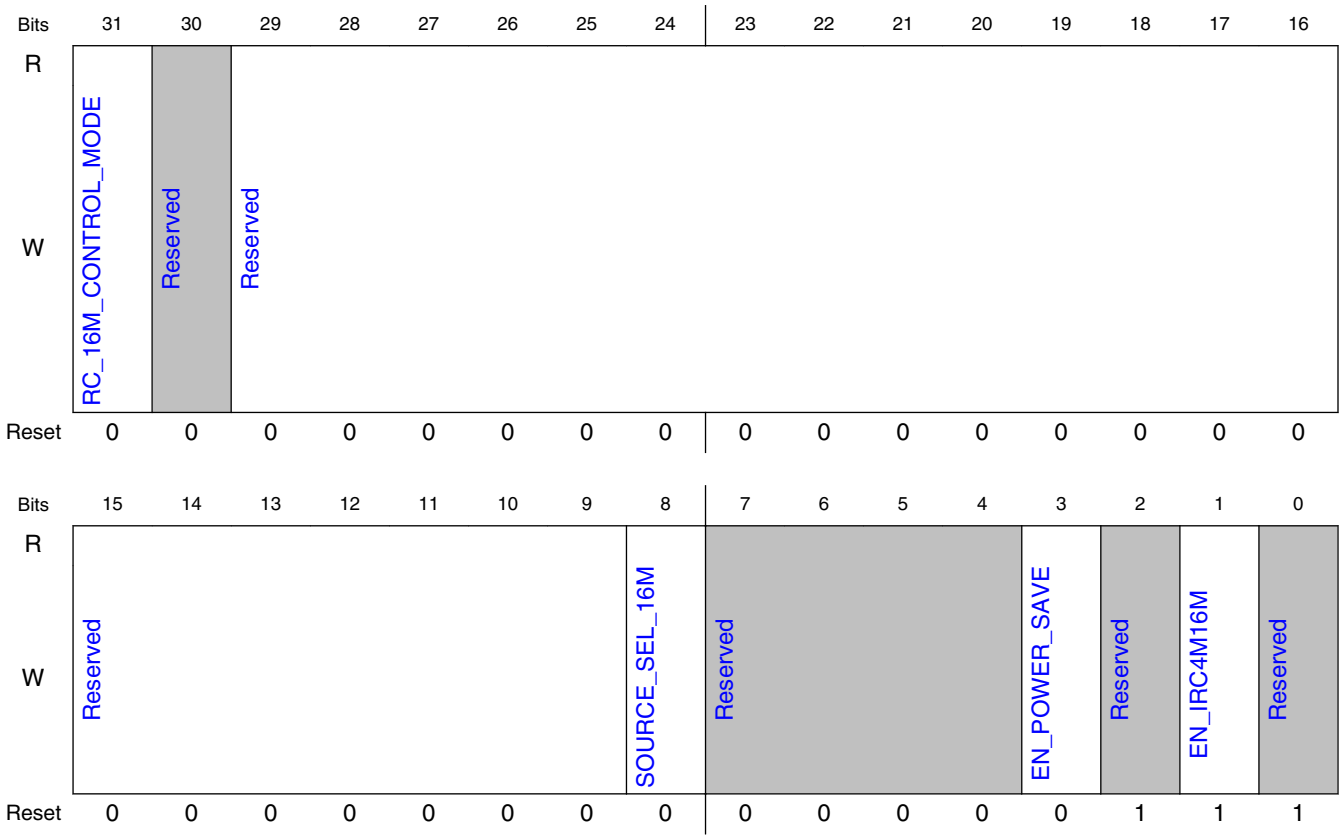
NOTE

The EN_IRC4M16M bit is used to disable/kill the output clocks while keeping the oscillator working. The oscillator should be disabled before powering it down.

16.5.1.7.1 Offset

Register	Offset
OSC_16M_CTRL	C0h

16.5.1.7.2 Diagram



16.5.1.7.3 Fields

Field	Description
31 RC_16M_CONTROL_MODE	Control Mode for 16MHz Oscillator This field selects between GPC mode and Software mode 0 - Software mode (default) 1 - GPC mode (Setpoint)
30 —	Reserved
29-9 —	Always set to zero
8 SOURCE_SEL_16M	Source select This is the source select for 16MHz RC Oscillator. The user can select between the 16MHz RCOSC or 24MHz OSC. 0 - 16MHz Oscillator 1 - 24MHz Oscillator
7-4	Reserved

Table continues on the next page...

Field	Description
—	
3 EN_POWER_SAVE	Power Save Enable Enable the power save mode function at 16MHz 0 - Disable 1 - Enable
2 -	Reserved
1 EN_IRC4M16M	Enable Clock Output This field enables clock output for 16MHz RCOSC (rc4m_en_irc4M16M_1p8v) 0 - Disable 1 - Enable
0 —	Reserved

16.5.2 OSC_RC_400M register descriptions

16.5.2.1 OSC_RC_400M memory map

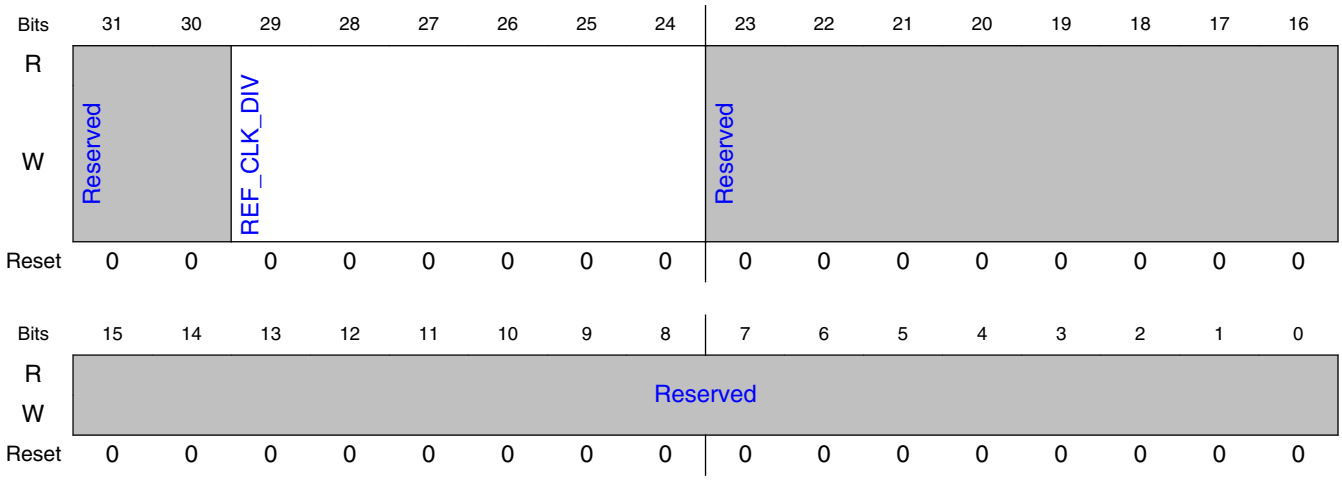
16.5.2.2 Control Register 0 (CTRL0)

This register contains analog control bits.

16.5.2.2.1 Offset

Register	Offset	Description
CTRL0	0h	Control Register 0
CTRL0_SET	4h	Writing a 1 to a bit in this register sets the corresponding bit in CTRL0
CTRL0_CLR	8h	Writing a 1 to a bit in this register clears the corresponding bit in CTRL0
CTRL0_TOG	Ch	Writing a 1 to a bit in this register toggles the corresponding bit in CTRL0

16.5.2.2.2 Diagram



16.5.2.2.3 Fields

Field	Description
31-30 —	Reserved
29-24 REF_CLK_DIV	Divide value for ref_clk to generate slow_clk (used inside this IP) 0: divide by 1 1-63: corresponding division by 1-63. The recommended divide value is 24.
23-0 —	Reserved This read-only field is reserved and always has the value 0.

16.5.2.3 Control Register 1 (CTRL1)

This register contains analog control bits.

16.5.2.3.1 Offset

Register	Offset	Description
CTRL1	10h	Control Register 1
CTRL1_SET	14h	Writing a 1 to a bit in this register sets the corresponding bit in CTRL1
CTRL1_CLR	18h	Writing a 1 to a bit in this register clears the corresponding bit in CTRL1

Table continues on the next page...

Register	Offset	Description
CTRL1_TOG	1Ch	Writing a 1 to a bit in this register toggles the corresponding bit in CTRL1

16.5.2.3.2 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R W	Reserved				HYST_PLUS				Reserved				HYST_MINUS			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

16.5.2.3.3 Fields

Field	Description
31-16 TARGET_COUNT	Target count for the fast clock This field is used to set the desired target for the fast clock (osc_out_400m). Value in no. of clock cycles of the fast_clk (osc_out_400m) per divided ref_clk.
15-12 —	Reserved This read-only field is reserved and always has the value 0.
11-8 HYST_PLUS	Positive hysteresis value for the tuned clock Set this value after the clock is tuned. Value in no. of clock cycles of the fast clock(osc_out_400m).
7-4 —	Reserved
3-0 HYST_MINUS	Negative hysteresis value for the tuned clock Set this value after the clock is tuned. Value in no. of clock cycles of the fast clock(osc_out_400m).

16.5.2.4 Control Register 2 (CTRL2)

This register contains analog control bits.

16.5.2.4.1 Offset

Register	Offset	Description
CTRL2	20h	Control Register 2
CTRL2_SET	24h	Writing a 1 to a bit in this register sets the corresponding bit in CTRL2
CTRL2_CLR	28h	Writing a 1 to a bit in this register clears the corresponding bit in CTRL2
CTRL2_TOG	2Ch	Writing a 1 to a bit in this register toggles the corresponding bit in CTRL2

16.5.2.4.2 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	OSC_TUNE_VAL								Reserved							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

16.5.2.4.3 Fields

Field	Description
31-24 OSC_TUNE_VAL	Program the oscillator frequency These bits determine the frequency of oscillator when tuning is not enabled Frequency varies with PVT. 0 - Lowest frequency. 255 - Highest frequency.
23-15 —	Reserved
14 TUNE_START	Start/Stop tuning 0 - Stop tuning and reset the tuning logic. Oscillator runs using programmed OSC_TUNE_VAL 1 - Start tuning
13	Reserved

Table continues on the next page...

Field	Description
—	This read-only field is reserved and always has the value 0.
12 TUNE_EN	Freeze/Unfreeze the tuning value 0 - Freezes the tuning at the current tuned value. Oscillator runs at the frozen tuning value 1 - Unfreezes and continues the tuning operation
11 —	Reserved This read-only field is reserved and always has the value 0.
10 TUNE_BYP	Bypass the tuning logic 0 - Use the output of tuning logic to run the oscillator 1 - Bypass the tuning logic and use the programmed OSC_TUNE_VAL to run the oscillator
9 —	Reserved This read-only field is reserved and always has the value 0.
8 —	Reserved
7-0 —	Reserved This read-only field is reserved and always has the value 0.

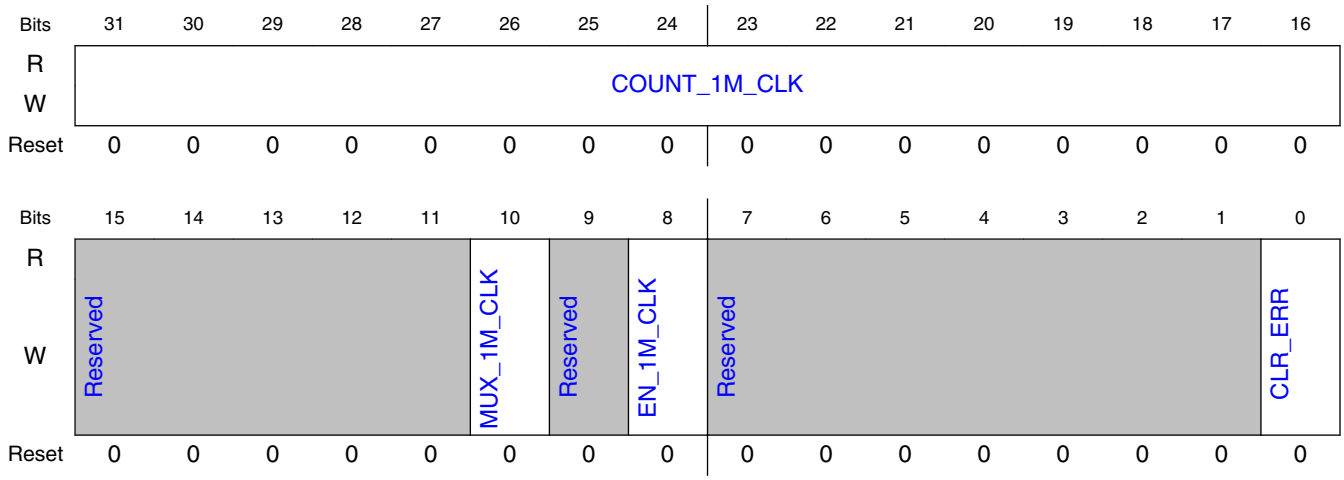
16.5.2.5 Control Register 3 (CTRL3)

This register contains analog control bits.

16.5.2.5.1 Offset

Register	Offset	Description
CTRL3	30h	Control Register 3
CTRL3_SET	34h	Writing a 1 to a bit in this register sets the corresponding bit in CTRL3
CTRL3_CLR	38h	Writing a 1 to a bit in this register clears the corresponding bit in CTRL3
CTRL3_TOG	3Ch	Writing a 1 to a bit in this register toggles the corresponding bit in CTRL3

16.5.2.5.2 Diagram



16.5.2.5.3 Fields

Field	Description
31-16 COUNT_1M_CLK	Count for the locked clk_1m_out This bit field is used to set the desired target for the locked clk_1m_out. Value in no. of clock cycles of the fast_clk (osc_out_400m) per divided ref_clk. **NOTE:** This value should be 4 to 8 counts less than CTRL1[TARGET_COUNT] - CTRL1[HYST_MINUS].
15-11 —	Reserved This read-only field is reserved and always has the value 0.
10 MUX_1M_CLK	Select free/locked 1MHz output 0 - Select free-running 1MHz to be put out on clk_1m_out 1 - Select locked 1MHz to be put out on clk_1m_out
9 —	Reserved This read-only field is reserved and always has the value 0.
8 EN_1M_CLK	Enable 1MHz output Clock Though the name is EN_1M_CLK, it's function is inverted in analog to make this clock enabled by default. This clock is used to keep time. 0 - Enable the output (clk_1m_out) 1 - Disable the output (clk_1m_out)
7-1 —	Reserved
0 CLR_ERR	Clear the error flag CLK1M_ERR 0 - No effect 1 - Clears the error flag CLK1M_ERR in status register STAT0

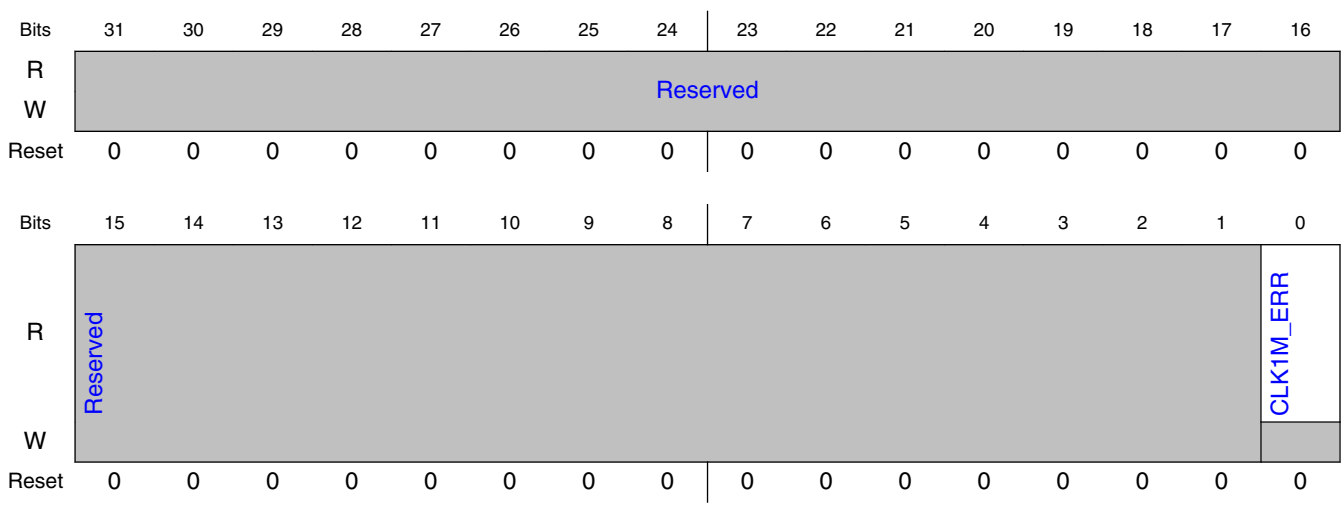
16.5.2.6 Status Register 0 (STAT0)

This register contains analog status bits.

16.5.2.6.1 Offset

Register	Offset	Description
STAT0	50h	Status Register 0
STAT0_SET	54h	Writing a 1 to a bit in this register sets the corresponding bit in STAT0
STAT0_CLR	58h	Writing a 1 to a bit in this register clears the corresponding bit in STAT0
STAT0_TOG	5Ch	Writing a 1 to a bit in this register toggles the corresponding bit in STAT0

16.5.2.6.2 Diagram



16.5.2.6.3 Fields

Field	Description
31-1 —	Reserved This read-only field is reserved and always has the value 0.
0 CLK1M_ERR	Error flag for clk_1m_locked Flag indicates that the count_1m count wasn't reached within one divided ref_clk period. 0 - No effect 1 - The count value has been reached within one divided ref_clk period

16.5.2.7 Status Register 1 (STAT1)

This register contains analog status bits.

16.5.2.7.1 Offset

Register	Offset	Description
STAT1	60h	Status Register 1
STAT1_SET	64h	Writing a 1 to a bit in this register sets the corresponding bit in STAT1
STAT1_CLR	68h	Writing a 1 to a bit in this register clears the corresponding bit in STAT1
STAT1_TOG	6Ch	Writing a 1 to a bit in this register toggles the corresponding bit in STAT1

16.5.2.7.2 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	CURR_COUNT_VAL															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R	Reserved															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

16.5.2.7.3 Fields

Field	Description
31-16 CURR_COUNT_VAL	Current count for the fast clock This field holds the current count during the tuning process. This value converges to TARGET_COUNT as tuning progresses.
15-0 —	Reserved This read-only field is reserved and always has the value 0.

16.5.2.8 Status Register 2 (STAT2)

This register contains analog status bits.

16.5.2.8.1 Offset

Register	Offset	Description
STAT2	70h	Status Register 2
STAT2_SET	74h	Writing a 1 to a bit in this register sets the corresponding bit in STAT2
STAT2_CLR	78h	Writing a 1 to a bit in this register clears the corresponding bit in STAT2
STAT2_TOG	7Ch	Writing a 1 to a bit in this register toggles the corresponding bit in STAT2

16.5.2.8.2 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	CURR_OSC_TUNE_VAL								Reserved							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

16.5.2.8.3 Fields

Field	Description
31-24	Current tuning value used by oscillator
CURR_OSC_TUNE_VAL	This bit field holds the current OSC_TUNE_VAL value which is being used by the oscillator. This value changes as the tuning progresses.
23-0	Reserved
—	This read-only field is reserved and always has the value 0.

Chapter 17
Power Management Unit (PMU)

17.1 Chip-specific PMU information

Table 17-1. Reference links to related information

17.2 Overview

The Power Management Unit (PMU) is designed to simplify the external power interface.

17.2.1 Block Diagram

The power architecture of the chip is illustrated in the figure below, which shows the typical use case of a single 3.3V power supply and a coin cell battery. Depending on the application, different power supply schemes can apply (e.g. DCDC bypassed).

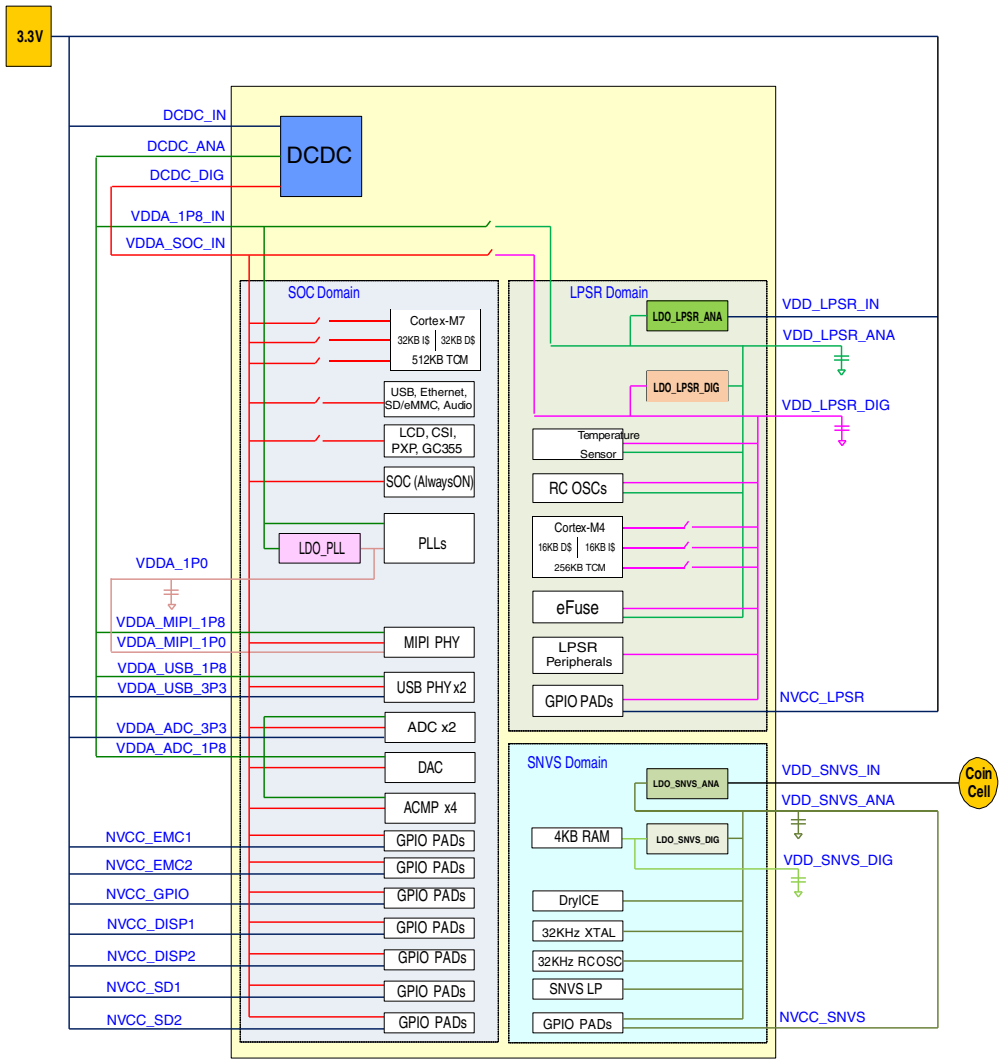

Figure 17-1. Power System Overview

17.2.2 Features

The PMU has the following components integrated for power management:

- One DCDC to generate core power supply, with dynamic voltage scaling capability
- LDOs to generate power for internal logics
- Multiple Power Switches for sophisticated power mode management

17.3 Functional Description

The PMU operations are detailed in the sections below.

17.3.1 Well-Bias configuration

The well-bias configuration is shown below. The NWELL is an adaptive, quiescent consumption, negative voltage output, switched regulator. The PWELL is an adaptive, quiescent consumption, positive voltage tracker, switched regulator. The NWELL and PWELL regulators are biased together, as either FBB or RBB, not both at the same time. Both regulators are connected to RVT and LVT transistors.

- For low-voltage threshold (LVT), FBB is supported. It provides enhanced SoC core performance at a cost of higher leakage.
- For regular-voltage threshold (RVT), RBB is supported. It reduces SoC core consumption with lower leakage.

When the system enters low-power mode, it normally decreases the power supply voltage, then turns on RBB. The VDDA_SOC_IN and VDD_LPSR_ANA supplies need to be settled before the well-bias regulator is turned on (WB_EN). Both supplies need to be settled for FBB as well.

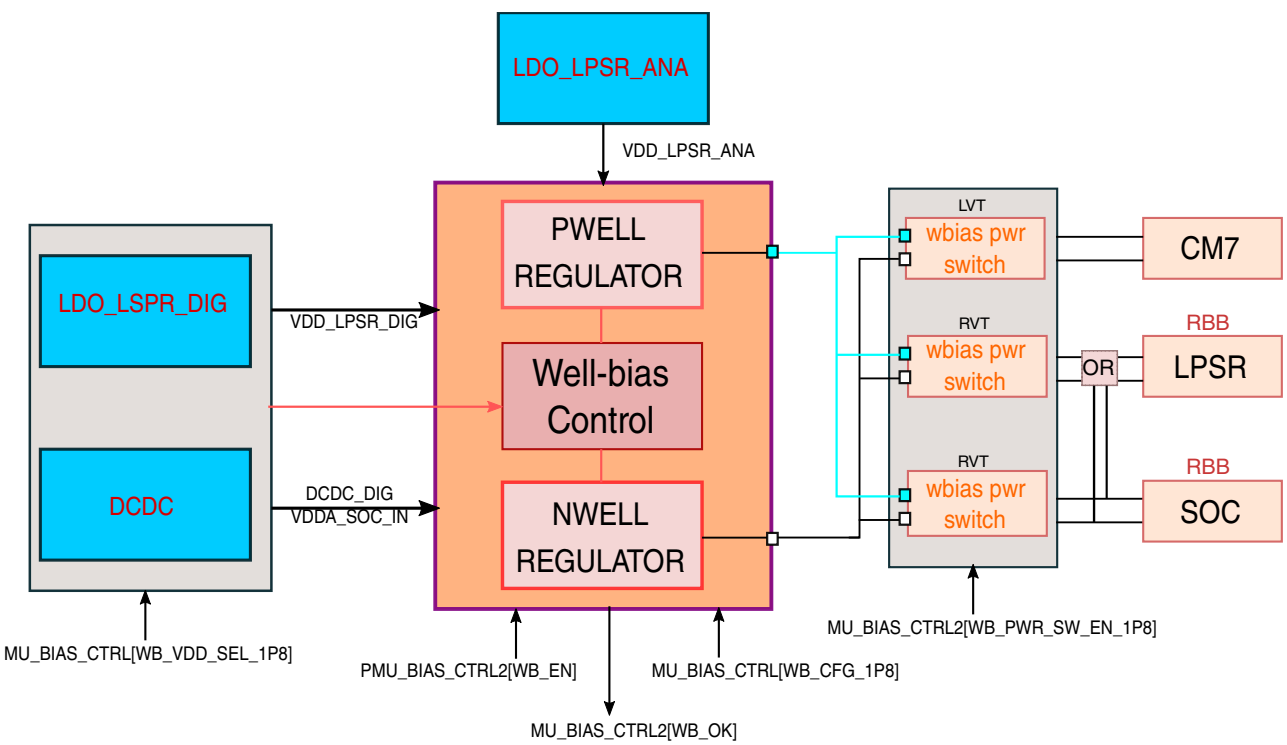

Figure 17-2. Well-Biasing Block Diagram

NOTE

The VDD selection (WB_VDD_SEL_1P8) depends on whether SoC RBB or LPSR RBB is set. This selection needs to be done before enabling well-bias.

17.3.1.1 Body Biasing (BB)

Forward Body Biasing (FBB) and Reverse Body Biasing (RBB) areis implemented to boost performance and reduce power. The implementation of BB in each power domain are listed below:

- FBB is implemented in Cortex-M7 Platform to achieve higher performance
- RBB is implemented in LPSR and SoC power domains to reduce power consumption in low-power modes

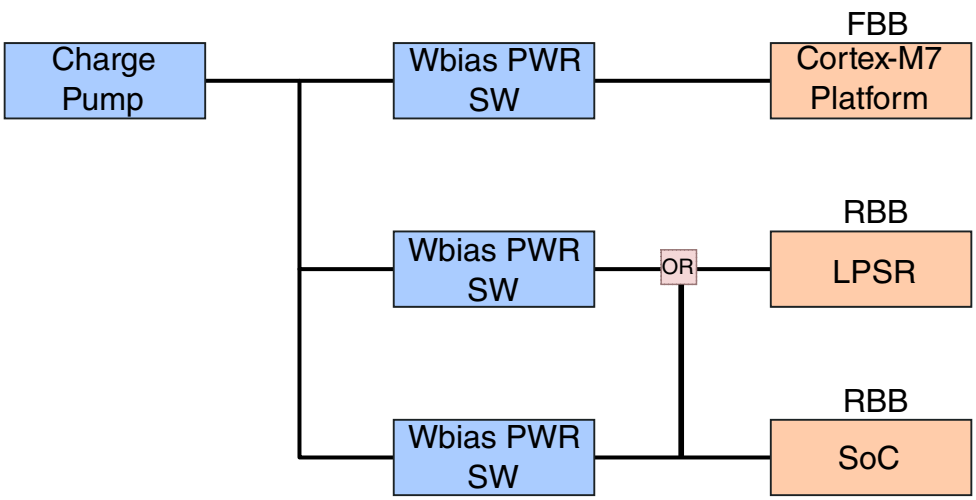

Figure 17-3. Body Biasing Diagram

NOTE

Software must ensure that FBB and RBB are not enabled simultaneously, only one can be used at a time.

17.3.2 Control Mode

The PMU supports two control modes that can be configured by x_CONTROL_MODE fields. These two modes are Sofware control mode and Hardware control mode.

- The Software control mode enables LDOs, switches, and bandgap to be fully configured by registers.
- The Hardware control mode enables the ON/OFF of the LDOs, LDO bypass switches, and bandgap to be configured by GPC Setpoints. The voltage of LPSR_DIG and operation modes of LDOs (lp_mode), are also configured by GPC Setpoints. The other settings remain unchanged.

The following table shows the functions controlled by GPC:

Table 17-2. Functions controlled by GPC

IP	ON/OFF Control	Operation Mode	Tracking Mode	Bypass Mode (Switch ON/ OFF)	Standby Mode (Low Power Mode)	Voltage Control
LDO_PLL	Y	-	-	-	Y	-
LPSR_ANA	-	HP/LP	Y	Y	HP/LP	-
LPSR_DIG	-	HP/LP	Y	Y	HP/LP	Y
REFTOP (Bandgap)	Y	-	-	-	Y	-
FBB_M7	Y	-	-	-	Y	-
RBB_SOC	Y	-	-	-	Y	-
RBB_LPSR	Y	-	-	-	Y	-

Each time there is a change in Setpoint, there will be two steps of requests - voltage down and voltage up. The new target is compared with the current setting to check if the voltage change should happen at each step. When there is a Setpoint change request, the 'done' signals will be generated until all the settings have been changed. When there is a standby in request, the acknowledge signal will be held high until the set modules are put into low-power mode. When there is standby out request, the acknowledge signal will held high until the modules are brought back from low power mode.

17.3.2.1 ON/OFF Control Mode

- The ON/OFF control for LDOs:
  - When LDO_x_CONTROL_MODE = 0 (Software control mode) LD0_x_ENABLE controls the ON/OFF
  - When LDO_x_CONTROL_MODE = 1 (Hardware / GPC control mode) system is in Setpoint n, and LDO_x_ENABLE_SP[ON_OFF_SETPOINTn] controls the ON/OFF
- Biasing ON/OFF:

  - When yBB_x_CONTROL_MODE = 0 (Software control mode) yBB_x_ENABLE controls the ON/OFF of the Biasing Circuit
  - When yBB_x_CONTROL_MODE = 1 (Hardware / GPC control mode) system is in Setpoint n, and yBB_x_ENABLE_SP[ON_OFF_SETPOINTn] controls the ON/OFF of the biasing circuit
- Bandgap ON/OFF Control:
  - When REF_CONTROL_MODE = 0 (Software control mode) REF_ENABLE controls the ON/OFF of the bandgap
  - When REF_CONTROL_MODE = 1 (Hardware / GPC control mode) system is in Setpoint n, and BANDGAP_ENABLE_SP[ON_OFF_SETPOINTn] controls the ON/OFF of the bandgap

NOTE

Software mode supports flexible control, but care and consideration should be followed in regards to analog dependecies and power structure sequences. In GPC mode, everything is handled precisely by hardware.

17.3.2.2 Low Power Control Mode

GPC will wait for an acknowledgement to be asserted before it continues to the next step. When standby sequence is initiated, GPC will wait for another acknowledgement to be asserted before it continues to the next step. When standby exit sequence is completed, LDO enters the low-power mode based on the following condition:

- When LDO_x_CONTROL_MODE = 0 (Software control mode), LDO_x_LP_MODE register is set
- When LDO_x_CONTROL_MODE = 1 (Hardware / GPC control mode) system is in Setpoint n, and LDO_x_LP_MODE_SP[LP_MODE_SETPOINTn] is set to 1

The LDOs can also enter low power mode based on following condition:

- When LDO_x_CONTROL_MODE = 0 (Software control mode) standby_request signal is asserted, and LDO_x_STBY_EN register is set to 1 (0 by default)
- When LDO_x_CONTROL_MODE = 1 (Hardware / GPC control mode) standby_request signal is asserted, and system in Setpoint n, and LDO_x_STBY_EN_SP[LP_MODE_SETPOINT] is set to 1

17.3.2.3 Tracking Mode

This mode is supported on LDO_LPSR_ANA and LDO_LPSR_DIG domains. When enabled on LDO_LPSR_DIG, it's output will track the VDD_SOC to confirm that the LPSR_DIG voltage is same as the VDD_SOC when bypass mode is enabled. When enabled on LDO_LPSR_ANA, its output will track the VDDA_1P8 to confirm the LPSR_ANA voltage is same as the VDDA_1P8 when bypass mode is enabled.

17.3.2.4 Bypass Mode

When bypass mode is enabled on LDO_LPSR_DIG, it's output will be shorted with VDD_SOC, and the LPSR_DIG domain will be supplied by DCDC_DIG. When bypass mode is enabled on LDO_LPSR_ANA, it's output will be shorted with VDDA_1P8, and the LPSR_ANA domain will be supplied by DCDC_ANA.

NOTE

When tracking is enabled, force low power mode to disable.
Tracking enable should happen before bypass enable and
Tracking disable should happen after bypass disable.

17.3.2.5 Setpoint Change Sequence

The following sequence should be followed to change the LDO_DIG voltage setpoint (Voltage Down):

- The Setpoint voltage down request is asserted by GPC
- The current Setpoint setting is captured, after detecting the rising edge offset point of voltage down request
- The current LDO voltage is compared with the new setting
- If the new setting is lower, the new settings are applied. If the new setting is higher, the request is ignored.
- The setpoint voltage down done signal is asserted

The following sequence should be followed to change the LDO_DIG voltage setpoint (Voltage Up):

- The setpoint voltage up request is asserted by GPC
- The current Setpoint setting after detecting the rising edge offset point of voltage up request
- The current LDO voltage is compared with the new setting

- If the new setting is higher, the new settings are applied. If the new setting is lower, the request is ignored.
- The setpoint voltage up done signal is asserted

17.3.2.6 Well Bias Enable Sequence

The following sequence should be followed to enable Well Bias:

- Set well bias setting(voltage, LVT/RVT)
  - PMU_BIAS_CTRL[1] is set to 1 (NWELL is configured to supply and LVT CORE,FBB)
  - PMU_BIAS_CTRL[12] is set to 1 to enable FBB correctly
  - All the other bits are set to 0
- Turn on CM7 FBB switch, and well bias (must be executed in the same step)
  - PMU_BIAS_CTRL2[WB_EN] is set to 1
  - PMU_BIAS_CTRL2[WB_PWR_SW_EN_1P8] is set to 1
  - All other bits set to 0
- Check the PMU_BIAS_CTRL2[WB_OK] bit to confirm Well Bias is stable

17.3.3 Clocks

The PMU doesn't have any relevant application clock sources.

17.4 External Signals

Please see the supply contact assignments in the datasheet for more information.

17.5 Memory Map and register definition

This section includes the PMU module memory map and detailed descriptions of all registers.

17.5.1 PMU register descriptions

17.5.1.1 PMU memory map

PMU base address: 40C8_4000h

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)
500	PMU_LDO_PLL_REGISTER (PMU_LDO_PLL)	32	RW	0000_0001

17.5.1.2 PMU_LDO_PLL_REGISTER (PMU_LDO_PLL)

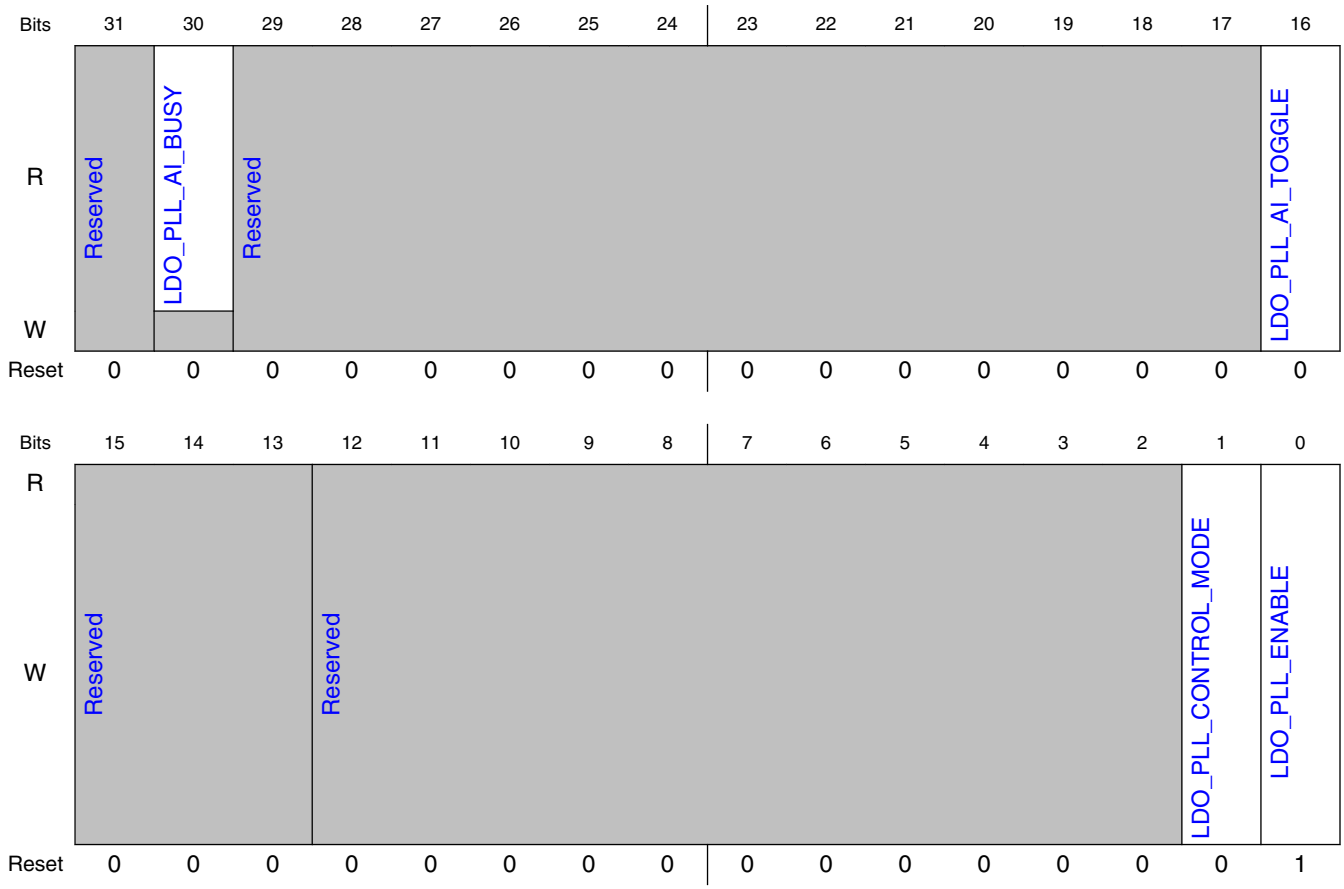
PMU_LDO_PLL_Regulator_Control_Register

This register defines the control and status bits for PLL regulator. This regulator is designed to power the digital portions of the analog cells

17.5.1.2.1 Offset

Register	Offset
PMU_LDO_PLL	500h

17.5.1.2.2 Diagram



17.5.1.2.3 Fields

Field	Description
31 —	Reserved
30 LDO_PLL_AI_BUSY	ldo_pll_busy For this AI bridge register field, there will be a detail description on how to use it.
29-17 —	Reserved Always set to zero (0).
16 LDO_PLL_AI_TOGGLE	ldo_pll_ai_toggle For this AI bridge register field, Please see 'Analog IP (AI) Interface' topic for details on how to use this bit.
15-13 —	Reserved Always set to zero (0).
12-2 —	Reserved

Table continues on the next page...

Field	Description
1 LDO_PLL_CONTROL_MODE	LDO_PLL_CONTROL_MODE LDO_PLL has two mode to for enable. One is software mode, the other is GPC mode(Setpoint). LDO_PLL_CONTROL_MODE select 0 - Software control mode 1 - Hardware / GPC control mode
0 LDO_PLL_ENABLE	LDO_PLL_ENABLE The usage of this bit is for software mode switching to gpc mode: If the Setpoint 0 is ldo_pll on : set this ldo_pll_enable to default state 1. Else the Setpoint 0 is ldo_pll off : set this ldo_pll_enable to state 0. After the mode switched to gpc mode, keep this bit as it is should be fine.

17.5.1.3 PMU_BIAS_CTRL_REGISTER (PMU_BIAS_CTRL)

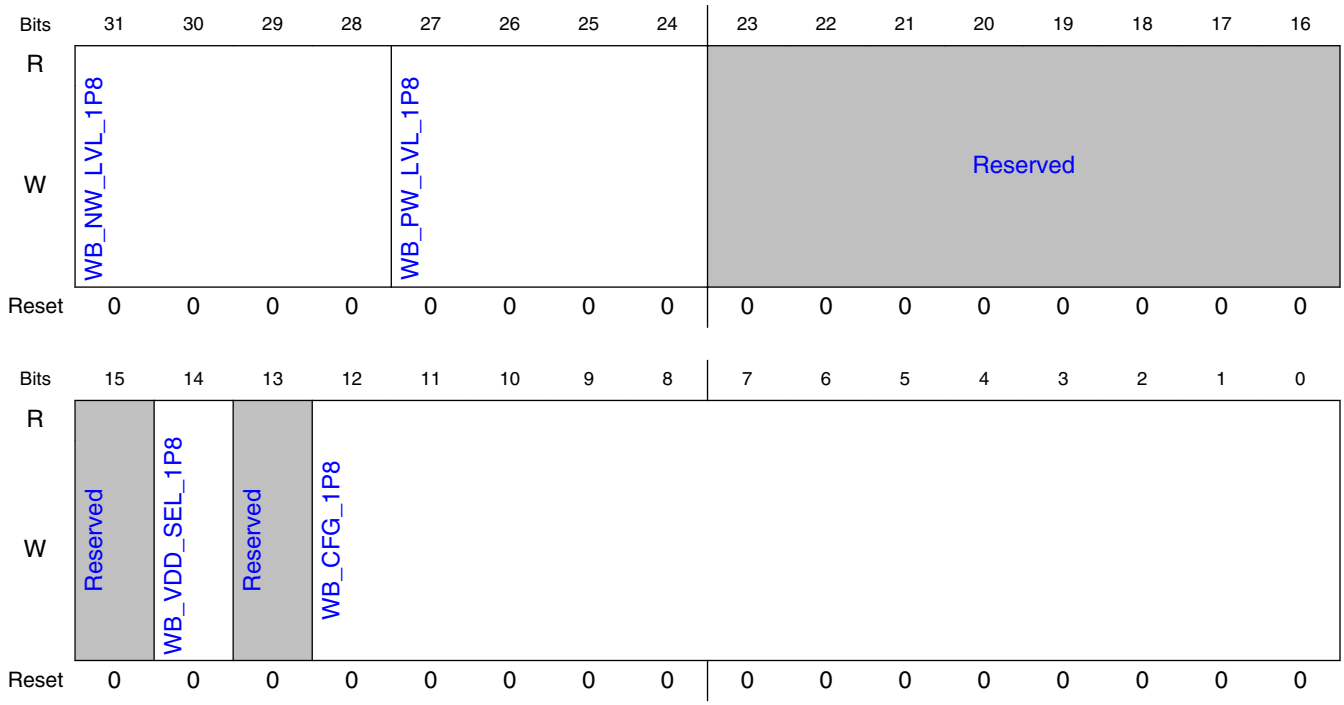
PMU_Well_BIAS_Control_Register

This register defines functions for wb bias.

17.5.1.3.1 Offset

Register	Offset
PMU_BIAS_CTRL	550h

17.5.1.3.2 Diagram



17.5.1.3.3 Fields

Field	Description
31-28 WB_NW_LVL_1P8	WB_NW_LVL_1P8 NW Output voltage range, RBB function enabled; valid range is 0000 ~ 1000. TRIM BUS.
27-24 WB_PW_LVL_1P8	WB_PW_LVL_1P8 PW Output voltage range selection. Valide range is 0000 ~ 1000 TRIM BUS.
23-15 —	Reserved
14 WB_VDD_SEL_1P8	wb_vdd_sel_1p8 Well bias VDD selector 1P8. There are two power sources (LPSR_DIG_LDO or DCDC). **NOTE:** This selection depends on which RBB is working, SOC RBB (DCDC) or LPSR RBB (LPSR_DIG_LDO). This select bit needs to be done before enabling wbias 0 - VDD_LV1 supplies the power stage and NWELL sampler (LPSR_DIG_LDO) 1 - VDD_LV2 supplies the power stage and NWELL sampler (DCDC)
13 —	Reserved
12-0 WB_CFG_1P8	wb_cfg_1p8 Well Bias Configuration 1P8.

Field	Description
	For bit 0 : • 0 PWELL and NWELL is turned on when wb_en_1p8 is set; • 1 PWELL regulator is turned on only when wb_en_1p8 is set. NWELL is kept disabled. For bit 1 : Body bias • 0 NWELL is configured to supply and RVT CORE - RBB. • 1 NWELL is configured to supply and LVT CORE - FBB. For bit 2-4 : Select size of bias area • 000 Imax = 180uA; Areamax-RVT = 6.00mm2 at 125C • 001 Imax = 150uA; Areamax-RVT = 5.00mm2 at 125C • 010 Imax = 120uA; Areamax-RVT = 4.00mm2 at 125C • 011 Imax = 90uA; Areamax-RVT = 3.00mm2 at 125C • 100 Imax = 60uA; Areamax-RVT = 2.00mm2 at 125C • 101 Imax = 45uA; Areamax-RVT = 0.15mm2 at 125C • 110 Imax = 30uA; Areamax-RVT = 1.0mm2 at 125C • 111 Imax = 15uA; Areamax-RVT = 0.50mm2 at 125C For bit 5 : Adaptive function • 1 Adaptive frequency disabled. Frequency determined by wb_cfg_1p8[8:6]. • 0 Frequency change after each half cycle Minimum frequency determined by wb_cfg_1p8[8:6] For bit 6-8 : Oscillator bits • 000 typical frequency = osc_freq/128 • 001 typical frequency = osc_freq/64 • 010 typical frequency = osc_freq/32 • 011 typical frequency =osc_freq/16 • 100 typical frequency = osc_freq/8 • 110 typical frequency = osc_freq/2 • 111 typical frequency = oscillator Frequency (osc_freq) For bit 9 : TRIM BUS. It is used to set an internal adaptive configuration. It configures the adaptive clock source. The options are: 1) the oscillator clock 2) clock synchronous with the Charge Pump clock. These 2 signals have the same frequency, but delayed one to other. It determines if the adaptive control signal changes the frequency in the same or in the next oscillator cycle. • 0 The option is the oscillator clock • 1 The option is clock synchronous with the Charge Pump clock For bit 10 - 11 : TRIM BUS • 00 no frequency reduction • 01 30% frequency reduction due to cap. increment. • 10 40% frequency reduction due to cap. increment. • 11 50% frequency reduction due to cap. increment. For bit 12 : • 1 Pull down option is enabled. • 0 Pull down option is disabled.

17.5.1.4 PMU_BIAS_CTRL2_REGISTER (PMU_BIAS_CTRL2)

Well Bias IP control register

This register defines the test mode function for wb bias.

17.5.1.4.1 Offset

Register	Offset
PMU_BIAS_CTRL2	560h

17.5.2 PMU_LDO_SNVS register descriptions

17.5.2.1 LDO_SNVS memory map

ANADIG base address: 40C8_4000h

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)
510	PMU_LDO_LPSR_ANA_REGISTER (PMU_LDO_LPSR_ANA)	32	RW	0000_0108
520	PMU_LDO_LPSR_DIG_2_REGISTER (PMU_LDO_LPSR_DIG_2)	32	RW	0000_0002
530	PMU_LDO_LPSR_DIG_REGISTER (PMU_LDO_LPSR_DIG)	32	RW	0130_1C05

17.5.2.2 PMU_LDO_LPSR_ANA_REGISTER (PMU_LDO_LPSR_ANA)

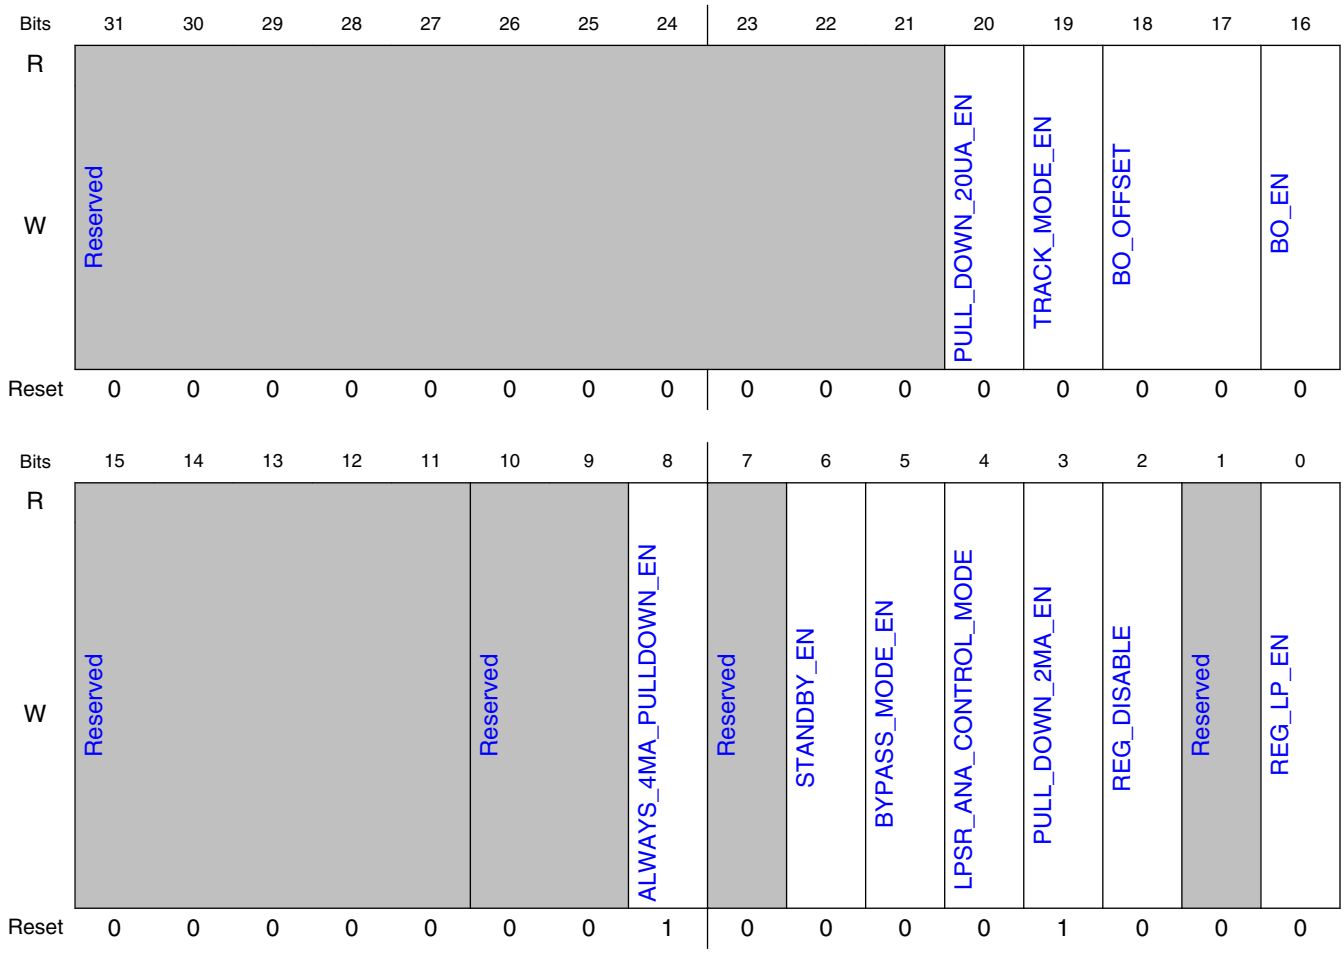
PMU_LDO_LPSR_ANA_Regulator_Control_Register

This register defines the control and status bits for LDO_LPSR_ANA regulator. This regulator is designed to power the digital portions of the analog cells

17.5.2.2.1 Offset

Register	Offset
PMU_LDO_LPSR_ANA	510h

17.5.2.2.2 Diagram



17.5.2.2.3 Fields

Field	Description
31-21 —	Reserved Always set to zero (0).
20 PULL_DOWN_20UA_EN	pull_down_20ua_en High: enable 20uA loading to prevent the overshoot.
19 TRACK_MODE_EN	Track Mode Enable This bit lets the power switch enter a preparation stage that allows power supply switching between LDO and DCDC. This bit should be set before the power supply switch and cleared after power switch is complete. This bit is used during software mode. 0 - Normal use 1 - Switch preparation

Table continues on the next page...

Field	Description
18-17 BO_OFFSET	bo_offset 00: 100mv 01: 75mv 10: 50mv 11: 25mv
16 BO_EN	BO_EN Enable the brown out detector.
15-11 —	Reserved Always set to zero (0).
10-9 —	Reserved Always set to zero (0).
8 ALWAYS_4MA_PULLDOWN_EN	always_4ma_pulldown_en High: enable 4mA loading to prevent the big voltage drop when a sharp loading coming.It's recommend to set this bit to high under the reset, and set it to low under the normal use case.
7 —	Reserved Always set to zero (0).
6 STANDBY_EN	standby_en This is the standby mode for LDO_LPSR_ANA
5 BYPASS_MODE_EN	bypass_mode_en Work together with track_mode_enable to ensure the LDO_1P8 can be bypassed by DCDC_1P8 well. This the bypass mode for lpsr_ana
4 LPSR_ANA_CONTROL_MODE	LPSR_ANA_CONTROL_MODE LPSR_ANA_CONTROL_MODE This bit is the mode select between software mode and GPC mode. 0 - SW Control. Software control mode 1 - HW Control. Hardware / GPC control mode
3 PULL_DOWN_2MA_EN	pull_down_2ma_en High: enable 2mA loading to prevent the overshoot.
2 REG_DISABLE	reg_disable high: disable the output of "vreg_1p8"
1 —	Reserved
0 REG_LP_EN	reg_lp_en High: enable the low-power mode of the ldo

17.5.2.3 PMU_LDO_LPSR_DIG_2_REGISTER (PMU_LDO_LPSR_DIG_2)

PMU_LDO_LPSR_DIG_2_Regulator_Control Register

This register defines the control and status bits for LDO_LPSR_DIG regulator. This regulator is designed to power the digital portions of the analog cells

24-20 VOLTAGE_SELECT	VOLTAGE_SELECT VOLTAGE SELECT for LPSR_DIG For lpsr_dig voltage switch to different voltage In SW mode, software is responsible to take care of the stepping time. In HW mode, hardware is responsible to take care of the stepping time. During the mode transistion, in case the lpsr_dig voltage is out of table, software is responsible to take care of the stepping time (i.e. mode transist), software calculates the steps difference multiply the stepping requirement, after the voltage is stable. GPC mode transistion is allowed. The values below are the stable voltage with the range in parentheses (e.g. Stable Voltage (Range)V). 00000 - Stable Voltage (range). 0.631 (+0.039)V 00001 - Stable Voltage (range). 0.65 (+0.041)V 00010 - Stable Voltage (range). 0.67 (+0.041)V 00011 - Stable Voltage (range). 0.689 (+0.043)V 00100 - Stable Voltage (range). 0.709 (+0.044)V 00101 - Stable Voltage (range). 0.728 (+0.045)V 00110 - Stable Voltage (range). 0.748 (+0.046)V 00111 - Stable Voltage (range). 0.767 (+0.047)V 01000 - Stable Voltage (range). 0.786 (+0.049)V 01001 - Stable Voltage (range). 0.806 (+0.05)V 01010 - Stable Voltage (range). 0.825 (+0.051)V 01011 - Stable Voltage (range). 0.845 (+0.052)V 01100 - Stable Voltage (range). 0.864 (+0.054)V 01101 - Stable Voltage (range). 0.883 (+0.055)V 01110 - Stable Voltage (range). 0.903 (+0.056)V 01111 - Stable Voltage (range). 0.922 (+0.057)V 10000 - Stable Voltage (range). 0.942 (+0.058)V 10001 - Stable Voltage (range). 0.961 (+0.06)V 10010 - Stable Voltage (range). 0.981 (+0.06)V 10011 - Stable Voltage (range). 1 (+0.062)V 10100 - Stable Voltage (range). 1.019 (+0.063)V 10101 - Stable Voltage (range). 1.039 (+0.064)V 10110 - Stable Voltage (range). 1.058 (+0.066)V 10111 - Stable Voltage (range). 1.078 (+0.066)V 11000 - Stable Voltage (range). 1.097 (+0.068)V 11001 - Stable Voltage (range). 1.117 (+0.069)V 11010 - Stable Voltage (range). 1.136 (+0.07)V 11011 - Stable Voltage (range). 1.155 (+0.072)V 11100 - Stable Voltage (range). 1.175 (+0.072)V 11101 - Stable Voltage (range). 1.194 (+0.074)V

Table continues on the next page...

Field	Description
	11110 - Stable Voltage (range). 1.214 (+0.075)V 11111 - Stable Voltage (range). 1.233 (+0.076)V
19 —	Reserved Always set to zero (0).
18 BYPASS_MODE	bypass_mode bypass_mode This mode is defined by ANALOG IP, and this bit is software mode control bit to enter this bypass mode or not.
17 TRACKING_MODE	tracking_mode tracking_mode. This mode is defined by ANALOG IP, and this bit is software mode control bit to enter this tracking mode or not.
16-7 —	Reserved Always set to zero (0).
6 STANDBY_EN	standby_en standby_en There is Standby mode defined in SOC, this bit is about whether to enter standby mode for lpsr_dig
5 LPSR_DIG_CONTROL_MODE	LPSR_DIG_CONTROL_MODE lpsr_dig_control_mode For LPSR DIG there is two mode for operation, one is software mode, the other is GPC mode. 0 - SW Control. Software control mode 1 - HW Control. Hardware / GPC control mode
4-3 —	Reserved Always set to zero (0).
2 REG_EN	ENABLE_ILIMIT Control bit to enable the current-limit circuitry in the regulator.
1-0 —	Reserved Always set to zero (0).

NOTE

PHY_LDO is also LDO_PLL.

18.2 Overview

The PHY LDO creates a regulated 1.0V output voltage for digital PHYs from an external 1.8V source. The PHY LDO is controlled through the AI interface.

18.2.1 Features

The PHY LDO has the following featurest:

- Analog 200 mA linear regulator
- 1.8V +/- 10% VDD external input
- 1.0V output

- Programmable adjustment in 0.25mV steps (0.6V to 1.375V)
- AI Interface

18.3 Memory Map and register definition

This section includes the PHY LDO module memory map and detailed descriptions of all registers.

NOTE

For related IPS Domain Slot control, please see IPS Domain Registers in Power Management Unit (PMU) chapter.

18.3.1 register descriptions

18.3.1.1 PHY LDO Memory Map

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)
0	Analog Control Register CTRL0 (CTRL0)	32	RW	0000_0000

Power management	PMU	Power Management Power Management Unit
Signal multiplexing	IOMUX	External Signals and Pin Multiplexing IOMUX
Interrupts, DMA Events and XBAR Assignments	-	Interrupts, DMA Events and XBAR Assignments

19.2 Overview

The General Power Controller (GPC) is the centralized power controller, which controls the power mode of the processor(s). The GPC takes the Wait For Interrupt (WFI) signal from CPU platforms, and wakeup events from peripherals, to determine the power mode based on the GPC power management policy. The GPC can also control the power mode transition.

19.2.1 Block diagram

The GPC block consists of the following sub-modules:

- CPU Mode Control (CMC): It contains CPU mode controllers, one for each CPU platform. They control CPU mode of CPU platforms and their private resources.
- UPI CM Mapping (UPI): The connection between CMC and CPU platform is directly hard-wired, but CPU platform can be assigned to any domain in the system. So this block is used to map CPU mode control signals into the correct domain.
- Setpoint Control (SPC): This controls Setpoint status and transition of system resources.
- Standby Control (SBC): It indicates which resource controllers go in and out from standby mode

The figure below shows the block diagram of the General Power Controller.

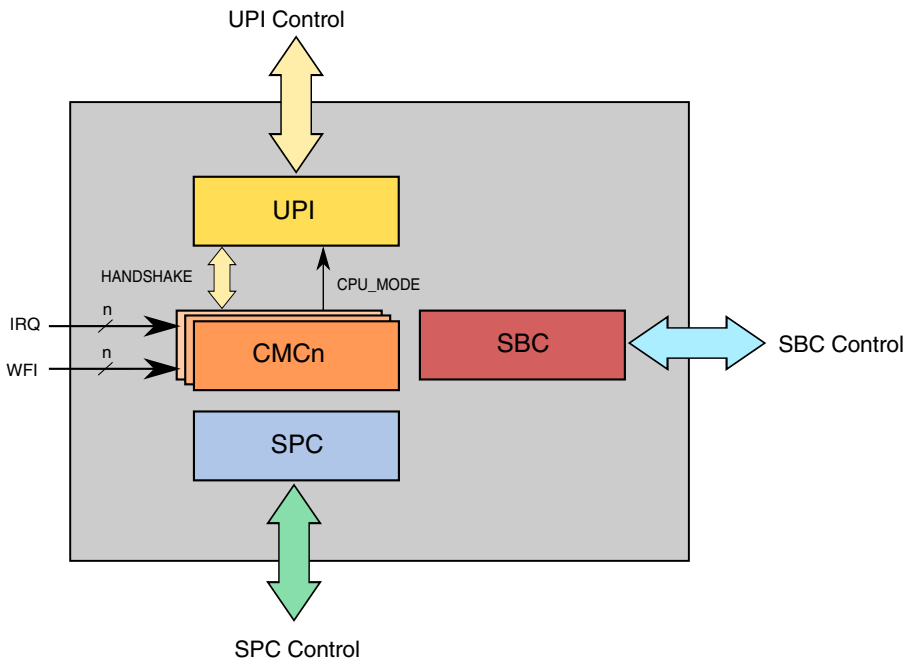

Figure 19-1. GPC block diagram

19.2.2 Features

The GPC includes the following features:

- Standby management
- Domain access control
- Controllable steps of sleep and wakeup sequence

19.3 Functional description

The following sections describe functional details of the GPC module.

19.3.1 CPU Mode Control (CMC)

The CPU mode is a power mode of the CPU platform. The following are the four CPU modes:

Table 19-2. CPU Modes

CPU Mode	Description
RUN	The CPU core is active and running under normal operation. All the blocks inside the CPU platform can be accessed when needed. The state of private resources are fully controlled by software configuration.
WAIT	The CPU is in WFI/WFE state, but can to get back to RUN mode with very short latency. In typical applications, the CPU will enter WAIT mode whenever there is no active thread running. In WAIT mode, the clock to the CPU core is gated off, the cache is clock gated, and the TCM is still active since there are other modules, such as DMA, that still needs access to it.
STOP	The CPU is in WFI/WFE state, and does not require an extremely short exit time. In STOP mode, the clocks to the CPU core, Cache, and TCM are all gated off. The clocks to the bus and peripherals are also gated off. This is the lowest power consumption mode without losing the state of the peripheral. When exiting from STOP mode, there is no need to re-initialize the peripherals.
SUSPEND	Entering SUSPEND mode is for lowest power consumption, and exit time is not critical. In SUSPEND mode, CPU, Cache, and peripherals are all power gated. The biggest difference between SUSPEND and STOP mode is the peripherals will be power gated. Because the peripherals are power gated, entering SUSPEND mode requires the CPU to save the state of the peripherals. When exiting from SUSPEND mode, the CPU needs to restore these states.

CPU Mode transitions happen when the following events occur:

- Sleep Event: CPU enters sleep state with WFI/WFE instruction
- Wakeup Event: Any unmasked IRQ wakeup

On a Sleep Event, the CPU has the option to enter WAIT/STOP/SUSPEND mode, or stay in RUN mode. The transition to WAIT/STOP/SUSPEND is called the sleep sequence, and the next state is configured by CM_MODE_CTRL[CPU_MODE_TARGET].

When CPU is in WAIT/STOP/SUSPEND mode, a wakeup request can wake the CPU, and bring it back to RUN mode. This is transition is called the wakeup sequence. The CM_IRQ_WAKEUP_MASK_n register selects which IRQs can wakeup the CPU platform. There are also non-IRQ requests, which can wakeup the CPU. These non-IRQ requests are configured by the CM_NON_IRQ_WAKEUP_MASK register.

During a CPU mode transition, the GPC communicates with the system resource controllers by sending the target CPU mode and transition step. Please see the UPI interface for more detials.

If a resource is set as private to a single CPU platform, the resource's power state will change with the CPU platform's mode. If a resource is set as shared by multiple CPU platforms, the resource controller needs to look at all the current modes of the CPU platforms to determine the power state of the resource.

19.3.2 Setpoint Control (SPC)

The GPC supports 16 Setpoints. Setpoints are implemented to configure the power state of Public Resources. Public Resources are system-level resources that aren't owned or controlled by any of the CPU platforms.

During Setpoint transition, GPC communicates with system resource controllers through the Unified Power Management Interface (UPI). Setpoint transition is triggered by a request from any of the CPU platforms. The triggers include the following events:

- CPU Sleep Event
  - A sleep event triggers a CPU mode transition, and CPU platform also requests a Setpoint transition after CPU mode transition completes. The field CM_SP_CTRL[CPU_SP_SLEEP_EN] controls whether Setpoint transition will be triggered, and the field CM_SP_CTRL[CPU_SP_SLEEP] controls which Setpoint the CMC want to transfer to.
- CPU Wakeup Event
  - An unmasked wakeup event triggers a CPU mode transition, and CPU platform requests for a Setpoint transition before CPU mode transition starts. The field CM_SP_CTRL[CPU_SP_WAKEUP_EN] controls whether Setpoint transition will be triggered, and the fields CM_SP_CTRL[CPU_SP_WAKEUP] and CM_SP_CTRL[CPU_SP_WAKEUP_SEL] control which set point the CMC want to transfer to.
- Software
  - CPU platform is in RUN mode and the SW running on the CPU core makes a write operation to CMC register CPU_SP_RUN_EN to request for a Setpoint transition. Register CPU_SP_RUN controls which Setpoint the CMC want to transfer to.

With CPU Mode and Setpoint defined properly, the Power Mode of a system is defined as a combination of the CPU Mode and Setpoint.

19.3.3 System Setpoint management

The SPC receives a Setpoint change request from CMCs, it then determines the Setpoint of the system, and manages the transition sequence. When a CMC Setpoint request is accepted, the Setpoint value can then be read from SPC SP_ACCEPTED_CPUn register.

If multiple CPU platforms want to enter different Setpoints, the SPC needs to calculate the final target Setpoint. There is a mapping table between each Setpoint of a CPU platform and the Setpoint, which it can accept. For example, CPU1 requests the system to transit to Setpoint 7 after it transits into STOP mode. CPU1 must provide a Setpoint list to show which Setpoints are also allowed besides SP-7. This is configured by the CMC CM_SPx_MAPPING Register. Below are examples of Setpoint list configurations:

- If CPU1_SP7_MAPPING register is set to 16'b00000000_10011111, CPU1 requests system to transition to SP-7 (bit 7), but also allows transitions to SP-0,1,2,3,4 (bits 0 to 4).
- If CPU0_SP4_MAPPING register is set to 16'b00000000_00010000, CPU0 has requested the system to transit to SP-4 after STOP.

In the SPC, the SP_SYS_STAT[SYS_SP_ALLOWED] field will be the ANDed result of allowed Setpoints from all CMCs. If all bits in SP_SYS_STAT[SYS_SP_ALLOWED] is 0, it means there are no Setpoints allowed by both platforms. This would be an invalid state, and there should be no Setpoint transition in this condition. GPC should generate an error IRQ. Below is an example of allowed Setpoint configuration:

- If SP_SYS_STAT[SYS_SP_ALLOWED] is 16'b00000000_00010000, it means only SP-4 is allowed. The system should transit to this Setpoint.

The calculated Setpoint number can be read at SPC CM_SP_STAT[CPU_SP_TARGET] register.

If more than one bit in SP_SYS_STAT[SYS_SP_ALLOWED] is set to 1, the Setpoint will be picked based on the following rules:

- If the allowed Setpoints match only one SP_CPU_REQ[SP_ACCEPTED_CPUn], this Setpoint will be used as SPC CM_SP_STAT[CPU_SP_TARGET]
- If the allowed Setpoints match more than one SP_CPU_REQ[SP_ACCEPTED_CPUn], the matched Setpoint with highest priority will be used as SPC CM_SP_STAT[CPU_SP_TARGET]
- If the allowed Setpoints do not match any of the SP_CPU_REQ[SP_ACCEPTED_CPUn], the CM_SP_STAT[CPU_SP_TARGET] will be the allowed Setpoint with highest priority

NOTE

The priority settings are set in the SPC SP_PRIORITY_x[SYS_SPn_PRIORITY] register configuration.

19.3.4 Standby Control (SBC)

Standby mode is a low-power mode that has distinguishing settings outside of CPU mode and Setpoint mode. Standby mode is related to state of all CPU platforms and has a much shorter transition time than Setpoint.

The CMC can send a standby request to SBC. The fields CM_STBY_CTRL[STBY_WAIT], CM_STBY_CTRL[STBY_STOP], and CM_STBY_CTRL[STBY_SUSPEND] will determine if the chip enters into Standby mode when the CPU enters WAIT mode, STOP mode, or SUSPEND mode respectively.

The SBC maintains the system standby status, and only when all CPU platforms send standby request, can the system enter into Standby mode. If a CPU is disabled by FUSE, GPC considers it in Standby mode by default.

19.3.5 Unified power management interface (UPI)

GPC does not control the state of the resource directly. During power mode transition, it communicates with the resource controllers through the UPI (Unified Power management Interface) to accomplish the power mode transition.

Handshake Method:

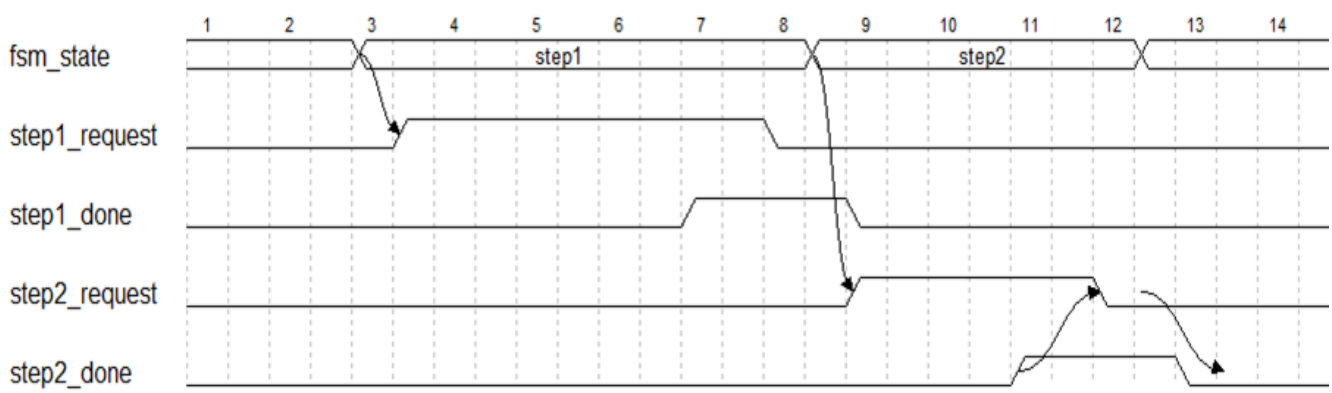

Figure 19-2. Handshake

19.3.6 Low Power Sequence

19.3.6.1 CPU mode transition flow

Each CMC has a state machine to control the sequence of CPU mode transition.

When CMC receives a sleep request from CPU platform, it starts the sleep sequence, it cannot be broken by wakeup request until finishing SLEEP_POWER request. In SLEEP_SP step, the SPC runs set point transition flow. In SLEEP_STBY step, the SBC runs standby transition flow. After the sleep sequence finishes, the CMC stays at IDLE_SLEEP and waits for a wakeup event to start wakeup sequence, which is showed in the left part of the diagram.

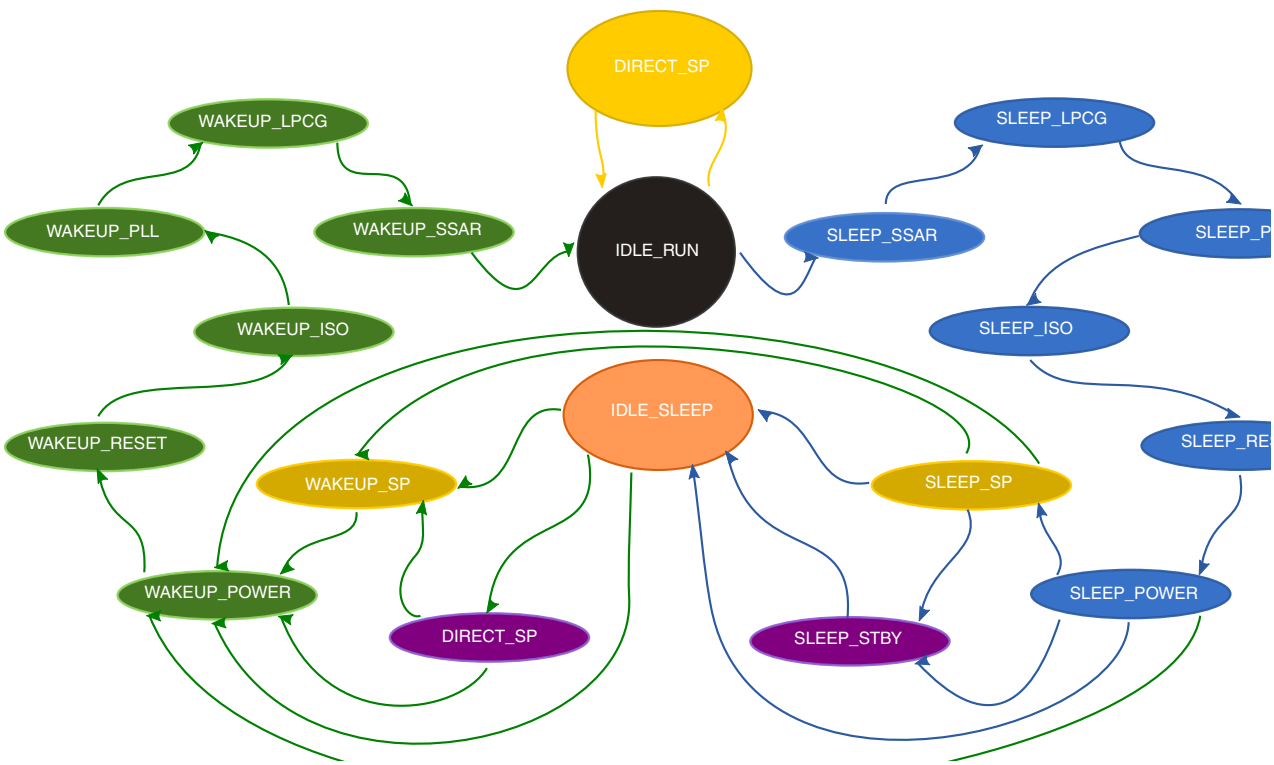

Figure 19-3. CPU Mode Transition Flow

19.3.6.2 Setpoint transition flow

The SPC has a state machine to control the sequence of Setpoint transition.

The SPC state machine starts after it receives a Setpoint change request from CMC. SPC uses one state to calculate whether or not it needs to change Setpoint based on all CMC status. If the calculated result is YES, the Setpoint transition sequence starts. This sequence cannot be broken by a wakeup request.

The Setpoint transition sequence contains both a sleep sequence and a wakeup sequence, because GPC doesn't know whether a Setpoint transition is a wakeup or sleep sequence. GPC sends all step requests by sequence, and the system resource controller determines which request need be processed.

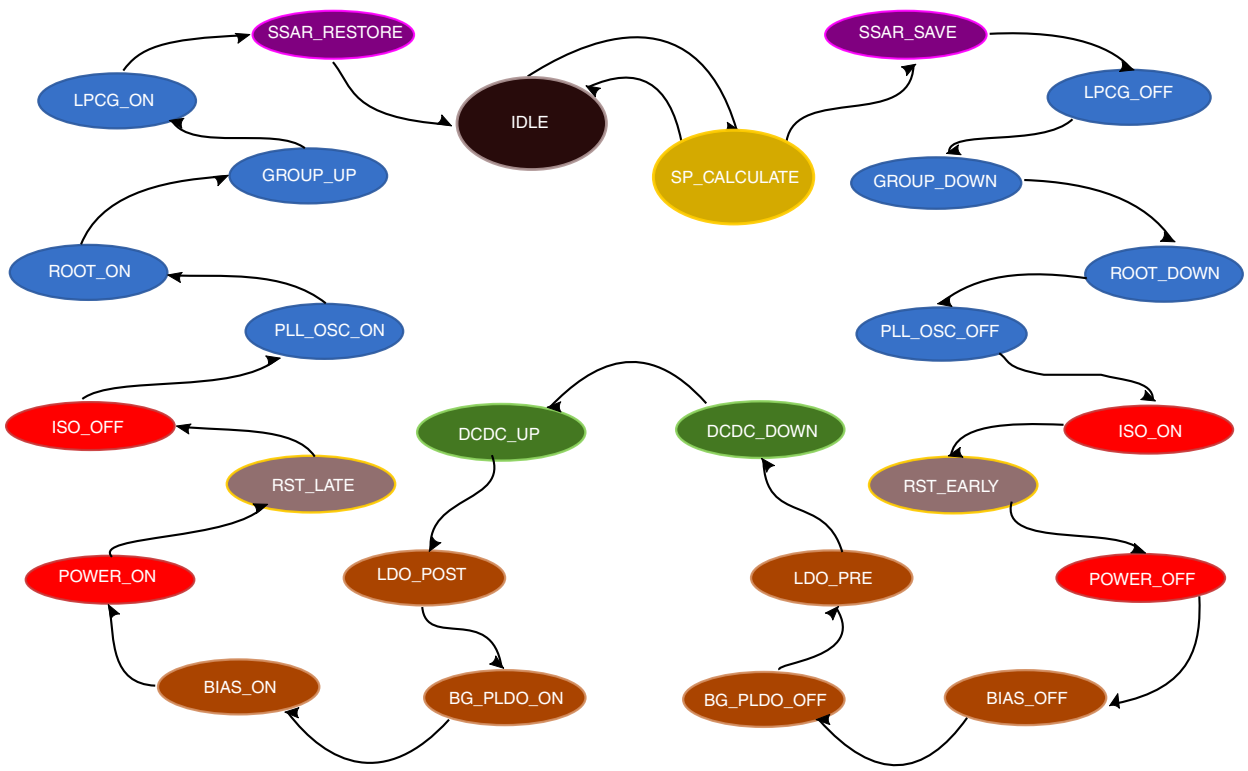

Figure 19-4. Setpoint Transition Flow

19.3.6.3 Standby transition flow

The SBC state machine starts when CMC sends a standby request, it looks at all CMC standby status, if any CPU platform is not in sleep mode or not allow standby, this standby request will be refused. The standby_in sequence can be broken after any step complete because of wakeup time requirement.

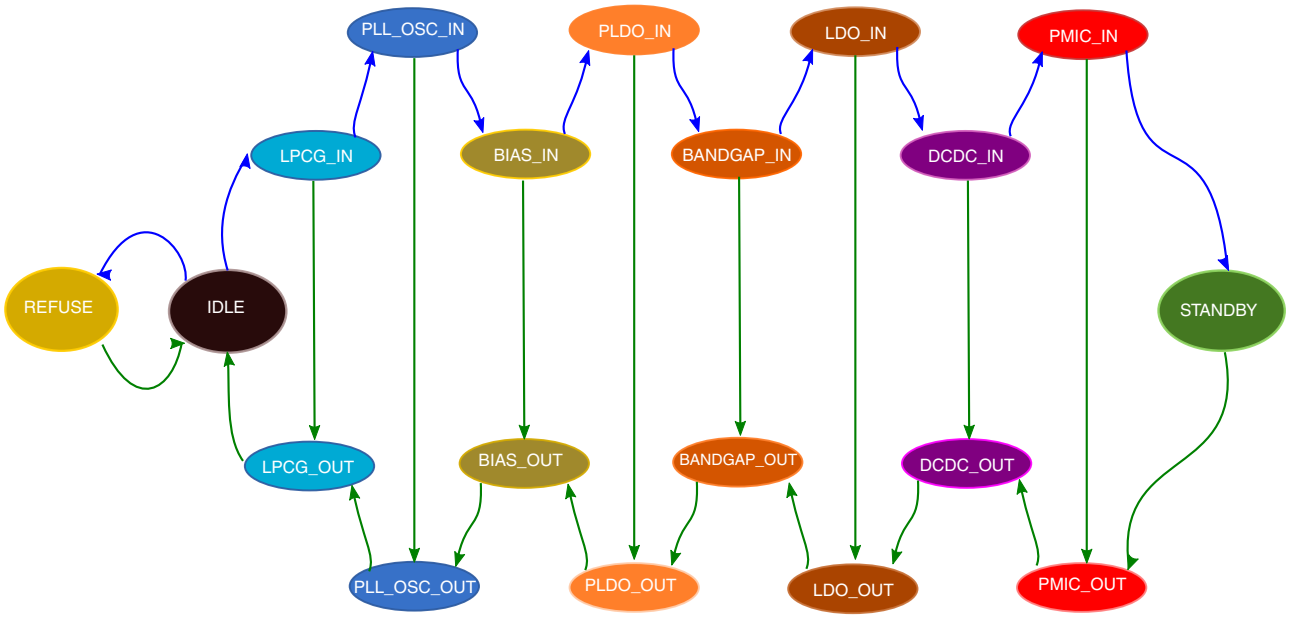

Figure 19-5. Standby transition flow

19.3.6.4 Step Control

For each step of transition, there is a control register to adjust the step duration.

The STEP_CNT[DISABLE] field to used to disable the step so that no request is sent out in this transition step. There is also a read only counter to record the time when step response is received.

19.3.7 System Domain

19.3.7.1 Domain assignment

Each CPU platform and the CMC connected to it can be assigned to the same domain.

Based on the domain assignment, a mapping mechanism between CPU platform and system domain is implemented inside GPC.

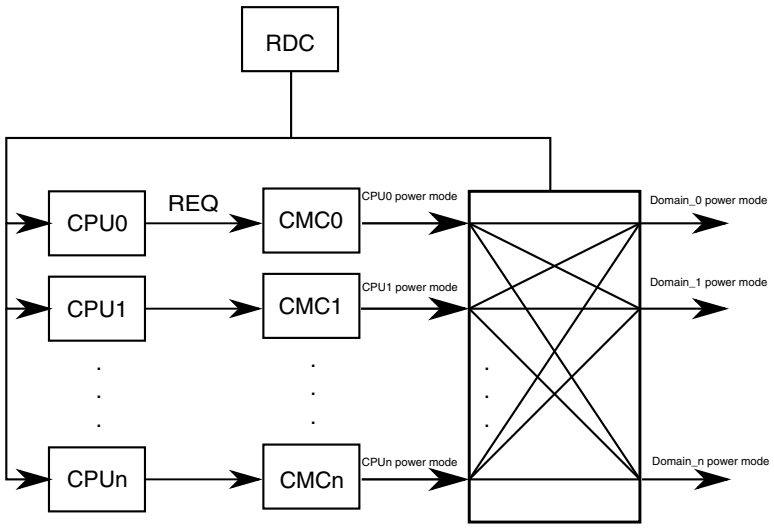

Figure 19-6. Domain Assignement

When more than one CMC is assigned to the same domain, a two stage priority selects which CMC can control the domain's UPI output. The first stage checks for the master_cpu flag from CMC. The master_cpu flag is enabled by register CM_MISC[MASTER_CPU]. The CMC with the master_cpu flag owns the Domain UPI output. If all or none of the CPUs own the master_cpu flag, the second stage priority assigns Domain UPI output to the lower indexed CMC.

19.3.7.2 Register Access Permissions

The GPC register access is controlled by the following registers and bitfields:

- CM_AUTHEN_CTRL register for CMC access permission
- SP_AUTHEN_CTRL register for SPC and SBC access permission.
- CM_AUTHEN_CTRL[WHITE_LIST] field configures which Domain IDs can write to the registers.
- x_AUTHEN_CTRL[USER] and x_AUTHEN_CTRL[NONSECURE] fields are used to set the privilege and security permission.
- CM_AUTHEN_CTRL[LOCK_CFG] locks configuration fields and should only be set at initialization.

19.3.8 Clocks

This section describes the clocks for the GPC module.

Table 19-3. Clocks

Clock	Description
ipg_clk	Main GPC clock. This clock originates from RCOSC and can be turned off by setting SP_ROSC_CTRL[SP_ALLOW_ROSC_OFF] when the system is in a Setpoint, which allows shutting of the RCOSC. After transitioning into Standby mode, the GPC will shut off the RCOSC.
32k_clk	32 kHz clock used to wakeup GPC and RCOSC. The 32 kHz clock isn't needed by ipg_clk since they are fully asynchronous

19.3.9 Interrupts

The interrupt inputs of CMC0 and CMC1 are independent and the same as the CPU platforms they are connected to. Each CMC has up to 256 IRQ input to wake up the core or system.

The following are the types of interrupts the GPC can generate:

- CM_INT_CTRL[SP_REQ_NOT_ALLOWED_SLEEP_INT]: Setpoint target is not allowed by MODE_MAPPING
- CM_INT_CTRL[SP_REQ_NOT_ALLOWED_WAKEUP_INT]: The wakeup Setpoint target is not allowed by RUN_MODE_MAPPING
- CM_INT_CTRL[SP_REQ_NOT_ALLOWED_SOFT_INT]: The software Setpoint target is not allowed by RUN_MODE_MAPPING
- SP_INT_CTRL[NO_ALLOWED_SP_INT]: No allowed Setpoint target for all CMCs

NOTE

All the interrupts share one pin, users need to check above registers to find out which violation occurs.

19.4 External Signals

There are no external signals pinned out for the GPC.

19.5 Initialization

See Low Power Sequence for low power entry and exit flow and considerations.

19.5.1 CPU Sleep Hold

There is a certain delay between the time the core falls asleep and when the core clock stops. If a wakeup IRQ appears inside this delay window, the core will process the IRQ and awake, but the GPC sleep sequence is still shutting off the core clock. Since the sleep sequence is not interruptable, this scenario may lead to unpredictable behavior.

To avoid this scenario, a CPU Sleep Hold is implemented to hold the core in the sleep state until the sleep sequence is finished. The GPC will then send a signal to release the core. The CM_MISC[SLEEP_HOLD_EN] field is used to enable this function.

The core clock can also be gated by a WFI event without any GPC sequence. The GPC uses a signal to clear this gate when a wakeup trigger occurs.

19.6 Memory Map and register definition

This section includes the GPC module memory map and detailed descriptions of all registers.

19.6.1 GPC_CPU register descriptions

19.6.1.1 gpc_cpu_ctrl memory map

19.6.1.2 CM Authentication Control (CM_AUTHEN_CTRL)

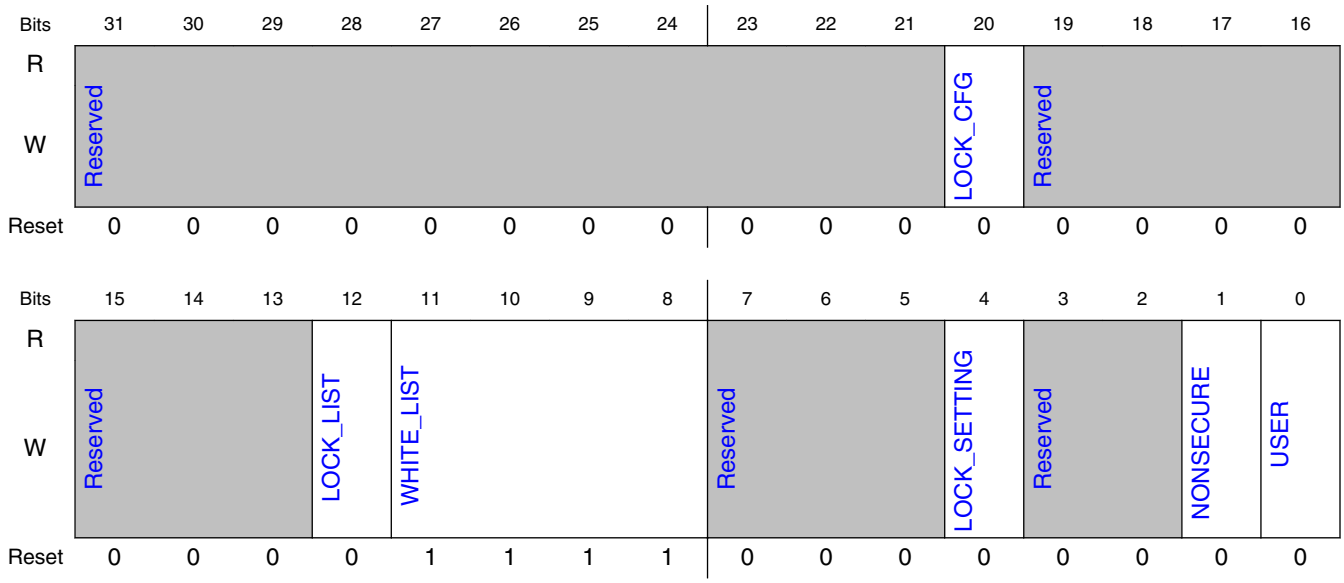
19.6.1.2.1 Offset

Register	Offset
CM_AUTHEN_CTRL	4h

19.6.1.2.2 Function

Authentication control for CMC

19.6.1.2.3 Diagram



19.6.1.2.4 Fields

Field	Function
31-21 —	Reserved
20 LOCK_CFG	Configuration lock this field is write once and can lock value of low power configuration fields. Unlocked by System Reset.
19-13 —	Reserved
12 LOCK_LIST	White list lock this field is write once and can lock value of WHITE_LIST field
11-8 WHITE_LIST	Domain ID white list when bit setting to 1, the corresponding domain ID can access CPU mode control registers. bit[0] for Domain 0, bit[1] for Domain 1, bit[2] for Domain 2, and bit[3] for Domain 3. Muliple bits with a value of 1 is permitted.
7-5 —	Reserved
4 LOCK_SETTING	Lock NONSECURE and USER this field is write once and can lock value of USER and NONSECURE field
3-2 —	Reserved
1 NONSECURE	Allow non-secure mode access 0b - Allow only secure mode to access CPU mode control registers 1b - Allow both secure and non-secure mode to access CPU mode control registers

Table continues on the next page...

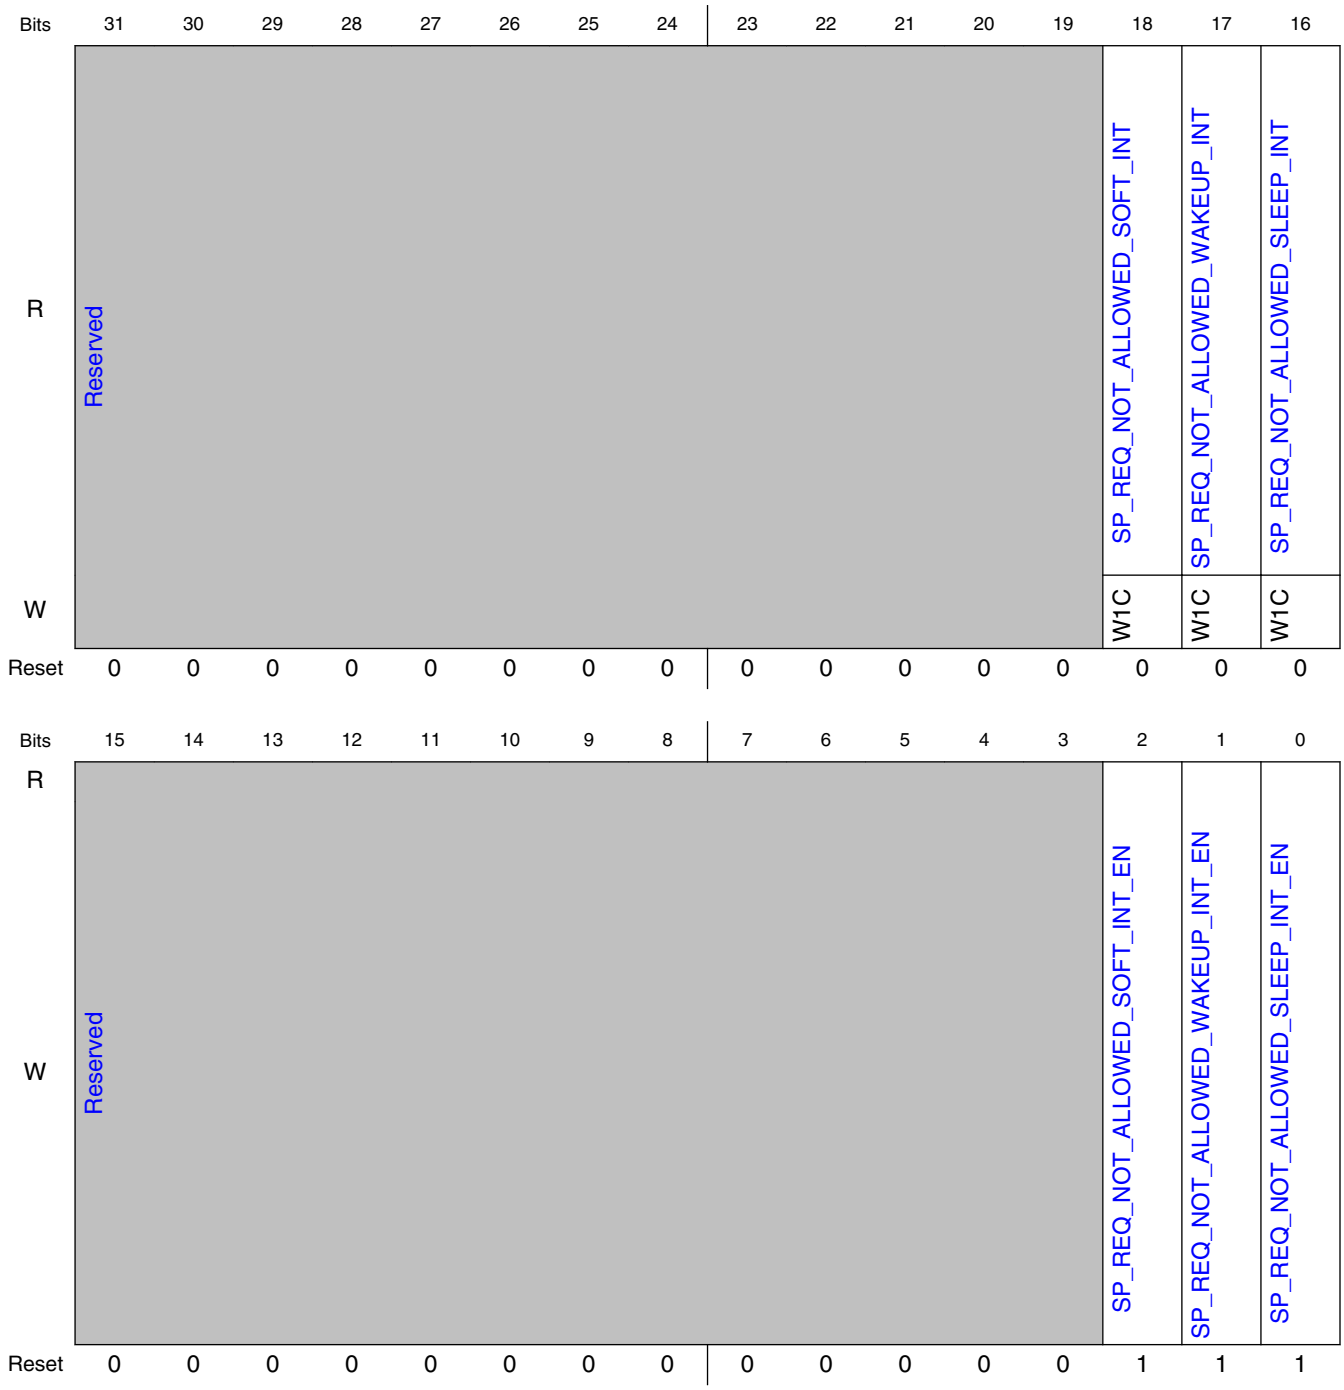
Field	Function
0 USER	Allow user mode access 0b - Allow only privilege mode to access CPU mode control registers 1b - Allow both privilege and user mode to access CPU mode control registers

19.6.1.3 CM Interrupt Control (CM_INT_CTRL)

19.6.1.3.1 Offset

Register	Offset
CM_INT_CTRL	8h

19.6.1.3.2 Diagram



19.6.1.3.3 Fields

Field	Function
31-19	Reserved

Table continues on the next page...

Field	Function
—	
18 SP_REQ_NOT_ALLOWED_SOFT_INT	sp_req_not_allowed_for_soft interrupt status and clear register when writing a "1" to CPU_SP_RUN_EN to trigger a software Setpoint transition request, if the target Setpoint in CPU_SP_RUN is not allowed by CM_RUN_MODE_MAPPING, this interrupt asserts.
17 SP_REQ_NOT_ALLOWED_WAKEUP_INT	sp_req_not_allowed_for_wakeup interrupt status and clear register for wakeup sequence, if the target Setpoint is not allowed by CM_RUN_MODE_MAPPING, this interrupt asserts. The target Setpoint is determined by CPU_SP_WAKEUP_EN, CPU_SP_WAKEUP_SEL, CPU_SP_WAKEUP and CPU_SP_CURRENT
16 SP_REQ_NOT_ALLOWED_SLEEP_INT	sp_req_not_allowed_for_sleep interrupt status and clear register during sleep sequence, if the target Setpoint is not allowed by CM_X_MODE_MAPPING, this interrupt asserts. The "X" is inside WAIT, STOP and SUSPEND, which is determined by CPU_MODE_TARGET. The target Setpoint is determined by CPU_SP_SLEEP if CPU_SP_SLEEP_EN set, and is determined by CPU_SP_CURRENT if CPU_SP_SLEEP_EN unset
15-3 —	Reserved
2 SP_REQ_NOT_ALLOWED_SOFT_INT_EN	sp_req_not_allowed_for_soft interrupt enable See SP_REQ_NOT_ALLOWED_SOFT_INT for more information. 0b - Interrupt disable 1b - Interrupt enable
1 SP_REQ_NOT_ALLOWED_WAKEUP_INT_EN	sp_req_not_allowed_for_wakeup interrupt enable See SP_REQ_NOT_ALLOWED_WAKEUP_INT for more information. 0b - Interrupt disable 1b - Interrupt enable
0 SP_REQ_NOT_ALLOWED_SLEEP_INT_EN	sp_req_not_allowed_for_sleep interrupt enable See SP_REQ_NOT_ALLOWED_SLEEP_INT for more information. 0b - Interrupt disable 1b - Interrupt enable

19.6.1.4 Miscellaneous (CM_MISC)

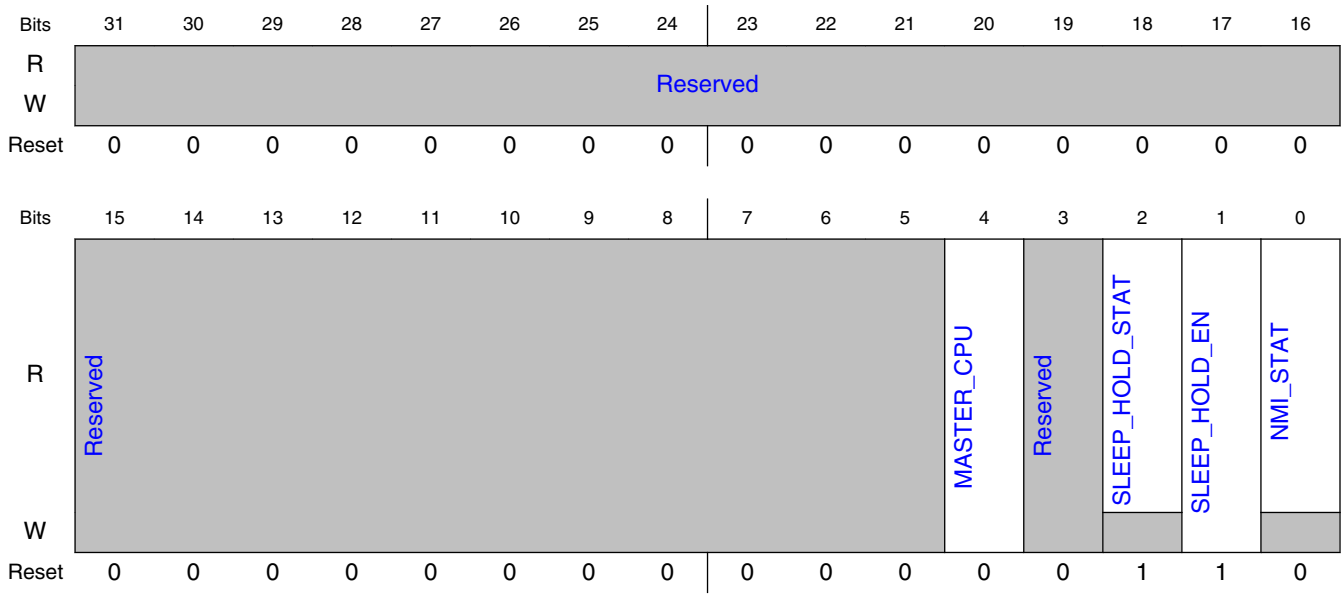
19.6.1.4.1 Offset

Register	Offset
CM_MISC	Ch

19.6.1.4.2 Function

Miscellaneous register

19.6.1.4.3 Diagram



19.6.1.4.4 Fields

Field	Function
31-5 —	Reserved
4 MASTER_CPU	Master CPU Indicate this CPU is a master CPU inside the domain, when mux the UPI domain output, the master CPU is selected if more than one CPU is assigned to same domain. Locked by LOCK_CFG field
3 —	Reserved
2 SLEEP_HOLD_STAT	Status of cpu_sleep_hold_ack_b
1 SLEEP_HOLD_EN	Allow cpu_sleep_hold_req assert during CPU low power status 0b - Disable cpu_sleep_hold_req 1b - Allow cpu_sleep_hold_req assert during CPU low power status
0 NMI_STAT	Non-masked interrupt status 0b - NMI is not asserting 1b - NMI is asserting

19.6.1.5 CPU mode control (CM_MODE_CTRL)

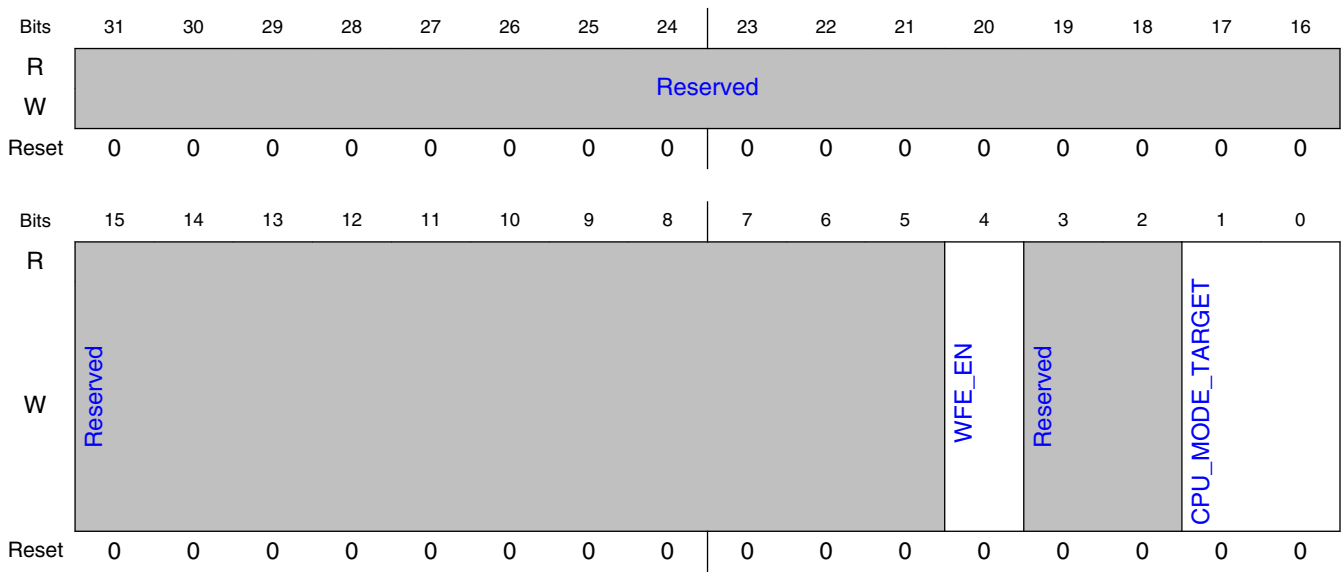
19.6.1.5.1 Offset

Register	Offset
CM_MODE_CTRL	10h

19.6.1.5.2 Function

CPU mode control register

19.6.1.5.3 Diagram



19.6.1.5.4 Fields

Field	Function
31-5 —	Reserved
4 WFE_EN	WFE assertion can be sleep event 0b - WFE assertion can not trigger low power 1b - WFE assertion can trigger low power
3-2 —	Reserved
1-0 CPU_MODE_TARGET	The CPU mode the CPU platform should transit to on next sleep event Important: Core MUST re-configure this field EACH TIME before entering sleep 00b - Stay in RUN mode 01b - Transit to WAIT mode 10b - Transit to STOP mode 11b - Transit to SUSPEND mode

27-16 —	Reserved
15-0 —	Reserved

19.6.1.37 CM Setpoint Control (CM_SP_CTRL)

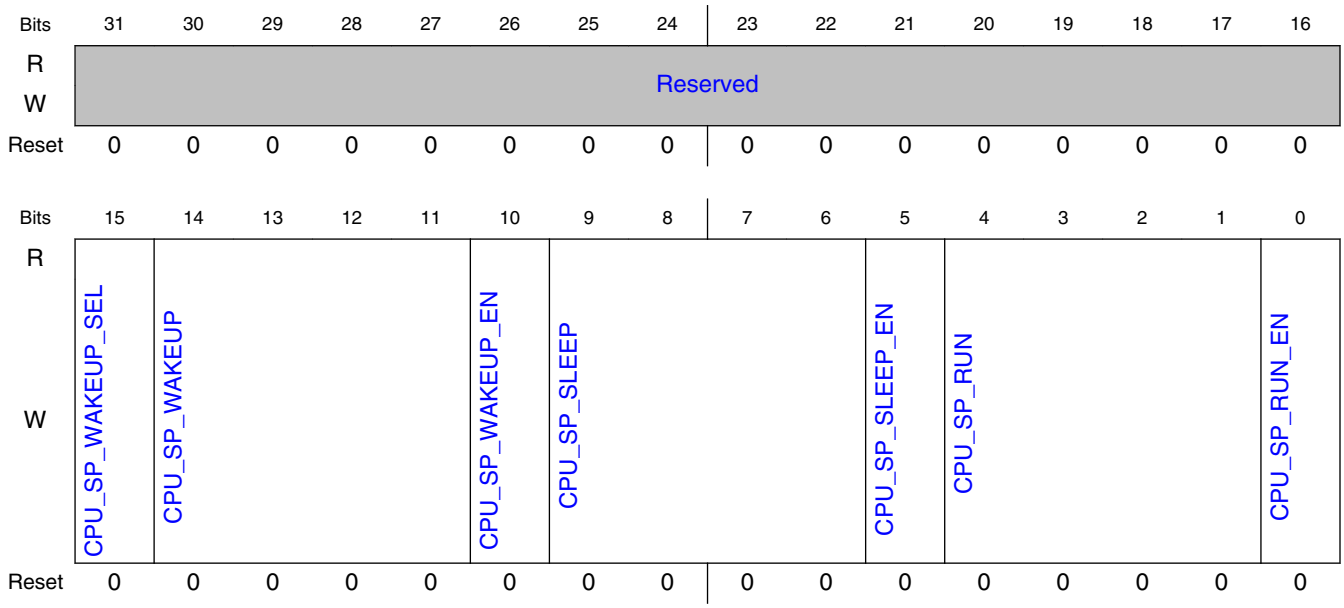
19.6.1.37.1 Offset

Register	Offset
CM_SP_CTRL	300h

19.6.1.37.2 Function

Setpoint control register.

19.6.1.37.3 Diagram



19.6.1.37.4 Fields

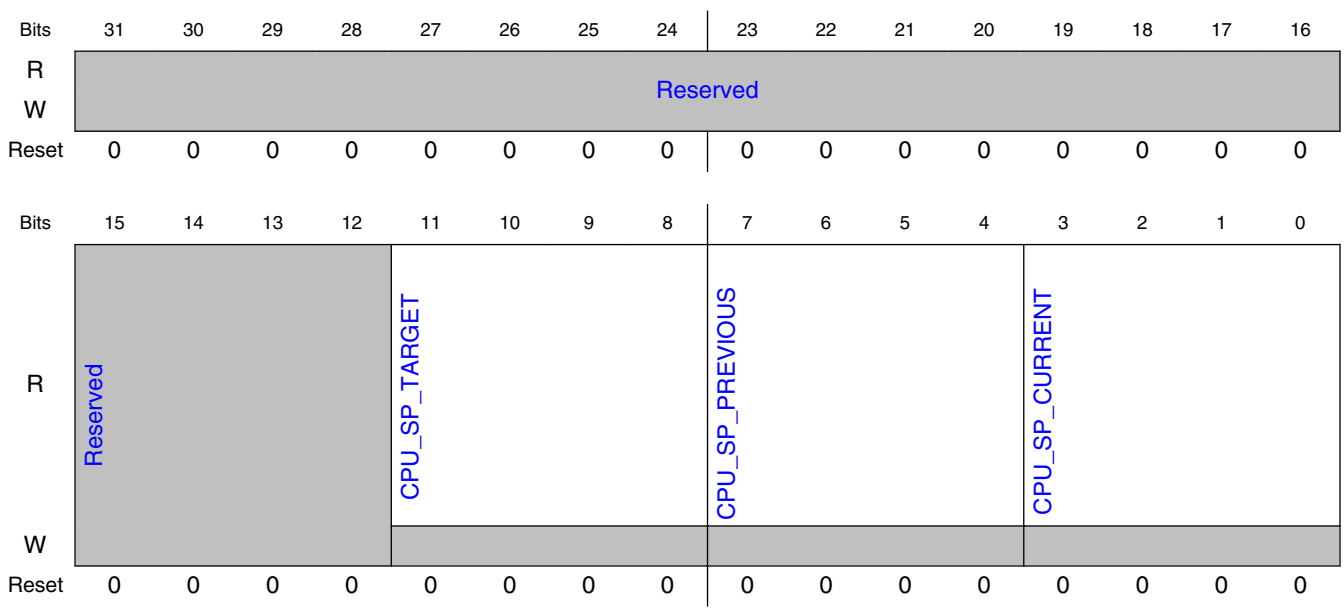
Field	Function
31-16 —	Reserved
15 CPU_SP_WAKEUP_SEL	Select the Setpoint transiton on the next CPU platform wakeup sequence 0b - Request SP transition to CPU_SP_WAKEUP 1b - Request SP transition to the Setpoint when the sleep event happens, which is captured in CPU_SP_PREVIOUS
14-11 CPU_SP_WAKEUP	The Setpoint that CPU want the system to transit to on next CPU platform wakeup sequence
10 CPU_SP_WAKEUP_EN	1 means enable Setpoint transition on next CPU platform wakeup sequence
9-6 CPU_SP_SLEEP	The Setpoint that CPU want the system to transit to on next CPU platform sleep sequence
5 CPU_SP_SLEEP_EN	1 means enable Setpoint transition on next CPU platform sleep sequence
4-1 CPU_SP_RUN	The Setpoint that CPU want the system to transit to when CPU_SP_RUN_EN is set
0 CPU_SP_RUN_EN	Request a Setpoint transition when this bit is set Write 1 will trigger Setpoint transition. The field is read as 1 until transition complete.

19.6.1.38 CM Setpoint Status (CM_SP_STAT)

19.6.1.38.1 Offset

Register	Offset
CM_SP_STAT	304h

19.6.1.38.2 Diagram



19.6.1.38.3 Fields

Field	Function
31-16 —	Reserved
15-12 —	Reserved
11-8 CPU_SP_TARGET	The requested Setpoint from the CPU platform 0000 - Setpoint 0 0001 - Setpoint 1 ...

Table continues on the next page...

Field	Function
	1111 - Setpoint 15
7-4 CPU_SP_PREVIOUS	The previous Setpoint of the system 0000 - Setpoint 0 0001 - Setpoint 1 ... 1111 - Setpoint 15
3-0 CPU_SP_CURRENT	The current Setpoint of the system 0000 - Setpoint 0 0001 - Setpoint 1 ... 1111 - Setpoint 15

19.6.1.39 CM Run Mode Setpoint Allowed (CM_RUN_MODE_MAPPING)

19.6.1.39.1 Offset

Register	Offset
CM_RUN_MODE_MAPPING	310h

19.6.1.39.2 Function

Allowed setpoint list for CPU RUN mode

19.6.1.39.3 Diagram

19.6.2.2 SP Authentication Control (SP_AUTHEN_CTRL)

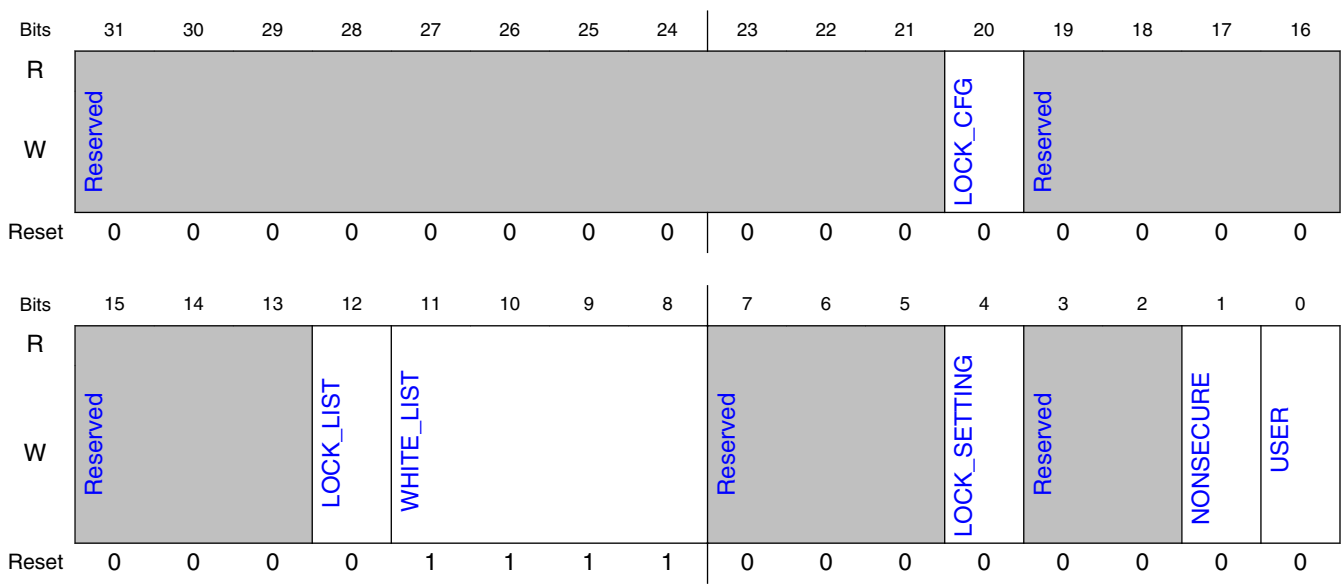
19.6.2.2.1 Offset

Register	Offset
SP_AUTHEN_CTRL	4h

19.6.2.2.2 Function

Authentication control of setpoint controller

19.6.2.2.3 Diagram



19.6.2.2.4 Fields

Field	Function
31-21	Reserved

Table continues on the next page...

Field	Function
—	
20 LOCK_CFG	Configuration lock this field is write once and can lock value of low power configuration fields
19-13 —	Reserved
12 LOCK_LIST	White list lock this field is write once and can lock value of WHITE_LIST field
11-8 WHITE_LIST	Domain ID white list when bit setting to 1, the corresponding domain ID can access CPU mode control registers
7-5 —	Reserved
4 LOCK_SETTING	Lock NONSECURE and USER this field is write once and can lock value of USER and NONSECURE field
3-2 —	Reserved
1 NONSECURE	Allow non-secure mode access 0b - Allow only secure mode to access setpoint control registers 1b - Allow both secure and non-secure mode to access setpoint control registers
0 USER	Allow user mode access 0b - Allow only privilege mode to access setpoint control registers 1b - Allow both privilege and user mode to access setpoint control registers

19.6.2.3 SP Interrupt Control (SP_INT_CTRL)

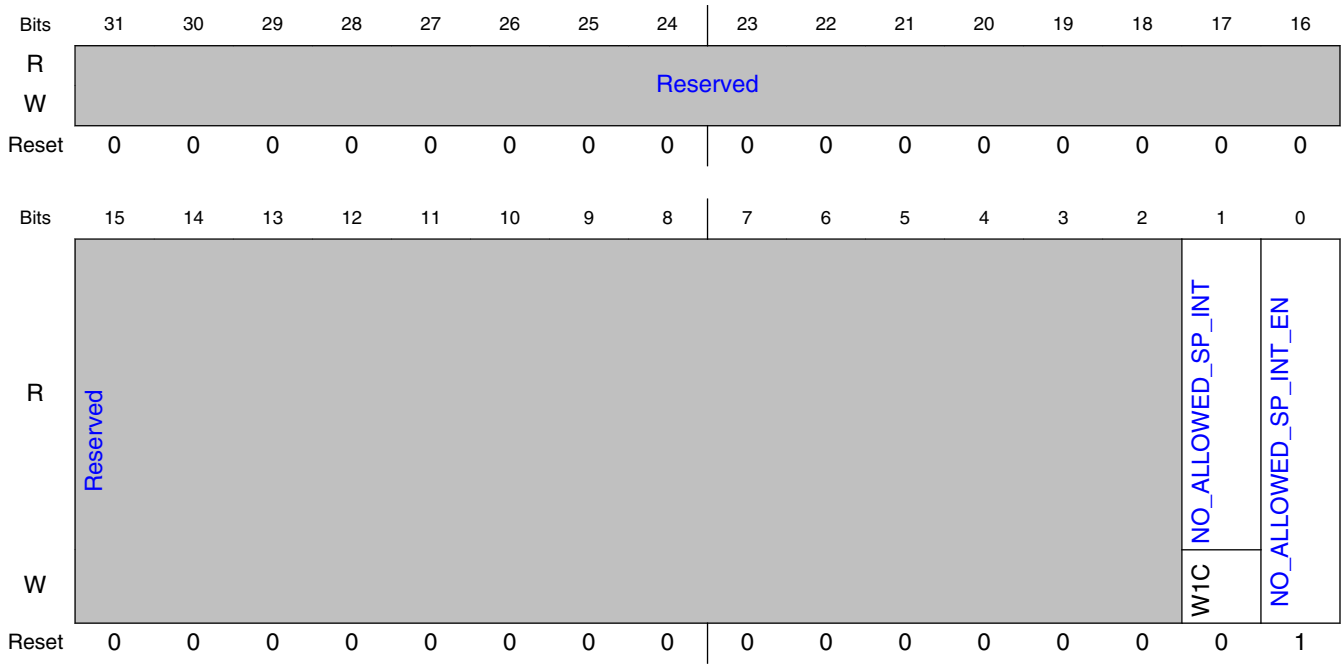
19.6.2.3.1 Offset

Register	Offset
SP_INT_CTRL	8h

19.6.2.3.2 Function

Setpoint controller interrupt control register

19.6.2.3.3 Diagram



19.6.2.3.4 Fields

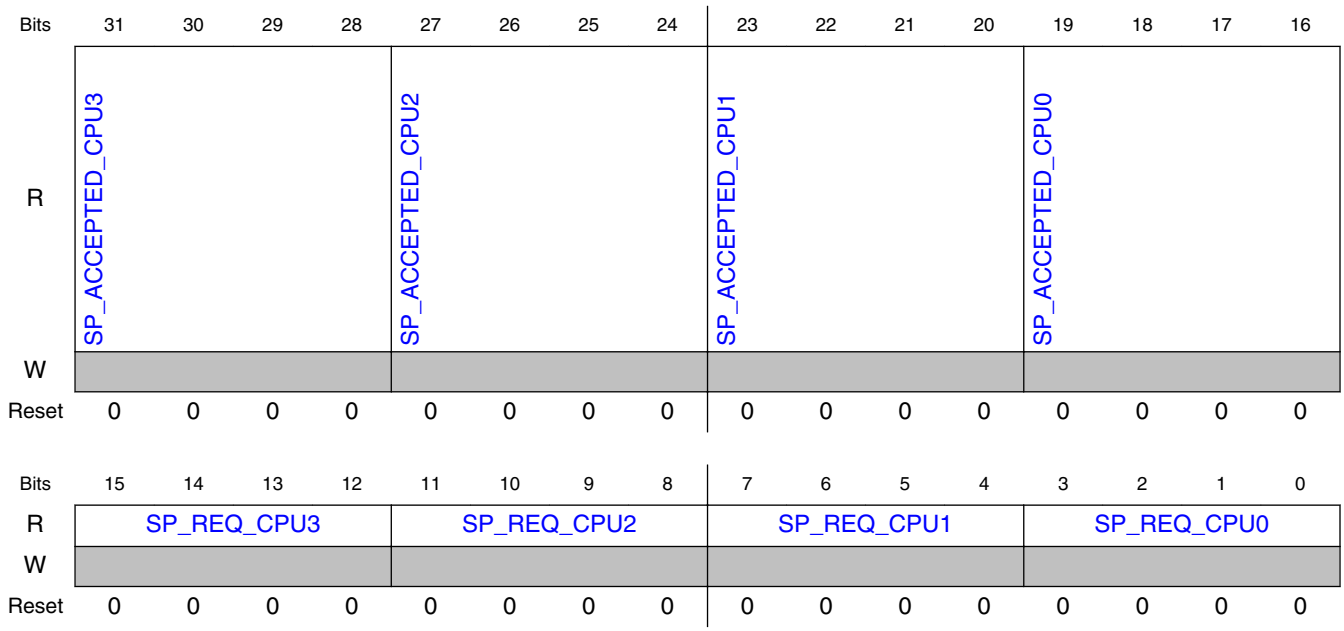
Field	Function
31-2 —	Reserved
1 NO_ALLOWED_SP_INT	no_allowed_set_point interrupt if the calculation result shows there is not any setpoint value can be allowed by all the CPU mode controller, this interrupt happens
0 NO_ALLOWED_SP_INT_EN	no_allowed_set_point interrupt enable 1 means enable to assert interrupt when no_allowed_set_point happens

19.6.2.4 CPU SP Request (SP_CPU_REQ)

19.6.2.4.1 Offset

Register	Offset
SP_CPU_REQ	10h

19.6.2.4.2 Diagram



19.6.2.4.3 Fields

Field	Function
31-28 SP_ACCEPTED_CPU3	CPU3 Setpoint accepted by SP controller 0000 - Setpoint 0 0001 - Setpoint 1 ... 1111 - Setpoint 15
27-24 SP_ACCEPTED_CPU2	CPU2 Setpoint accepted by SP controller 0000 - Setpoint 0 0001 - Setpoint 1 ... 1111 - Setpoint 15
23-20 SP_ACCEPTED_CPU1	CPU1 Setpoint accepted by SP controller 0000 - Setpoint 0 0001 - Setpoint 1 ... 1111 - Setpoint 15
19-16 SP_ACCEPTED_CPU0	CPU0 Setpoint accepted by SP controller 0000 - Setpoint 0 0001 - Setpoint 1

Table continues on the next page...

Field	Function
	... 1111 - Setpoint 15
15-12 SP_REQ_CPU3	Setpoint requested by CPU3 0000 - Setpoint 0 0001 - Setpoint 1 ... 1111 - Setpoint 15
11-8 SP_REQ_CPU2	Setpoint requested by CPU2 0000 - Setpoint 0 0001 - Setpoint 1 ... 1111 - Setpoint 15
7-4 SP_REQ_CPU1	Setpoint requested by CPU1 0000 - Setpoint 0 0001 - Setpoint 1 ... 1111 - Setpoint 15
3-0 SP_REQ_CPU0	Setpoint requested by CPU0 0000 - Setpoint 0 0001 - Setpoint 1 ... 1111 - Setpoint 15

19.6.2.5 SP System Status (SP_SYS_STAT)

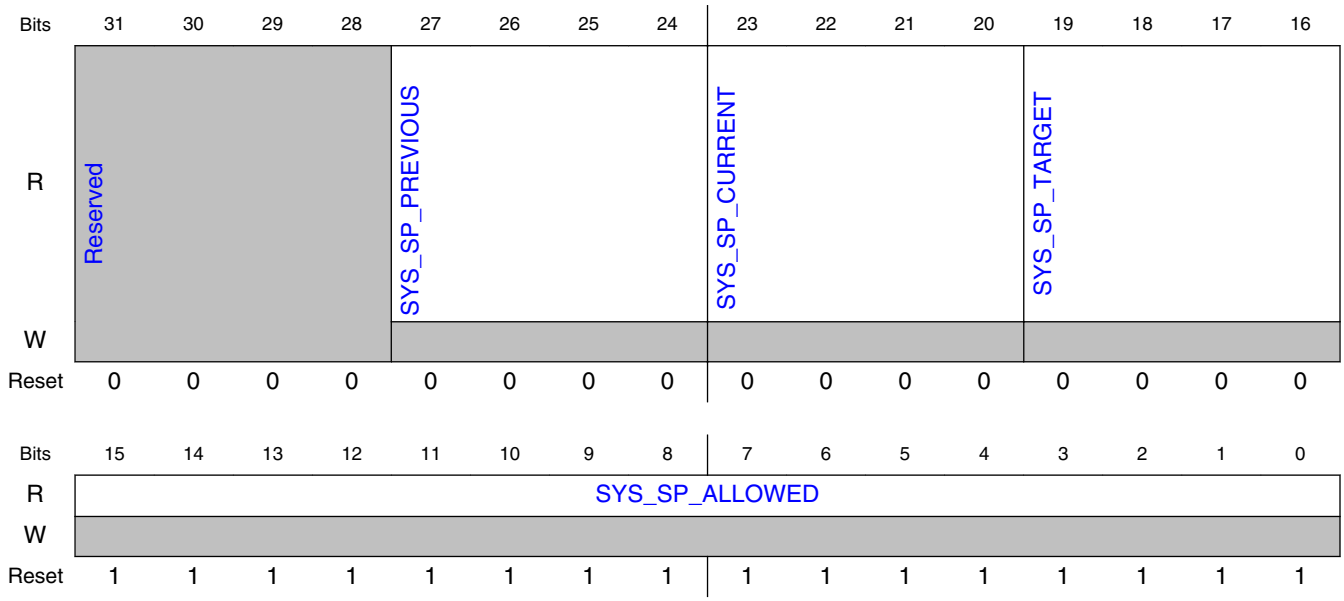
19.6.2.5.1 Offset

Register	Offset
SP_SYS_STAT	14h

19.6.2.5.2 Function

.

19.6.2.5.3 Diagram



19.6.2.5.4 Fields

Field	Function
31-28 —	Reserved
27-24 SYS_SP_PREVIOUS	Previous Setpoint, only valid when not SP trans busy 0000 - Setpoint 0 0001 - Setpoint 1 ... 1111 - Setpoint 15
23-20 SYS_SP_CURRENT	Current Setpoint, only valid when not SP trans busy 0000 - Setpoint 0 0001 - Setpoint 1 ... 1111 - Setpoint 15
19-16 SYS_SP_TARGET	The Setpoint chosen as the target setpoint 0000 - Setpoint 0 0001 - Setpoint 1 ... 1111 - Setpoint 15
15-0 SYS_SP_ALLOWED	Allowed Setpoints by all current CPU Setpoint requests This field is the ANDed result of allowed Setpoints from all CMCs. If all bits are 0, there are no Setpoints, and no Setpoint transitions are allowed. See System Setpoint Management topic for more information.

Field	Function
	Bit 0: Setpoint 0 is allowed Bit 1: Setpoint 1 is allowed ... Bit 15: Setpoint 15 is allowed

Chapter 20
Power Gating and Memory Controller (PGMC)

20.1 Chip-specific Power Gating and Memory Controller (PGMC) information

Table 20-1. Reference links to related information

Topic	Related module(s)	Reference
System memory map	-	System Memory Map
Clocking	CCM	Clock Management Clock Control Module (CCM)
Power management	PMU	Power Management Power Management Unit
Signal multiplexing	IOMUX	External Signals and Pin Multiplexing IOMUX
Interrupts, DMA Events and XBAR Assignments	-	Interrupts, DMA Events and XBAR Assignments

20.2 Overview

The Power Gating and Memory Controller (PGMC) is a power management component that controls power gating of power domains and memory low power mode. This module is similar to a resource controller based on Unified Power Management Architecture (UPMA). The PGMC uses the Unified Power Management Interface (UPI) to control power switch, state save/restore, PMIC standby, and memory low power mode according to CPU mode, Setpoints, and standby status.

20.2.1 Block Diagram

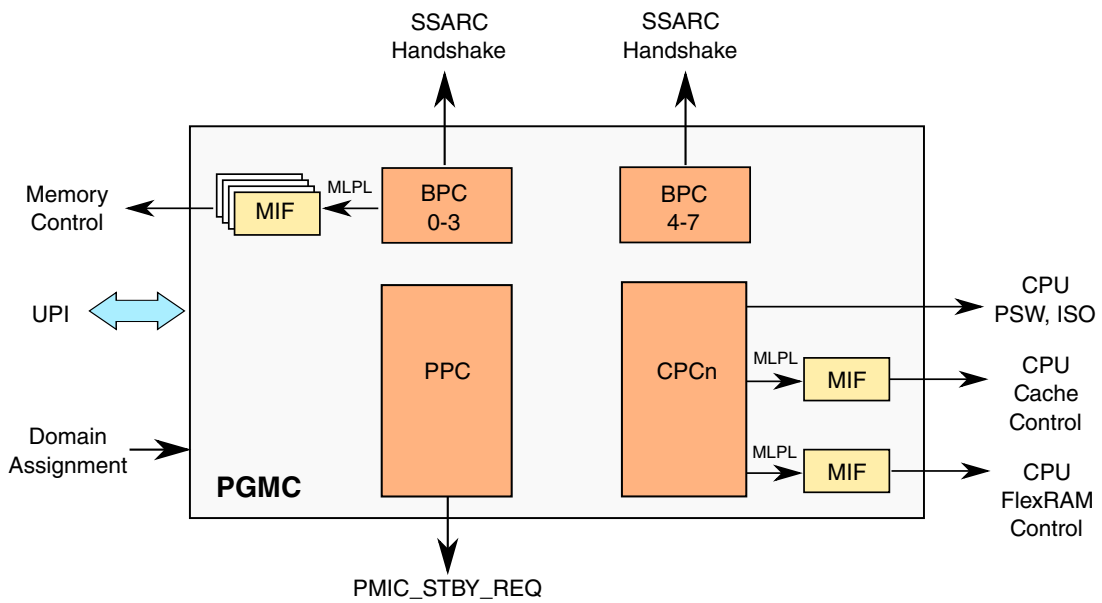

Figure 20-1. PGMC block diagram

There are three submodules for the PGMC block. They are:

- Basic Power Controller (BPC)
  - Controls power domains with simple isolation and power switch
- CPU Power Controller (CPC)
  - Controls CPU platform with complex power domain and sequence requirement
- PMIC Power Controller (PPC)
  - Controls PMIC standby mode outside of the chip

NOTE

The Memory Interface (MIF) block is designed for dedicated technology of memory.

20.2.2 Features

The PGMC includes the following features:

- Automatic power domain control based on UPI sequence
- Software power domain control
- Programmable registers to adjust low power sequence timing
- System domain assignment and restriction
- Programmable memory low power behavior

20.3 Functional description

The following sections describe functional details of the PGMC block.

20.3.1 Power Controller Assignment

The following table shows the power domains of the chip and the BPC it is controlled by. Please see the domain assignment in the clock and power management chapter for more details.

Table 20-2. Power Controller Assignment

Power Domain	Assignment
BPC0	MEGAMIX
BPC1	DISPLAYMIX
BPC2	WAKEUPMIX
BPC3	LPSRMIX
BPC4	MIPIPHY
BPC5	Virtual
BPC6	Virtual
BPC7	Virtual

NOTE

- BPC4 is used for MIPIPHY, which has only power switch and isolation. There is no memory to be controlled.
- Virtual power domains do not physically exist, but are used to trigger SSARC to save and restore, status and data.
- BPC can also control memories inside the target power domain, so each power domain will have a corresponding MIF.

The following table shows the cores controlled by CPCs.

CPC	Assignment
CPC0	CM7
CPC1	CM4

The following table shows the control areas of the MIFs.

MIF	Assignment
MIF0	Cache
MIF1	Local Memory

PPC and it's MIF is used for PMIC.

20.3.2 Control Mode

Resource domain is assigned by RDC or register configuration. For example, one CPU platform and its private clock and private peripherals can be assigned to a same resource domain.

Power domain is the region with same power or same non-interchangeable power supply.

The controllers can be configured to three kinds of control mode via x_MODE[CTRL_MODE] field, where x could be PPC, CPC_CORE, or BPC.

- 2’b00 means disable the low power control
- 2’b01 means the Power Controller belongs to a resource domain and is controlled by the domain’s CPU power mode
- 2’b10 means the Power Controller is a system resource and controlled by Setpoint mode.
- 2'b11 is Reserved

When x_MODE[CTRL_MODE] is 2'b01, the resource domain assignment is set in x_MODE[DOMAIN_ASSIGN] field.

- BPC can be set to be controlled by either CPU mode or Setpoint mode. The domain assignment is register programmable.
- PPC can only be set to Setpoint mode, and is controlled by standby request.
- CPC core can only be controlled by CPU mode. The CPC cache and local memory can be controlled either by CPU mode or Setpoint mode. The domain assignment of all CPC parts are hardware controlled by RDC, and cannot be programmed inside PGMC.

20.3.3 Power on and Power off

The BPC and CPC core can turn on or shut off the power domain. The behavior contains power switch (PSW) and isolation (ISO). The power switch consists of high fan-out PSW, low fan-out PSW, and their acknowledge signal.

- If x_MODE[CTRL_MODE] == 2'b01 (where x could be BPC or CPC_CORE), then x_POWER_CTRL[PWR_OFF_AT_WAIT], x_POWER_CTRL[PWR_OFF_AT_STOP], and x_POWER_CTRL[PWR_OFF_SUSPEND] fields set which CPU mode the power domain should be powered off.
- If x_MODE[CTRL_MODE] == 2'b10, then BPC_POWER_CTRL[PWR_OFF_AT_SP] sets the Setpoint the power domain should be powered off.

The registers x_PDN_CTRL and x_PUP_CTRL, control the delay time before PSW and ISO toggle. They are used to achieve timing sequence requirement. The requirement can be between PSW and ISO, or between different power domains. Please note that the default delay should be sufficient.

Software can use x_POWER_CTRL[ISO_OFF_SOFT], x_POWER_CTRL[ISO_ON_SOFT], x_POWER_CTRL[PSW_OFF_SOFT], and x_POWER_CTRL[PSW_ON_SOFT] fields to directly control the PSW and ISO.

20.3.4 State Save and Restore

When a power domain is powered off, its status is lost. If it happens, the State Save and Restore Controller (SSARC) will automatically save the data before power off and restore it after power on. The BPC sends save and restore request to SSAR and completes the handshake.

BPC controls SSAR requests for their corresponding power domains. The virtual power domains are purposed so other system data can be saved and restored in any CPU mode or Setpoint mode, even if the data is in non-switchable power domains.

The registers BPC_SSAR_SAVE_CTRL and BPC_SSAR_RESTORE_CTRL can control the SSAR request. The register BPC_SSAR_ACK_CTRL can be used to control the delay and wait response behaviour.

20.3.5 Memory Low Power Control

The memory low power control determines the Memory Low Power Level (MLPL) under CPU Mode or Setpoint. Part of the memory low power control is the Memory Interface (MIF), which sends control signal details to memory, according to the MLPL

request. The memory behavior for MLPL is programmable inside MIF, to simplify software design, the MIF register default value can be directly used without any programming.

Table 20-3. MIF Default Configuration

MLPL	description	HS	LS	IG	STDBY	arr off	per off	SLEEP	sw1 off	sw2 off	iso_en	comment
0	reserved											
1	high speed	H	L	L	L	L	L	L	L	H	L	over drive
2	reserved											
3	normal	L	L	L	L	L	L	L	L	H	L	
4	low speed	L	H	L	L	L	L	L	L	H	L	under drive
5	input gating	L	L	H	L	L	L	L	L	H	L	
6	standby	L	L	H	H	L	L	L	L	H	L	low leakage
7	reserved											
8	sleep	L	L	L	L	L	L	H	L	H	L	retention
9	arr on per off	L	L	L	L	L	H	H	L	H	H	retention
10	arr off per on	L	L	L	L	H	L	H	L	H	L	
11	arr off per off	L	L	L	L	H	H	H	L	H	H	data lost
12												
13	sw2	L	L	L	L	L	L	H	H	L	L	low voltage
14	sw2 per off	L	L	L	L	L	H	H	H	L	H	low voltage
15	sw1sw2 off	L	L	L	L	L	L	H	H	H	H	data lost

The above table shows the MIF default configuration. These values can be changed by the user.

NOTE

The default MLPL is normal.

There are special requirements regarding the SLEEP and INITN pin, on power ramp-up. The memory SLEEP and INITN pin should be enabled by the VDD-not-ready flag. The PGMC also provides an option, by enabling the BYPASS_VDD_OK field, the SLEEP and INITN pin is not affected by the VDD-not-ready flag.

The power switch architecture supported by MIF is shown below:

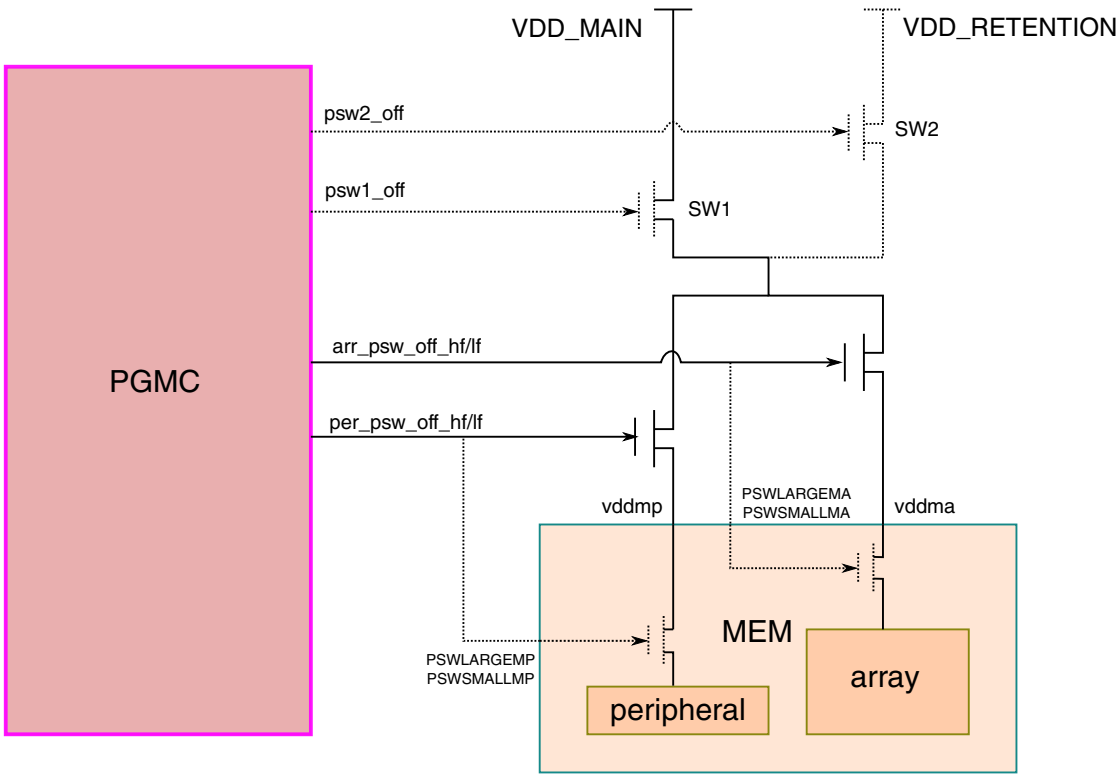

Figure 20-2. Power Switch Architecture Diagram

20.3.6 PMIC Standby

When the system is in standby mode, PPC can send PMIC_STBY_REQ to the external PMIC outside, thus enabling PMIC to provide a standby voltage.

The PPC_STBY_SP_CTRL[STBY_ON_AT_SP_SLEEP] field defines the Setpoint, which the PPC should send PMIC_STBY_REQ when the system is in standby mode.

20.3.7 Clocks

The table found here describes the clock sources for SSARC. Please see the Clock Control chapter for clock setting, configuration, and gating information.

Table 20-4. Clocks

Clock Name	Description
ipg_clk	Main functional clock
ipg_clk_s	Bus clock, same as ipg_clk source
clk_32k	Low speed clock

20.3.8 Reset

The PGMC module has one asynchronous active-low reset:

- System Reset (reset_b)

Please see the System Reset Controller (SRC) chapter for more details on system resets.

20.4 External Signals

Table 20-5. External Signals

External Signals	Description	Direction
PMIC_STBY_REQ	Signal notifies external power management IC (PMIC) to move from functional voltage to standby voltage.	O

20.5 Initialization

20.5.1 UPI Handshake

The following diagram shows an example in which a Setpoint transition is seen.

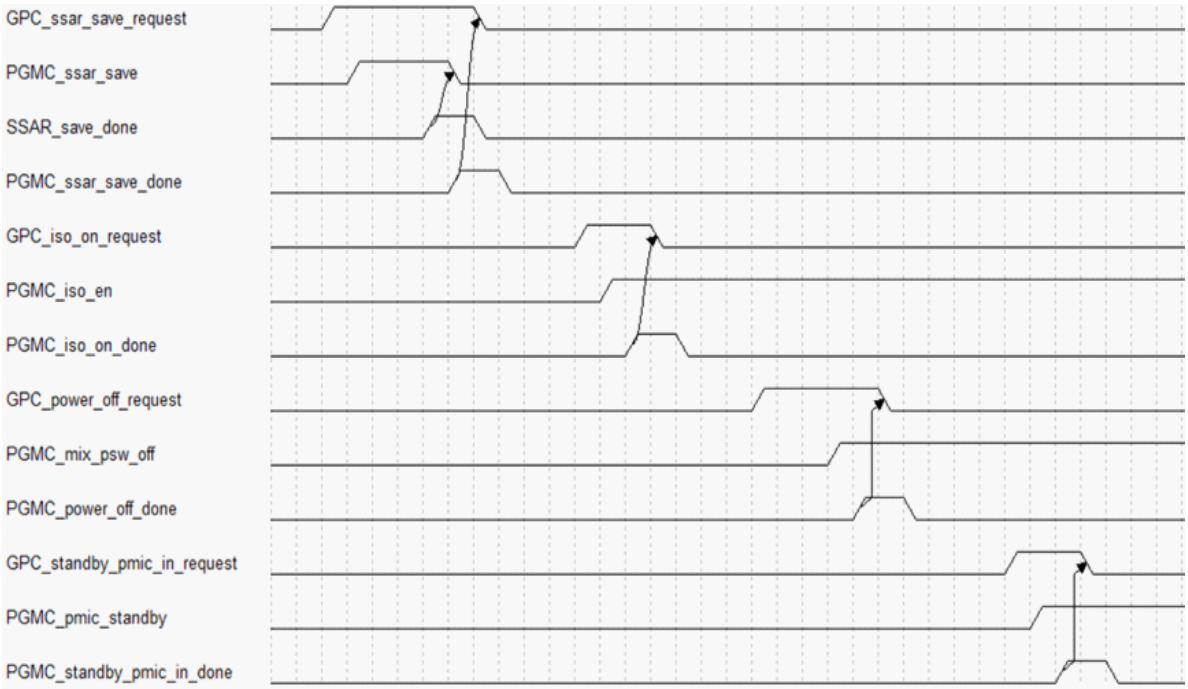

Figure 20-3. UPI Handshake

20.5.2 Register Access Permission

For PGMC register access, the register x_AUTHEN_CTRL is used to control access permission. The CPC and MPC shares AUTHEN_CTRL with their MIFs.

20.6 Memory Map and register definition

This section includes the PGMC module memory map and detailed descriptions of all registers.

Power management	PMU	Power Management Power Management Unit
Signal multiplexing	IOMUX	External Signals and Pin Multiplexing IOMUX
Interrupts, DMA Events and XBAR Assignments	-	Interrupts, DMA Events and XBAR Assignments

NOTE

The on-chip DCDC converter is suitable for consumer and industrial applications up to the rated temperature specified in their respective market datasheets. For automotive applications, please check the automotive datasheet or consult with your NXP representative for appropriate power supply requirements.

21.2 Overview

The DCDC Converter (DCDC) is a synchronous buck mode DC-DC converter with two outputs. The DCDC is used for generating the power supply for the chip's core logic.

21.2.1 Block diagram

The block diagram of the DCDC module is provided below:

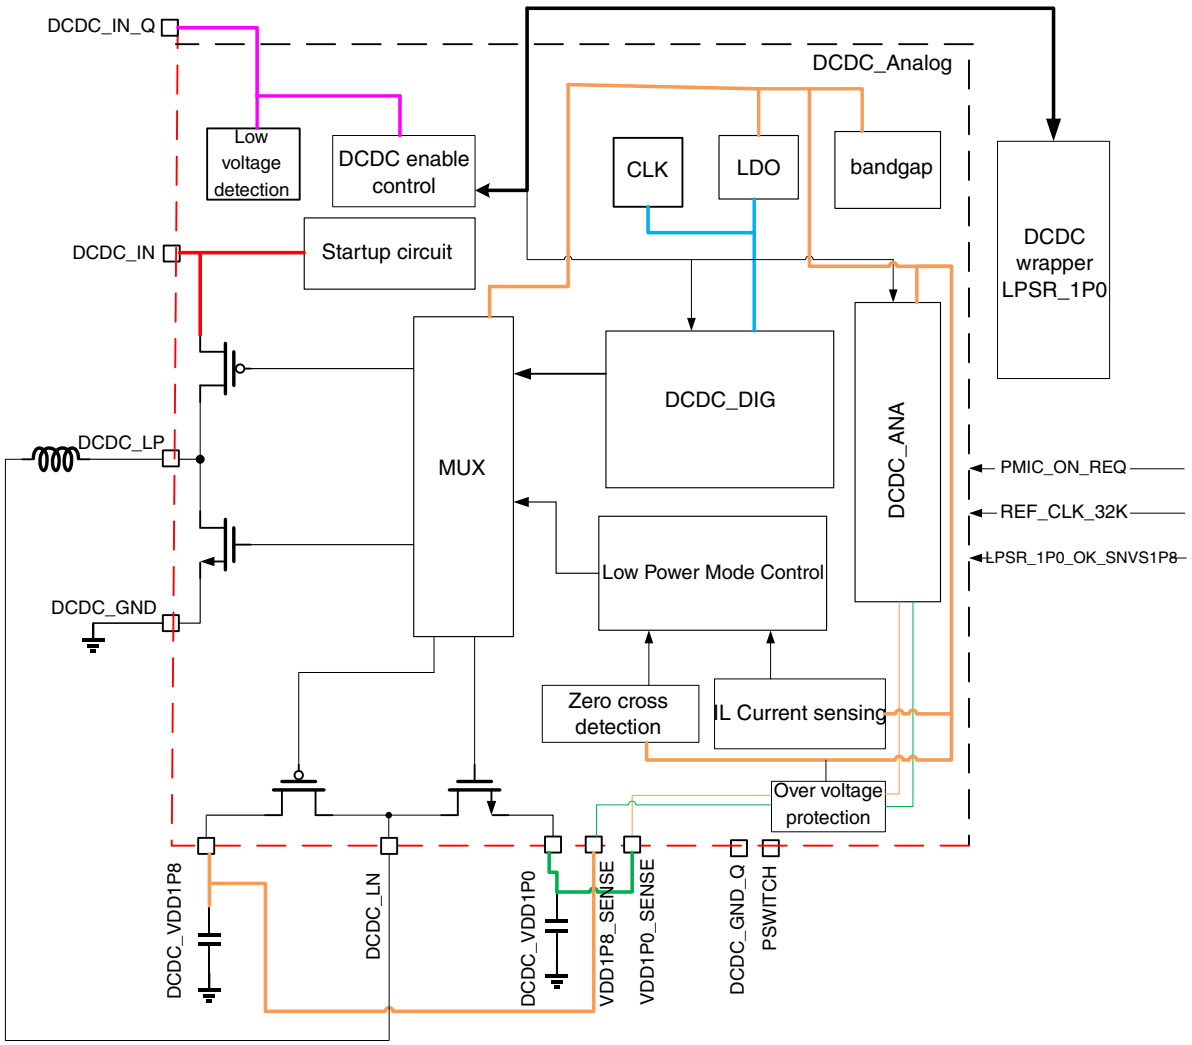

Figure 21-1. DCDC block diagram

21.2.2 Features

The DCDC includes the following features:

- Buck mode only, 3.3V input with 1.8V and 1.0V outputs.
- DCDC_PSWITCH pin to turn on DCDC
- Continuous conduction mode (CCM) and discontinuous conduction mode (DCM) operation.
- RUN mode and LP (low-power) mode

    - RUN mode supports CCM and DCM
- Automatic pulse skipping
- Overcurrent and overvoltage protection
- Low-input voltage detection

21.3 Functional description

The DCDC converter is a synchronous step-down converter with two outputs using one inductor. In run mode, it can operate on continuous conduction mode or discontinuous conduction mode, depending on the level of the load current. Discontinuous conduction mode needs to be enabled through register configuration.

DCDC can be configured to operate on LP (low-power) mode when the load current is less than 50mA. During the LP mode, the converter operates in pulse mode with a minimum quiescent current to maintain high efficiency.

21.3.1 Application mode

DCDC has one application mode, which is configured by the DCDC_MODE Pad:

- **Application mode 0**: DCDC_IN is connected to 3.3 V, and DCDC output is 1.8 V and 1.0 V. DCDC_MODE is tied to ground.

21.3.2 Functional Modes

- Run Mode
    - Continuous Conduction Mode
    - Discontinuos Conduction Mode - improved efficency and same working state as Continuous Conduction Mode
- Low-Power Mode
    - Improved efficiency
    - Ripple is a little bit higher than Run Mode

21.3.3 Operation

The DCDC is a synchronous buck converter. An illustration of the power switch arrangment is shown below.

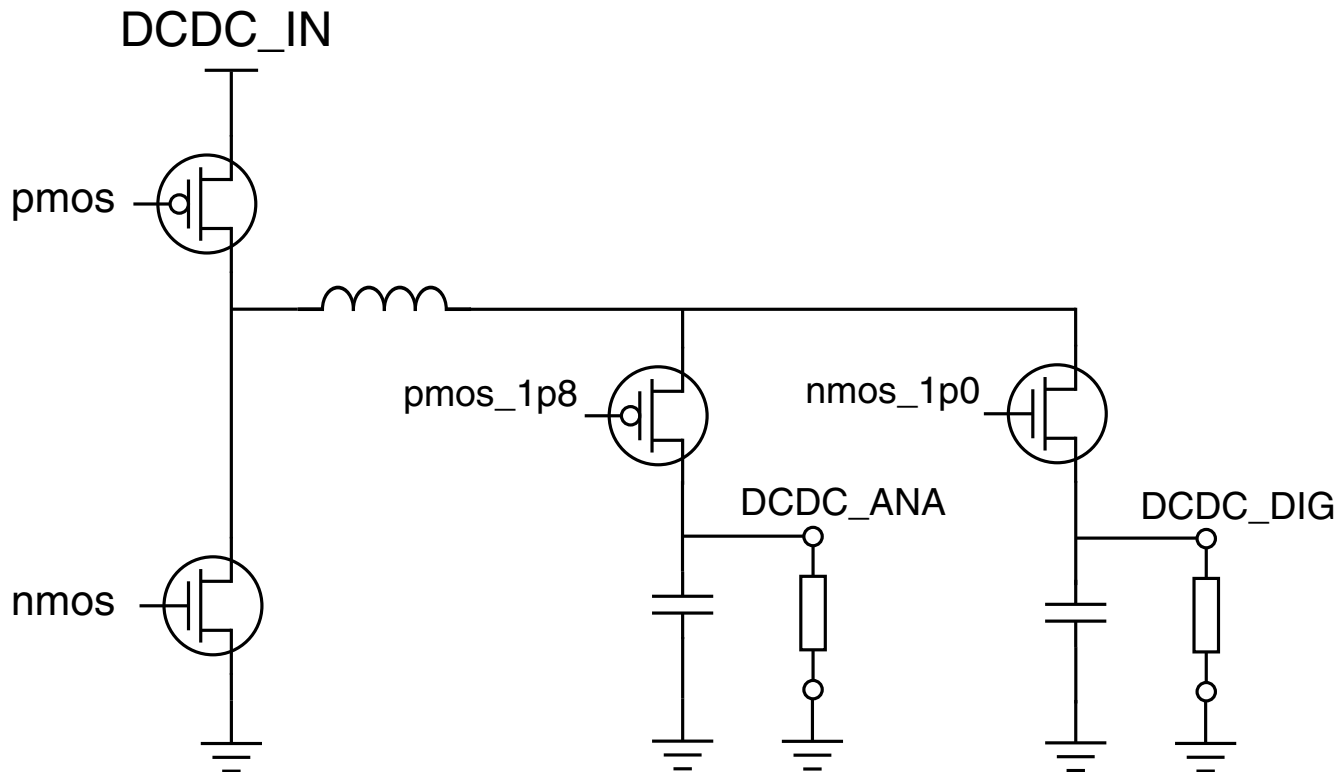

Figure 21-2. DCDC Power Switches

The DCDC features zero cross detection for Discontinuos Conduction Mode. This functionality is enabled by the REG0[PWD_ZCD] bit. pmos_1p8 and nmos_1p0 would not be turned on simultaneously. The DCDC control loop will determine which output is more starved for charging, and turn on it's switch. When one output is charged, the other one is sustained by the big capacitor.

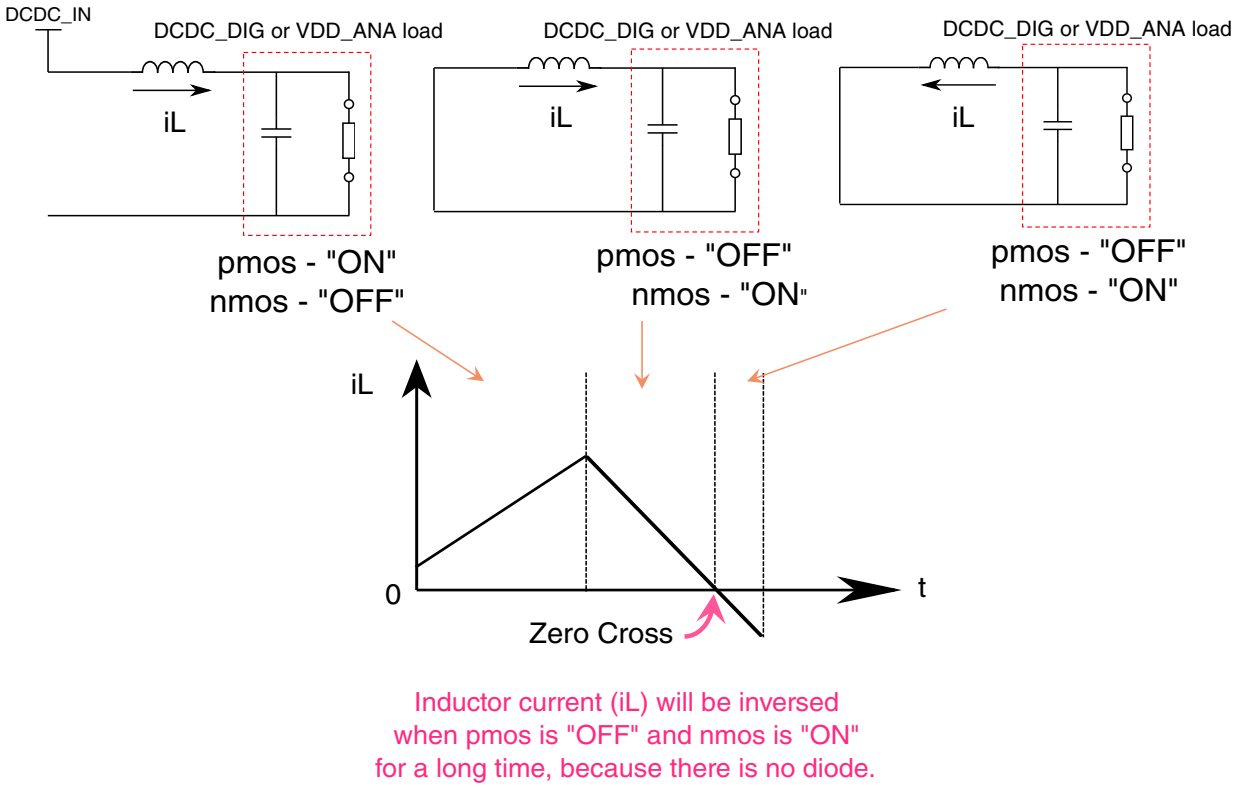

Figure 21-3. Zero Cross Detection

Working as the CCM, the inductor current (iL) will be inversed during the cycle of pmos is "OFF" and nmos is "ON" if the current loading is half of the current ripple of the inductor. Working as the DCM, zero cross detector will be turned on, it will turn off nmos to stop the current of inductor from being inversed, so the current of the inductor will remain zero until the next charging cycle starts. Therefore DCM can improve the efficiency.

21.3.4 Overcurrent, Overvoltage, and Low Voltage Detection

DCDC supports the following three protection functions:

1. Overcurrent protection
   - In run mode, DCDC will shut down when detecting abnormal large current in the P-type power switch (threshold - 1.5A or 2A, which can be programmed by register).
   - In power-save mode, DCDC will stop charging the inductor when detecting large current in the P-type power switch (threshold - 200 to 250mA).
2. Overvoltage protection - DCDC will shut down when detecting high voltage on either of the two outputs (typical 2.5V for DCDC_ANA and 1.5V for DCDC_DIG).
3. Low-Voltage Detection - DCDC will shut down when detecting the input voltage is too low (typical 2.6V for DCDC_IN).

NOTE

Please see the Chip Datasheet for the specified values.

21.3.5 Clocks

This section describes clocks and special clocking requirements for the DCDC module.

Table 21-2. Clocks

Clock	Description
ipg_clk	Peripheral Clock
clk_24M	24 MHz reference clock

The diagram below illustrates the logical selection of the 24M clock when auto clock switching is disabled:

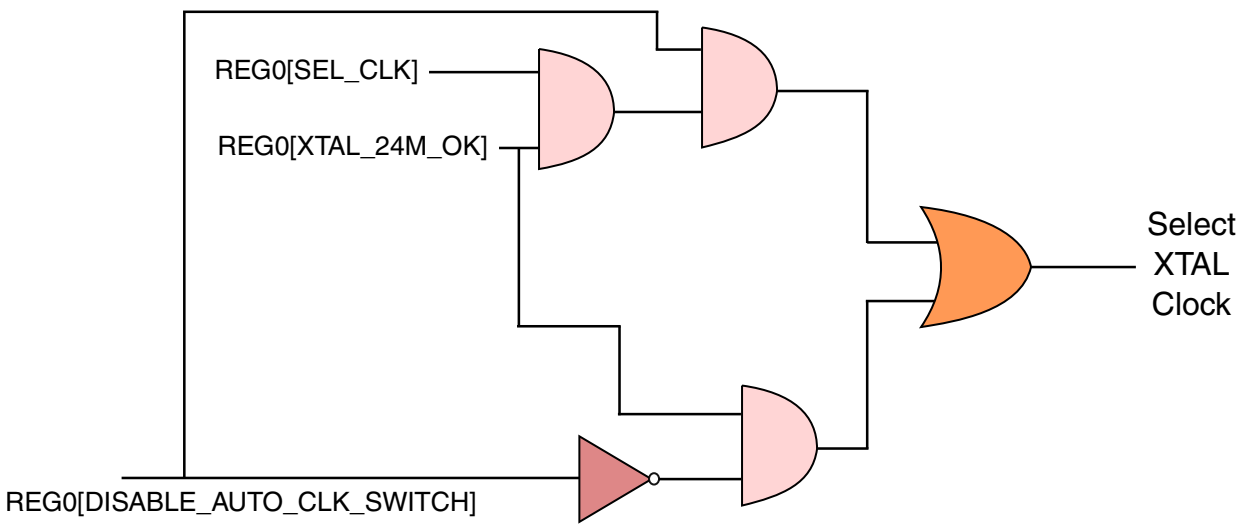

Figure 21-4. 24M Clock Selection

21.3.6 Interrupts

Please see the IRQ chapter for any assigned interrupts.

21.4 External Signals

Table 21-3. External Signals

External Signals	Power Domain	Description	Direction
DCDC_ANA	DCDC_ANA	DCDC 1P8 output	O
DCDC_ANA_SENSE	DCDC_ANA	The PAD used to provide 1P8V power to DCDC analog module and the sense point for DCDC feedback loop. It is connected to the 1.8V output of DCDC on the board.	I
DCDC_DIG	DCDC_DIG	DCDC 1P0 output	O
DCDC_DIG_SENSE	DCDC_DIG	The PAD used to provide 1P0V power to DCDC analog module and the sense point for DCDC feedback loop. It is connected to the 1.0V output of DCDC on the board.	I
DCDC_IN	DCDC_IN	The DCDC input which is connected to the power switch of DCDC	I
DCDC_LP	DCDC_IN	The PAD connected to one terminal of the external inductor on the board.	IO
DCDC_LN	DCDC_IN	The PAD connected to another terminal of the external inductor on the board.	IO
DCDC_GND	DCDC_IN	Ground PAD which is connected to DCDC power switch	O
DCDC_IN_Q	DCDC_IN	Analog power supply used by some analog modules of DCDC. It is from the same source as DCDC_IN, but is split from DCDC_IN, in order to make it more quiet.	I
DCDC_GND_Q	DCDC_IN	Ground PAD used by the analog module of DCDC	O
DCDC_PSWITCH	DCDC_IN	The PAD which can bypass the DCDC	I
DCDC_MODE	DCDC_IN	The PAD which is used to distinguish between application mode “0” and “1”. Please refer to the Application Mode section for more information.	I
lpsr_1p0_dig_ok	SNVS_1P8	The signal in SNVS 1P8 domain. It indicates that LPSR 1P0 power is OK.	I
PMIC_ON_REQ	SNVS_1P8	The request signal from SNVS 1P8 to turn on DCDC	I

21.5 Initialization

To enable DCDC, the following conditions must be met:

1. Power supply SNVS_1P8, LPSR_1P0 and DCDC_IN are available
2. 32kHz Clock in the SNVS_1P8 domain is available
3. Provide DCDC with 1ms of reset time after DCDC_IN powers up

4. PMIC_ON_REQ && lpsr_1p0_dig_ok && CTRL0[ENABLE] && DCDC_PSWITCH = 1'b1

The Power up sequence is:

- Power SNVS_1P8
- DCDC_IN powered up
- Delay 1ms reset time
- PMIC_ON_REQ && LPSR_1P0_OK_SNVS1P8 && DCDC_EN && DCDC_PSWITCH = 1'b1
- DCDC startup

21.6 Application Information

21.6.1 Typical Application

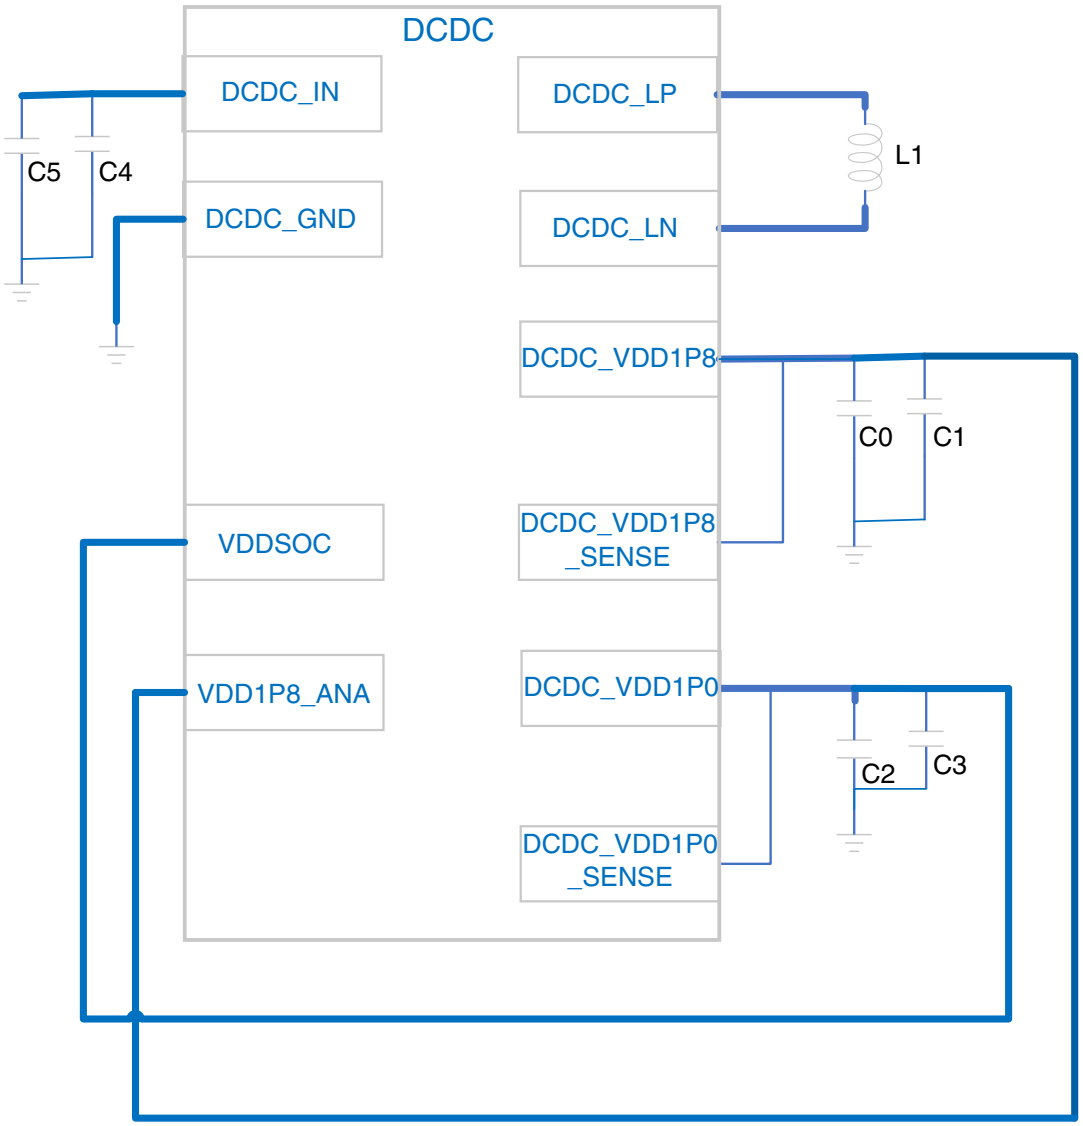

Figure 21-5. DCDC

Table 21-4. DCDC Component List

Component	Description	Recommendation
L1	Inductance needed by DCDC	4.7uH with low DC resistance (less than 0.1 ohm ESR) inductor to minimize conduction losses.
C0	High-frequency decoupling capacitor	At least 0.1uF.
C1	Filter capacitor on DCDC_ANA output	A 33uF with low ESR (less than 0.02 ohm ESR) capacitor for small ripple.
C2	High frequency decoupling capacitor	At least 0.1uF.
C3	Filter capacitors DCDC_DIG output	A 33uF with low ESR (less than 0.02 ohm ESR) capacitor for small ripple. Need a 66uF on DCDC_DIG output if the loading on it is larger than 500mA.

Table continues on the next page...

Table 21-4. DCDC Component List (continued)

Component	Description	Recommendation
C4	High-frequency decoupling capacitor for DCDC_IN	At least 0.1uF. The parasitic inductance of the routing from C4 to DCDC_IN, of the chip on the board, should be less than 0.5nH.
C5	Filter capacitor of DCDC_IN.	A 10uF (or greater) with low ESR capacitor. Increase capacitance (no limit) for better input-voltage filtering.

NOTE

It is very important to place C0, C1, C2, C3, C4 as close to the pin as possible.

NOTE

Please see the chip datasheet for specification details.

21.6.2 Recommended configuration

It is recommended to use the CCM mode.

21.7 Memory Map and register definition

This section includes the DCDC module memory map and detailed descriptions of all registers.

Field	Function
31 STS_DC_OK	DCDC Output OK This is the status bit indicates if the DCDC output voltages (ANA and DIG) are stable. The lock time depends on the loading and the DCDC mode. 0b - DCDC is settling 1b - DCDC already settled
30 —	Reserved
29 XTAL_24M_OK	24M XTAL OK This bit determines if the DCDC uses the internal ring oscillator or the xtal 24M. 0b - DCDC uses internal ring oscillator 1b - DCDC uses xtal 24M
28	Reserved

Table continues on the next page...

Field	Function
—	
27 XTALOK_DISABLE	Disable xtalok detection circuit This is a debug bit which should not be changed in real case. This bit disables and bypasses the clock 24 MHz reference clock detector. 0b - Enable xtalok detection circuit 1b - Disable xtalok detection circuit and always outputs OK signal "1"
26 PWD_CMP_OFFSET	power down the out-of-range detection comparator The out-of-range comparator monitors the output voltage of DCDC. When the DCDC output voltage is out of range, this comparator will speed up DCDC control loop in an attempt to bring the DCDC output voltage back in range. PWD_CMP_OFFSET must be set to 0 (out-of-range comparator on) if LOOPCTRL_EN_RCSCALE is to be used to speed up the transient response. 0b - Out-of-range comparator powered up 1b - Out-of-range comparator powered down
25 —	Reserved
24 —	Reserved
23 —	Reserved
22 —	Reserved
21 LP_HIGH_HYS	Low Power High Hysteric Value Adjust hysteretic value in low power from 12.5mV to 25mV 0b - Adjust hysteretic value in low power to 12.5mV 1b - Adjust hysteretic value in low power to 25mV
20 —	Reserved
19-18 —	Reserved
17 PWD_HIGH_VDD1P0_DET	Power Down High Voltage Detection for VDD1P0 Power down overvoltage detection comparator for the VDD1P0 output. 0b - Overvoltage detection comparator for the VDD1P0 output is enabled 1b - Overvoltage detection comparator for the VDD1P0 output is disabled
16 PWD_HIGH_VDD1P8_DET	Power Down High Voltage Detection for VDD1P8 Power down overvoltage detection comparator for the VDD1P8 output. 0b - Overvoltage detection comparator for the VDD1P8 output is enabled 1b - Overvoltage detection comparator for the VDD1P8 output is disabled
15-12 —	Reserved
11 PWD_CMP_DCDC_IN_DET	Set to "1" to power down the low voltage detection comparator 0b - Low voltage detection comparator is enabled 1b - Low voltage detection comparator is disabled

Table continues on the next page...

Field	Function
10-9 —	Reserved
8 PWD_OVERCUR_DET	Power down overcurrent detection comparator 0b - Overcurrent detection comparator is enabled 1b - Overcurrent detection comparator is disabled
7-5 CUR_SNS_THRSH	Current Sense (detector) Threshold Set the threshold of current detector, if the peak current of the inductor exceeds the threshold, the current detector will assert. CUR_SNS_THRSH[1] is used to set overcurrent threshold in RUN mode - 0 is 1.5A, 1 is 2A CUR_SNS_THRSH[0] is used to set overcurrent threshold in LP (low-power) mode - 0 is 250mA, 1 is 200mA
4 PWD_CUR_SNS_CMP	Power down signal of the current detector Power down the control signal of the current detector. 0b - Current Detector powered up 1b - Current Detector powered down
3 PWD_OSC_INT	Power down internal ring oscillator Only set this bit when 24 MHz xtal oscillator is available. 0b - Internal ring oscillator powered up 1b - Internal ring oscillator powered down
2 SEL_CLK	Select Clock Select 24 MHz Crystal clock for DCDC, **when DISABLE_AUTO_CLK_SWITCH is set.** If DISABLE_AUTO_CLK_SWITCH is set to 0 and 24M xtal is OK, the clock source will switch from internal ring oscillator to 24M xtal automatically. If DISABLE_AUTO_CLK_SWITCH is set to 1, SEL_CLK will determine which clock source the DCDC uses: if SEL_CLK=0, DCDC will use internal ring oscillator, if SEL_CLK=1, DCDC will use 24M xtal. 0b - DCDC uses internal ring oscillator 1b - DCDC uses 24M xtal
1 DISABLE_AUTO_CLK_SWITCH	Disable Auto Clock Switch Disable automatic clock switch from internal oscillator to xtal clock. 0b - If DISABLE_AUTO_CLK_SWITCH is set to 0 and 24M xtal is OK, the clock source will switch from internal ring oscillator to 24M xtal automatically 1b - If DISABLE_AUTO_CLK_SWITCH is set to 1, SEL_CLK will determine which clock source the DCDC uses
0 PWD_ZCD	Power Down Zero Cross Detection Power down the zero cross detection function for discontinuous conductor mode. 0b - Zero cross detetion function powered up 1b - Zero cross detetion function powered down

19-13 —	Reserved
12-11 LP_CMP_ISRC_SEL	Low Power Comparator Current Bias set the current bias of low power comparator. 00b - 50nA 01b - 100nA 10b - 200nA 11b - 400nA
10-6 VBG_TRIM	Trim Bandgap Voltage Trim step is 3mV. 0_0000b - 0.452V 1_0000b - 0.5V 1_1111b - 0.545V
5 —	Reserved
4 RLOAD_REG_EN_LPSR	Load Resistor Enable This controls the load resistor of the internal regulator of DCDC. Connecting the load resistor to the internal LDO in RUN mode, improves the startup ripple of the LDO, but the load resistor will consume additional current. Once the STS_DC_OK asserts, the load resistor can be disconnected. 0b - Disconnect load resistor 1b - Connect load resistor
3 DM_CTRL	DM Control Set it to "1" when DCM is enabled. 0b - No change to ripple when the discontinuous current is present in DCM. 1b - Improves ripple when the inductor current goes to zero in DCM.
2-0 —	Reserved

21.7.1.6 DCDC Register 2 (REG2)

21.7.1.6.1 Offset

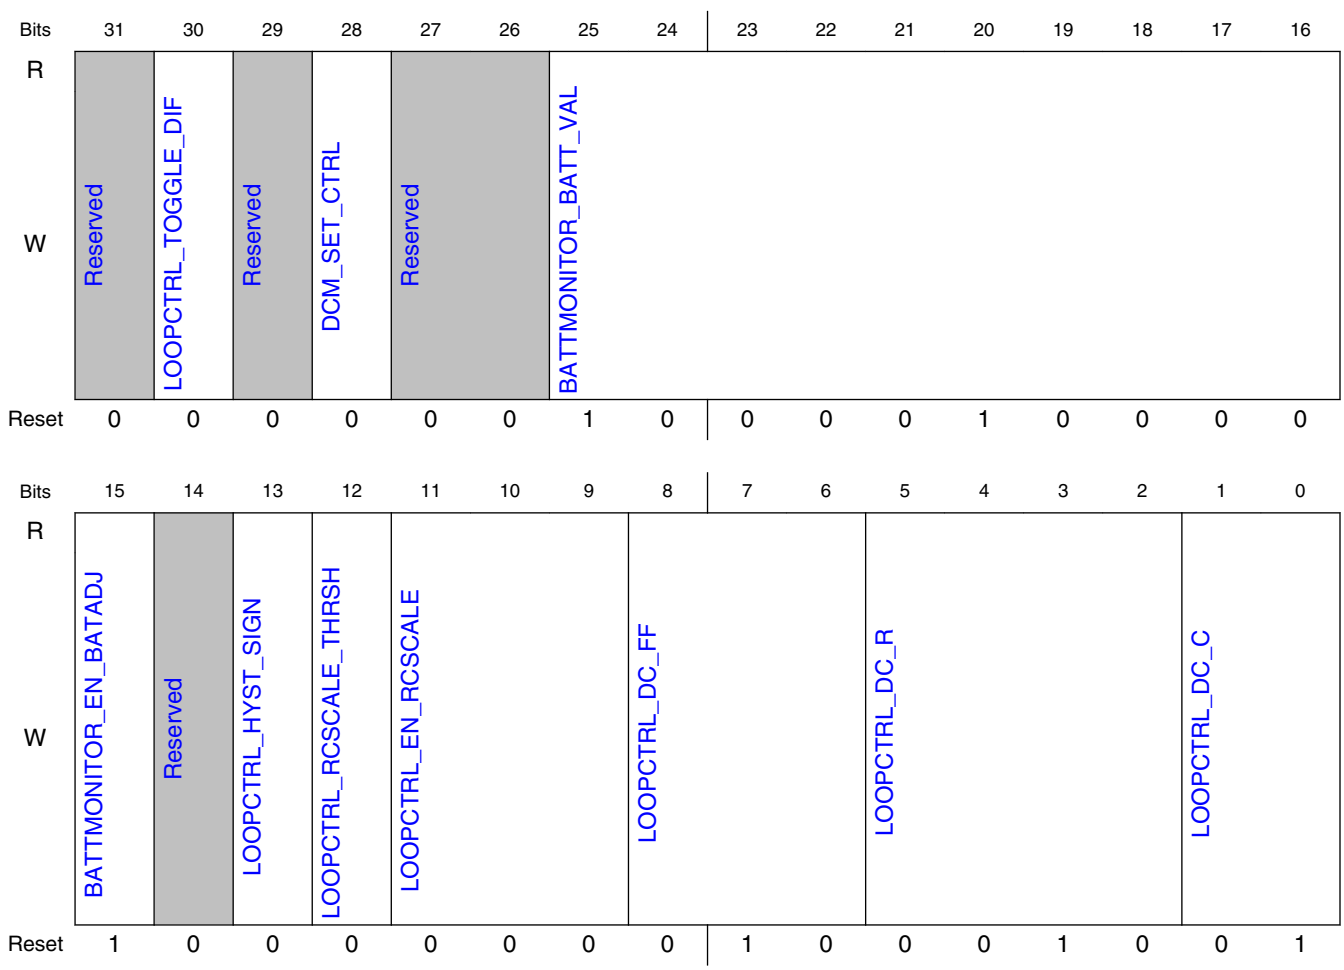
Register	Offset
REG2	10h

21.7.1.6.2 Function

DCDC register 2

This register controls various high-level functions of the DCDC

21.7.1.6.3 Diagram



21.7.1.6.4 Fields

Field	Function
31 —	Reserved
30 LOOPCTRL_TOGGLE_DIF	Set high to enable supply stepping to change only after the differential control loop has toggled as well. This should eliminate any chance of large transients when supply voltage changes are made.
29 —	Reserved
28 DCM_SET_CTRL	DCM Set Control Set high to improve the transition from heavy load to light load. **NOTE:** The REG2[DCM_SET_CTRL] should be set to 1'b1 if there is a current backflow to DCDC output in an application.
27-26 —	Reserved
25-16 BATTMONITOR_BATT_VAL	Software should be configured to place the battery voltage in this register measured with an 8-mV LSB resolution through the ADC. This value is used by the DCDC converter and must be correct before setting BATTMONITOR_EN_BATADJ.
15 BATTMONITOR_EN_BATADJ	This bit enables the DCDC to improve efficiency and minimize ripple using the information from the BATT_VAL field. It is very important that the BATT_VAL contain accurate information before setting EN_BATADJ.
14 —	Reserved
13 LOOPCTRL_HYST_SIGN	Invert the sign of the hysteresis in DCDC analog comparators.
12 LOOPCTRL_RCSCALE_THRSH	Increase the threshold detection for RC scale circuit.
11-9 LOOPCTRL_EN_RCSCALE	Enable RC Scale This enables the analog circuit of the DCDC to respond faster under transient load conditions. Higher the value, faster the response. 0x5 is the highest setting. 0x6 - 0x7: Not available
8-6 LOOPCTRL_DC_FF	Two's complement feed forward step in duty cycle in the switching DCDC converter. Each time this field makes a transition from 0x0, the loop filter of the DCDC converter is stepped once by a value proportional to the change. This can be used to force a certain control loop behavior, such as improving response under known heavy load transients.
5-2 LOOPCTRL_DC_R	Magnitude of proportional control parameter in the switching DCDC converter control loop.
1-0 LOOPCTRL_DC_C	Ratio of integral control parameter to proportional control parameter in the switching DCDC converter, and can be used to optimize efficiency and loop response.

21.7.1.7 DCDC Register 3 (REG3)

21.7.1.7.1 Offset

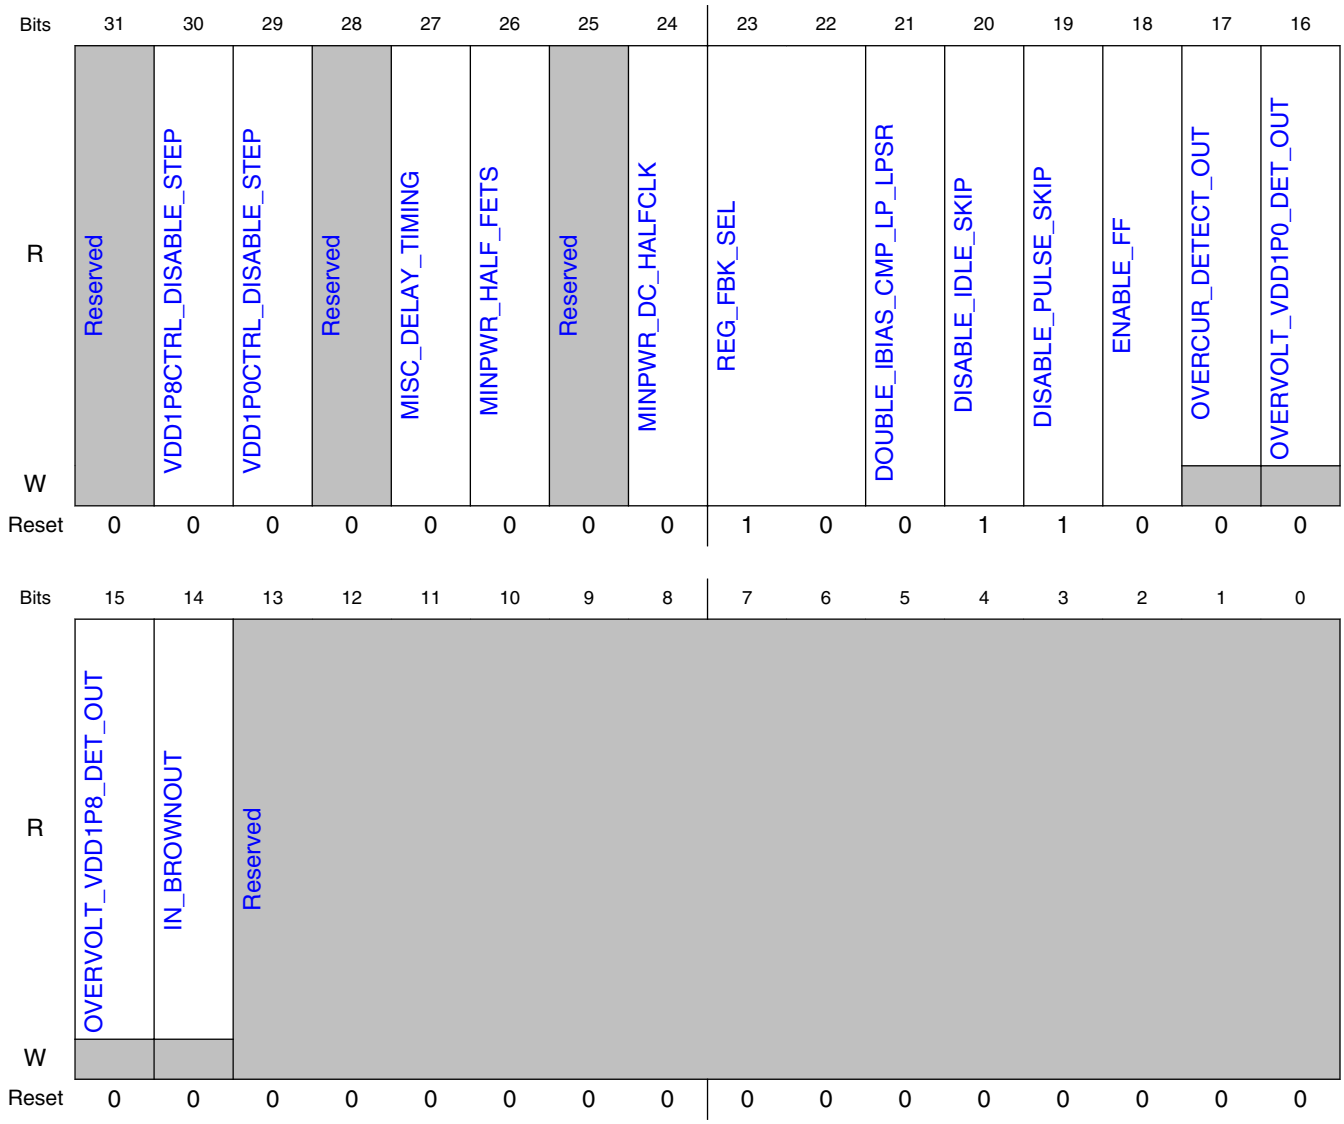
Register	Offset
REG3	14h

21.7.1.7.2 Function

DCDC register 3

This register controls various high-level functions of the DCDC

21.7.1.7.3 Diagram



21.7.1.7.4 Fields

Field	Function
31 —	Reserved
30 VDD1P8CTRL_DISABLE_STEP	Disable Step for VDD1P8 Disable stepping for VDD1P8. Must set this bit before entering low power modes. 0b - Enable stepping for VDD1P8 1b - Disable stepping for VDD1P8
29	Disable Step for VDD1P0 Disable stepping for VDD1P0. Must set this bit before entering low power modes.

Table continues on the next page...

Field	Function
VDD1P0CTRL_DISABLE_STEP	0b - Enable stepping for VDD1P0 1b - Disable stepping for VDD1P0
28 —	Reserved
27 MISC_DELAY_TIMING	Miscellaneous Delay Timing Ajust delay to reduce ground noise.
26 MINPWR_HALF_FETS	Use half switch FET
25 —	Reserved
24 MINPWR_DC_HALFCLK	Set DCDC clock to half freqeuncy for continuous mode. 0b - DCDC clock remains at full frequency for continuous mode 1b - DCDC clock set to half frequency for continuous mode
23-22 REG_FBK_SEL	Select the feedback point of the internal regulator
21 DOUBLE_IBIAS_CMP_LP_LPSR	1b - Double the bias current of the comparator for low-voltage detector in LP (low-power) mode
20 DISABLE_IDLE_SKIP	0b - Enable the idle skip function. The DCDC will be idle when out-of-range comparator detects the output voltage is higher than the target by 25mV. This function requires the out-of-range comparator to be enabled (PWD_CMP_OFFSET=0).
19 DISABLE_PULSE_SKIP	Disable Pulse Skip 0b - Stop charging if the duty cycle is lower than what is set by NEGLIMIT_IN
18 ENABLE_FF	1b - Enable feed-forward (FF) function that can speed up transient settling.
17 OVERCUR_DETECT_OUT	signal "1" when overcurrent happens. 1b - Overcurrent
16 OVERVOLT_VDD1P0_DET_OUT	signal "1" when overvoltage on the VDD1P0 output happens 1b - VDD1P0 Overvoltage
15 OVERVOLT_VDD1P8_DET_OUT	signal "1" when overvoltage on the VDD1P8 output happens 1b - VDD1P8 Overvoltage
14 IN_BROWNOUT	signal "1" when the voltage on DCDC_IN is lower than 2.6V 1b - DCDC_IN is lower than 2.6V
13-0 —	Reserved

NOTE

The temperature sensor registers are accessed through the Analog IP (AI) Interface.

22.2 Overview

The Temperature Sensor (TMPSNS) implements a temperature sensor/conversion function based on a temperature-dependent voltage to time conversion.

22.2.1 Block diagram

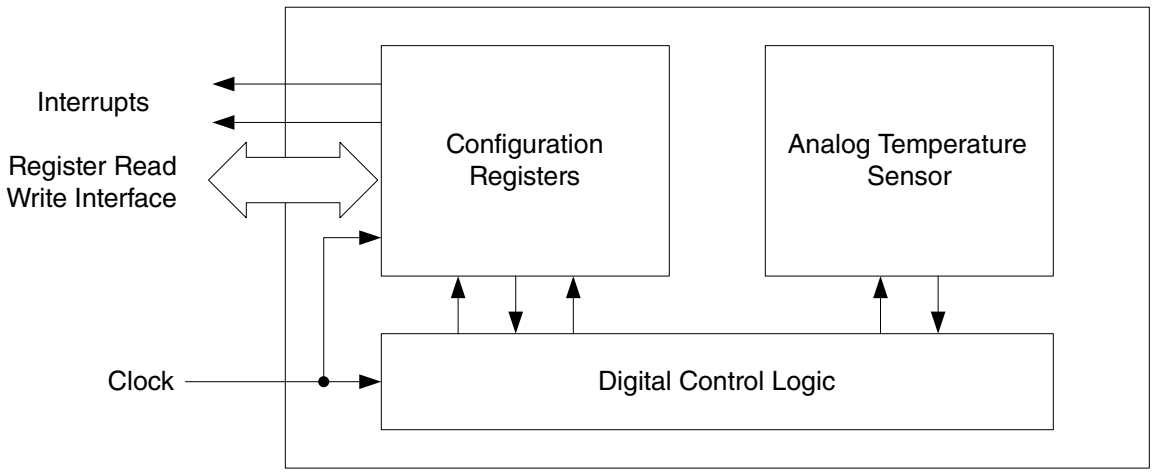

Figure 22-1. Temperature sensor block diagram

22.2.2 Features

The Temperature Sensor supports the following features:

- Temperature Alarm Interrupts to indicate if temperature is beyond the programmed thresholds.
  - Three tier alarms supported viz., Low, High and Panic.
- Single, and Continuous Measurement Mode

22.3 Functional description

The temperature sensor module features alarm functions that can raise independent interrupt signals if the temperature is above two high-temperature thresholds and below a low temperature threshold. These temperature thresholds are programmable and designated as low, high and panic temperature. The panic threshold is a special programmable threshold in that if the temperature increases above this value and the temperature-panic-reset interrupt is enabled in the System Reset Controller, the hardware will assume that software no longer has control over the thermal situation and will initiate a reset of the chip. In order to avoid false panic temperature initiated resets, the panic alarm will not fire until the temperature panic condition has been met for four consecutive conversion cycles. A self-repeating mode can also be programmed which executes a temperature sensing operation based on a programmed delay.

Since the high and low temperature thresholds are programmable, they form a sliding temperature bracket that can be tailored to the application's needs. For example, at startup software can set the low temperature threshold to the minimum temperature code and the high temperature threshold to a maximum operating temperature for the system.

The system can then use this module to monitor the on-die temperature and take appropriate actions such as throttling back the core frequency when a the high temperature interrupt is set. Once the high temperature interrupt is set then the system can program the low temperature threshold to a desired cool down temperature. The system would then switch to monitoring the low temperature alarm and wait for its interrupt to be set. With this scheme, once the low temperature interrupt is set, then software could be assured that the temperature has cooled down to a safe level and the process could be repeated.

22.3.1 Modes of Operation

The following modes are supported in Temperature Sensor:

- Single Measurement Mode
  - Performs one measurement per Start indication from software.
  - Finish bit asserted on every measurement completion.
- Continuous Measurement Mode
  - Performs continuous measurements (once initiated by software) at the rate defined by CTRL1[FREQ]
  - Frequency of measurements programmable by software
  - Finish bit asserts on every measurement completion, if previously cleared.

22.3.2 Temperature Sensing

The value returned by the Temperature Sensor in STATUS0[TEMP_VAL] does not indicate the actual temperature. The temperature value can be obtained by the following equation:

$$temp_{diode} = - ts_{21} - \frac{\sqrt{ts_{21}^2 - 4 * ts_{22} * (ts_{20} + ts_{25c} - ts_{meas})}}{2 * ts_{22}}$$

Where:

ts_{22} = 0.002

ts_{21} = - 5.39

ts_{20} = 133.6

ts_{meas} is the measured temperature value from STATUS0[TEMP_VAL]

ts_{25c} comes from fuse

22.3.3 Clocks

This module uses a 24MHz reference clock from the 24MHz crystal oscillator.

22.3.4 Reset

All resets are controlled through the Analog IP (AI) Interface.

22.3.5 Interrupts

All interrupts are controlled through the Analog IP (AI) Interface.

22.4 External Signals

This module does not have any SoC level pins.

22.5 Initialization

There are no special considerations for initializing this module. The CTRL[PWD] and CTRL[PWD_FUL] bits are used to power down the temperature sensor.

22.6 Application Information

22.6.1 Configuration Steps

The following steps should be followed when configuring the Temperature Sensor in Single Measurement Mode.

1. Set CTRL0[V_SEL]=0 to select normal temperature measuring mode
2. Write the appropriate threshold values in RANGE0 and RANGE1 registers for the Panic, High and Low Temperature Alarms to trigger. Please refer to section "Temperature Sensing" to determine the value to be programmed based on desired temperature value.
3. Enable appropriate interrupts by setting the corresponding interrupt enable bits to '1' in the CTRL1 register.
4. Power up the analog section by setting the CTRL1[PWD] and CTRL1[PWD_FULL] bits to '0'.
5. Ensure that the CTRL1[FREQ] field is set to 0.
6. Set the CTRL1[START] bit to 1 to enable the measurement process.
7. Poll the STATUS0[FINISH] bit to determine the completion of the measurement.
8. Read the measured value in the STATUS0[TEMP_VAL] field. Refer to Temperature Sensing to determine the actual temperature value based on the measured value.
9. Clear the CTRL1[FINISH] bit by writing '1' to it.
10. Clear the CTRL1[START] bit by writing '0' to it. This is important to start the next single measurement.

Repeat the steps 6 to 10 to start another measurement cycle.

The following steps change when configuring the Temperature Sensor in Multiple Measurement Mode.

- In Step 5, set the desired frequency of measurement by writing a non-zero value in CTRL1[FREQ] field. This field determines the number of idle clock cycles between two conversions. The next measurement starts after counting these clock cycles.
- Repeat Steps 7 to 9 to keep getting continuous measurements.
- Perform Step 10 only when continuous mode is to be exited.

22.7 Memory Map and register definition

The memory map and descriptions of all registers are shown below.

NOTE

For related IPS Domain Slot control, please see IPS Domain Registers in Power Management Unit (PMU) chapter.

22.7.1 Temperature Sensor Memory Map register descriptions

The memory map comprises of 32-bit aligned registers which can be accessed via 8, or 16 or 32-bit accesses only. Write access to reserved locations will generate transfer error. Read access to reserved locations will also generate transfer error and the read data bus will show all 0s.

The module will not check for correctness of programmed values in the registers and software must ensure that correct values are being written.

NOTE

All register bit fields are shadowed except CTRL0, and STATUS0 . Shadowed bit fields can be changed only when CTRL1[START] = '0' or CTRL1[PWD] = '1'. Changing shadowed bit fields at other time will take effect only when START bit is toggled from '0' to '1' or PWD bit is toggled from '1' to '0'. CTRL0, STATUS0 can be changed irrespective of the START and PWD bit values.

22.7.1.1 TMPSNS memory map

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)

50	Temperature Sensor Status Register 0 (STATUS0)	32	W1C	0000_0000

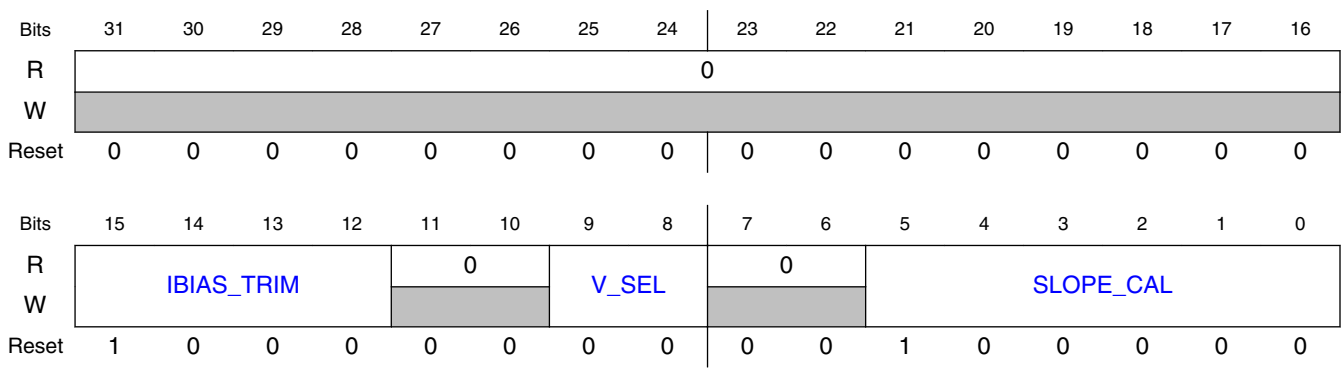
22.7.1.2 Temperature Sensor Control Register 0 (CTRL0)

Configures the analog temperature sensor control.

22.7.1.2.1 Offset

Register	Offset	Description
CTRL0	0h	Temperature Sensor Control Register 0
CTRL0_SET	4h	Writing a 1 to a bit in this register sets the corresponding bit in CTRL0
CTRL0_CLR	8h	Writing a 1 to a bit in this register clears the corresponding bit in CTRL0
CTRL0_TOG	Ch	Writing a 1 to a bit in this register toggles the corresponding bit in CTRL0

22.7.1.2.2 Diagram



22.7.1.2.3 Fields

Field	Description
31-16 —	Reserved field. Reads only zeros.

Table continues on the next page...

Field	Description
15-12 IBIAS_TRIM	Current bias trim value This field defines the trim setting for the bias current that's used for ramp slope calibration. Note: The trim value is loaded from the fuse.
11-10 —	Reserved field. Reads only zeros.
9-8 V_SEL	Voltage Select Determines the voltage that will be detected by the temperature sensor. 00 - Normal temperature measuring mode 01-10 - Reserved
7-6 —	Reserved field. Reads only zeros.
5-0 SLOPE_CAL	Ramp slope calibration control This field provides the calibration for the ramp slope of temperature sensor with trimming capacitor value. Note: This value is loaded from the fuse.

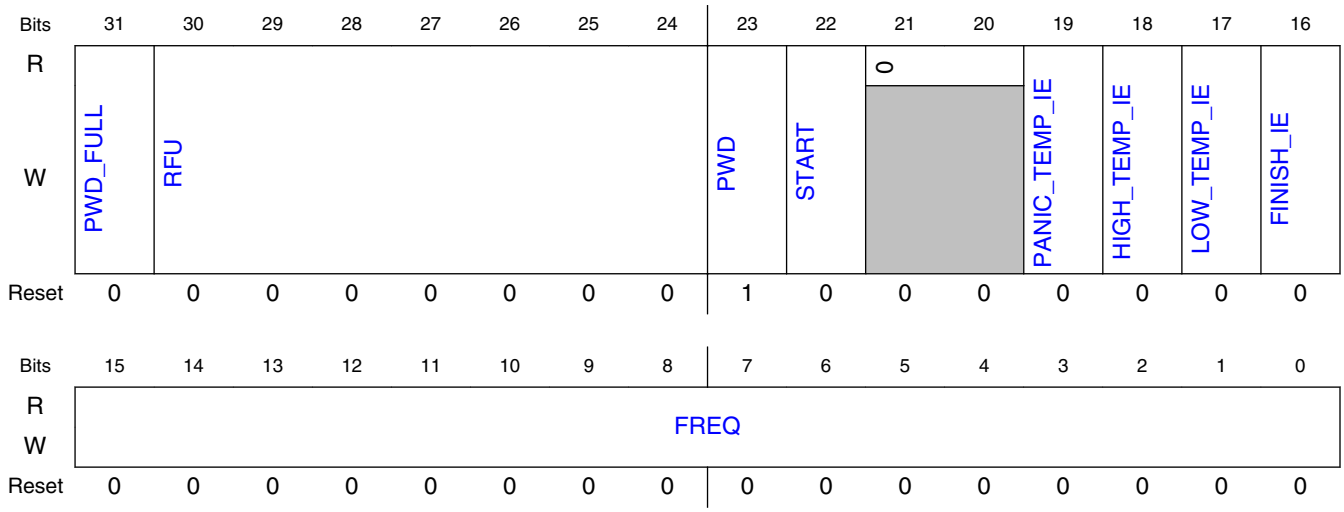
22.7.1.3 Temperature Sensor Control Register 1 (CTRL1)

Configures the digital temperature sensor control and mode of operation (Single Read or Continuous Read).

22.7.1.3.1 Offset

Register	Offset	Description
CTRL1	10h	Temperature Sensor Control Register 1
CTRL1_SET	14h	Writing a 1 to a bit in this register sets the corresponding bit in CTRL1
CTRL1_CLR	18h	Writing a 1 to a bit in this register clears the corresponding bit in CTRL1
CTRL1_TOG	1Ch	Writing a 1 to a bit in this register toggles the corresponding bit in CTRL1

22.7.1.3.2 Diagram



22.7.1.3.3 Fields

Field	Description
31 PWD_FULL	Temperature Sensor Full Power Down Full power down of the temperature sensor including bias. 0 - Sensor is active 1 - Sensor is powered down
30-24 RFU	Read/Writeable field. Reserved for future use
23 PWD	Temperature Sensor Power Down Powers down the temperature sensor except bias circuit. 0 - Sensor is active 1 - Sensor is powered down
22 START	Start Temperature Measurement Initiates the temperature reading in either Single Read or Continuous Read modes. For single reading, this bit must be set to 0 and then to 1 for every reading. For continuous reading, this bit can be left at '1' and set to '0' only when measurement is to be stopped. 0 - No new temperature reading taken 1 - Initiate a new temperature reading
21-20 —	Reserved field. Reads only zeros
19 PANIC_TEMP_IE	Panic temperature interrupt enable Enables assertion of interrupt when measured temperature is greater than or equal to the programmed panic temperature value. 0 - Interrupt is disabled 1 - Interrupt is enabled

Table continues on the next page...

Field	Description
18 HIGH_TEMP_IE	High temperature interrupt enable Enables assertion of interrupt when measured temperature is greater than or equal to the programmed high temperature value. 0 - Interrupt is disabled 1 - Interrupt is enabled
17 LOW_TEMP_IE	Low temperature interrupt enable Enables assertion of interrupt when measured temperature is lower than or equal to the programmed low temperature value. 0 - Interrupt is disabled 1 - Interrupt is enabled
16 FINISH_IE	Measurement finished interrupt enable Enables assertion of interrupt when temperature measurement is complete. 0 - Interrupt is disabled 1 - Interrupt is enabled
15-0 FREQ	Temperature Measurement Frequency Number of clock cycles of 24MHz clock that will be counted between two temperature readings. If this field is set to 0, the sensor will work in Single Reading mode, where a new temperature reading will be available, every time the CTRL1[START] bit is set to 1. For non-zero values, the sensor will work in Continuous Reading mode, where a new temperature reading will be initiated once the programmed period expires after the end of current temperature reading. CTRL1[START] bit should be kept 1 for continuous conversion. 0000000000000000 - Single Reading Mode. New reading available every time CTRL1[START] bit is set to 1 from 0. 0000000000000001-1111111111111111 - Continuous Reading Mode. Next temperature reading taken after programmed number of cycles after current reading is complete.

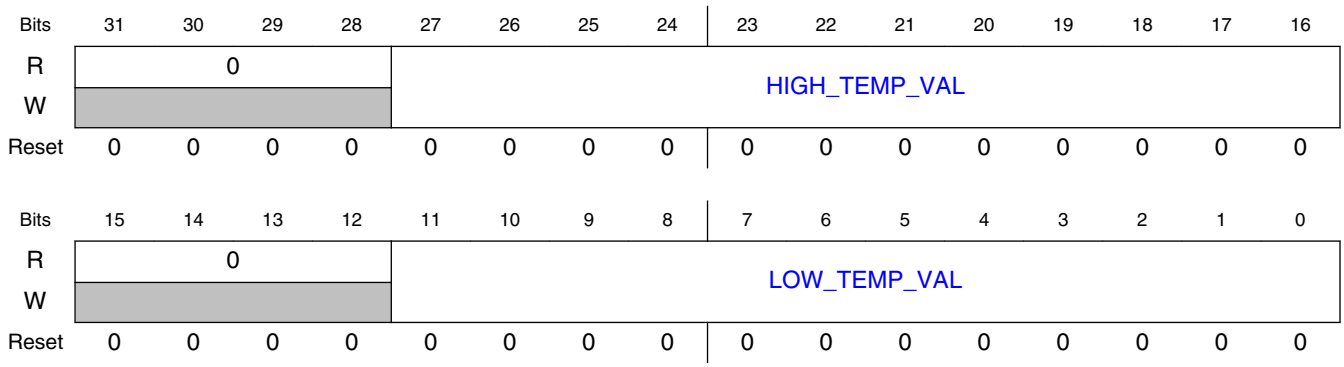
22.7.1.4 Temperature Sensor Range Register 0 (RANGE0)

Configures the ranges for generation of High and Low temperature alarms.

22.7.1.4.1 Offset

Register	Offset	Description
RANGE0	20h	Temperature Sensor Range Register 0
RANGE0_SET	24h	Writing a 1 to a bit in this register sets the corresponding bit in RANGE0
RANGE0_CLR	28h	Writing a 1 to a bit in this register clears the corresponding bit in RANGE0
RANGE0_TOG	2Ch	Writing a 1 to a bit in this register toggles the corresponding bit in RANGE0

22.7.1.4.2 Diagram



22.7.1.4.3 Fields

Field	Description
31-28 —	Reserved field. Reads only zeros.
27-16 HIGH_TEMP_VAL	High temperature threshold value High temperature threshold value (number of clock counts) below which the STATUS0[HIGH_TEMP] status bit will be set.
15-12 —	Reserved field. Reads only zeros.
11-0 LOW_TEMP_VAL	Low temperature threshold value Low temperature threshold value (number of clock counts) above which the LOW_TEMP status bit will be set.

22.7.1.5 Temperature Sensor Range Register 1 (RANGE1)

Configures the ranges for generation of Low temperature alarm.

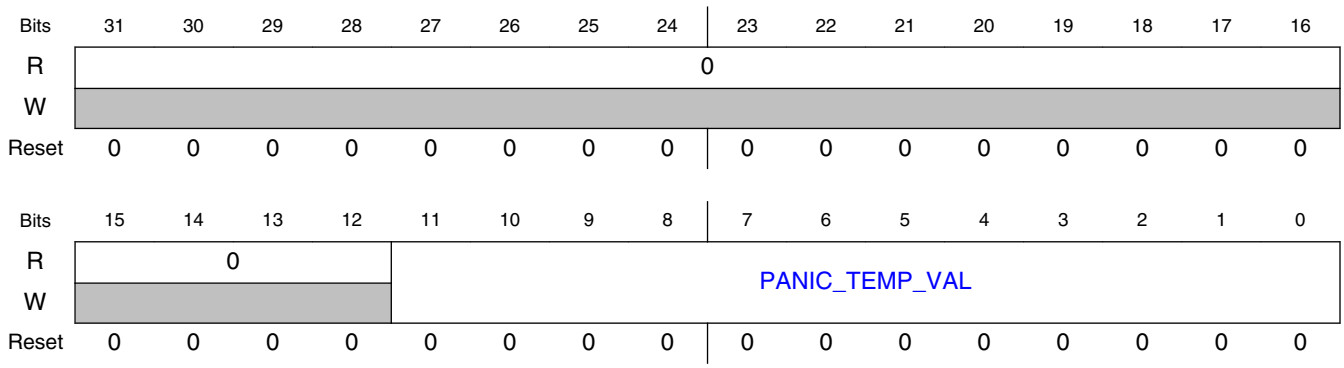
22.7.1.5.1 Offset

Register	Offset	Description
RANGE1	30h	Temperature Sensor Range Register 1
RANGE1_SET	34h	Writing a 1 to a bit in this register sets the corresponding bit in RANGE1
RANGE1_CLR	38h	Writing a 1 to a bit in this register clears the corresponding bit in RANGE1

Table continues on the next page...

Register	Offset	Description
RANGE1_TOG	3Ch	Writing a 1 to a bit in this register toggles the corresponding bit in RANGE1

22.7.1.5.2 Diagram



22.7.1.5.3 Fields

Field	Description
31-12 —	Reserved field. Reads only zeros.
11-0 PANIC_TEMP_VAL	Panic temperature threshold value Panic temperature threshold value (number of clock counts) below which the STATUS0[PANIC_TEMP] status bit will be set.

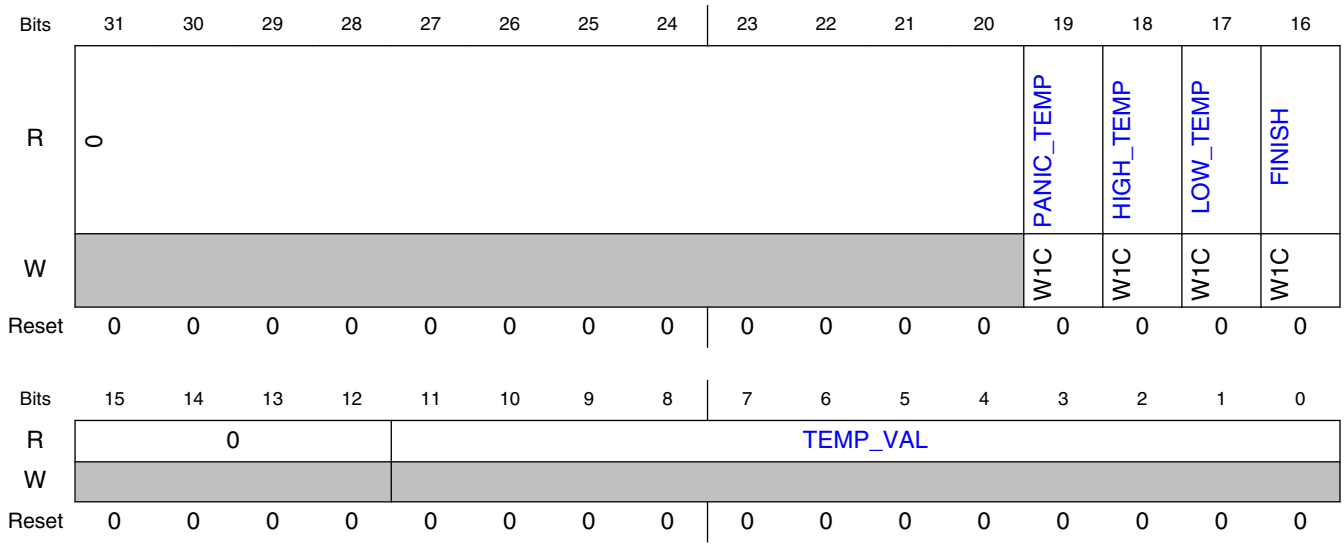
22.7.1.6 Temperature Sensor Status Register 0 (STATUS0)

Provides status and measured value from the temperature sensor.

22.7.1.6.1 Offset

Register	Offset
STATUS0	50h

22.7.1.6.2 Diagram



22.7.1.6.3 Fields

Field	Description
31-20 —	Reserved
19 PANIC_TEMP	Panic temperature alarm bit Asserts when measured temperature is above the programmed panic temperature threshold. 0 - No Panic temperature alert 1 - Panic temperature alert
18 HIGH_TEMP	High temperature alarm bit Asserts when measured temperature is above the programmed high temperature threshold. 0 - No High temperature alert 1 - High temperature alert
17 LOW_TEMP	Low temperature alarm bit Asserts when measured temperature is below the programmed low temperature threshold. 0 - No Low temperature alert 1 - Low temperature alert
16 FINISH	Temperature measurement complete Indicates that the temperature sensor has completed measuring the temperature value and the measured value is available in the STATUS0[TEMP_VAL] for reading. This bit should be cleared by writing 1 to acknowledge that the temperature reading has been read out. 0 - Temperature sensor is busy (if CTRL1[START] = 1)or no new reading has been initiated (if CTRL1[START] = 0) 1 - Temperature reading is complete and new temperature value available for reading
15-12	Reserved field. Reads only zeros

Table continues on the next page...

Field	Description
—	
11-0 TEMP_VAL	Measured temperature value Clock counts corresponding to the measured temperature by the sensor. Valid when STATUS0[FINISH] bit is asserted. This count needs to be converted as per formula (refer to Temperature Sensing) to get the actual temperature value.

22.7.2 Temperature Sensor Analog register descriptions

22.7.2.1 TEMPSENSOR memory map

TEMPSENSOR Analog base address: 40C8_4000h

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)
400	Tempsensor Register (TEMPSENSOR)	32	RW	0000_0000
430	TEMPSNS_OTP_TRIM_VALUE_REGISTER (TEMPSNS_OTP_TRIM_VALUE)	32	RO	0000_0000

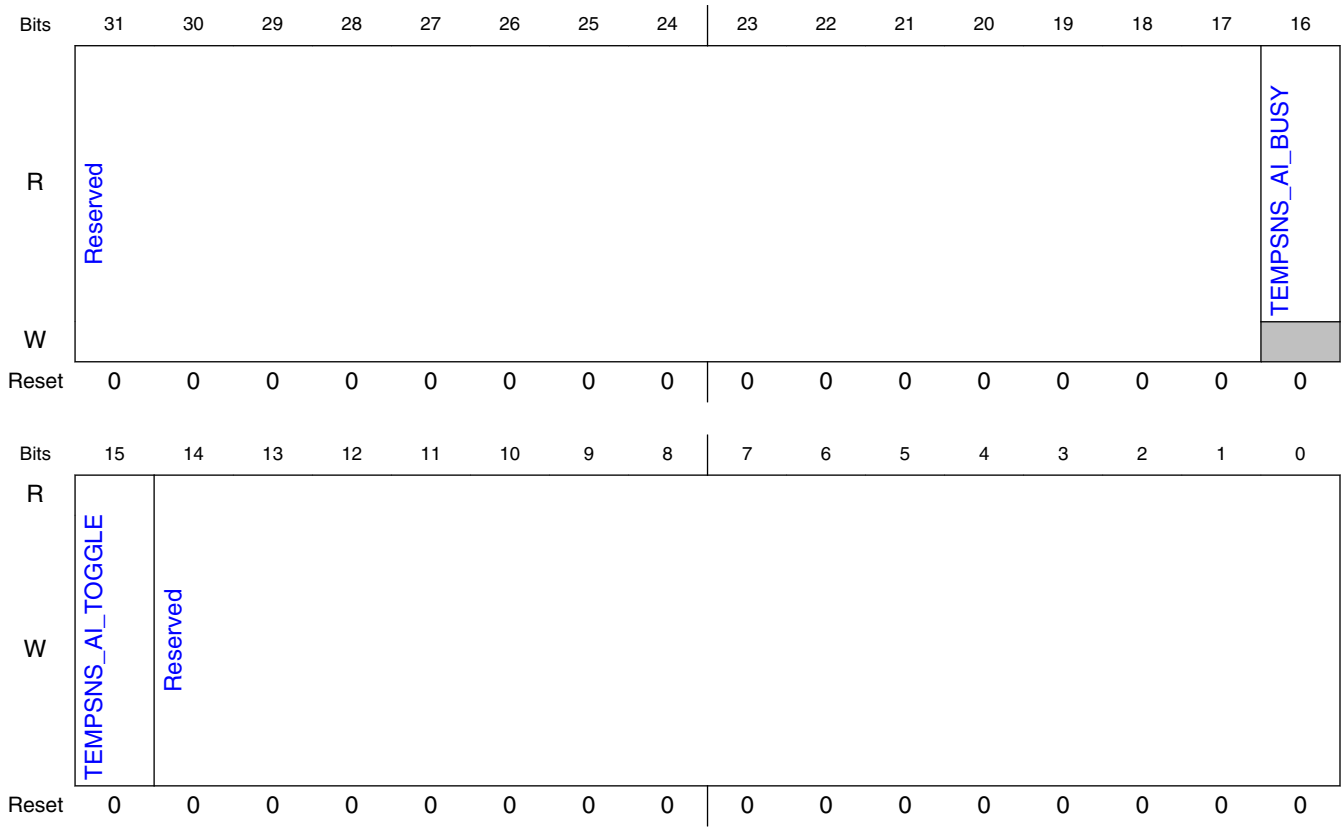
22.7.2.2 Tempsensor Register (TEMPSENSOR)

This register defines the basic settings for access to the temperature sensor through Analog IP (AI) Interface.

22.7.2.2.1 Offset

Register	Offset
TEMPSENSOR	400h

22.7.2.2.2 Diagram



22.7.2.2.3 Fields

Field	Description
31-17 —	Always set to zero
16 TEMPSNS_AI_BUSY	AI Busy monitor Please see 'Analog IP (AI) Interface' topic for details on how to use this bit.
15 TEMPSNS_AI_TOGGLE	AI toggle Please see 'Analog IP (AI) Interface' topic for details on how to use this bit.
14-0 —	Reserved

22.7.2.3 TEMPSNS_OTP_TRIM_VALUE_REGISTER (TEMPSNS_OTP_TRIM_VALUE)

This is the control for TRIM bus control. For ANATOP, this is the source from software register inside ANATOP.

22.7.2.3.1 Offset

Register	Offset
TEMPSNS_OTP_TRIM_VALUE	430h

Chapter 23
State Save and Restore Controller (SSARC)

23.1 Chip-specific State Save and Restore Controller (SSARC) information

Table 23-1. Reference links to related information

Topic	Related module(s)	Reference
System memory map	-	System Memory Map
Clocking	CCM	Clock Management Clock Control Module (CCM)
Power management	PMU	Power Management Power Management Unit
Signal multiplexing	IOMUX	External Signals and Pin Multiplexing IOMUX
Interrupts, DMA Events and XBAR Assignments	-	Interrupts, DMA Events and XBAR Assignments

23.2 Overview

The State Save and Restore Controller (SSARC) saves the registers of functional modules in memory before power down and restores the registers from memory after the module is powered up.

23.2.1 Block diagram

The block diagram of the SSARC module is provided below:

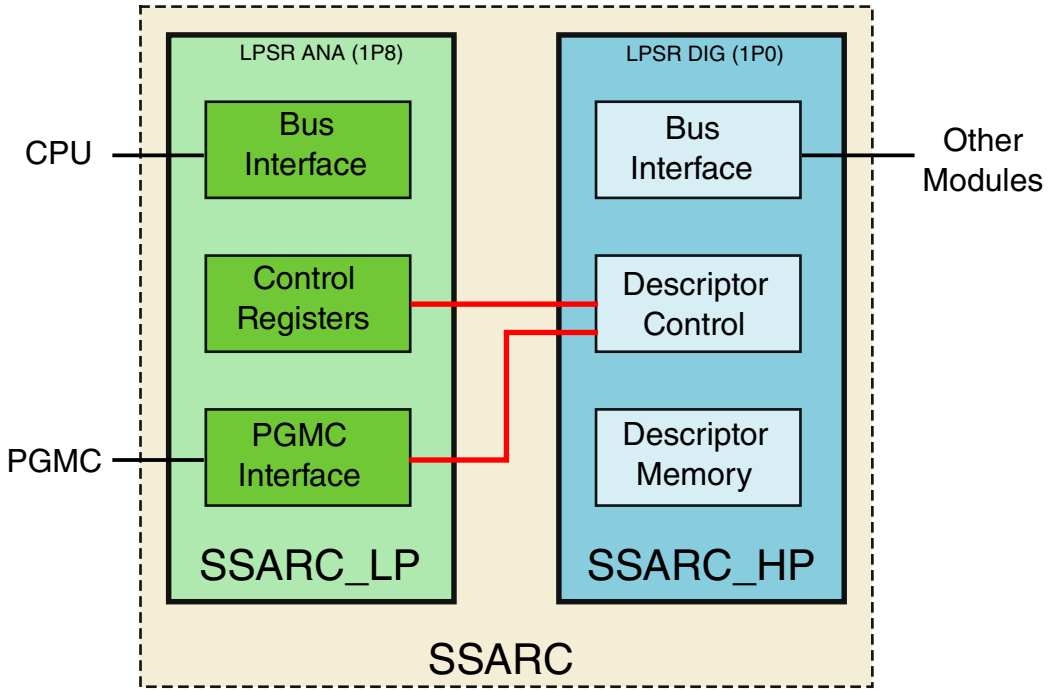

Figure 23-1. SSARC block diagram

23.2.2 Features

The SSARC features the following interfaces:

- The SSARC_HP interface, for read and write access to other functional module registers.
- The SSARC_LP interface, for CPU to configure the SSARC module.

The SSARC features a PGMC interface for the following:

- Save request for each power domain (save_req)
- Save done for each power domain (save_done)
- Restore request for each power domain (restore_req)
- Restore done for each power domain (restore_done)

NOTE

The save and restore signals are mapped to the PGMC BPCs.

23.3 Functional description

The operation of the SSARC is described in the following sections.

23.3.1 Descriptors

The SSARC register save and restore operations are handled as descriptors. Software needs to configure these descriptors like CPU instructions, before using SSARC. Each descriptor acts as one instruction that can save, restore, write value, and delay. See the SRAM registers for more information.

This module supports up to 1024 descriptors. These descriptors are stored in memory and 1024 descriptors requires 1024x72-bit of memory. Each descriptor is mapped to a 16B (4 words) aligned address. And this is allocated from the 4KB offset of the overall SSARC address.

The descriptors used by the system require initialization. If a descriptor is not initialized, its value could be random data. However, if descriptors are not used, there is no need to initialize them.

23.3.2 Descriptor function

The 1024 descriptors are divided into 16 groups and each group contains a number of continuous descriptors. Each group has a set of control registers - DESC_CTRL0_n, DESC_CTRL1_n, DESC_ADDR_UP_n, and DESC_ADDR_DOWN_n (n represents 0-15 groups)

The DESC_CTRL0_n registers are used to control the descriptors are mapped to a given group and set the save and restore order used to process the descriptors.

NOTE

There are no limitations on the number of descriptors that can be designated as a part of a single group. For example, SW can designate one group of 1024 descriptors.

The descriptors are controlled based on the group. Each group can be mapped to save and restore request from one power domain. When a request is asserted externally, the module will perform a state save/restore function for every descriptor in this group.

The DESC_CTRL1_n register is used to map each group to a particular power domain 1-7.

Each group also allows SW to trigger its save/restore operation.

Each group has two configurable priority settings:

- PRIORITY_SAVE[3:0]: 0 has highest priority, and 15 has lowest priority
- PRIORITY_RESTORE[3:0]: 0 has highest priority, and 15 has lowest priority

NOTE

Multiple groups can be configured with the same DESC_CTRL1_n_[POWER_DOMAIN] value.

Save operation usually does not have a very strong requirement on the priority, since the register values are always available before power down. However, Restore operation need priority, because security settings need to be restored first, such are RDC and XRDC.

23.3.3 Permission Control

After lock, the register for this group can only be accessed by the CPU from the domain. The access read/write from the bus interface will use the setting as its Domain ID (DID[1:0]). More details are provided in the register section.

23.3.4 Clocks

The table found here describes the clock sources for SSARC. Please see the Clock Control chapter for clock setting, configuration, and gating information.

Table 23-2. Clocks

Clock Name	Description
ipg_clk	Peripheral access clock connected to SSARC_LP
ahb_clk	SSARC_HP and SSARC_LP clock

23.3.5 Reset

The SSARC module has two resets:

- System Reset
- SSARC_LP Reset

Please see the System Reset Controller (SRC) chapter for more details.

23.3.6 Interrupts

Please see the INT_STATUS register for more information on local interrupt generation.

23.4 External Signals

There are no external signals pinned out for the SSARC. Please see the Features section for details on external SSARC interfaces.

23.5 Initialization

The following steps are required for the initialization of the SSARC save and restore functions:

1. PGMC asserts save request signal (save_req)
2. SSARC gets the request, and checks if any group is assigned to this power domain
3. If multiple groups are assigned, the higher priority group will be triggered first
4. SSARC reads the descriptors belonging to this group
5. SSARC issues read/write operation through the bus interface based on the descriptor
6. SSARC moves to the next descriptor, and so on, until all the descriptors in this group are triggered
7. If there are other groups pending, SSARC moves on to the next group
8. After all the groups are triggered, SSARC asserts save done signal (save_done)

23.6 Memory Map and register definition

This section includes the SSARC module memory map and detailed descriptions of all registers.

23.6.1 SRAM Registers register descriptions

23.6.1.1 SRAM memory map

sram base address: 40CB_4000h

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)
0 - 3FF0	Description Address Register (SRAM0_0 - SRAM0_1023)	32	RW	Table 23-2

Table continues on the next page...

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)
4 - 3FF4	Description Data Register (SRAM1_0 - SRAM1_1023)	32	RW	Table 23-2
8 - 3FF8	Description Control Register (SRAM2_0 - SRAM2_1023)	32	RW	Table 23-2

23.6.1.2 Description Address Register (SRAM0_0 - SRAM0_1023)

The SRAM array is 1024x72 bits and is split 3 ways between SRAM0[31:0]_n, SRAM1[63:32]_n, and SRAM2[71:64]_n, where n = 0 to 1024. This register represents the first 32 bits (1024x[31:0]) of the SRAM space.

23.6.1.2.1 Offset

For a = 0 to 1023:

Register	Offset
SRAM0_a	0h + (a × 10h)

23.6.1.2.2 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	ADDR															
Reset	u	u	u	u	u	u	u	u	u	u	u	u	u	u	u	u

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	ADDR															
Reset	u	u	u	u	u	u	u	u	u	u	u	u	u	u	u	u

23.6.1.2.3 Fields

Field	Description
31-0 ADDR	Address field This field describes the 32-bit address of the register to be saved/restored

23.6.1.3 Description Data Register (SRAM1_0 - SRAM1_1023)

The SRAM array is 1024x72 bits and is split 3 ways between SRAM0[31:0]_n, SRAM1[63:32]_n, and SRAM2[71:64]_n, where n = 0 to 1024. This register represents the second 32 bits (1024x[63:32]) of the SRAM space.

23.6.1.3.1 Offset

For a = 0 to 1023:

Register	Offset
SRAM1_a	4h + (a × 10h)

23.6.1.3.2 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	DATA															
Reset	u	u	u	u	u	u	u	u	u	u	u	u	u	u	u	u

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	DATA															
Reset	u	u	u	u	u	u	u	u	u	u	u	u	u	u	u	u

23.6.1.3.3 Fields

Field	Description
31-0 DATA	Data field This field depends on the setting of the SRAM2_n[TYPE] bitfield. When SRAM2_n[TYPE]=W0 (0x1 - W0 - Write), this field retains the value to be written to the register on restore When SRAM2_n[TYPE]=SR (0x0 - SR - Save Read), this field will be loaded with the register value on save operation

23.6.1.4 Description Control Register (SRAM2_0 - SRAM2_1023)

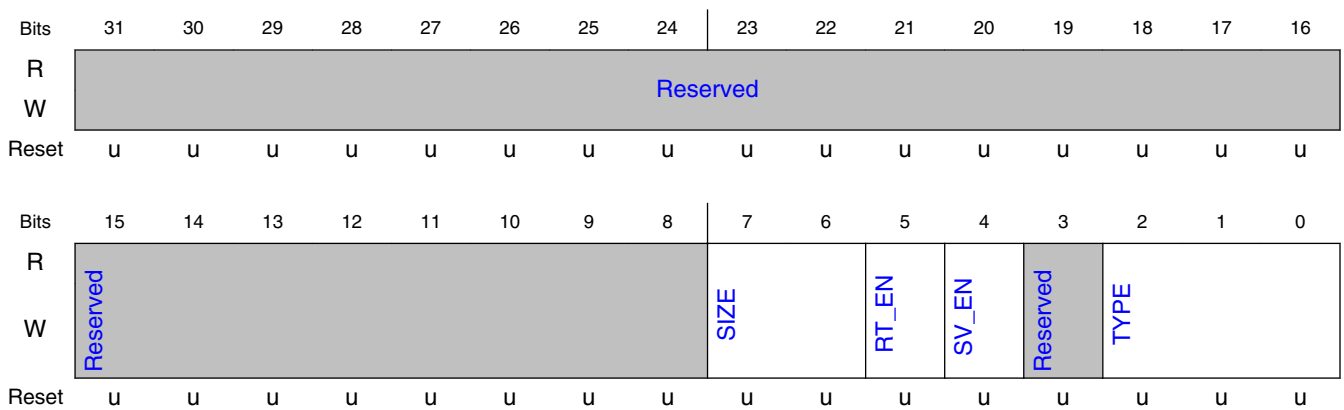
The SRAM array is 1024x72 bits and is split 3 ways between SRAM0[31:0]_n, SRAM1[63:32]_n, and SRAM2[71:64]_n, where n = 0 to 1024. This register represents the last 8 bits (1024x[71:64]) of the SRAM space.

23.6.1.4.1 Offset

For a = 0 to 1023:

Register	Offset
SRAM2_a	8h + (a × 10h)

23.6.1.4.2 Diagram



23.6.1.4.3 Fields

Field	Description
31-8 —	Reserved
7-6 SIZE	Size field 00 - 8-bit 01 - 16-bit 10 - 32-bit 11 - Reserved
5 RT_EN	Restore Enable Software can allocate one descriptor for both save and restore by setting both RT_EN and SV_EN. 0 - Do not use this descriptor for the restore operation

Table continues on the next page...

Field	Description
	1 - Use this descriptor for the restore operation
4 SV_EN	Save Enable Software can allocate one descriptor for both save and restore by setting both RT_EN and SV_EN. 0 - Do not use this descriptor in the save operation 1 - Use this descriptor in the save operation
3 —	Reserved
2-0 TYPE	Type field This field describes the type of operation on SRAM1_n[DATA] 000 - Read the register value on save operation and write it back on restore operation 001 - Always write a fixed value from SRAM1_n[DATA] 010 - Read register, OR with the SRAM1_n[DATA], and write it back 011 - Read register, AND with the SRAM1_n[DATA], and write it back 100 - Delay for number of cycles based on the SRAM1_n[DATA] 101 - Read the register until read_data[31:0] & SRAM1_n[DATA] == 0 110 - Read the register until read_data[31:0] & SRAM1_n[DATA] != 0 111 - Reserved

23.6.2 SSARC Registers register descriptions

23.6.2.1 SSARC memory map

ssarc base address: 40CB_8000h

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)
0 - 1E0	Descriptor Control0 a Register (DESC_CTRL0_0 - DESC_CTRL0_15)	32	RW	0000_0000
4 - 1E4	Descriptor Control1 a Register (DESC_CTRL1_0 - DESC_CTRL1_15)	32	RW	0000_0000
8 - 1E8	Descriptor Address Up a Register (DESC_ADDR_UP_0 - DESC_ADDR_UP_15)	32	RW	0000_0000
C - 1EC	Descriptor Address Down a Register (DESC_ADDR_DOWN_0 - DESC_ADDR_DOWN_15)	32	RW	0000_0000
200	Control Register (CTRL)	32	RW	0000_0000

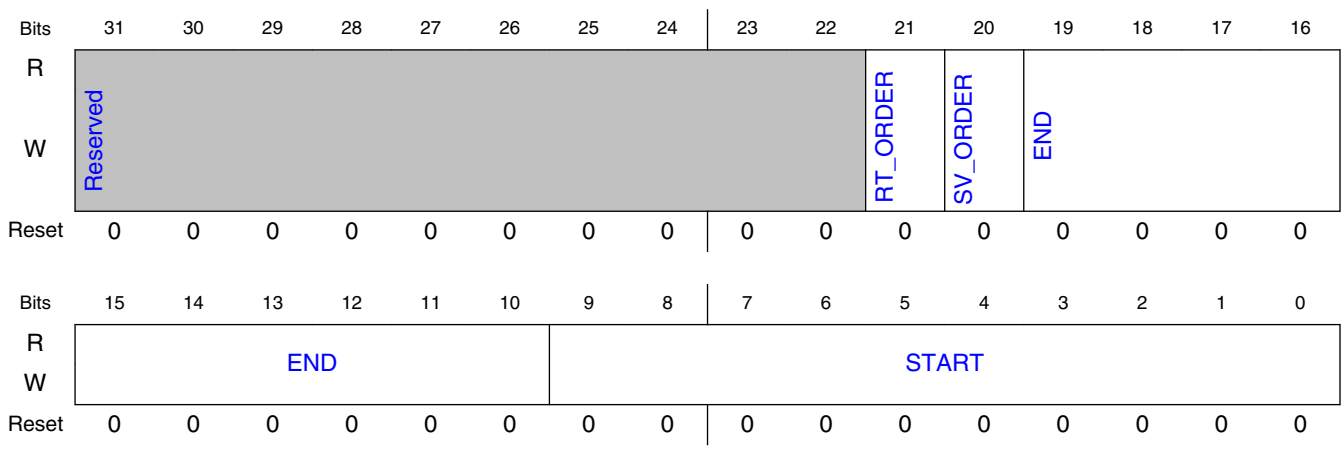
23.6.2.2 Descriptor Control0 a Register (DESC_CTRL0_0 - DESC_CTRL0_15)

23.6.2.2.1 Offset

For a = 0 to 15:

Register	Offset
DESC_CTRL0_a	0h + (a × 20h)

23.6.2.2.2 Diagram



23.6.2.2.3 Fields

Field	Description
31-22 —	Reserved

Table continues on the next page...

Field	Description
21 RT_ORDER	Restore order This field defines the order descriptors within the group are processed when restoring register values 0 - Descriptors within the group are processed from start to end 1 - Descriptors within the group are processed from end to start
20 SV_ORDER	Save Order This field defines the order descriptors within the group are processed when saving register values 0 - Descriptors within the group are processed from start to end 1 - Descriptors within the group are processed from end to start
19-10 END	End index This field describes the Index of the last descriptor that belongs to this group. It can be anywhere from 0-1023.
9-0 START	Start index This field describes the Index of the first descriptor that belongs to this group. It can be anywhere from 0-1023.

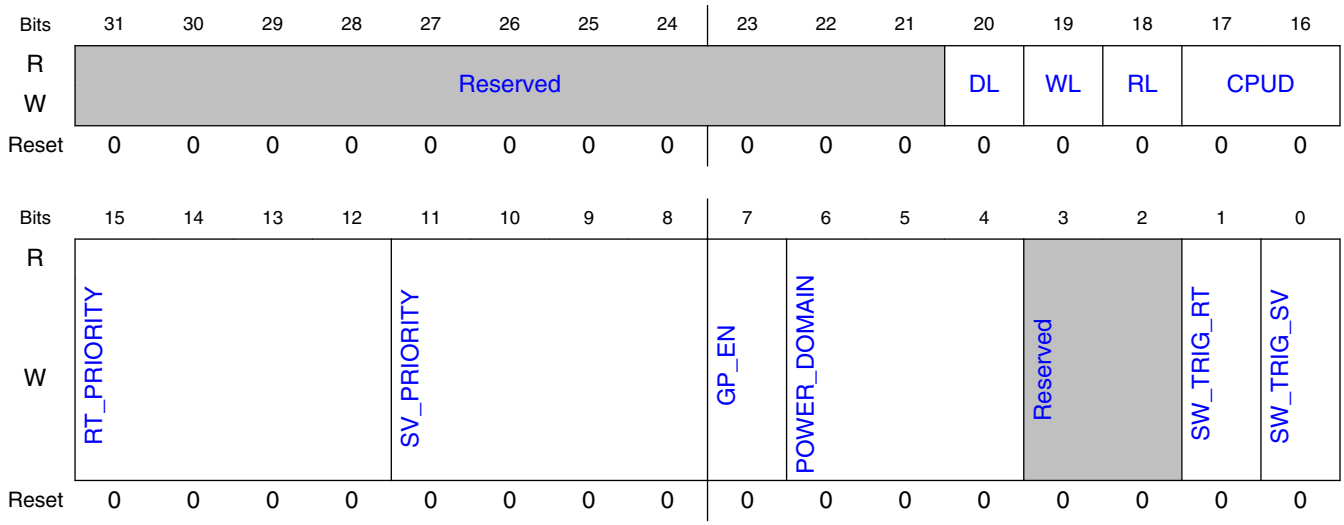
23.6.2.3 Descriptor Control1 a Register (DESC_CTRL1_0 - DESC_CTRL1_15)

23.6.2.3.1 Offset

For a = 0 to 15:

Register	Offset
DESC_CTRL1_a	4h + (a × 20h)

23.6.2.3.2 Diagram



23.6.2.3.3 Fields

Field	Description
31-21 —	Reserved
20 DL	Domain lock This bitfield locks the configuration of the CPU domain. Once locked, only the access from the same domain is allowed, access from other domain will be blocked. This includes both the control registers for the group and descriptors assigned to the group. This is a sticky bit. After it has been set, it can only be cleared by POR. 0 - Unlock 1 - Lock
19 WL	Write Lock This bit can be used to block all write accesses to the control registers and descriptors for the group. All writes are blocked--no dependency on domain. This is a sticky bit. After it has been set, it can only be cleared by POR. 0 - Group is unlocked (write access allowed) 1 - Group is locked (write access not allowed)
18 RL	Read Lock Lock the read access to the control register and descriptors in this group, no dependency on domain. Once set, the sticky bit can be only cleared by POR. 0 - Group is unlocked (read access allowed) 1 - Group is locked (read access not allowed)
17-16 CPUD	CPU Domain The ownership of this group: After lock, the register for this group can only be accessed by the CPU from the domain. The access read/write from the bus interface will use the setting as its Domain ID (DID[1:0]).
15-12	Restore Priority

Table continues on the next page...

Field	Description
RT_PRIORITY	Restore priority of current group, 0 has highest priority, 15 has lowest priority f two or more groups are configured with the same POWER_DOMAIN value, then the value of this field is used to determine the priority used to process each of the groups for restore operations.
11-8 SV_PRIORITY	Save Priority Save priority of current group, 0 has highest priority, 15 has lowest priority
7 GP_EN	Group Enable This field determines if the group is processed for save and restore operations 0 - Group disabled 1 - Group enabled
6-4 POWER_DOMAIN	This field describes the mapping (0-7) to external request signals from different domains. Please see the PGMC chapter for the BPC power domain assignments. 000 - PGMC_BPC0 001 - PGMC_BPC1 010 - PGMC_BPC2 011 - PGMC_BPC3 100 - PGMC_BPC4 101 - PGMC_BPC5 110 - PGMC_BPC6 111 - PGMC_BPC7
3-2 —	Reserved
1 SW_TRIG_RT	Software trigger restore Set this bit manually to trigger a restore operation. This bit will automatically clear when the restore operation is complete. 0 - No software restore request/software restore request complete 1 - Request a software restore operation/software restore operation in progress
0 SW_TRIG_SV	Software trigger save Set this bit to trigger save operation, hardware will clear it after assert interrupt 0 - No software save request/software restore request complete 1 - Request a software save operation/software restore operation in progress

23.6.2.4 Descriptor Address Up a Register (DESC_ADDR_UP_0 - DESC_ADDR_UP_15)

23.6.2.4.1 Offset

For a = 0 to 15:

Register	Offset
DESC_ADDR_UP_a	8h + (a × 20h)

23.6.2.4.2 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	ADDR_UP															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	ADDR_UP															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

23.6.2.4.3 Fields

Field	Description
31-0 ADDR_UP	Address field (High) Highest address that can be accessed for the descriptors in this group If a descriptor attempts an access to an address larger than this value, the INT_STATUS[ADDR_ERR] bit will set and processing of additional descriptors in the group will abort.

23.6.2.5 Descriptor Address Down a Register (DESC_ADDR_DOWN_0 - DESC_ADDR_DOWN_15)

23.6.2.5.1 Offset

For a = 0 to 15:

Register	Offset
DESC_ADDR_DOWN_a	Ch + (a × 20h)

23.6.2.5.2 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	ADDR_DOWN															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	ADDR_DOWN															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

23.6.2.5.3 Fields

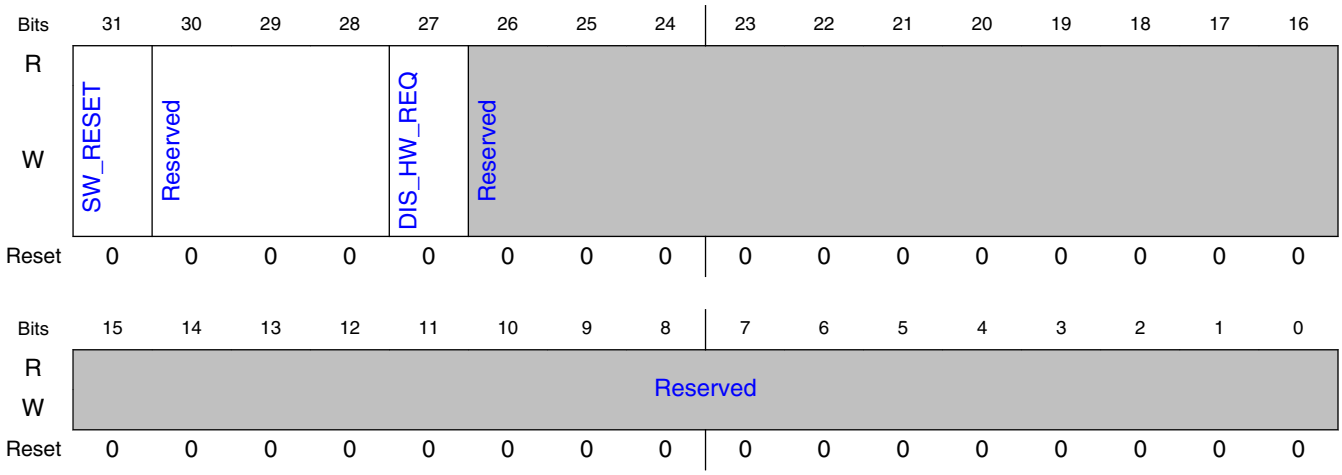
Field	Description
31-0 ADDR_DOWN	Address field (Low) Lowest address that can be accessed for the descriptors in this group If a descriptor attempts an access to an address lower than this value, the INT_STATUS[ADDR_ERR] bit will set and processing of additional descriptors in the group will abort.

23.6.2.6 Control Register (CTRL)

23.6.2.6.1 Offset

Register	Offset
CTRL	200h

23.6.2.6.2 Diagram



23.6.2.6.3 Fields

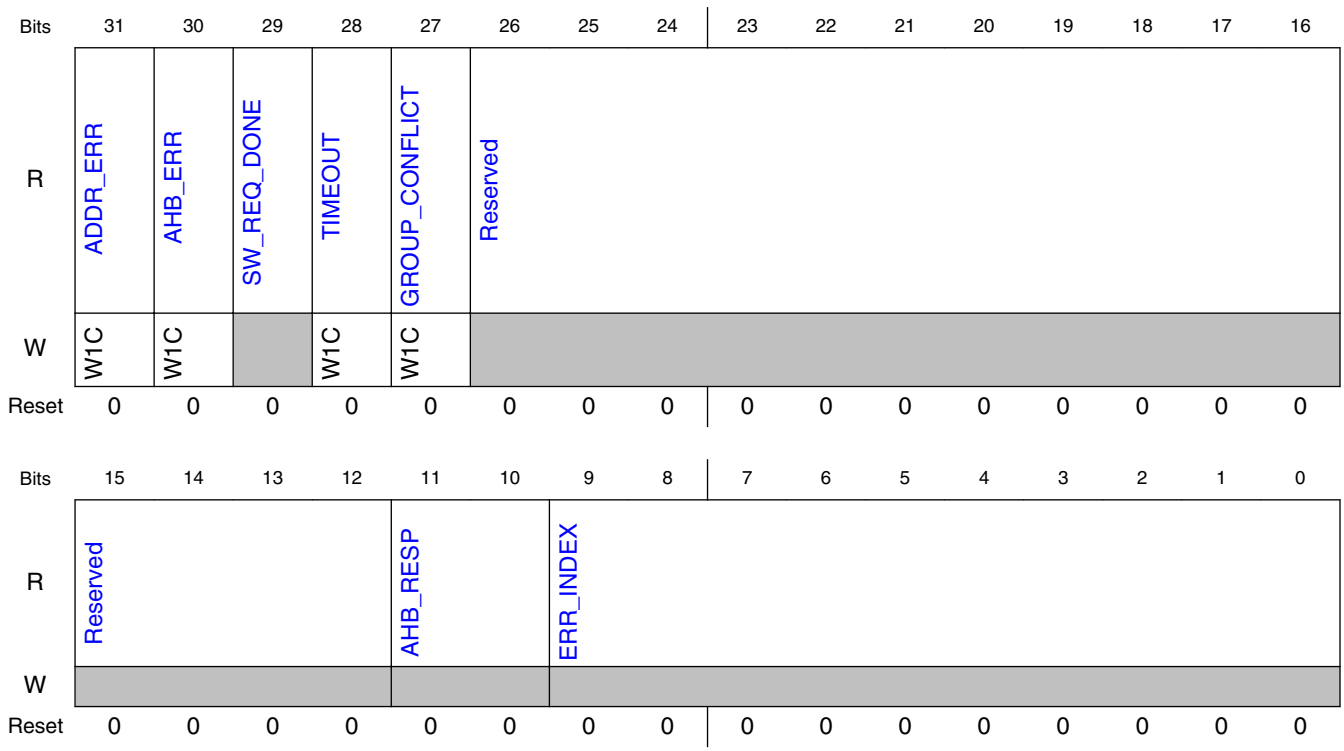
Field	Description
31 SW_RESET	Software reset This software reset is used to reset the logic inside SSARC_LP and SSARC_HP, including the internal state machine, which can be used when a fault may cause the SSARC block to hang. The SW_RESET will not reset the DESC_x Registers, since they have domain control/lock control registers. The SW_RESET will also not reset the Descriptors inside SRAM, which is not part of SSARC block. Please ensure enough delay is met to reset the SSARC block (at least 10us), then clear it.
30-28 —	Reserved
27 DIS_HW_REQ	Save/Restore request disable This bit can be used to disable save/restore requests from the PGMC module. Software triggered requests using SW_TRIGGER_SV and SW_TRIGGER_RT can still be used. 0 - PGMC save/restore requests enabled 1 - PGMC save/restore requests disabled
26-0 —	Reserved

23.6.2.7 Interrupt Status Register (INT_STATUS)

23.6.2.7.1 Offset

Register	Offset
INT_STATUS	204h

23.6.2.7.2 Diagram



23.6.2.7.3 Fields

Field	Description
31 ADDR_ERR	Address Error field If the descriptor address is not in the range (from desc_addr_low to desc_addr_up), assert addr_err. This bit is write 1 to clear. 0 - No address error 1 - An address error has occurred
30 AHB_ERR	AHB Error field If any AHB master access receives none-OKAY hresp, it will assert this bit when ssarc_hp_done. The error type can be seen in INT_STATUS[AHB_RESP]. Note, if multiple errors occur, only the last error will be kept 0 - No AHB error

Table continues on the next page...

Field	Description
	1 - An AHB error has occurred
29 SW_REQ_DONE	Software Request Done This field indicates if A software triggered save or restore process is completed. For more details see SW_DONE_STATUS register. This bit will only clear if all the bits in the SW_DONE_STATUS register are cleared. 0 - No software triggered requests or software triggered request still in progress 1 - Atleast one software triggered has been complete
28 TIMEOUT	Timeout field This field indicates if processing of a group has exceeded the time out value configured in the HP_TIMEOUT register 0 - No timeout event 1 - A timeout event has occurred
27 GROUP_CONFLICT	Group Conflict field This field gives error interrupt when one group is pending or in progress, and another request for same group is received from hardware. It should not occur in normal circumstances. Save and restore for same group should be treated as different request. If one group is pending or process, and another request for same group is received from software, it will be ignored. 0 - No group conflict error 1 - A group conflict error has occurred
26-12 —	Reserved
11-10 AHB_RESP	AHB Bus response field
9-0 ERR_INDEX	Error Index This field indicates which descriptor will trigger the AHB_ERR or ADDR_ERR interrupt. This block contains 1024 descriptors and this field represents the index of the descriptor that generated the error.

23.6.2.8 HP Timeout Register (HP_TIMEOUT)

23.6.2.8.1 Offset

Register	Offset
HP_TIMEOUT	20Ch

Chapter 24
Secure Non-Volatile Storage (SNVS)

24.1 Chip-specific SNVS information

Table 24-1. Reference links to related information

Topic	Related module(s)	Reference
System memory map	-	System Memory Map
Clocking	CCM	Clock Management Clock Control Module (CCM)
Power management	PMU	Power Management Power Management Unit
Signal multiplexing	IOMUX	External Signals and Pin Multiplexing IOMUX
Interrupts, DMA Events and XBAR Assignments	-	Interrupts, DMA Events and XBAR Assignments

24.2 Overview

The Secure Non-Volatile Storage (SNVS) is a companion module to the CAAM module.

The SNVS non-security functionality is described in this document, but the SNVS security functionality is described only in the Security Reference Manual.

24.2.1 Block diagram

The following figure illustrates the structure of SNVS.

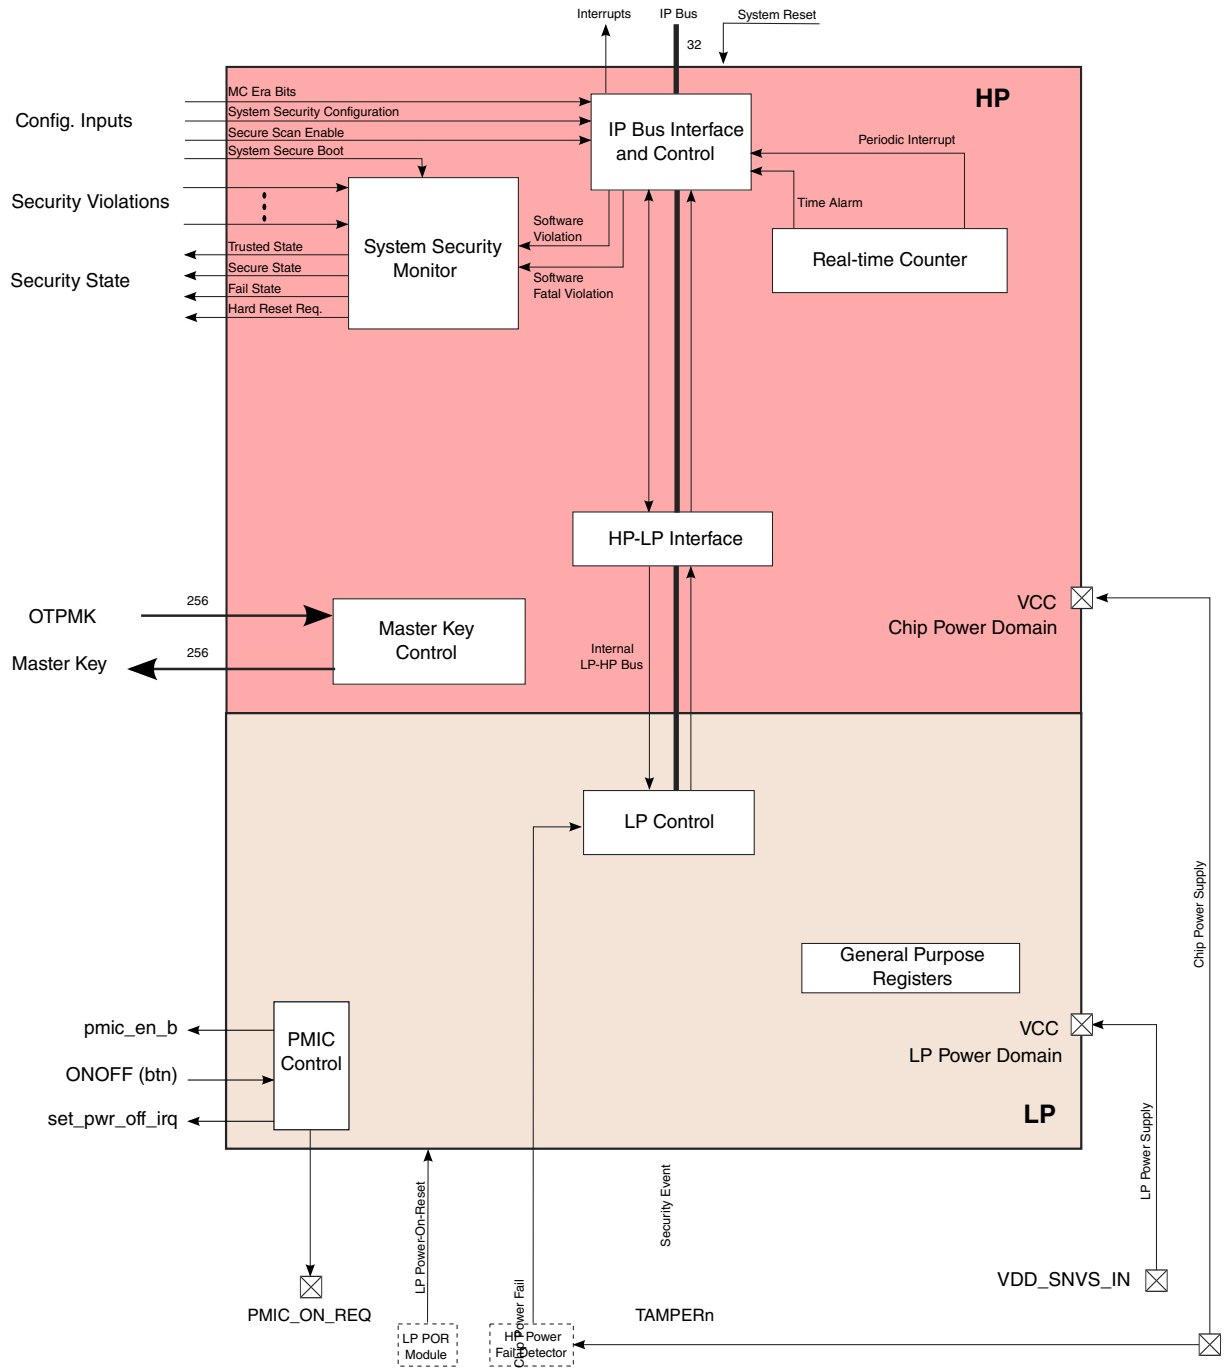

Figure 24-1. SNVS Block Diagram

24.2.2 Features

The following table summarizes the features of SNVS:

Table 24-2. SNVS feature list

Feature	Description	Links for Further Information
Real time counter (RTC)	• The RTC is driven by a dedicated clock, which is off when the system power is down. • Programmable time alarm interrupt • Periodic interrupt can be generated with software-selected frequency.	SNVS_HP Real Time Counter
General-purpose register	• The general-purpose register is available to software to store 128 bits of data. • The general-purpose register is zeroized when a security violation is detected. • If the SNVS_LP power input is connected to an uninterrupted power supply (see SNVS power domains), the general-purpose register value is retained even if the main chip is powered down.	Using the General-Purpose Register
Register access restrictions	• Some registers/values can be written only once per boot cycle.	privileged and non-privileged registers
Wakeup from power off	• Input signal from off chip requests SNVS_LP to power on the main SoC (Assuming that the SNVS_LP power input is connected to an uninterrupted power supply (see SNVS power domains). • Hardware debounces the input signal using software-specified signal bounce characteristics	LP Wake-Up Interrupt Enable

24.3 SNVS functional description

SNVS implements several non-security features that involve software interaction:

- reading or writing the Realtime Counter (RTC) (This is a non-privileged operation.) - software can also instruct SNVS to load the current SRTC value into the RTC
- reading or writing the General Purpose Register (GPR) (Note that there may be a significant delay when reading or writing registers in the LP section if the LP clock is different from the HP clock.)

The following sections describe in more detail the operation of SNVS.

24.3.1 SNVS power domains

In some versions of SNVS (including this version), the LP (Low Power) section is implemented in an independent power domain from the HP (High Power) section, and most other logic on the chip. Throughout the SNVS documentation whenever mention is made of "always-on" logic, this assumes a version of SNVS that implements an independent power domain for the LP section, and that the power for this section is supplied by an uninterrupted power supply. The purpose for the independent power domain is so that data can be retained and certain logic can remain functional even when the main chip logic is powered down. But this is possible only if the LP domain remains

powered via an uninterrupted power supply when the main chip power domain is powered off. Usually this uninterrupted power supply would be a battery, with possibly some power management logic to power the LP section from main power (and perhaps recharge the battery) when main power is on, and switch to battery power when the main power is off. In versions of SNVS with an independent LP power domain the LP section can be electrically isolated from the rest of the chip logic to ensure that its logic does not get corrupted when the main chip is powered down. If the battery runs down or is removed, an LP POR will occur when the LP section next powers up. Note that some OEMs may choose to connect LP power to HP/main chip power and dispense with a battery. In that case the SNVS will operate the same as an SNVS without an independent LP power domain. No state will be retained in the LP section when the chip is powered down, and an LP POR will occur whenever there is an HP POR.

24.3.2 Digital Low-Voltage Detector (LVD)

SNVS_LP incorporates a mechanism to detect interruptions of the SNVS_LP power supply that might cause the LP control, status, and secure counter values to change. The mechanism works as follows:

1. The LVD register (LPLVDR) is loaded with the known specific value 4173_6166h as part of the SNVS initialization process.
2. Subsequently, this register's value is continuously compared to the hardwired value 4173_6166h.
3. If the comparison indicates that any bit has changed, a low-voltage violation is asserted.

Digital low-voltage detection is always enabled and cannot be disabled. At LP POR this register is reset to all 0's, so the hardwired comparison fails and a low-voltage violation is reported. Therefore, before programming any feature in the SNVS the low-voltage violation should be cleared. The initialization software should write the proper value (4173_6166h) into LPLVDR (see SNVS_LP Digital Low-Voltage Detector Register (LPLVDR)) and should then clear the low-voltage event record in the LP status register (see SNVS_LP Status Register (LPSR)).

The following figure shows the LVD mechanism.

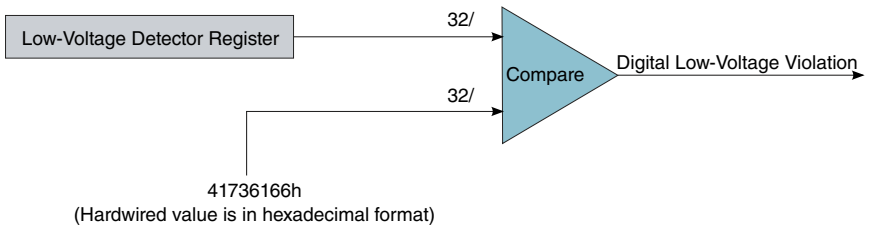

Figure 24-2. Digital low-voltage detector

24.3.3 Runtime Procedures

SNVS implements a number of features that are intended to be accessed by software at runtime (as opposed to accessed at boot time). These features include:

- Real Time Clock (see SNVS_HP Real Time Counter)
- General Purpose Register (see Using the General-Purpose Register)

Procedures for using these features are described in the following sections.

24.3.3.1 Using SNVS Timer Facilities

SNVS incorporates timer facilities that can optionally generate an interrupt at a specified time. As described in the following sections, SNVS_HP incorporates a Real Time Counter that is available for general use, and SNVS_LP incorporates a Secure Real Time Counter intended for security applications.

24.3.3.1.1 SNVS_HP Real Time Counter

SNVS_HP implements a real time counter that can be read or written by any application; it has no privileged software access restrictions. When the chip is powered down the RTC is not active and it is reset at chip POR. The RTC can be used to generate a functional interrupt request either at a specific time, or at a specific frequency, or both. To generate an interrupt request at a specific time HPTA_EN is set to 0, the desired time is written to HPTA_MS and HPTA_LS and then HPTA_EN is set to 1. HPTA_EN, HPTA_MS and HPTA_LS can be written by any software that has access to SNVS registers; there are no privileged access restrictions. The counter can be synchronized to the SNVS_LP SRTC by writing to the HP_TS bit of SNVS_HP Control Register. This is particularly useful if the SNVS_LP is powered from an uninterrupted power source because the RTC can then be set from a chip-internal time source.

24.3.3.1.2 RTC/SRTC control bits setting

All SNVS registers are programmed from the register bus, consequently any software-initiated changes are synchronized with the IP clock. Several registers can also change synchronously with the RTC/SRTC clock after they are programmed. To avoid IP clock and RTC/SRTC clock synchronization issues, the following values can be changed only when the corresponding function is disabled.

Table 24-3. RTC/SRTC synchronized values list

Function	Value/register	Control bit setting
HP section		
HP Real Time Counter	HPRTCMR and HPRTCLR Registers	RTC_EN = 0 : HPRTCMR/HPRTCLR **can** be programmed RTC_EN = 1 : HPRTCMR/HPRTCLR **cannot** be programmed
HP Time Alarm	HPTAMR and HPTALR Registers	HPTA_EN = 0 : HPTAMR/HPTALR **can** be programmed HPTA_EN = 1 : HPTAMR/HPTALR **cannot** be programmed
LP section		
LP Secure Real Time Counter	LPRTCMR and LPRTCLR Registers	SRTC_ENV = 0 : LPRTCMR/LPRTCLR **can** be programmed SRTC_ENV = 1 : LPRTCMR/LPRTCLR **cannot** be programmed
LP Time Alarm	LPTAR Register	LPTA_EN = 0 : LPTAR **can** be programmed LPTA_EN = 1 : LPTAR **cannot** be programmed

Use the following steps to program synchronized values:

1. Check the enable bit value. If set, clear it.

2. Verify that the enable bit is cleared. There are two reasons to verify the enable bit's setting:

- Enable bit clearing does not happen immediately; it takes three IP clock cycles and two RTC/SRTC clock cycles to change the enable bit's value.
- If the enable bit is locked for programming, it cannot be cleared.

3. Program the desired value.

4. Set the enable bit; it takes three IP clock cycles and two RTC/SRTC clock cycles for the bit to set.

NOTE

Incrementing the value programmed into RTC/SRTC registers by two compensates for the two RTC/SRTC clock cycle delay that is required to enable the counter.

24.3.3.1.3 Reading RTC and SRTC values

Software should follow the following procedure to ensure that it has read correct data from the RTC (HPRTCMR and HPRTCLR) and SRTC (LPSRTCMR and LPSRTCLR) registers:

- Read the most-significant half and the least-significant half of the RTC/SRTC and then read both halves again. If the values read are the same both times, the value is correct.
- If the two consecutive pairs of reads yield different results, perform two more reads.

The worst case scenario may require three sessions of two consecutive pairs of reads. There are several reasons that the values may be incorrectly read initially:

- Synchronization issues between the RTC/SRTC clock and the system clock
- Since the counter continues to increment, there may be a carry from the least-significant 32-bits to the most-significant bits in between reading the two halves of the counter

24.3.3.2 Using Other SNVS Registers

The sections below describe how to use the General Purpose Register.Monotonic Counter.The sections below describe how to use the General Purpose Register and the Monotonic Counter.

24.3.3.2.1 Using the General-Purpose Register

SNVS implements a 128-bit general-purpose register allows software to store a small amount of data. To maintain backward compatibility with versions of SNVS that implement only a 32-bit general purpose register, the most-significant word of the general purpose register is aliased to the original legacy address, and to maintain backward compatibility with versions of snvs_module_name that implement a 128-bit general purpose register, the most-significant half of the general purpose register is aliased to the previous legacy address address. The data in the GPR will be retained during system power-down mode as long as the SNVS_LP remains powered by an uninterrupted power source.

24.3.4 Clocks

The SNVS has the following clock sources:

- System peripheral clock input. This clock is used by the SNVS's internal logic, for example, the Security State Machine. This clock can be gated outside of the module when the SNVS indicates that it is not in use.
- HP RTC clock. This clock is used by SNVS_HP real-time counter. This clock does not need to be synchronous with other clocks.

24.3.5 Reset

The table below shows the different resets associated with this module.

Table 24-4. Reset summary

Reset	Source	Characteristics	Internally resets
HP hard	ipg_hard_async_reset_b	active-low, asynchronous	All SNVS_HP and SNVS_LP registers and flops.
LP Power On Reset (POR)	lp_por_b	active-low, asynchronous	All SNVS_LP registers and flops.
LP software reset	software	active-high, synchronous, one cycle	All SNVS_LP registers and flops. The LP software reset can be asserted if not disabled.

24.4 External Signals

Table 24-5. External Signals

Signal	Description	Direction
TAMPERn	External Tamper signals	I
PMIC_ON_REQ	PMIC ON Request signal	I

24.5 Initialization of SNVS

SNVS is implemented in two sections (HP and LP) that both must be initialized by software. If the SNVS_LP is powered by an uninterrupted power source that is separate from main SoC power, then SNVS can operate in either of two modes, depending upon whether the main SoC power is on or off.

- During main SoC power-down SNVS_HP is powered-down, but SNVS_LP is powered from the backup power supply and is electrically isolated from the rest of the chip. In this mode SNVS_LP keeps its registers' values and monitors the SNVS_LP tamper detection inputs, but the LP registers cannot be read or written.
- During main SoC power-up the isolation of SNVS_LP is disabled and both SNVS_HP and SNVS_LP are powered from the main SoC power. Both LP and HP registers can be read and written (locks and privilege modes permitting). Signals between the SNVS_HP and SNVS_LP sections are enabled and all SNVS functions are operational.

Since the HP and LP sections reside in different power domains, the POR for the two sections can occur at different times. If the SNVS_LP section remains powered by an uninterrupted power source when the main SoC power is off, SNVS_LP is initialized rarely, typically once when the device is first powered on and again whenever the battery is replaced. During main SoC power-up the isolation of SNVS_LP is disabled and both SNVS_HP and SNVS_LP are powered from the main SoC power. Signals between the SNVS_HP and SNVS_LP sections are enabled and all SNVS functions are operational. The SNVS_HP section is powered from the main SoC power, so it must be initialized after the device is powered on. If the SNVS_LP section is powered from the main SoC power rather than from an uninterrupted power source, the SNVS_LP section must also be initialized at SoC POR.

- Initializing the LP section
  - The following steps should be completed to properly initialize the SNVS LP section (required only on LP POR, i.e. when the battery is replaced):
    - Software should write the proper initialization value (41736166h) into the LP Digital Low-Voltage Detector Register and clear the low-voltage event record in the LP status register. See Digital Low-Voltage Detector (LVD) for more details.
- Initializing the HP section
  - The following steps should be completed to properly initialize the SNVS HP section (required on HP POR, i.e. SoC POR):
    - Perform normal boot to put the SNVS into a functional state (Non-secure, Trusted, Secure) (see HP Command Register, SSM_ST bitfield).
    - Program SNVS general functions/configurations (see HP Control Register).

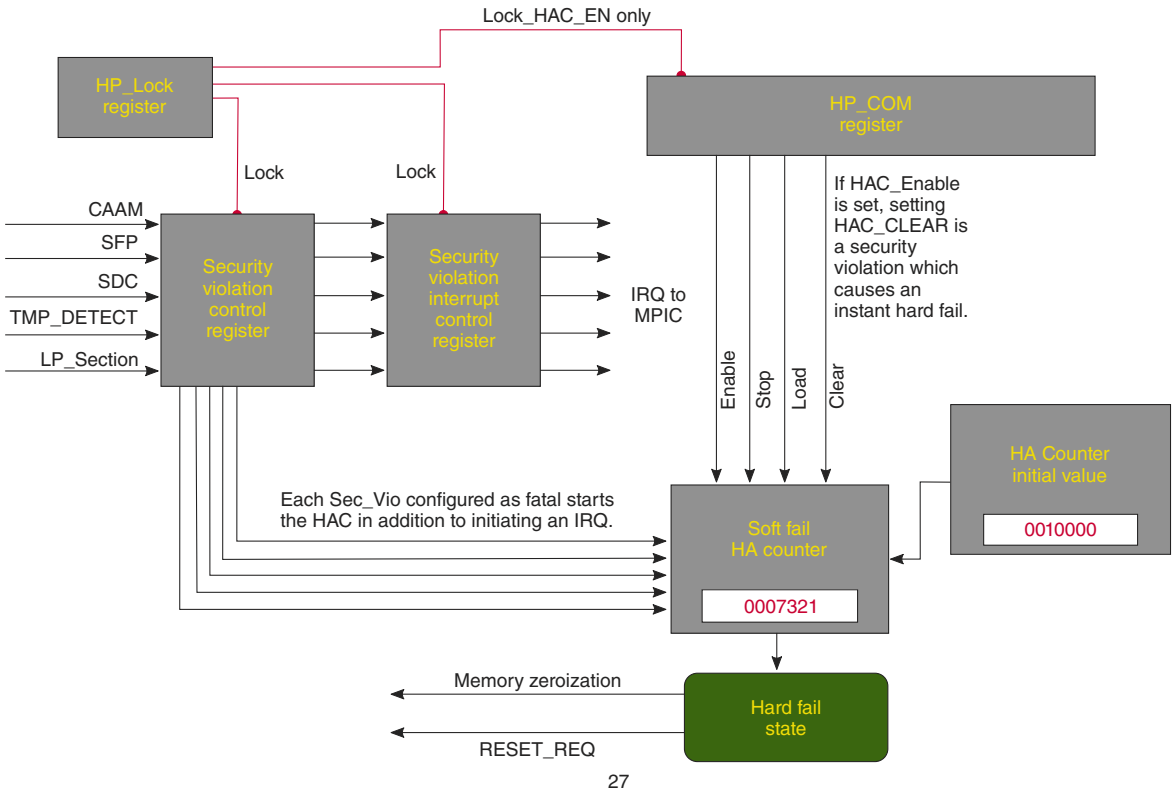

Figure 24-3. Relationship Between the Registers

24.6 Memory Map and register definition

This section contains detailed register descriptions for the SNVS registers. Each description includes a standard register diagram and register table. The register table provides detailed descriptions of the register bit and field functions, in bit order.

SNVS registers consist of two types:

- Privileged read/write accessible
- Non-privileged read/write accessible

Privileged read/write accessible registers can only be accessed for read/write by privileged software. Unauthorized write accesses are ignored, and unauthorized read accesses return zero. Non-privileged software can access privileged access registers when the non-privileged software access enable bit is set in the SNVS_HP Command Register.

- Non-Secure
- Trusted
- Secure

Non-privileged read/write accessible registers are read/write accessible by any software.

The LP register values are set only on LP POR and are unaffected by System (HP) POR. The HP registers are set only on System POR and are unaffected by LP POR.

The following table shows the SNVS main memory map.

NOTE

For more information on security-related bitfields, see the Security Reference Manual.

24.6.1 SNVS register descriptions

24.6.1.1 SNVS memory map

SNVS base address: 40C9_0000h

24.6.1.3.3 Fields

Field	Description
31-28 —	Reserved
27 BTN_MASK	Button interrupt mask. This bit is used to mask the button (BTN) interrupt request. 0: Interrupt disabled 1: Interrupt enabled
26-24	Button Configuration.

Table continues on the next page...

Field	Description
BTN_CONFIG	This field is used to configure which feature of the button (BTN) input signal constitutes "active". 000: Button signal is active high 001: Button signal is active low 010: Button signal is active on the falling edge 011: Button signal is active on the rising edge 100: Button signal is active on any edge All other patterns are Reserved
23-17 —	Reserved
16 —	Reserved
15 —	Reserved
14-10 HPCALB_VAL	HP Calibration Value Defines signed calibration value for the HP Real Time Counter. This field can be programmed only when RTC Calibration is disabled (HPCALB_EN is not set). This is a 5-bit 2's complement value, hence the allowable calibration values are in the range from -16 to +15 counts per 32768 ticks of the counter. 00000 - +0 counts per each 32768 ticks of the counter 00001 - +1 counts per each 32768 ticks of the counter 00010 - +2 counts per each 32768 ticks of the counter 01111 - +15 counts per each 32768 ticks of the counter 10000 - -16 counts per each 32768 ticks of the counter 10001 - -15 counts per each 32768 ticks of the counter 11110 - -2 counts per each 32768 ticks of the counter 11111 - -1 counts per each 32768 ticks of the counter
9 —	Reserved
8 HPCALB_EN	HP Real Time Counter Calibration Enabled Indicates that the time calibration mechanism is enabled. 0 - HP Timer calibration disabled 1 - HP Timer calibration enabled
7-4 PI_FREQ	Periodic Interrupt Frequency Defines frequency of the periodic interrupt. The interrupt is generated when a zero-to-one or one-to-zero transition occurs on the selected bit of the HP Real Time Counter and Real Time Counter and Periodic Interrupt are both enabled (RTC_EN and PI_EN are set). It is recommended to program this field when Periodic Interrupt is disabled (PI_EN is not set). The possible frequencies are: 0000 - - bit 0 of the HPRTCLR is selected as a source of the periodic interrupt 0001 - - bit 1 of the HPRTCLR is selected as a source of the periodic interrupt 0010 - - bit 2 of the HPRTCLR is selected as a source of the periodic interrupt 0011 - - bit 3 of the HPRTCLR is selected as a source of the periodic interrupt 0100 - - bit 4 of the HPRTCLR is selected as a source of the periodic interrupt

Table continues on the next page...

Field	Description
	0101 - - bit 5 of the HPRTCLR is selected as a source of the periodic interrupt 0110 - - bit 6 of the HPRTCLR is selected as a source of the periodic interrupt 0111 - - bit 7 of the HPRTCLR is selected as a source of the periodic interrupt 1000 - - bit 8 of the HPRTCLR is selected as a source of the periodic interrupt 1001 - - bit 9 of the HPRTCLR is selected as a source of the periodic interrupt 1010 - - bit 10 of the HPRTCLR is selected as a source of the periodic interrupt 1011 - - bit 11 of the HPRTCLR is selected as a source of the periodic interrupt 1100 - - bit 12 of the HPRTCLR is selected as a source of the periodic interrupt 1101 - - bit 13 of the HPRTCLR is selected as a source of the periodic interrupt 1110 - - bit 14 of the HPRTCLR is selected as a source of the periodic interrupt 1111 - - bit 15 of the HPRTCLR is selected as a source of the periodic interrupt
3 PI_EN	HP Periodic Interrupt Enable The periodic interrupt can be generated only if the HP Real Time Counter is enabled. 0 - HP Periodic Interrupt is disabled 1 - HP Periodic Interrupt is enabled
2 DIS_PI	Disable periodic interrupt in the functional interrupt 0 - Periodic interrupt will trigger a functional interrupt 1 - Disable periodic interrupt in the function interrupt
1 HPTA_EN	HP Time Alarm Enable When set, the time alarm interrupt is generated if the value in the HP Time Alarm Registers is equal to the value of the HP Real Time Counter. This bit syncs with the 32KHz clock. It won't update with the bus clock. 0 - HP Time Alarm Interrupt is disabled 1 - HP Time Alarm Interrupt is enabled
0 RTC_EN	HP Real Time Counter Enable. This bit syncs with the 32KHz clock. It won't update with the bus clock. 0 - RTC is disabled 1 - RTC is enabled

24.6.1.4 SNVS_HP Status Register (HPSR)

The HP Status Register reflects the internal state of the SNVS. This is *not* a privileged write register.

24.6.1.12.3 Fields

Field	Description
31-16	Monotonic Counter Era Bits
MC_ERA_BITS	These bits are inputs to the module and typically connect to fuses. When the Monotonic Counter is in use (i.e. enabled and valid and powered by an uninterrupted power source), and the boot software detects that the Monotonic Counter most-significant 16 Bits and Monotonic Counter LSB Register have been reset (MC_ENV=0), the boot software can take action to ensure that the value in the monotonic counter remains monotonic (i.e. never decreasing). The action is to blow an additional MC_ERA_BITS fuse. Since the MC_ERA_BITS field forms the most-significant field of the monotonic counter, blowing an additional fuse guarantees that the new monotonic counter value is higher than any previous value.
15-0	Monotonic Counter most-significant 16 Bits

Field	Description
MON_COUNTER	**Note that writing to this register does *not* change the value of this field to the value that was written.** **The 48-bit monotonic counter value (consisting of LPSMCMR[MON_COUNTER] prepended to LPSMCLR[MON_COUNTER]) is incremented by one when:** • A write transaction to the LPSMCMR or LPSMCLR register is detected. • The MC_ENV bit is set. • MC_SL and MC_HL bits are not set. This value can be reset only by LP POR.

24.6.1.13 SNVS_LP Secure Monotonic Counter LSB Register (LPSMCLR)

The SNVS_LP Secure Monotonic Counter LSB Register contains the 32 least-significant bits of the monotonic counter. The MC is incremented by one if there is a write command to the LPSMCMR or LPSMCLR register. This is a non-privileged read-only register.

24.6.1.13.1 Offset

Register	Offset
LPSMCLR	60h

31-0 GPR	General Purpose Register When GPR_SL or GPR_HL bit is set, the register cannot be programmed.

24.6.1.17 SNVS_LP General Purpose Registers 0 .. 3 (LPGPR0 - LPGPR3)

The SNVS_LP General Purpose Register is a 128-bit read/write register located in SNVS_LP, which can be used by any application for retaining data during an SoC power-down mode. This is a privileged read/write register. The full GPR register is accessed as 4 32-bit registers located in successive word addresses starting at offset 100h. For backward compatibility with earlier versions of SNVS, LPGPR0..LPGPR3 are aliased at the earlier offset of 90h and LPGPR0 is also aliased at its original offset of 68h. New software should access the GPR register at the preferred offset of 100h. The GPR will be automatically zeroized when an enabled security event occurs, unless GPR zeroization is disabled via the GPR_Z_DIS bit in the LP Control Register.

24.6.1.17.1 Offset

NOTE

The CPU2 and CPU3 fields are not used in this chip.

25.2 Overview

The System Reset Controller (SRC) is responsible for the generation of all the system reset signals and boot argument latching.

25.2.1 Block Diagram

The figure below shows a high-level block diagram of the SRC.

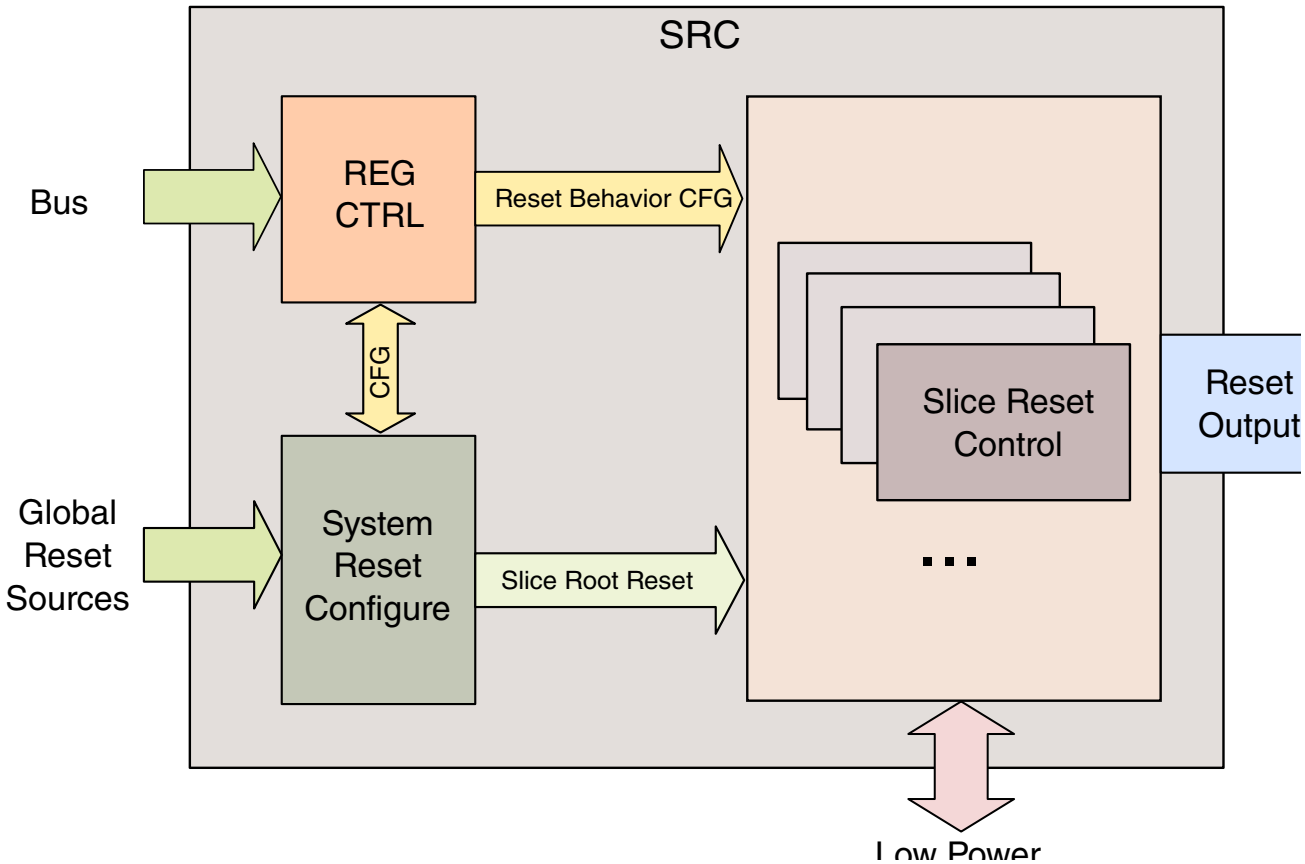

Figure 25-1. SRC High-Level Diagram

25.2.2 Features

The SRC includes the following features:

- Receives and handles the resets from all the reset sources
- Resets the appropriate domains based upon the reset sources and low-power behavior
- Latches the SRC_BOOT_MODE pins and boot configuration signals from the on-chip Fuse or the SRC_BT_CFG pins.

25.3 Functional Description

The reset control determines the source and type of reset, and performs the necessary reset qualification and stretching sequences. Based on the type of reset, the reset logic generates the reset sequence for the entire chip.

The boot argument latching includes the SRC_BOOT_MODE pin and SRC_BT_CFG pin latch, when the system comes out of reset.

25.3.1 Reset and Power Scheme

The chip presumes the following system reset and power schemes. Please see the power managament chapter for more details on the specific power sources, controls, and domains.

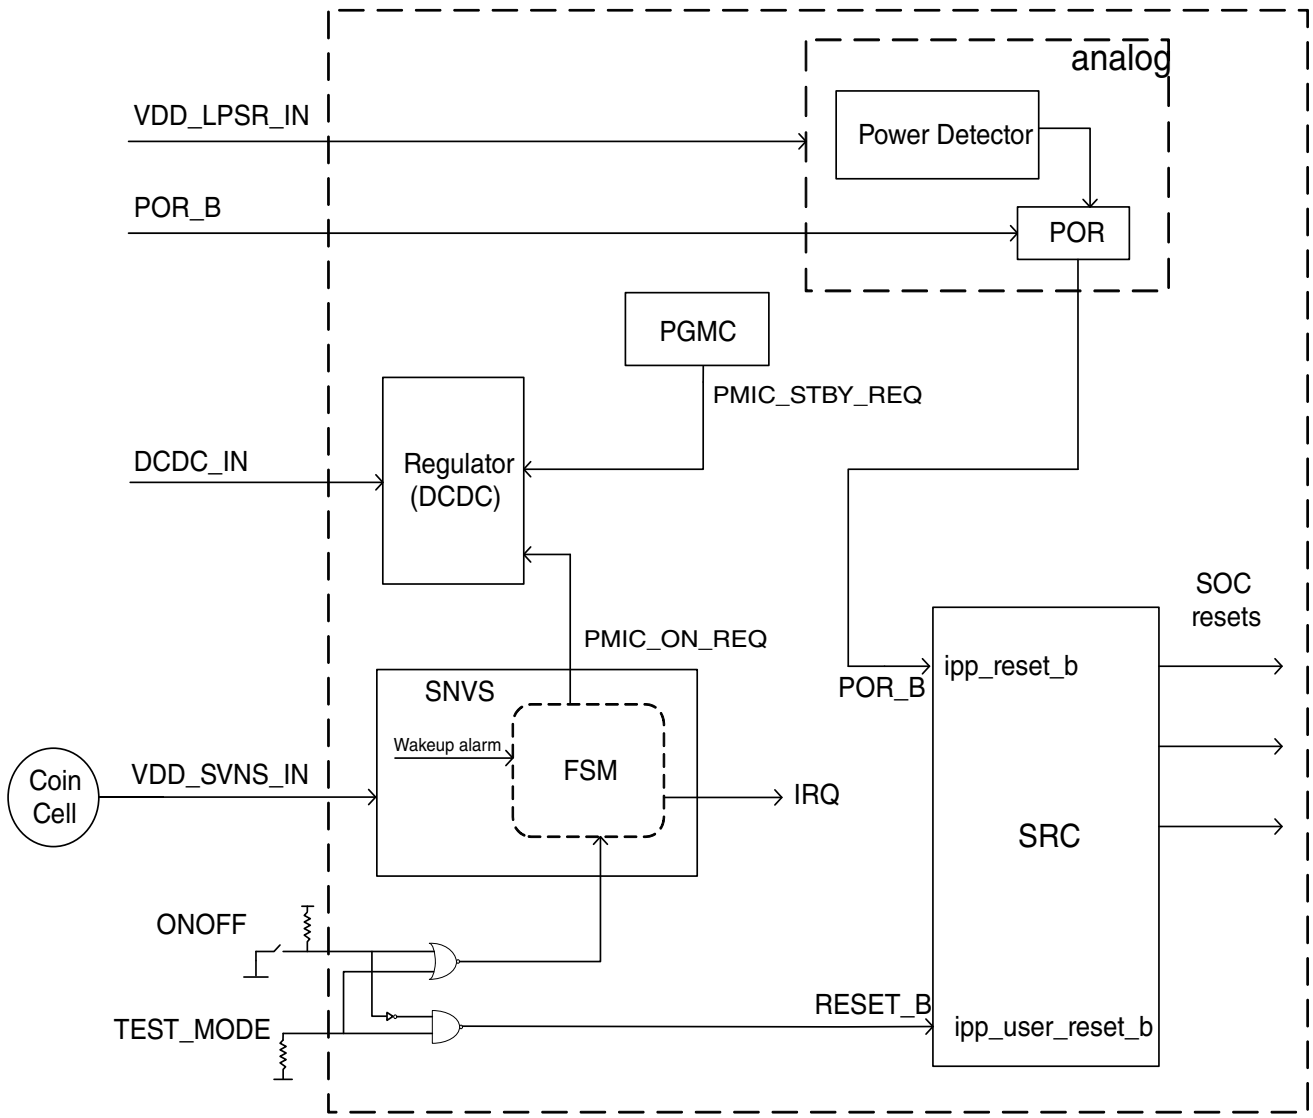

Figure 25-2. Chip Reset with on-chip DCDC

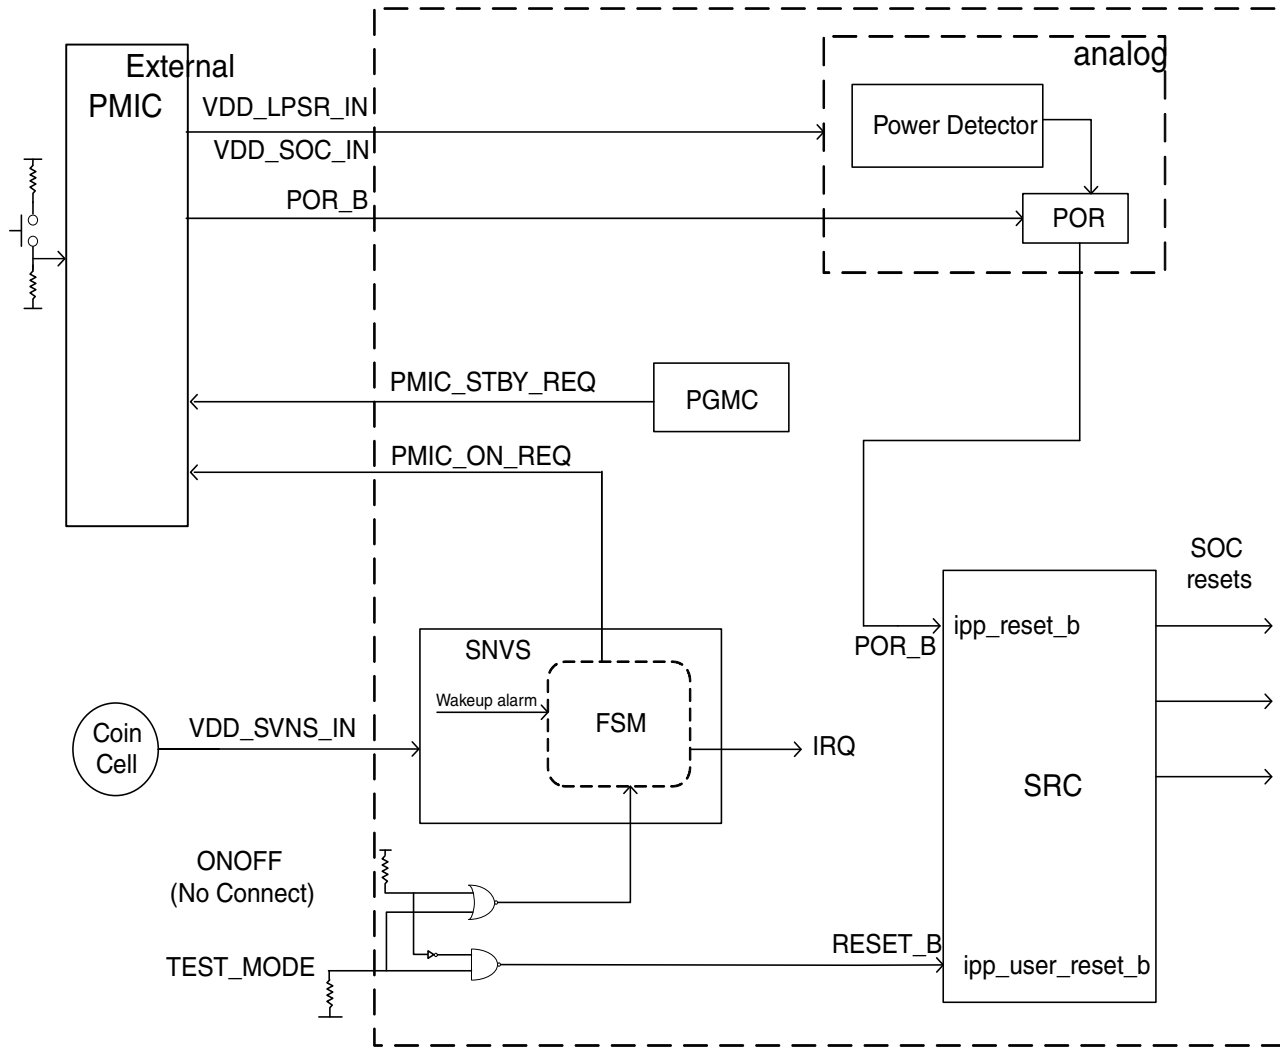

Figure 25-3. Chip Reset with external PMIC

25.3.2 Finite State Machine (FSM)

The FSM Operation of the SRC is illustrated below. The details of the states are explained in the table as well.

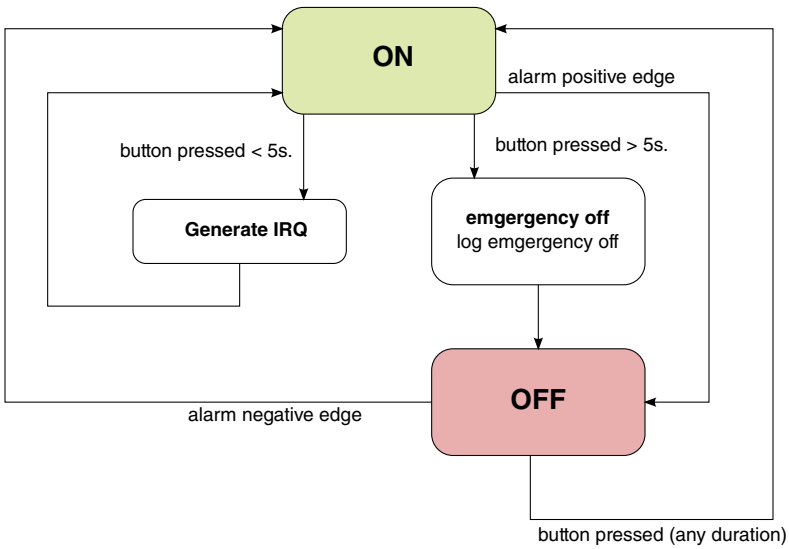

Figure 25-4. FSM Operation

The table below describes the ON-OFF state mechanism:

State	Configuration with external PMIC	Configuration with on-chip DCDC
ON, first time	1. SNVS is powered, PMIC_ON_REQ goes to '1'. 2. When PMIC button is pressed, PMIC powers on.	1. SNVS is powered, PMIC_ON_REQ goes to '1'. 2. 2VDD_LPSR_IN and DCDC_IN are powered. 3. Drive DCDC_PSWITCH to high, 1 ms after DCDC_IN is powered. 4. DCDC regulator is enabled.
Normal ON to OFF, by button (ONOFF pin)	1. Button is pressed (short duration) on the external PMIC. 2. IRQ is sent to SoC from the external PMIC. 3. SoC is programing PMIC for power off when PMIC_STBY_REQ is asserted. 4. In low-power mode, the PMIC_STBY_REQ is asserted according to the PGMC configuration. PMIC gates SoC supplies.	1. ONOFF button is pressed (short duration, less than 5s). 2. IRQ is sent to SoC from FSM. 3. Alarm timer is set by software routine and started. 4. Upon wakeup alarm assertion to '1', PMIC_ON_REQ goes '0'. 5. DCDC regulator goes OFF.
Emergency On to OFF, by button	1. Button is pressed long way on the external PMIC. 2. PMIC is powering off.	1. ONOFF Button is pressed for longer than 5 seconds on the SoC. 2. FSM validates button pressed for 5 seconds. 3. Emergency power off is logged, PMIC_ON_REQ goes '0' 4. DCDC regulator goes OFF.
OFF to ON, by button	1. Button is pressed on the external PMIC. 2. PMIC is powering on.	1. ONOFF button is pressed on the SoC. 2. PMIC_ON_REQ goes '1' 3. DCDC regulator powers ON.

Table continues on the next page...

State	Configuration with external PMIC	Configuration with on-chip DCDC
OFF to ON, by timer alarm	1. Timer alarm in SNVS is programmed by s/w before SoC goes OFF. 2. SoC enters OFF mode. 3. Upon timer limit, the wakeup alarm goes ‘0’. PMIC_ON_REQ goes ‘1’. 4. PMIC receives assertion of PMIC_ON_REQ and wakes up.	1. Timer alarm in SNVS is programmed by 2. software before SoC goes OFF. 3. SoC enters OFF mode. 4. Upon timer limit, wakeup alarm goes '0'. PMIC_ON_REQ goes '1'. 5. DCDC regulator is enabled by PMIC_ON_REQ= 1.

25.3.3 Reset Control

This section details the reset control of this device. There are four situations, which will cause a reset event. They are:

- Power-on reset (POR)
- Global system reset request
- Software configuration
- Low-power mode transaction

The System Reset Configure, as shown in the block diagram, receives reset requests from all the potential reset sources and generates the Slice Root Reset to the reset slices, named as Slice Reset Control. The Slice Reset Control will help determine the reset behavior according to the slice configuration and the system low-power status after the slice root reset de-assertion.

The independent reset domains in the system have dedicated reset slices, which generate the dedicated reset signal for each reset domain.

The table below shows the Slice Index and the Slice ID of each Slice Reset Control.

Table 25-2. Slice Reset Control List

Slice Index	Slice ID	Description
0	MEGA	Audio, ENET, uSDHC, USB
1	DISPLAY	Display
2	WAKEUP	Memory, Debug, Analog, Timers
3	LPSR	Power, Clocking, Reset, DMA
4	M4CORE	Cortex-M4 Platform
5	M7CORE	Cortex-M7 Platform
6	M4DEBUG	CM4 Debug
7	M7DEBUG	CM7 Debug
8	USBPHY1	USB PHY1
9	USBPHY2	USB PHY2
10	CM4MEM	LMEM

Table continues on the next page...

Table 25-2. Slice Reset Control List (continued)

Slice Index	Slice ID	Description
11	CM7MEM	FlexRAM
12	Reserved	Reserved
13	Reserved	Reserved
14	Reserved	Reserved
15	Reserved	Reserved

25.3.4 Reset behavior of the Power-on Reset

The Power-on Reset (POR) will assert when the chip is powered ON or the POR_B pin is active. The POR will reset all of the chip except the Secure Non-Volatile Storage (SNVS) block.

25.3.5 Reset behavior under the global system reset sources

The Slice Reset Control will determine the reset behavior based on the power mode transaction and the software reset request. The table below shows the global system reset sources.

Table 25-3. Global System Reset Sources

Reset sources	Description
M7_req_rst	Asserts when software writes SYSRESETREQ bit of register APPLICATION_INTERRUPT_CONTROL_REGISTER in CM7
M7_lockup_rst	Asserts when CM7 lock up
M4_req_rst	Asserts when software write SYSRESETREQ bit of register APPLICATION_INTERRUPT_CONTROL_REGISTER in CM4
M4_lockup_rst	Asserts when CM4 lock up
csu_rst	Asserts when the security violation happens in SNVS
ipp_user_reset_b	Asserts when the ONOFF pad is pressed down in test mode
wdog_rst	Asserts when the peripheral WDOG timeouts
jtag_rst_b	Assert when the debugger asserts the reset request in Boundary Scanning mode
jtag_sw_b	Assert when the debugger asserts software reset by JTAG
wdog3_rst	Asserts when the peripheral WDOG3 timeouts
wdog4_rst	Asserts when the peripheral WDOG4 timeouts
tempsense_rst	Assert when the Temper Sensor requests a software reset
overvolt_rst	Assert when the DCDC requests Over Voltage reset

All the reset sources can be disabled by writing the corresponding bit with 2'b11 in the SRC_SRMR. The reset generated by the global reset sources will reset all of the system except for the same part of WDOG which is reset when the POR asserted, and some IPs.

25.3.6 Reset behavior by software configuration

There are ten reset slices. One slice for each dedicated reset domain in the system. Software can write the CTRL_x[SW_RESET] bit of the Slice Control Register, for each reset slice, to request a reset to it's own reset domain.

The CTRL_xx[SW_RESET] bit is a self-clearing bit. The reset is asserted when the CTRL_x[SW_RESET] bit is set to 1'b1, and it will be cleared when the reset sequence is finished.

25.3.7 Reset behavior under the low-power mode transition

When some of the reset domains are powered-down then they need an accurate reset sequence for themselves. The user can define the behavior under different low-power modes for each reset domain, by configuring the Slice Setpoint Config Register and Slice Domain Config Register.

The user can determine if the reset behavior is controlled by CPU low-power mode or by Setpoint status, by configuring the AUTHEN_x[SETPOINT_MODE] bit and AUTHEN_x[DOMAIN_MODE] bit in the Slice Authentication Register.

When in Domain Mode, the reset will be asserted and held active if the system enters a CPU low-power mode, if it's reset domain is configured to be in reset. It will come out of reset when the system enters another CPU low-power mode, if it's reset domain is configured to be not in reset. The timing of the reset behavior under CPU low-power mode transaction is shown in the figure below.

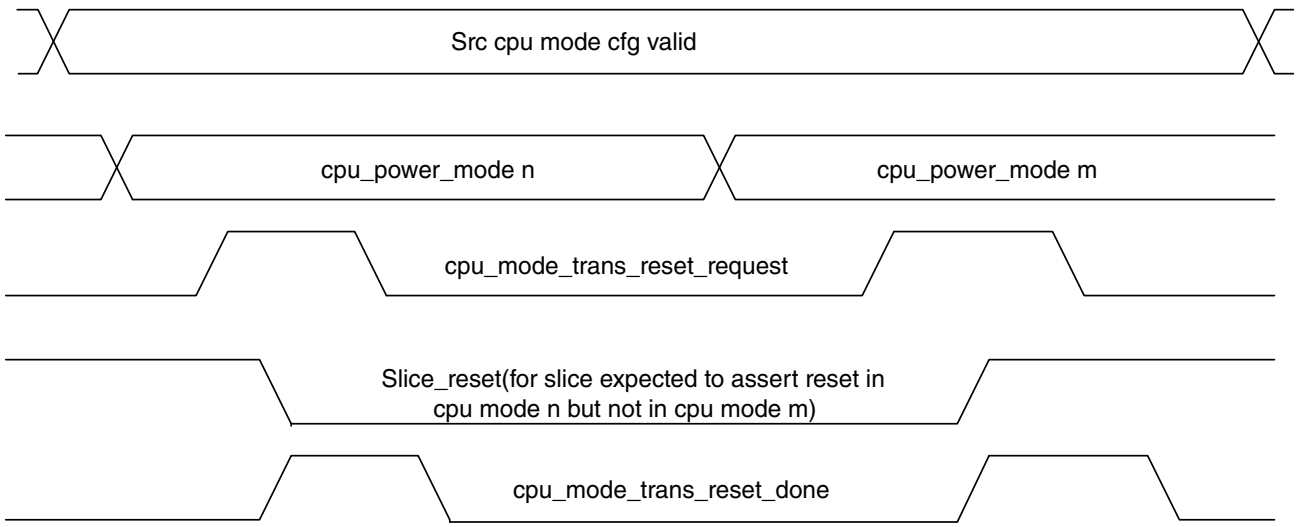

Figure 25-5. The timing of the reset behavior under CPU low-power mode transaction

The timing of the reset behavior under system Setpoint transaction is shown in the figure below.

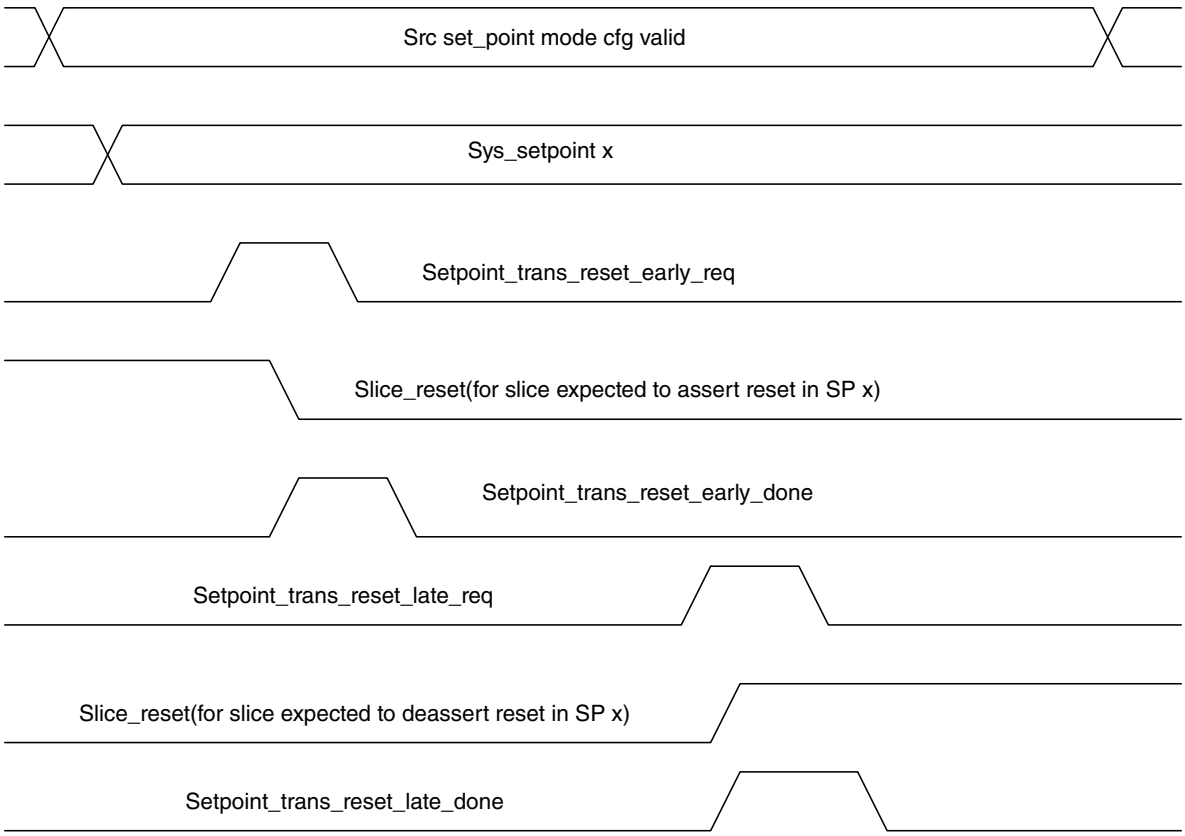

Figure 25-6. The timing of the reset behavior under the system Setpoint transaction

25.3.8 SRC_BOOT_MODE Pin and SRC_BT_CFG Pin Latching

The exact boot sequence is controlled by the values of the SRC_BOOT_MODE pins on this device. The value of the SRC_BOOT_MODE pins will be latched after values of the on-chip Fuses are latched.

After latching, the values of the SRC_BOOT_MODE pins and the BT_FUSE_SEL e-fuse are used to determine other booting options (named as BOOT_CFG) as described in the SBMR1 registers.

The BOOT_CFG bits can be provided to the SRC from either e-fuses named as BOOT_CFG or from SRC_BT_CFG pins. This is determined by the BT_FUSE_SEL fuse setting.

- If BT_FUSE_SEL fuse setting = 1’b1, the BOOT_CFG is provided from BOOT_CFG fuses.
- If BT_FUSE_SEL fuse setting = 1’b0, the BOOT_CFG is taken from SRC_BT_CFG and SRC_BOOT_MODE pins.

Please see the fusemap for more details.

25.3.9 Clocks

The table below describes the relevant SRC clock sources.

Table 25-4. SRC Clocks

Clock name	Description
ipg_clk	Peripheral clock
ipg_clk_s	Peripheral access clock. This clock is typically the same source as the ipg_clk.

NOTE

Please see the clock controller for clock setting, configuration, and gating information.

25.4 External Signals

This table describes the SRC external signals.

Table 25-5. External Signals

Signal	Description	Direction
SRC_POR_B	Power on reset input pin, active low.	I
SRC_BT_CFGn	Boot configuration pins. The values are sampled during system reset and can be read in the SBMR1 register. See the boot chapter for specific boot configuration settings, and the pin mux chapter for pin assignments.	I
SRC_BOOT_MODE	Boot mode selection pins. The values are sampled during system reset and can be read in the SBMR2 register. See the boot chapter for specific boot configuration settings, and the pin mux chapter for pin assignments.	I
RESET_B (ONOFF)	Reset Signal to ONOFF pin, active low.	O

25.5 Initialization

25.5.1 Power-On Reset and power sequencing

The following conditions must be met for Power-Up:

- VDD_SNVS_IN supply must be turned on before any other power supply, or be connected (shorted) with VDD_LPSR_IN and DCDC_IN supply

- If a coin cell is used to power VDD_SNVS_IN, then ensure that it is connected before any other supply is switched on
- When the internal DCDC is enabled, an external delay circuit is required to delay the DCDC_PSWITCH signal at least 1ms after DCDC_IN is stable
- POR_B should be held low during the entire power up sequence

Similarly, for Power-Down, the following conditions must be met:

- VDD_SNVS_IN supply must be turned off after any other power supply, or be connected (shorted) with VDD_LPSR_IN and DCDC_IN supply
- If a coin cell is used to power VDD_SNVS_IN, then ensure that it is removed after any other supply is switched off

25.6 Memory Map and register definition

This section includes the SRC module memory map and detailed descriptions of all registers.

25.6.1 SRC register descriptions

25.6.1.1 SRC memory map

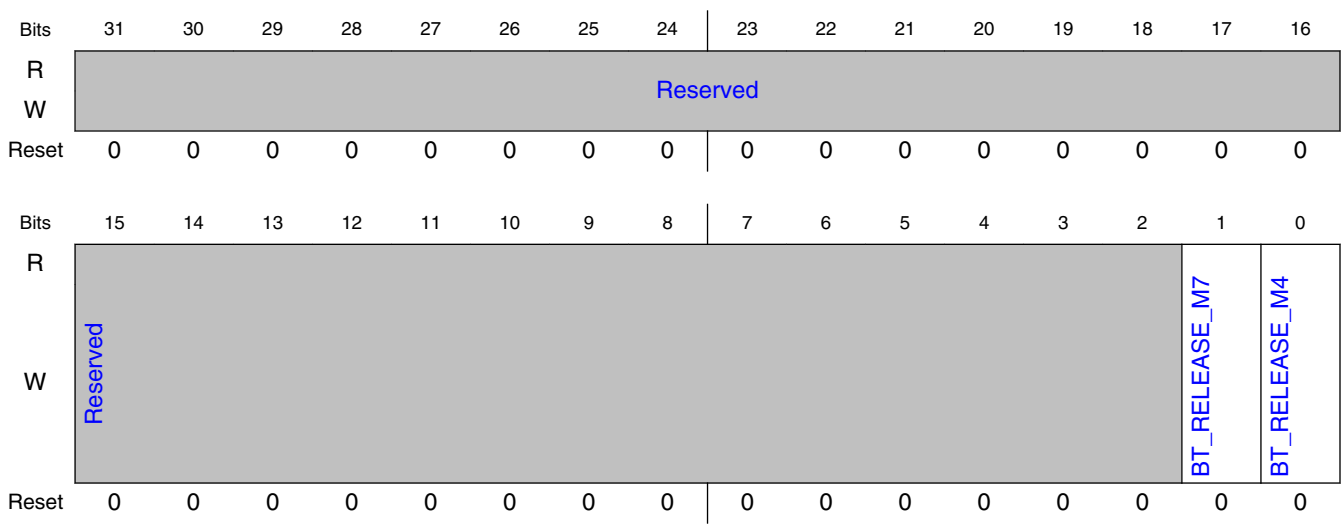
25.6.1.2 SRC Control Register (SCR)

The Reset control register (SCR), contains bits that control operation of the reset controller.

25.6.1.2.1 Offset

Register	Offset
SCR	0h

25.6.1.2.2 Diagram



25.6.1.2.3 Fields

Field	Description
31-2 —	Reserved
1 BT_RELEASE_M7	cm7 core reset will be held until boot core write this bit to 1 to release it. 0 - cm7 core reset is asserted 1 - cm7 core reset is released
0 BT_RELEASE_M4	cm4 core reset will be held until boot core write this bit to 1 to release it. 0 - cm4 core reset is asserted 1 - cm4 core reset is released

25.6.1.3 SRC Reset Mode Register (SRMR)

The Reset Mode Register (SRMR), contains bits that control reset behavior of reset sources. A reset source can reset a single core or entire SoC, depending on its corresponding mask bit value.

NOTE

Only valid to reset either a single core or entire system. Should be ensured by software.

25.6.1.3.1 Offset

Register	Offset
SRMR	4h

25.6.1.3.2 Diagram

25.6.1.5.3 Fields

Field	Description
31-26 —	Reserved
25-24 BMOD	BMOD[1:0] shows the latched state of the BOOT_MODE1 and BOOT_MODE0 signals on the rising edge of POR_B. See the Boot mode pin settings section of System Boot.
23-16 —	Reserved
15-5 —	Reserved
4 BT_FUSE_SEL	BT_FUSE_SEL shows the state of the BT_FUSE_SEL fuse. See fusemap for additional information on this fuse.1 Reset is a result of the mentioned case.
3-2 —	Reserved
1-0 SEC_CONFIG	SECONFIG[1] shows the state of the SECONFIG[1] fuse. See Fusemap for additional information on this fuse. SECONFIG[0] shows the state of the SECONFIG[0] fuse. This fuse is shown as reserved in fusemap (address 0x440[1]) because it does not have a user-relevant function.

25.6.1.6 SRC Reset Status Register (SRSR)

The SRSR is a write to one clear register which records the source of the reset events for the chip. The SRC reset status register will capture all the reset sources that have occurred. This register is reset on ipp_reset_b. This is a read-write register.

Writing zero does not have any effect. Writing one will clear the corresponding bit. When the system comes out of reset, this register will have bits set corresponding to all the reset sources that occurred during system reset. Software has to take care to clear this register by writing one after every reset that occurs so that the register will contain the information of recently occurred reset.

Since M4 and M7 core might be reset by different source, reset status register must provide each core with dedicated bits. Bits [15:0] are assigned to M7 core and [31:16] are assigned to M4 core.

25.6.1.6.1 Offset

Register	Offset
SRSR	10h

25.6.1.6.3 Fields

Field	Description
31 —	Reserved
30 CDOG_RST_M4	Indicates a reset has been caused by CDOG reset. 0 - Reset is not a result of the mentioned case. 1 - Reset is a result of the mentioned case.
29 OVERVOLT_RST_M4	Indicates a reset has been caused by power suppy voltage over the highest permitted level. 0 - Reset is not a result of the mentioned case. 1 - Reset is a result of the mentioned case.
28	Indicates a reset has been caused by M7 CPU lockup or software setting of SYSRESETREQ bit in Application Interrupt and Reset Control Register of the ARM core. Software needs to set some GPR bit

Table continues on the next page...

Field	Description
M7_LOCKUP_M4	before writing SYSRESETREQ bit and use the GPR bit to distinguish if the reset is caused by SYSRESETREQ or CPU lockup. 0 - Reset is not a result of the mentioned case. 1 - Reset is a result of the mentioned case.
27 M7_REQUEST_M4	Indicates whether reset was the result of m7 reset request. 0 - Reset is not a result of m7 reset request. 1 - Reset is a result of m7 reset request.
26 TEMPSENSE_RST_B_M4	Temper Sensor software reset. Indicates whether the reset was the result of software reset from on-chip Temperature Sensor. 0 - Reset is not a result of software reset from Temperature Sensor. 1 - Reset is a result of software reset from Temperature Sensor.
25 WDOG4_RST_B_M4	IC Watchdog4 Time-out reset. Indicates whether the reset was the result of the watchdog4 time-out event. 0 - Reset is not a result of the watchdog4 time-out event. 1 - Reset is a result of the watchdog4 time-out event.
24 WDOG3_RST_B_M4	IC Watchdog3 Time-out reset. Indicates whether the reset was the result of the watchdog3 time-out event. 0 - Reset is not a result of the watchdog3 time-out event. 1 - Reset is a result of the watchdog3 time-out event.
23 JTAG_SW_RST_M4	JTAG software reset. Indicates whether the reset was the result of software reset from JTAG. 0 - Reset is not a result of software reset from JTAG. 1 - Reset is a result of software reset from JTAG.
22 JTAG_RST_B_M4	HIGH - Z JTAG reset. Indicates whether the reset was the result of HIGH-Z reset from JTAG. 0 - Reset is not a result of HIGH-Z reset from JTAG. 1 - Reset is a result of HIGH-Z reset from JTAG.
21 WDOG_RST_B_M4	IC Watchdog Time-out reset. Indicates whether the reset was the result of the watchdog time-out event. 0 - Reset is not a result of the watchdog time-out event. 1 - Reset is a result of the watchdog time-out event.
20 IPP_USER_RESET_B_M4	Indicates whether the reset was the result of the ipp_user_reset_b qualified reset. 0 - Reset is not a result of the ipp_user_reset_b qualified as COLD reset event. 1 - Reset is a result of the ipp_user_reset_b qualified as COLD reset event.
19 CSU_RESET_B_M4	Indicates whether the reset was the result of the csu_reset_b input. 0 - Reset is not a result of the csu_reset_b event. 1 - Reset is a result of the csu_reset_b event.
18 M4_LOCKUP_M4	Indicates a reset has been caused by M4 CPU lockup or software setting of SYSRESETREQ bit in Application Interrupt and Reset Control Register of the ARM core. Software needs to set some GPR bit before writing SYSRESETREQ bit and use the GPR bit to distinguish if the reset is caused by SYSRESETREQ or CPU lockup. 0 - Reset is not a result of the mentioned case. 1 - Reset is a result of the mentioned case.
17	Indicates whether reset was the result of m4 reset request

Table continues on the next page...

Field	Description
M4_REQUEST_M4	0 - Reset is not a result of m4 reset request. 1 - Reset is a result of m4 reset request.
16 IPP_RESET_B_M4	Indicates whether reset was the result of ipp_reset_b pin (Power-up sequence) 0 - Reset is not a result of ipp_reset_b pin. 1 - Reset is a result of ipp_reset_b pin.
15 —	Reserved
14 CDOG_RST_M7	Indicates a reset has been caused by CDOG reset. 0 - Reset is not a result of the mentioned case. 1 - Reset is a result of the mentioned case.
13 OVERVOLT_RST_M7	Indicates a reset has been caused by power suppy voltage over the highest permitted level. 0 - Reset is not a result of the mentioned case. 1 - Reset is a result of the mentioned case.
12 M4_LOCKUP_M7	Indicates a reset has been caused by M4 CPU lockup or software setting of SYSRESETREQ bit in Application Interrupt and Reset Control Register of the ARM core. Software needs to set some GPR bit before writing SYSRESETREQ bit and use the GPR bit to distinguish if the reset is caused by SYSRESETREQ or CPU lockup. 0 - Reset is not a result of the mentioned case. 1 - Reset is a result of the mentioned case.
11 M4_REQUEST_M7	Indicates whether reset was the result of m4 reset request. 0 - Reset is not a result of m4 reset request. 1 - Reset is a result of m4 reset request.
10 TEMPSENSE_RST_B_M7	Temper Sensor software reset. Indicates whether the reset was the result of software reset from on-chip Temperature Sensor. 0 - Reset is not a result of software reset from Temperature Sensor. 1 - Reset is a result of software reset from Temperature Sensor.
9 WDOG4_RST_B_M7	IC Watchdog4 Time-out reset. Indicates whether the reset was the result of the watchdog4 time-out event. 0 - Reset is not a result of the watchdog4 time-out event. 1 - Reset is a result of the watchdog4 time-out event.
8 WDOG3_RST_B_M7	IC Watchdog3 Time-out reset. Indicates whether the reset was the result of the watchdog3 time-out event. 0 - Reset is not a result of the watchdog3 time-out event. 1 - Reset is a result of the watchdog3 time-out event.
7 JTAG_SW_RST_M7	JTAG software reset. Indicates whether the reset was the result of software reset from JTAG. 0 - Reset is not a result of software reset from JTAG. 1 - Reset is a result of software reset from JTAG.
6 JTAG_RST_B_M7	HIGH - Z JTAG reset. Indicates whether the reset was the result of HIGH-Z reset from JTAG. 0 - Reset is not a result of HIGH-Z reset from JTAG. 1 - Reset is a result of HIGH-Z reset from JTAG.
5	IC Watchdog Time-out reset. Indicates whether the reset was the result of the watchdog time-out event.

Chapter 26
Fusemap

26.1 Overview

This section details the various fuses and their associated configuration settings. There is one main fuse array with an associated supplementary array.

This chapter also describes various modes and the selection of the required boot devices.

NOTE

The fuses marked as “Reserved” are reserved for NXP internal (and future) use only, or are security related. Customers must not attempt to burn these, because the IC behavior may be unpredictable. The reserved fuses can be read as either '0' or '1'. Security-related fuses are described in the Security Reference Manual (SRM) for this device.

26.1.1 Bank redundancy vs Error correction code (ECC)

There are two mechanisms used by the fuse block to ensure that its values are correct. Each of these is performed on a word by word basis; however, the selected option is hardwired on a bank by bank basis.

Fuses can generally only be set from 0 to 1 and the most common failure is a 1 appearing as a 0. The simplest mechanism to verify these failures is redundancy. Redundancy is when two bits are OR'd together so that if either is set, then the output value is a 1.

In this case only 16 of the 32 bits are available (bits 15:0 are automatically copied to 31:16) and checked on read. The ECC bits 38:32 are not used in this case. The value here is that each pair of bits can be programmed at different times. This allows for multiple programming operations on a word, so bits can be configured at different times.

NOTE

In shadow registers, the inverted version of [15:0] will show in [31:16]. In the fuse array, [31:16] is the same as [15:0].

The more complex ECC mechanism is used when higher numbers of bits must be stored and configured at the same time in a group of 32. In this case, when written, the ECC must be calculated to allow an ECC correction, when read any one bit of failure will be corrected, 2 bits will be detected (and an error flag asserted) by the controller.

The majority of the main arrays use ECC, however, the first 128 words use redundancy to accommodate the monotonic array.

NOTE

The monotonic array requires redundancy, not ECC, as it's programmed individually

NOTE

As the ECC is generated for the whole word, the whole word must be setup at one time and individual bits cannot be modified independently.

26.1.2 Lock bits

There are two kinds of lock bits, write lock and read lock.

The write lock bits are used by the controller to control writing/programming of the fuse bits and the shadow registers (which hold the value read from the fuses). Each word can be write locked independently, which means that it can no longer be programmed. If the word is write locked, only read is permitted and the overwriting of the shadow registers is not permitted. If the word is not locked, then it can be read sensed and programmed and the shadow registers can be overwritten (to allow emulation of programming without actually blowing fuses). The supplemental array of fuses are always override locked.

Read lock bits are a specific set of fuses that give you the ability to block bus access to specific words. Read locks are on parts of the array consisting of multiple words. The bits for these are stored in the supplementary array section in the last word.

For fuse words using redundancy mode, the word is write locked by setting the OCOTP CTRL[WORDLOCK] bit when programming that fuse word. The write lock will apply to the entire word and cannot be used for partial locking. Fuse words using ECC mode can only be programmed one time, so they are automatically write locked after they are programmed. Each fuse word has write lock bits.

26.2 Boot Fusemap

This section describes the various modes and the selection of the required boot devices.

A separate map is given for each and every boot device. The device select is specified by the BOOT_CFG1[7:4] fuses.

Table 26-1. Boot device select

Boot Device	BOOT_CFG1[7]	BOOT_CFG1[6]	BOOT_CFG1[5]	BOOT_CFG1[4]
FlexSPI (Serial NOR)	0	0	0	0
SD	0	1	x	x
MMC/eMMC	1	0	x	x
SEMC (NAND)	0	0	1	x
FlexSPI (Serial NAND)	1	1	x	x

NOTE

The fuses marked as “Reserved” are reserved for NXP internal (and future) use only. Customers **must not** attempt to burn these, because the IC behavior may be unpredictable. The reserved fuses can be read as either '0' or '1'. Security-related fuses are described in the Security Reference Manual (SRM) for this device.

NOTE

Security-related fuses are shown as reserved here. For details, refer to the Security Reference Manual.

27.2 Overview

This section contains information describing the On-Chip OTP controller (OCOTP_CTRL) along with details about the block functionality and implementation.

In this document, the words "eFuse" and "OTP" are interchangeable. OCOTP refers to the hardware block itself.

27.2.1 Block Diagram

The system level block diagram for OCOTP is provided below.

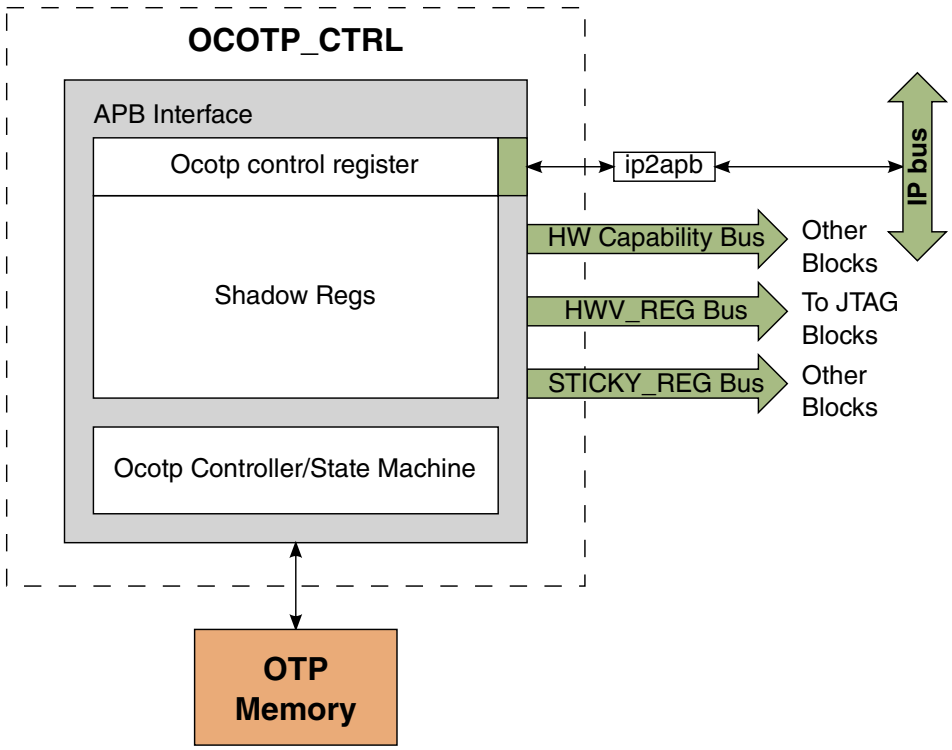

Figure 27-1. OCOTP System Level Block Diagram

27.2.2 Features

The OCOTP provides the following features :

- 32-bit word restricted program and read to 8 kbit of eFuse.
- Loading and housing of eFuse content into shadow registers
- Memory-mapped (restricted) access to shadow registers
- Generation of STICKY_REG which consists of sticky register bits
- Provides program-protect and read-protect of eFuse
- Provides read protection of shadow register
- Supports Error-correcting code (ECC) mode programming and reading for all the user fuse words
- Supports redundancy mode programming and reading for all the supplementary fuse words

27.3 Functional Description

27.3.1 Operations

The IP bus interface of the OCOTP has the following functions.

- Configure control registers for programming and reading all the fuse words
- Read shadow registers

OCOTP configuration for programs and reads are performed on 32-bit words for software (SW) convenience. For writes, the 32-bit word reflects the "write-mask". Bit fields with 0 will not be programmed and bit fields with 1 will be programmed.

NOTE

For fuse words that use ECC, the fuse word can only be programmed one time, otherwise it will report single-bit error correction (SEC) / double-bit error detection (DED) issues in read or reload. Refer to the fusemap chapter to identifiy which fuse words use ECC for error correction.

NOTE

For fuse words that use redundant bits, the fuse word can be programmed more than one time (not the same fuse bit). Refer to the fusemap chapter to identifiy which fuse words use redundant bits for error correction.

The full 8 Kbits of fuses are implemented in one physical OTP memory block. The 8 kbit is divided into 32 banks by function, where each bank has 8 fuse words (8 x 32-bit = 256 bits per bank).

27.3.1.1 Shadow Register Reload

All fuse words in efuse box are shadowed. This means that at reset, fuse values are read and then copied into memory-mapped shadow registers. If fuses are subsequently programmed, the shadow registers should be reloaded to keep them coherent with the fuse bank arrays.

The "reload shadows" feature allows the user to force a reload of the shadow registers without having to reset the device. To force a reload, complete the following steps:

1. Check that CTRL[BUSY] and CTRL[ERROR] are clear. Overlapped accesses are not supported by the controller. Any pending write, read, or reload must be completed before a new access can be requested.
2. Set the CTRL[RELOAD_SHADOWS] bit. OCOTP will read all the fuses one by one and put it into corresponding shadow register.
3. Wait for CTRL[BUSY] and CTRL[RELOAD_SHADOWS] to be cleared by the controller.
4. Check the values of OUT_STATUS[SEC_RELOAD] and OUT_STATUS[DED_RELOAD].
   - If OUT_STATUS[SEC_RELOAD] is set, it indicates at least one single bit correction happened when reloading.
   - If OUT_STATUS[DED_RELOAD] is set, it indicates at least one double-bit error happened when reloading. That is, one or more fuse words are not correct when reading from eFuse.

The controller will automatically clear the CTRL[RELOAD_SHADOWS] bit after the successful completion of the operation.

27.3.1.2 Fuse and Shadow Register Read

All shadow registers are always readable through the IPS bus except some secret key regions. When their corresponding fuse lock bits are set, the shadow registers also become read locked. After read locking, reading from these registers will return 0xBADABADA.

In addition, CTRL[ERROR] will be set. It must be cleared by software before any new write, read, or reload access can be issued. Subsequent reads to unlocked shadow registers will still work successfully.

To read fuse words directly from the fusebox instead of the shadow registers, complete the following steps:

1. Check that CTRL[BUSY] and CTRL[ERROR] are clear. Overlapped accesses are not supported by the controller. Any pending write, read, or reload must be completed before a read access can be requested.
2. Write the requested fuse address to CTRL[ADDR].
3. Set READ_CTRL[READ_FUSE] to start the read operation.
4. Wait for the controller to clear CTRL[BUSY]. A read request to a protected or locked region will result in no OTP access and no setting of CTRL[BUSY]. In addition, CTRL[ERROR] will be set. It must be cleared by software before any new access can be issued.

5. Read READ_FUSE_DATA to get fuse word value. READ_FUSE_DATA will be 0xBADABADA when CTRL[ERROR] is set.
6. After reading is completed, it needs to check OUT_STATUS[DED] value to confirm if read fuse value is correct. If it is 1, read fuse value is wrong, otherwise it is correct.

27.3.1.3 Fuse Writes

In order to avoid "rogue" code performing erroneous writes to OTP, a special unlocking sequence is required for writes to the fuse banks. To program fuse bank complete the following steps:

1. Check that CTRL[BUSY] and CTRL[ERROR] are clear. Overlapped accesses are not supported by the controller. Any pending write, read, or reload must be completed before a write access can be requested.
2. Write the requested address to CTRL[ADDR] and program the unlock code into CTRL[WR_UNLOCK]. The unlock code must be programmed for each write access. The unlock code is documented in the register description. Both the unlock code and address can be written in the same operation.
3. When programming fuse word, OCOTP_CTRL will auto select ECC or redundancy mode to program the fuse word according to fuse map definition. In ECC mode, the 32 fuse bits in one word can only be written one time. In redundancy mode, the word can be written more than one time as long as they are different fuse bits. For the fuse word which needs be programmed with ECC mode, it is recommended to set CTRL[WORDLOCK] with unlock code and address in same operation.
4. Write the data to the DATA register. This will automatically set CTRL[BUSY] and clear CTRL[WR_UNLOCK]. Bit fields with 1's will result in that OTP bit being programmed. Bit fields with 0's will be ignored. At the same time that the write is accepted, the controller makes an internal copy of CTRL[ADDR] which cannot be updated until the next write sequence is initiated. This copy guarantees that erroneous writes to CTRL[ADDR] will not affect an active write operation. During the write operation, DATA cannot be modified. If the requested fuse word is locked, the programming request will not be performed. Checking the appropriate LOCKEDn register before attempting to program is recommended
5. Wait for the controller to clear CTRL[BUSY]. A write request to a protected or locked region will result in no OTP access and no setting of CTRL[BUSY]. In addition CTRL[ERROR] will be set. It must be cleared by software before any new write access can be issued.
6. Check the values of OUT_STATUS[PROGFAIL] and OUT_STATUS[LOCKED]. If either of these two bits is set, it indicates that programming has failed.

It should be noted that write latencies to OTP are numbers of 10 micro-seconds per word. The write latency is based on the number of "1" bits being written. For example, to program half the fuse bits in one 32-bt word requires 10 us x 16.

27.3.1.4 Bank redundancy vs ECC

There are two mechanisms used by the fuse block to ensure that its values are correct. Each of these is performed on a word by word basis, however, the selected option is hardwired on a bank by bank basis.

Fuses can generally only be set from 0 to 1 and the most common failure is a 1 appearing as a 0. The simplest mechanism to verify these failures is redundancy. Redundancy is when two bits are OR'd together so that if either is set, then the output value is a 1.

In this case only 16 of the 32 bits are available (bits 15:0 are automatically copied to 31:16) and checked on read. The value here is that each pair of bits can be programmed at different times. This allows for multiple programming operations on a word, so bits can be configured at different times.

NOTE

In shadow registers, the inverted version of [15:0] will show in [31:16]. In the fuse array, [31:16] is the same as [15:0].

The more complex ECC mechanism is used when higher numbers of bits must be stored and configured at the same time in a group of 32. When written, the ECC must be calculated to allow an ECC correction. When read, any one bit of failure will be corrected, 2 bits will be detected (and an error flag asserted) by the controller.

NOTE

As the ECC is generated for the whole word, the whole word must be setup at one time and individual bits cannot be modified independently.

27.3.1.5 Error Conditions

The CTRL[ERROR] bit will be set under the following conditions:

- A read is performed to a shadow register which has been read locked.
- A program is performed to a non-existent fuse word
- A read is performed to a fuse word which has been read locked.
- Overlapping access - a read, write, or reload is attempted while a read, write, or reload is already in progress.

27.3.1.6 Write Postamble

Due to internal electrical characteristics of the OTP during writes, all OTP operations (direct reads, shadow reloads, or other writes) following a write must wait at least 2 µs after CTRL[BUSY] clears. The delay guarantees programming voltages on-chip reach a steady state when exiting a write sequence.

A recommended software sequence to meet the postamble requirements is as follows:

1. Issue the write and poll for CTRL[BUSY].
2. After CTRL[BUSY] is clear, wait 2 µs.
3. Perform the next OTP operation.

27.3.1.7 Power control of OTP memory

For every fuse operation, the controller will automatically enable power to OTP memory. It is SW responsibility to shut off power to OTP memory in idle status to save power.

1. After system power-up, SW should write 1 to PDN[PDN] to shut off power to the OTP array.
2. After fuse program/read triggered by SW are completed, SW should write 1 to PDN[PDN] to shut off power to the OTP array unless additional fuse operations are needed.

27.3.2 Fuse Shadow Memory Footprint

The OTP memory footprint is shown in the following figure. The registers are grouped by lock region. Their names correspond to the fusemap names.

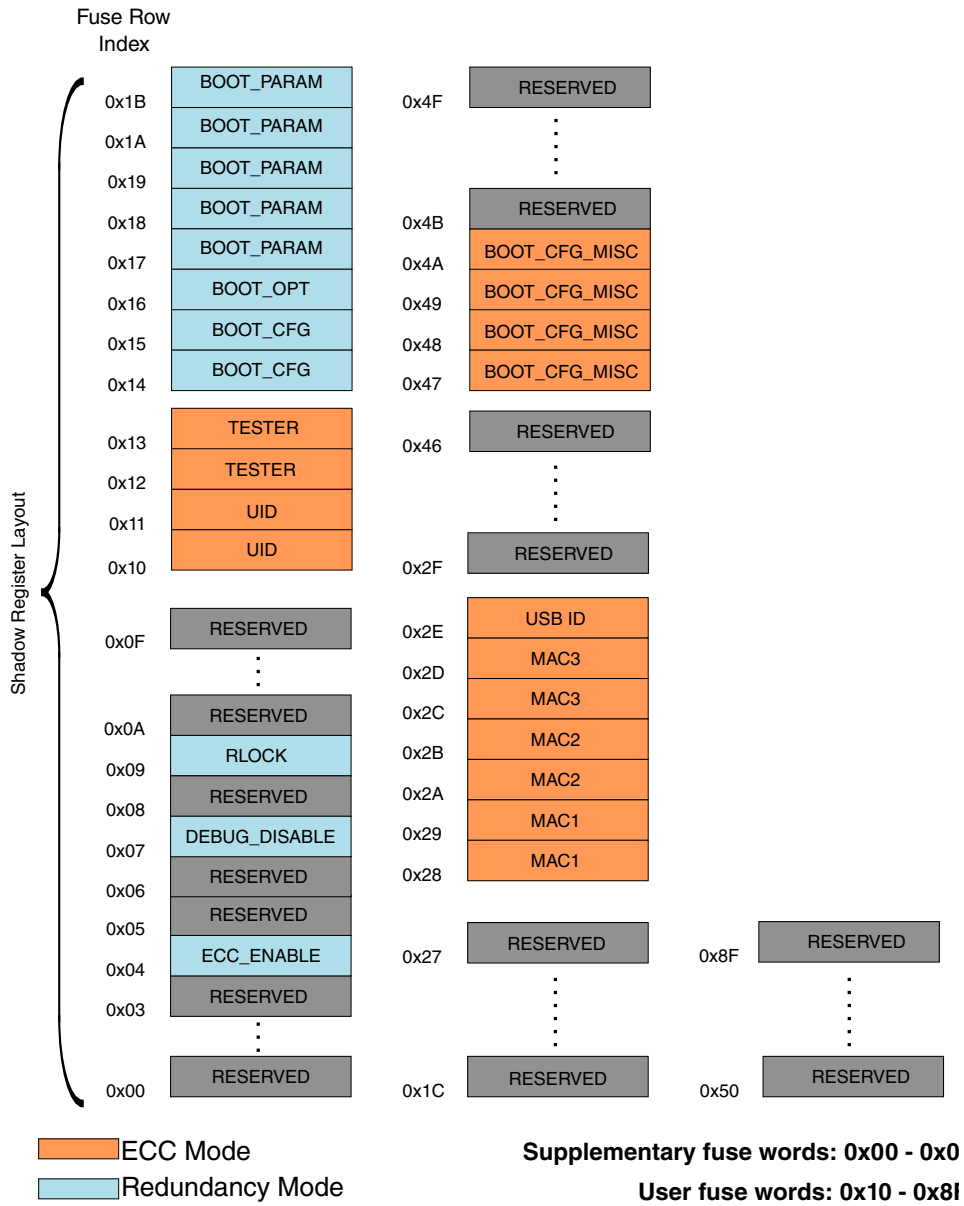

Figure 27-2. OTP Memory Footprint

NOTE

The device includes additional fuses that are not readable through shadow registers. Fuse row indexes 0xB0-0x110, must be read directly from the fusebox. Refer to Fuse and Shadow Register Read for details.

27.3.3 Resets

The OCOTP is always active. The shadow registers automatically load the appropriate OTP contents after reset is deasserted. During this load-time CTRL[BUSY] is set.

27.3.4 Clocks

The table found here describes the clock sources for OCOTP. Please see the chip-specific clocking section for clock setting, configuration and gating information.

Table 27-2. OCOTP Clocks

Clock name	Description
ipg_clk	Peripheral clock
ipg_clk_s	Peripheral access clock

27.4 External Signals

There are no external signals pinned out for OCOTP.

27.5 Fuse Map

See the Fusemap chapter of this reference manual for more information.

27.6 Memory Map/Register Definition

The OCOTP Memory Map/Register Definition can be found here.

NOTE

Writing or reading an unimplemented register address in the OCOTP Controller will not send a bus error and read data will be 0.

27.6.1.2 OTP Controller Control and Status Register (CTRL)

27.6.1.2.1 Offset

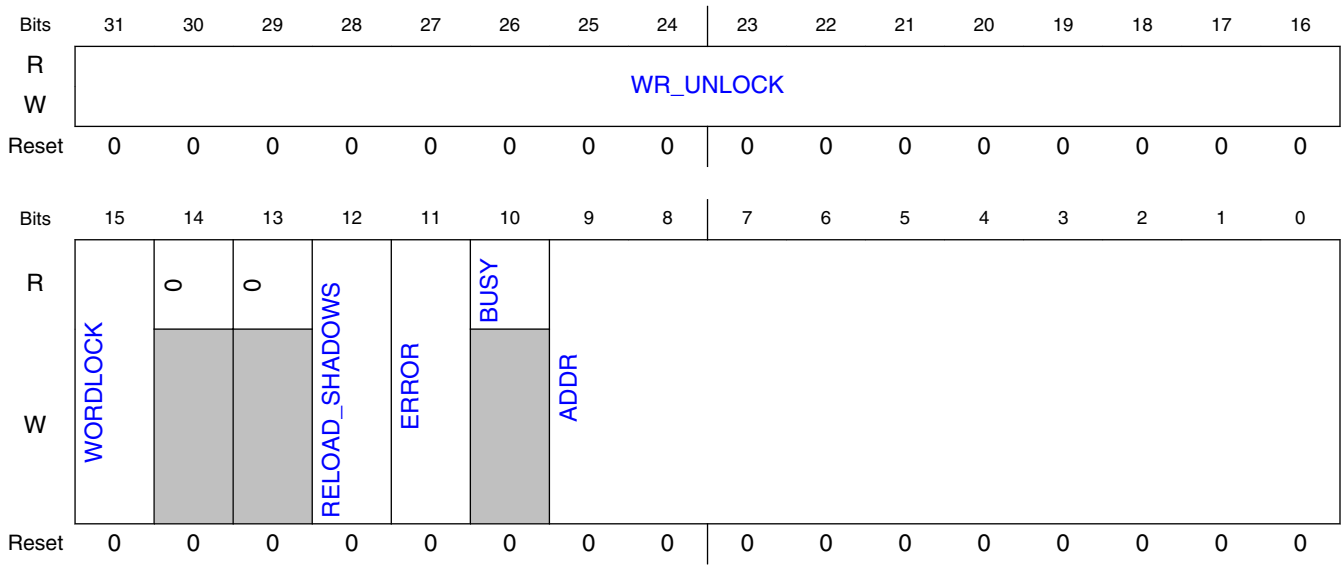
This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
CTRL	0h	OTP Controller Control and Status Register
CTRL_SET	4h	Writing 1 to a bit in this register ensures that the corresponding bit in CTRL is 1
CTRL_CLR	8h	Writing 1 to a bit in this register ensures that the corresponding bit in CTRL is 0
CTRL_TOG	Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in CTRL

27.6.1.2.2 Function

The OCOTP Control and Status Register provides the necessary software interface for performing read and write operations to the On-Chip OTP. The control fields such as WR_UNLOCK, ADDR, BUSY, and ERROR may be used in conjunction with the DATA register to perform write operations. Read operations to the On-Chip OTP involve ADDR, BUSY, and ERROR bit fields and the READ_CTRL register. The read value is saved in the READ_FUSE_DATA register.

27.6.1.2.3 Diagram



27.6.1.2.4 Fields

Field	Function
31-16 WR_UNLOCK	Write unlock Write 0x3E77 to enable OTP write accesses. **NOTE:** This register must be unlocked on a write-by-write basis (a write is initiated when DATA is written), so the UNLOCK bit field must contain the correct key value during all writes to DATA, otherwise, a write shall not be initiated. This field is automatically cleared after a successful write completion (clearing of BUSY). Values not listed are reserved. 0000_0000_0000_0000b - OTP write access is locked. 0011_1110_0111_0111b - OTP write access is unlocked.
15 WORDLOCK	Lock fuse word Set this bit to 1 to lock fuse word whose programming mode is redundancy mode. **NOTE:** This bit has no effect on fuse words using ECC mode. ECC fuse words are automatically locked when they are programmed. 0b - No change to LOCK bit when programming a word using redundancy 1b - LOCK bit for fuse word will be set after successfully programming a word using redundancy
14 —	Reserved
13 —	Reserved
12	Reload Shadow Registers

Table continues on the next page...

Field	Function
RELOAD_SHADOWS	This bit can be set to force the re-loading of the shadow registers. This operation will automatically set BUSY. After the shadow registers have been re-loaded, BUSY and RELOAD_SHADOWS are automatically cleared by the controller. 0b - Do not force shadow register re-load. 1b - Force shadow register re-load. This bit is cleared automatically after shadow registers are re-loaded.
11 ERROR	Locked Region Access Error This bit is set by the controller when an access to a locked region (OTP or shadow register) is requested. It must be cleared before any further access can be performed. This bit can only be set by the controller. Reset this bit by writing a one to the CTRL_CLR[ERROR] bit and not by writing to the HW_OCOTP_CTRL register. 0b - No error. 1b - Error - access to a locked region requested.
10 BUSY	OTP controller status bit This bit is automatically set by the controller when a write or read access to the OTP is started. When set, no new write access or read access to OTP (including RELOAD_SHADOWS) can be performed. This bit is cleared by the controller when an access is completed. After reset (or after setting RELOAD_SHADOWS), this bit is set by the controller until the HW/SW and LOCK registers are successfully copied, after which time it is automatically cleared by the controller. 0b - No write or read access to OTP started. 1b - Write or read access to OTP started.
9-0 ADDR	OTP write and read access address register Specifies one of the 272 word address locations. There are 16 supplementary fuse words and 256 user fuse words. The ADDR value to be specified can be calculated as follows: ((Address that is to be programmed/read) - 0x800) >> 4 For example, to program or read address 0x960, ADDR value should be set to 0x16 ((0x960 - 0x800) >> 4). If a valid access is accepted by the controller, the controller makes an internal copy of this value. This internal copy will not be updated until the access is complete. Address values not specified below are invalid. 00_0000_0000b-00_0000_1111b - Address of one of the 16 supplementary fuse words in OTP memory. 00_0001_0000b-01_0000_1111b - Address of one of the 256 user fuse words in OTP memory.

27.6.1.3 OTP Controller PDN Register (PDN)

27.6.1.3.1 Offset

Register	Offset
PDN	10h

27.6.1.3.2 Function

This register specifies power control for the OTP fuse array.

27.6.1.3.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	0															PDN
W																W1C
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

27.6.1.3.4 Fields

Field	Function
31-1 —	Reserved
0 PDN	PDN value This bit indicates the PDN value of the OTP memory. If 1 is written to this bit, PDN value will be 0. Writing 0 to this bit will have no effect. **NOTE:** SW should write 1 to this bit to shut off power to the OTP memory, after system power up. At the beginning of every fuse operation, HW will auto enable power to OTP memory. After every fuse operation, SW should write 1 to this bit to shut off power to the OTP memory and avoid unnecessary power wasting. 0b - OTP memory is not powered 1b - OTP memory is powered

27.6.1.4 OTP Controller Write Data Register (DATA)

27.6.1.4.1 Offset

Register	Offset
DATA	20h

27.6.1.4.2 Function

This register is used in conjunction with the CTRL register to perform one-time writes to the OTP. See Fuse Writes for operating details.

27.6.1.4.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R W	DATA															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

27.6.1.4.4 Fields

Field	Function
31-0 DATA	Data Used to initiate a write to OTP. See Fuse Writes for operating details.

27.6.1.5 OTP Controller Read Control Register (READ_CTRL)

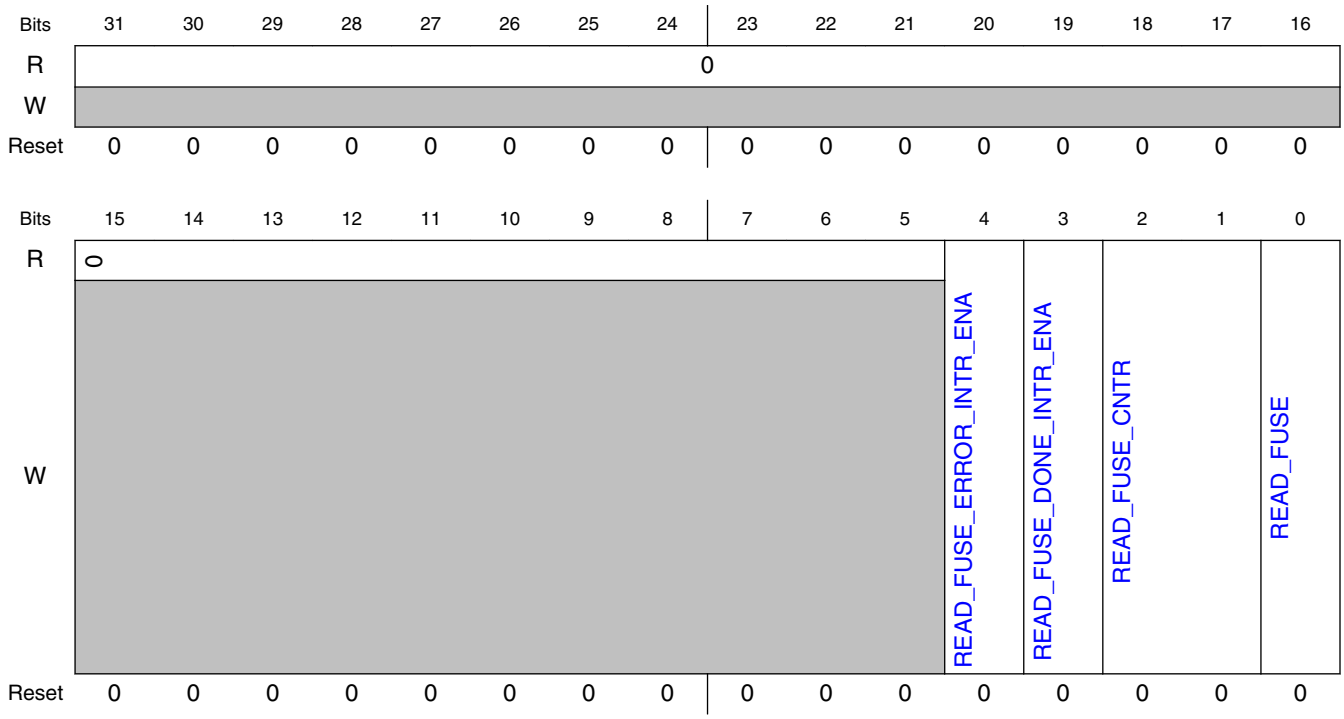
27.6.1.5.1 Offset

Register	Offset
READ_CTRL	30h

27.6.1.5.2 Function

This register is used in conjunction with the CTRL register to perform one time reads to the OTP. See Fuse and Shadow Register Read for operating details.

27.6.1.5.3 Diagram



27.6.1.5.4 Fields

Field	Function
31-5 —	Reserved
4 READ_FUSE_ERROR_INTR_ENA	Enable read-error interrupt 0b - Disable 1b - Enable
3 READ_FUSE_DONE_INTR_ENA	Enable read-done interrupt 0b - Disable 1b - Enable
2-1 READ_FUSE_CNTR	Number of words to read. 00b - 1 word 01b - 2 words 10b - 3 words 11b - 4 words
0 READ_FUSE	Read Fuse Used to initiate a read from OTP. See Fuse and Shadow Register Read for operating details. 0b - Do not initiate a read from OTP 1b - Initiate a read from OTP

27.6.1.6 8K OTP Memory STATUS Register (OUT_STATUS)

27.6.1.6.1 Offset

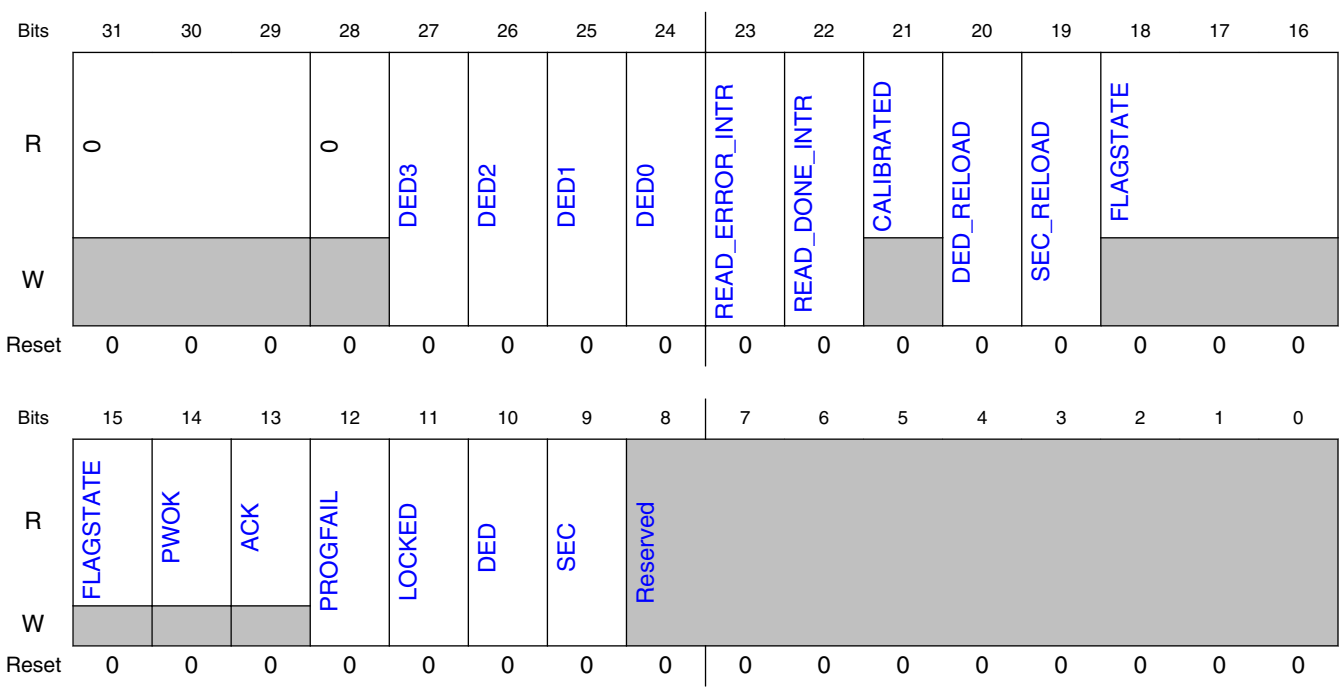
This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
OUT_STATUS	90h	8K OTP Memory STATUS Register
OUT_STATUS_SET	94h	Writing 1 to a bit in this register ensures that the corresponding bit in OUT_STATUS is 1
OUT_STATUS_CLR	98h	Writing 1 to a bit in this register ensures that the corresponding bit in OUT_STATUS is 0
OUT_STATUS_TOG	9Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in OUT_STATUS

27.6.1.6.2 Function

This register stores output signals of OTP memory for programming and reading OTP memory.

27.6.1.6.3 Diagram



27.6.1.6.4 Fields

Field	Function
31-29 —	Reserved
28 —	Reserved
27 DED3	Double error detect Indicates double error has been detected (no correction) when reading one fuse word. This bit can only be set by the controller. Reset this bit by writing a one to the SCT clear address space and not by a general write.
26 DED2	Double error detect Indicates double error has been detected (no correction) when reading one fuse word. This bit can only be set by the controller. Reset this bit by writing a one to the SCT clear address space and not by a general write.
25 DED1	Double error detect Indicates double error has been detected (no correction) when reading one fuse word. This bit can only be set by the controller. Reset this bit by writing a one to the SCT clear address space and not by a general write.
24 DED0	Double error detect Indicates double error has been detected (no correction) when reading one fuse word. This bit can only be set by the controller. Reset this bit by writing a one to the SCT clear address space and not by a general write.
23 READ_ERROR_INTR	Fuse read error indicates that error occurred during the read fuse operation. **NOTE:** When READ_ERROR_INTR is set to 1, it means read operation finished with an error, while READ_DONE_INTR would keep this bit 0. 0b - Read operation finished with out any error 1b - Read operation finished with an error
22 READ_DONE_INTR	Read fuse done Indicates read fuse operation was done successfully (no error occurred)
21 CALIBRATED	Calibrated status Indicates OTP memory calibrated status.
20 DED_RELOAD	Indicates double error detection occured on reload Indicates double error detection ever happens in reset reload or reload by setting CTRL[RELOAD_SHADOWS] bit. This bit can only be set by the controller. Reset this bit by writing a one to the SCT clear address space and not by a general write.
19 SEC_RELOAD	Indicates single error correction occured on reload Indicates single error correction ever happens in reset reload or reload by setting CTRL[RELOAD_SHADOWS] bit. This bit can only be set by the controller. Reset this bit by writing a one to the SCT clear address space and not by a general write.
18-15 FLAGSTATE	Flag state Indicates OTP memory current state.
14	Power OK

Table continues on the next page...

Field	Function
PWOK	Indicates that power vdd and vdd1 of OTP memory are in operating range.
13 ACK	Acknowledge Indicates operation acknowledgement from OTP memory
12 PROGFAIL	Programming failed Indicates that programming failed. This bit can only be set by the controller. Reset this bit by writing a one to the SCT clear address space and not by a general write.
11 LOCKED	Word Locked Indicates if a word is locked or not when programming or reading. If this bit is asserted when programming one fuse word, it means that the current programming operation has failed since the fuse word is already locked. This bit can only be set by the controller. Reset this bit by writing a one to the SCT clear address space and not by a general write.
10 DED	Double error detect Indicates that 2 errors have been detected (no correction) when reading one fuse word. This bit can only be set by the controller. Reset this bit by writing a one to the SCT clear address space and not by a general write.
9 SEC	Single Error Correct Indicates that one error has been corrected in data or ECC syndrome when reading one fuse word. This bit can only be set by the controller. Reset this bit by writing a one to the SCT clear address space and not by a general write.
8-0 —	Reserved

27.6.1.7 OTP Controller Version Register (VERSION)

27.6.1.7.1 Offset

Register	Offset
VERSION	B0h

27.6.1.7.2 Function

This register indicates the RTL version in use.

27.6.1.7.3 Diagram

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

27.6.1.13.4 Fields

Field	Function
31-0 BIT_LOCK	Each bit controls the corresponding bit in supplementary fuse word 13 and its shadow register. If one bit is 1, the corresponding bit cannot be written. The reset value of this register is 32'h0. After reset is de-asserted, '1' can only be written to each bit of this register once. The value of the bit cannot go back to '0' until the next reset is asserted.

Chapter 28
External Memory Controllers

28.1 Overview

This chip has these external memory interfaces and controllers:

- Smart External Memory Controller (SEMC)
- eSD/eMMC/SDIO Interface
- Flexible Serial Peripheral Interface (FlexSPI)

28.2 eMMC/eSD/SDIO

This chip has two Ultra Secured Digital Host Controller (uSDHC) modules for SD/eMMC interface. It provides the interface between the host system and the SD/SDIO/MMC cards.

The key features include:

- Support SD/SDIO standard, up to version 3.0
- Support MMC standard, up to version 5.0
- Support 3.3V and 1.8V operation.

28.3 Flexible Serial Peripheral Interface

There are two Flexible Serial Peripheral Interfaces - FlexSPI1 and FlexSPI2. Each FlexSPI host controller supports two SPI ports - A and B. Each port supports up two chip select outputs. Each port of FlexSPI2 supports Single/Dual/Quad/Octal mode data transfer (1/2/4/8 bidirectional data lines), while each port of FlexSPI1 supports Single/Dual/Quad mode data transfer (1/2/4 bidirectional data lines).

FlexSPI1 uses 4-bit bus with ports A and B, while FlexSPI2 uses 8-bit bus with ports A and B.

The key features includes:

- Support both SDR mode and DDR mode
- Support Individual/Parallel mode
- HyperBus device (HyperFlash/HyperRAM)

Chapter 29
Smart External Memory Controller (SEMC)

29.1 Chip-specific SEMC information

Table 29-1. Reference links to related information

Topic	Related module(s)	Reference
System memory map	-	System Memory Map

Power management	PMU	Power Management Power Management Unit
Signal multiplexing	IOMUX	External Signals and Pin Multiplexing IOMUX
Interrupts, DMA Events and XBAR Assignments	-	Interrupts, DMA Events and XBAR Assignments

29.2 Overview

The SEMC is a multi-standard memory controller optimized for both high-performance and low pin-count. It can support multiple external memories in the same application with shared address and data pins. The interfaces supported include SDRAM, NOR Flash, SRAM, NAND Flash, and 8080 display interface.

29.2.1 Block Diagram

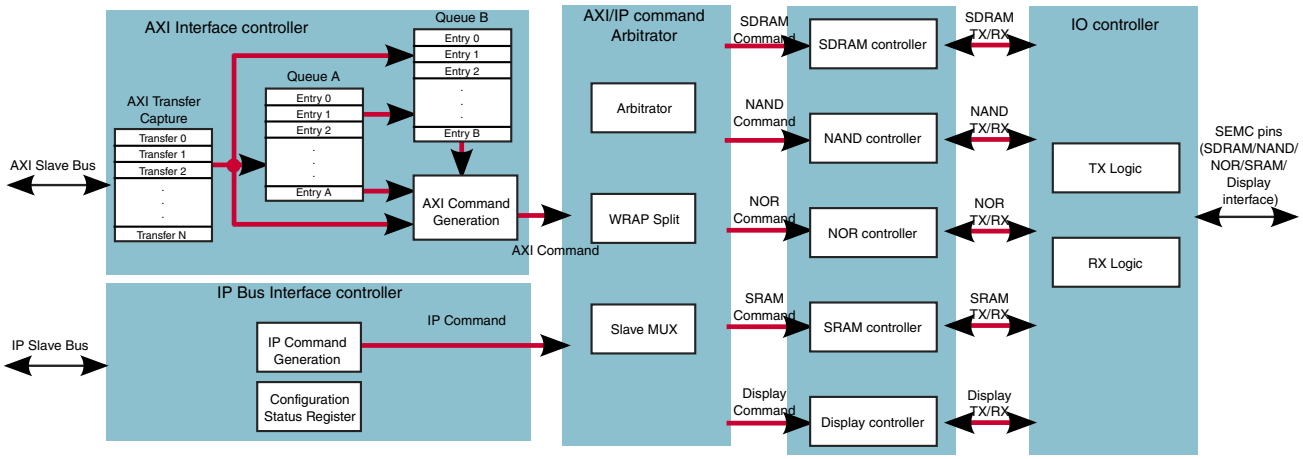

Figure 29-1. SEMC Block Diagram

29.2.2 Features

The SEMC includes the following features:

- Memory space:
  - Supports 12 memory regions:
    - Region #0 for SDRAM CS0 device
    - Region #1 for SDRAM CS1 device
    - Region #2 for SDRAM CS2 device
    - Region #3 for SDRAM CS3 device
    - Region #4 and #8 for NAND device (IP command and AXI command use different region to avoid large region address range on AXI interface)
    - Region #5 for NOR device
    - Region #6 for SRAM CS0 device
    - Region #7 for 8080 display frame buffer
    - Region #9 for SRAM CS1 device
    - Region #10 for SRAM CS2 device
    - Region #11 for SRAM CS3 device
  - Each region is configurable for base address, memory size and valid bit
- AXI slave interface
  - Supports 16 outstanding transfers (total including both reads and writes)
    - Supports 8 outstanding write transfers
    - Supports 16 outstanding read transfers
  - Multi-device access pattern optimization with Queue A

        - 8 entries command reordering in Queue A
        - Adjustable arbitration scheme based on QoS priority, latency and efficiency
    - SDRAM access pattern optimization with Queue B
        - 8 entries command reordering in Queue B
        - Adjustable arbitration scheme based on QoS priority, latency and efficiency
    - Memory-mapped AXI interface for read and write access
    - Supports 32/16/8 bit access
- IP Bus interface
    - Internal configuration register access
    - Trigger device access such as device initialization/configuration/read/write (IP command)
- SDRAM interface
    - Supports 8/16/32 bit modes
    - Supports 4 Chip Select (CS) and each CS up to 1024Mb
- NAND Flash interface
    - Supports 8/16 bit modes
    - No hardware ECC
    - Supports device which is capable of cache read/write operations
    - Supports page based read/write operation
    - Supports 32 bit transfer size for AXI write operation
    - Up to 512GB
- NOR Flash interface
    - Supports 8/16 bit modes
    - Supports ADMUX, AADM and Non-ADMUX modes
    - NOR Flash write access is supported only by IP command
    - Up to 4096Mb memory size

NOTE

- For 16 bit devices, up to 4096Mb memory size
- For 8 bit devices, up to 2048Mb memory size

- SRAM interface
    - Supports SRAM and Pseudo SRAM
    - Supports 8/16 bit modes
    - Supports ADMUX, AADM and Non-ADMUX modes
    - Up to 4 Chip Select (CS)
    - Up to 4096Mb memory size

NOTE

- For 16 bit devices, up to 4096Mb memory size
- For 8 bit devices, up to 2048Mb memory size

- 8080 display interface

    - Supports 8/16 bit modes
    - No tearing effect support
- Misc
    - Dynamic I/O sharing which enables multiple external memory device in parallel
    - Up to 7 Chip Select (CS) signals
    - Supports Address Latch Enable (ALE) for SRAM/NOR device

29.3 Functional Description

The following sections describe functional details of the SEMC module.

29.3.1 Operations

The following sections describe operations of the SEMC module.

29.3.1.1 Modes of Operation

The SEMC supports the following operation modes:

- Module Disable mode

  In module disable mode, the internal clock is gated for low power, but access to configuration and status registers is available.

  This mode is entered by setting MCR[MDIS], and exited by clearing MCR[MDIS]. Software should poll STS0[IDLE] to make sure there are no pending transactions before entering module disable mode.

- Stop mode

  When the system requires the SEMC to enter stop mode, the SEMC waits for all transactions to complete (STS0[IDLE]=1) and returns acknowledge handshake to system. The system can gate off the SEMC clock after the stop acknowledge handshake is returned. There is no clock gating within the SEMC module.

  The SEMC exits this mode immediately when the system stop mode request is negated.

- Normal mode

Access to external devices and internal registers are available in normal mode. The SEMC clock is not gated internally.

29.3.1.2 Device Access by AXI Command

Devices can be accessed by AXI bus access directly. AXI command is the device access sequence triggered by AXI bus access. The device access sequence for AXI commands is described in the following sections.

NOTE

- The AXI bus memory map for each device is defined by Base Registers.
- There is no software configuration or polling needed for AXI command.
- AXI command is the first choice to access device memory. IP command is suitable for other access, such as device register/OTP space access, device initialization, etc.
- IP command can be used to access memory like AXI command, but it is not recommended if AXI command is available. IP command access is low efficiency.

29.3.1.2.1 Bus Master Control Registers (BMCRn) Configuration

BMCRn can be used to balance external memory access efficiency, urgency and latency based on the requirements of a specific application.

29.3.1.2.1.1 BMCR0 Register Configuration

For Queue A controlled by BMCR0, the arbitration logic adopts a weight based algorithm that assigns each command in the reordering queue with a final score.

The arbitration logic calculates a SCORE for each command based on the formula below, where the weighting factor for each parameter is controlled by the BMCR0 configuration. The command with the highest SCORE is served first.

SCORE = QOS*WQOS + AGE*WAGE/4 + WSH + WRWS

1. QOS stands for AxQOS of AXI bus, and WQOS is the weight factor of QOS.
2. AGE stands for the wait period for each command in queue, and WAGE is the weight factor of AGE.
3. WSH stands for weight of slave hit without read/write switch scenario.
4. WRWS stands for weight of slave hit with read/write switch scenario.

Recommend to set BMCR0 with 0x0 for applications that require restrict sequence of transactions, such as stack is allocated in SDRAM. The write and read transactions to the same address might be reordered if transactions in the queue is reordered, and it might crash the routine. WQOS can be non-zero value if needed, meanwhile WAGE must be non-zero value as well. In any case, WBR, WRWS, and WPH should be 0x0.

29.3.1.2.1.2 BMCR1 Register Configuration

For Queue B controlled by BMCR1, the arbitration logic adopts a weight based algorithm that assigns each command in the reordering queue with a final score.

The arbitration logic calculates SCORE for each SDRAM command based on the formula below. The command with the highest SCORE is served first.

SCORE = QOS*WQOS + AGE*WAGE/4 + WPH + WBR + WRWS

1. QOS stands for AxQOS of AXI bus, and WQOS is the weight factor of QOS.
2. AGE stands for the wait period for each command in queue, and WAGE is the weight factor of AGE.
3. WPH stands for weight of page hit scenario.
4. WBR stands for weight of bank rotation/switch scenario.
5. WRWS stands for weight of slave hit without read/write switch scenario.

Recommend to set BMCR1 with 0x0 for applications that require restrict sequence of transactions, such as stack is allocated in SDRAM. The write and read transactions to the same address might be reordered if transactions in the queue is reordered, and it might crash the routine. WQOS can be non-zero value if needed, meanwhile WAGE must be non-zero value as well. Anyway, WRWS, WBR and WPH should be 0x0.

29.3.1.3 Device Access by IP Command

Devices can be accessed (initialized/configured/read/written) by IP bus access also. IP command is the device access sequence triggered by IP bus access. The device access sequence for IP command is described in the following sections.

Device access can be triggered by IP command using the following steps:

1. Set IPCR0/IPCR1/IPCR2/IPTXDAT registers for device address, data size, write mask and write data.
2. Set IPCMD register with valid command code (IPCMD[CMD]) and command key (IPCMD[KEY]).
3. Wait for IP command done (INTR[IPCMDDONE] sets).
4. Read the device data from IPRXDAT register. This is for read access only.

NOTE

- If device address or command code setting is not valid, an IP command error interrupt is generated (INTR[IPCMDERR]) and no device access occurs.
- If another IP command is triggered when the previous IP command has not finished yet, an IP command error interrupt is generated.
- IPCR0/IPCR1/IPCR2/IPTXDAT registers are protected when an IP command is in progress. Any write access to these registers is ignored until the IP command completes.
- The IPCR0 slave address field must be configured even if the memory does not require an address for the selected command (such as WRITE ENABLE command). The SEMC determines the slave device by decoding the device address.
- The slave device is limited to NAND when IPCMD[KEY] is 0x5AA5.

29.3.1.4 SDRAM Controller Operations

This section describes the operations of SDRAM controller.

29.3.1.4.1 SDRAM Address Multiplexing

SDRAMs use a multiplexed address split into rows, columns, and banks. Figure 29-2 shows how the bits of the linear address sent to the SEMC are split up into the row, column, and bank addresses sent to the SDRAM memory device.

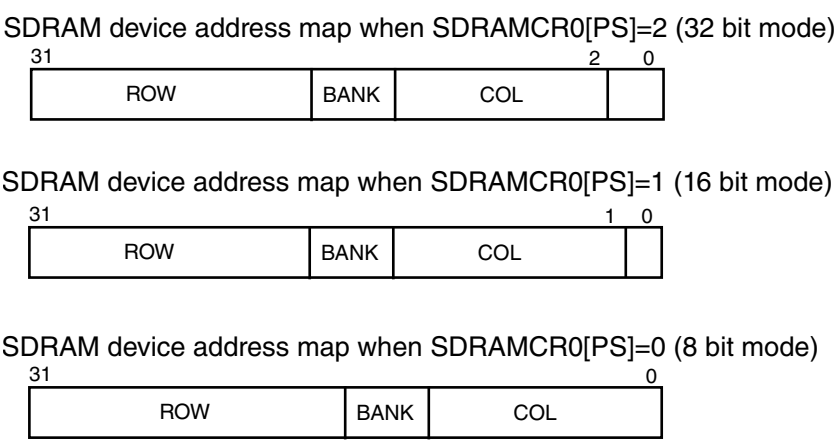

Figure 29-2. SDRAM Device Address Multiplexing

NOTE

- SDRAM address consists of row, bank and column address bits.
- Column address bits offset is bit 0 if SDRAMCR0[PS]=0, bit 1 if SDRAMCR0[PS]=1, bit 2 if SDRAMCR0[PS]=2. Column address bit width is determined by SDRAMCR0[COL] and SDRAMCR0[COL8].
- Bank address bits offset is determined by SDRAMCR0[PS], SDRAMCR0[COL] and SDRAMCR0[COL8]. Bank address bit width is determined by SDRAMCR0[BANK2].
- Row address bits offset is determined by SDRAMCR0[PS], SDRAMCR0[COL], SDRAMCR0[COL8] and SDRAMCR0[BANK2]. Row address bit width is determined by external SDRAM device.
- SDRAM device base address on SoC is configured by BR0, BR1, BR2 and BR3 registers.

29.3.1.4.2 SDRAM Access by IP Command

Table 29-2 lists the SDRAM access types that are triggered by IP commands.

Table 29-2. SDRAM IP Command

Command	Code	Comment
EXTENDED MODE REGISTER SET	0x5	Writes the extended mode register inside the SDRAM memory
DEEP POWER DOWN	0x6	Puts the SDRAM into deep power down mode
READ	0x8	Reads from the SDRAM memory
WRITE	0x9	Writes to the SDRAM memory
MODE REGISTER SET	0xA	Writes the mode register inside the SDRAM memory
ACTIVE	0xB	Sends a new bank and row address to the memory
AUTO REFRESH	0xC	Auto refresh
SELF REFRESH	0xD	Puts the SDRAM into low power data retention mode. The memory cannot be accessed while in self refresh mode.
PRECHARGE	0xE	Closes the currently active row for the specified bank
PRECHARGE ALL	0xF	Closes the active rows for all banks

29.3.1.4.2.1 READ

When an IP command is triggered with command code - READ, the SEMC will send a READ command to the SDRAM device.

Figure 29-3 shows the sequence for IP command - READ.

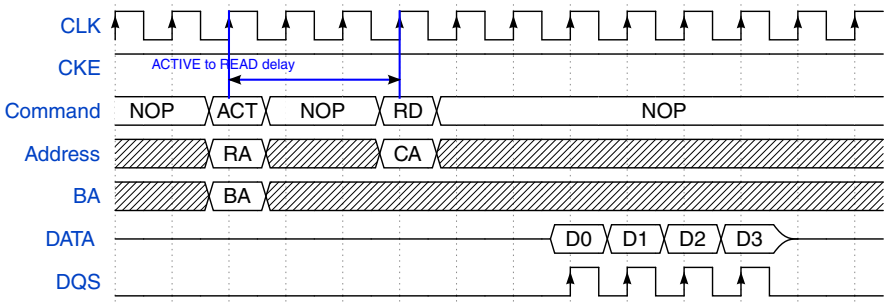

Figure 29-3. IP Command - SDRAM READ

NOTE

- It is supported but not recommended to send READ command with IP command trigger. The SEMC should read SDRAM device by AXI command.
- Read address is from IPCR0 register, read data is sent to IPRXDAT register.
- For this example:
  - ACTIVE to READ/WRITE delay is 3 (SDRAMCR1[ACT2RW]=2)

29.3.1.4.2.2 WRITE

When an IP command is triggered with command code - WRITE, the SEMC will send a WRITE command to the SDRAM device.

Figure 29-4 shows the sequence for IP command - WRITE.

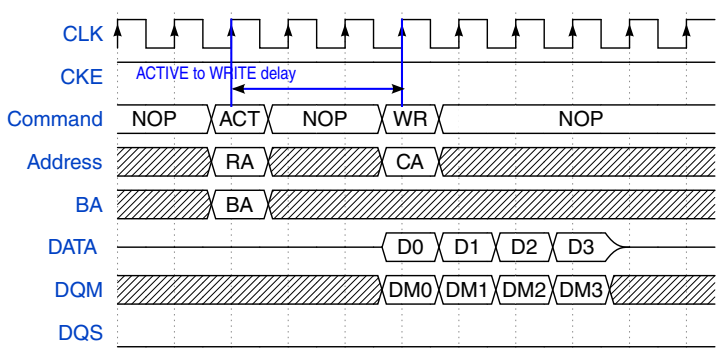

Figure 29-4. IP Command - SDRAM WRITE

NOTE

- It is supported but not recommended to send WRITE command with IP command trigger. The SEMC should write SDRAM device by AXI command.

- Write address is from IPCR0 register, write data is from IPTXDAT register, write mask is from IPCR2 register.
- For this example:
  - ACTIVE to READ/WRITE delay is 3 (SDRAMCR1[ACT2RW]=2)

29.3.1.4.2.3 MODE REGISTER SET

When an IP command is triggered with command code - MODE REGISTER SET, the SEMC will send a MODE REGISTER SET command to the SDRAM device.

Figure 29-5 shows the sequence for IP command - MODE REGISTER SET.

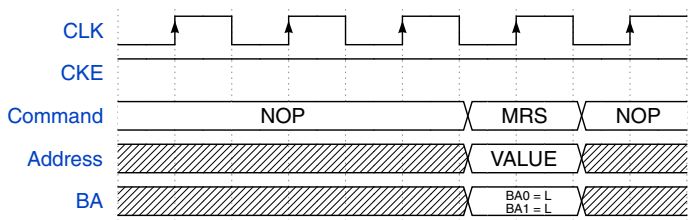

Figure 29-5. IP Command - SDRAM MODE REGISTER SET

NOTE

- MODE REGISTER SET command triggered by IP command should be used for SDRAM device initialization only.
- The "Value" of Address comes from IPTXDAT[12:0] register.

29.3.1.4.2.4 EXTENDED MODE REGISTER SET

When an IP command is triggered with command code - EXTENDED MODE REGISTER SET, the SEMC will send an EXTENDED MODE REGISTER SET command to the SDRAM device.

Figure 29-6 shows the sequence for IP command - EXTENDED MODE REGISTER SET.

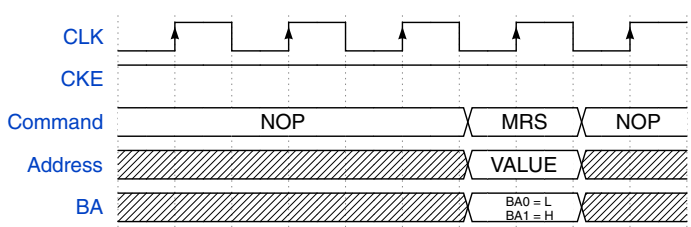

Figure 29-6. IP Command - EXTENDED SDRAM MODE REGISTER SET

NOTE

- EXTENDED MODE REGISTER SET command triggered by IP command should be used for SDRAM device initialization only.
- The "Value" of Address comes from IPTXDAT[12:0] register.

29.3.1.4.2.5 DEEP POWER DOWN

When an IP command is triggered with command code - DEEP POWER DOWN, the SEMC will send a DEEP POWER DOWN command to the SDRAM device.

Figure 29-7 shows the sequence for IP command - DEEP POWER DOWN.

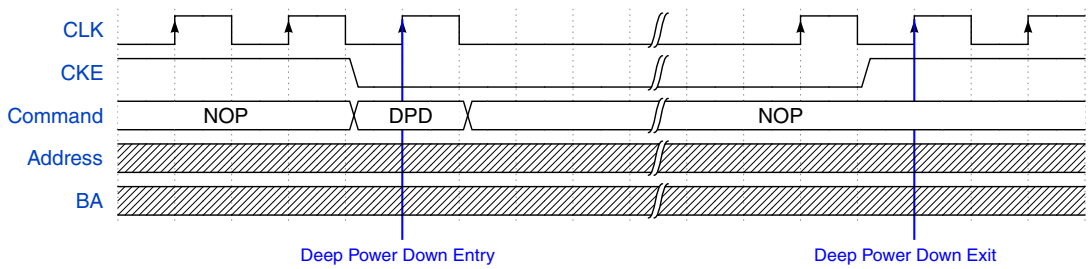

Figure 29-7. IP Command - DEEP POWER DOWN

NOTE

- The SEMC sends PRECHARGE ALL command to close any opened page on device before sending DEEP POWER DOWN command. There is no PRECHARGE ALL command if no pages on the selected device are open.
- Deep Power Mode is exited by any IP or AXI command.

29.3.1.4.2.6 ACTIVE

When an IP command is triggered with command code - ACTIVE, the SEMC will send an ACTIVE command to the SDRAM device.

Figure 29-8 shows the sequence for IP command - ACTIVE.

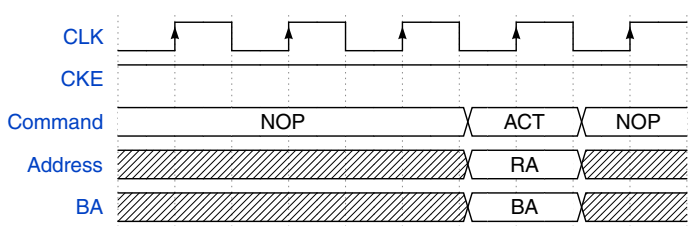

Figure 29-8. IP Command - SDRAM ACTIVE

NOTE

- It is supported but not recommended to send ACTIVE command with an IP command trigger. The SEMC can handle page management for READ/WRITE/AUTO REFRESH/SELF REFRESH etc.

29.3.1.4.2.7 AUTO REFRESH

When an IP command is triggered with command code - AUTO REFRESH, the SEMC will send an AUTO REFRESH command to the SDRAM device.

Figure 29-9 shows the sequence for IP command - AUTO REFRESH.

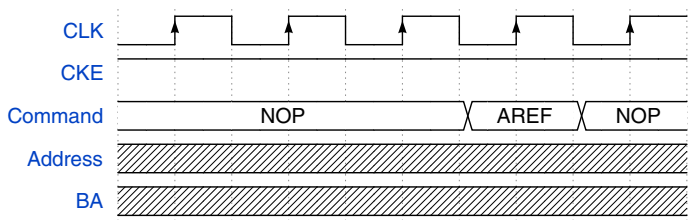

Figure 29-9. IP Command - SDRAM AUTO REFRESH

NOTE

- There is only one AUTO REFRESH command sent when triggered by IP command and only one device is accessed.
- The SEMC sends PRECHARGE ALL command to close any opened page on device before sending AUTO REFRESH command. There is no PRECHARGE ALL command if no pages on the selected device are open.
- AUTO REFRESH command triggered by IP command should be used for SDRAM device initialization only. For entering auto refresh during normal operation, set SDRAMCR3[REN] to 1 and the SEMC will send AUTO REFRESH command automatically.

29.3.1.4.2.8 SELF REFRESH

When a SELF REFRESH IP command is requested for any SDRAM device, the SEMC will send a SELF REFRESH command to all SDRAM devices. After the SELF REFRESH command is completed, all SDRAM devices should be in self refresh mode and the SEMC keeps this mode on SDRAM interface (SEMC_CKE=0 and SEMC_CLK=0).

The SEMC brings all SDRAM devices out of self refresh mode when there is any new IP command or AXI command triggered to an SDRAM device.

Figure 29-10 shows the sequence for self refresh entering and exiting by AXI command.

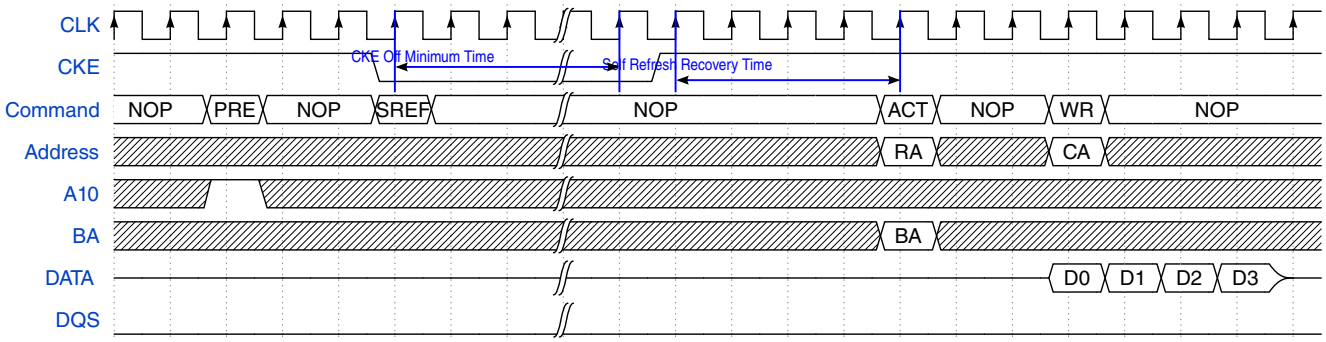

Figure 29-10. IP Command - SDRAM SELF REFRESH

NOTE

- The SEMC sends PRECHARGE ALL command to close any opened page on device before entering self refresh mode. There is no PRECHARGE ALL command if no page is opened at any device.
- SELF REFRESH command sends to all devices.
- It is not recommended to put device into self refresh mode by IP command triggering although it is supported. Recommend to put device into self refresh mode by the SEMC STOP mode instead.
- Disable the SEMC auto refresh enable bit (SDRAMCR3[REN]=0) before entering self refresh mode, otherwise the SEMC may bring devices out of self refresh mode.
- For this example:
  - Self refresh recovery time is 4 clock cycles (SDRAMCR2[SRRC]=3)
  - CKE off minimum time is 4 clock cycles (SDRAMCR1[CKEOFF]=3)
  - The SEMC brings SDRAM out of self refresh mode when an AXI write command is triggered.

29.3.1.4.2.9 PRECHARGE

When an IP command is triggered with command code - PRECHARGE, The SEMC will send a PRECHARGE command to the SDRAM device.

Figure 29-11 shows the sequence for IP command - PRECHARGE.

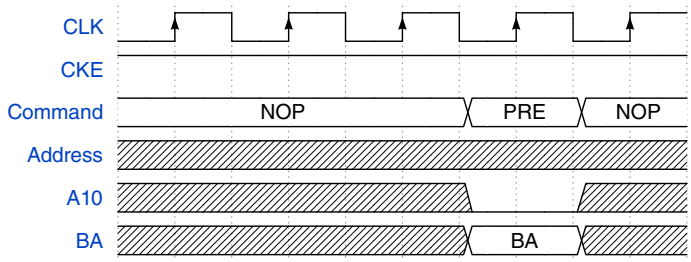

Figure 29-11. IP Command - SDRAM PRECHARGE

NOTE

- It is not recommended to send PRECHARGE command triggered by IP command although it is supported. The SEMC can handle page management for READ/WRITE/ AUTO REFRESH/SELF REFRESH etc.

29.3.1.4.2.10 PRECHARGE ALL

When an IP command is triggered with command code - PRECHARGE ALL, the SEMC will send a PRECHARGE ALL command to the SDRAM device.

Figure 29-12 shows the sequence for IP command - PRECHARGE ALL.

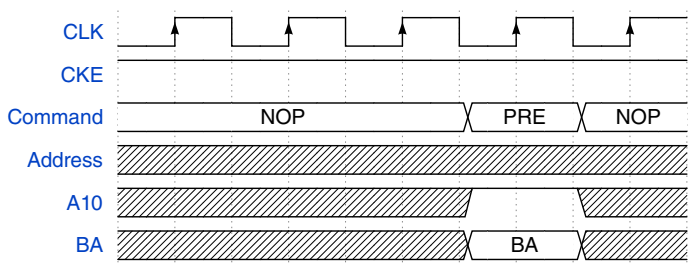

Figure 29-12. IP Command - SDRAM PRECHARGE ALL

NOTE

- It is not recommended to send PRECHARGE ALL command triggered by IP command although it is supported. The SEMC can handle page management for READ/WRITE/AUTO REFRESH/SELF REFRESH etc.
- PRECHARGE ALL command triggered by IP command should be used for SDRAM device initialization only.

29.3.1.4.2.11 Combination of IP Commands

Figure 29-13 shows a combination sequence of IP commands, that includes AUTO REFRESH, ACTIVE, WRITE and PRECHARGE IP commands.

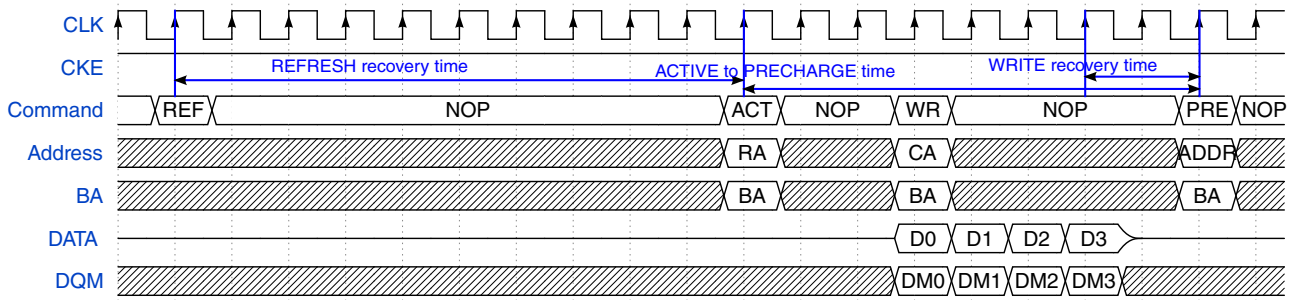

Figure 29-13. IP Command - AUTO REFRESH, ACTIVE, WRITE and PRECHARGE

NOTE

- For this example:
  - REFRESH recovery time is 10 clock cycles (SDRAMCR1[RFRC]=9)
  - WRITE recovery time is 2 clock cycles (SDRAMCR1[WRC]=1)
  - ACTIVE to PRECHARGE minimum time is 6 clock cycles (SDRAMCR1[ACT2PRE]=5). Current ACTIVE to PRECHARGE time is 8 clock cycles by the limitation of WRITE burst beats and recovery time.

29.3.1.4.3 SDRAM Device Access by AXI Command

SDRAM device read/write access can be triggered by AXI Command. For AXI read access, the SEMC will send READ commands to SDRAM device automatically and return data on AXI bus. For AXI write access, the SEMC will save AXI bus write data and send WRITE commands to the SDRAM device automatically.

29.3.1.4.3.1 Read Access

Figure 29-14 shows an SDRAM read triggered by an AXI command.

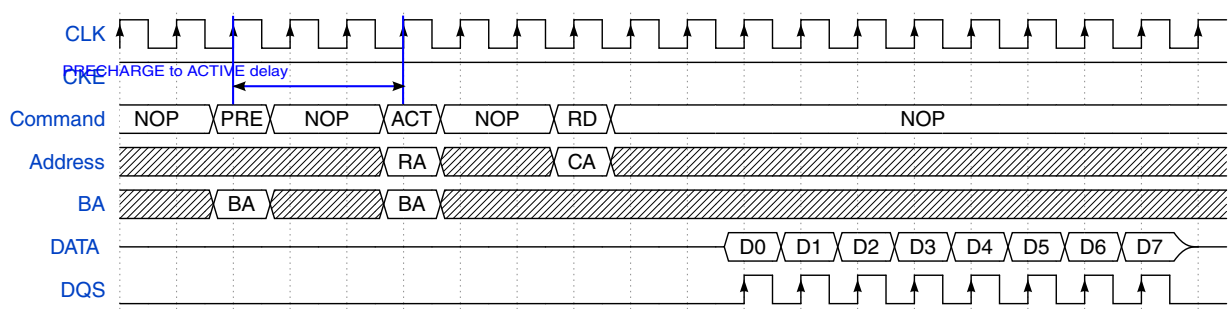

Figure 29-14. AXI Command - SDRAM READ

NOTE

- The SEMC opens/closes pages automatically for current AXI command.
- For this example:
  - CAS latency is 3 (SDRAMCR0[CL]=3)
  - Burst length is 8 (SDRAMCR0[BL]=3)
  - PRECHARGE to ACTIVE delay is 3 clock cycles (SDRAMCR1[PRE2ACT]=2)

29.3.1.4.3.2 Write Access

Figure 29-15 shows an SDRAM write triggered by an AXI command.

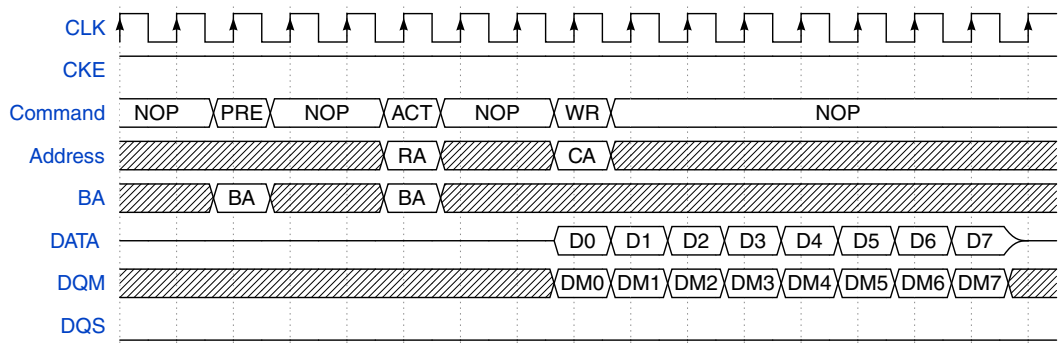

Figure 29-15. AXI Command - SDRAM WRITE

NOTE

- The SEMC opens/closes pages automatically for current AXI command.
- SDRAM device burst length is 8 in this example. The SEMC may send multiple WRITE commands if AXI burst size is larger than SDRAM burst length.

29.3.1.4.3.3 Pipelined Access

Figure 29-16 shows an SDRAM pipelined read access that is triggered by AXI bus read access.

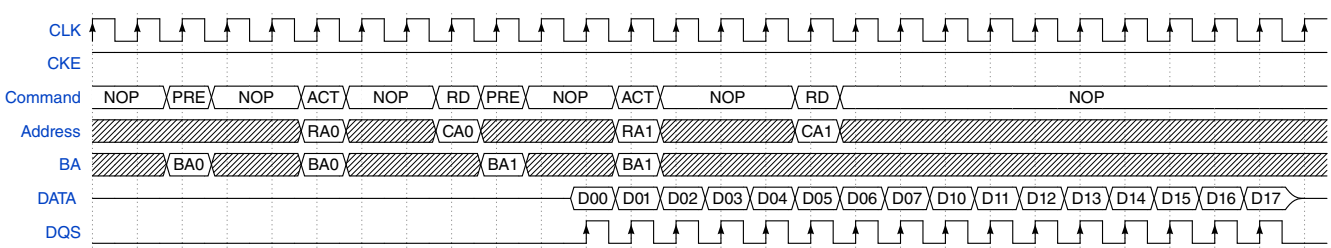

Figure 29-16. AXI Command - Pipelined SDRAM Read

NOTE

- The SEMC opens/closes pages automatically for next AXI command during SDRAM Read burst.
- Data D0x is from CA0, and data D1x is from CA1. This naming rule is also applied to the following SDRAM figures.

Figure 29-17 shows the SDRAM device pipelined write access that triggered by AXI bus write access.

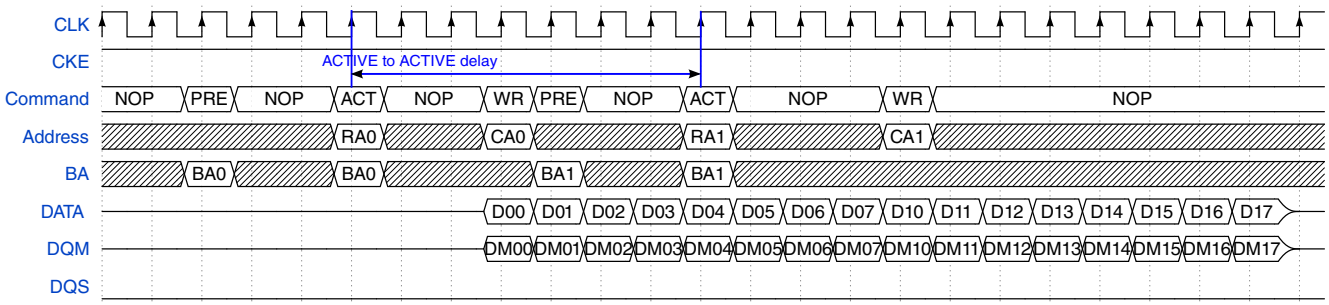

Figure 29-17. AXI Command - Pipelined SDRAM Write

NOTE

- The SEMC opens/closes pages automatically for next AXI command during SDRAM Write burst.

29.3.1.4.3.4 SDRAM Back-to-Back Access

This section describes the SDRAM back-to-back access.

29.3.1.4.3.4.1 Read-to-Read Access

Figure 29-18 shows SDRAM read-to-read access timing when CL=1.

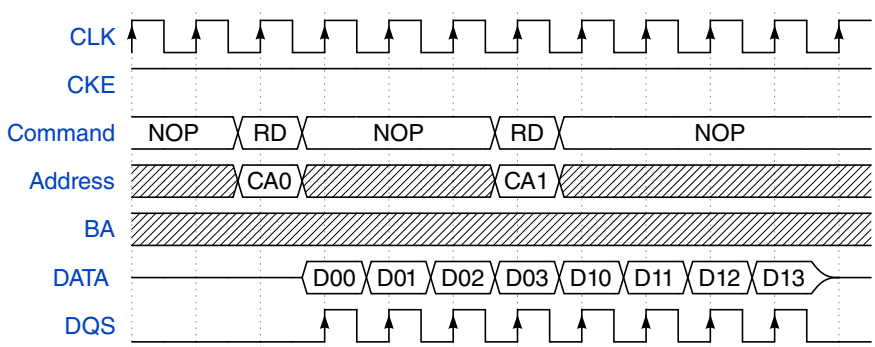

Figure 29-18. SDRAM Read-to-Read Access (CL=1)

Figure 29-19 shows SDRAM read-to-read access timing when CL=2.

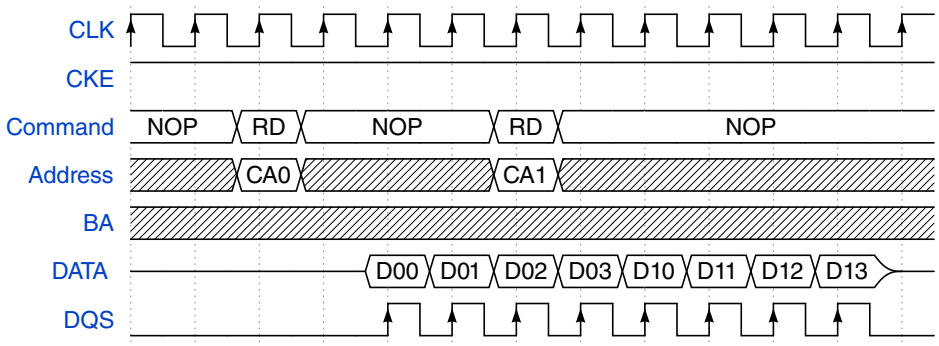

Figure 29-19. SDRAM Read-to-Read Access (CL=2)

Figure 29-20 shows SDRAM read-to-read access timing when CL=3.

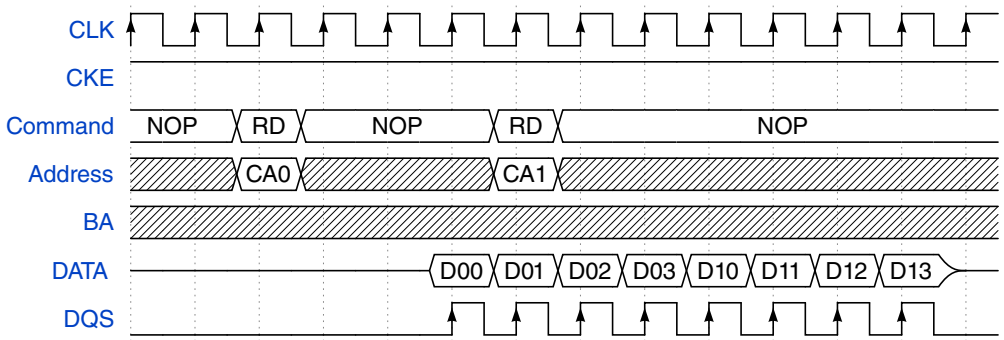

Figure 29-20. SDRAM Read-to-Read Access (CL=3)

29.3.1.4.3.4.2 Read-to-Write Access

Figure 29-21 shows SDRAM read-to-write access timing when CL=1.

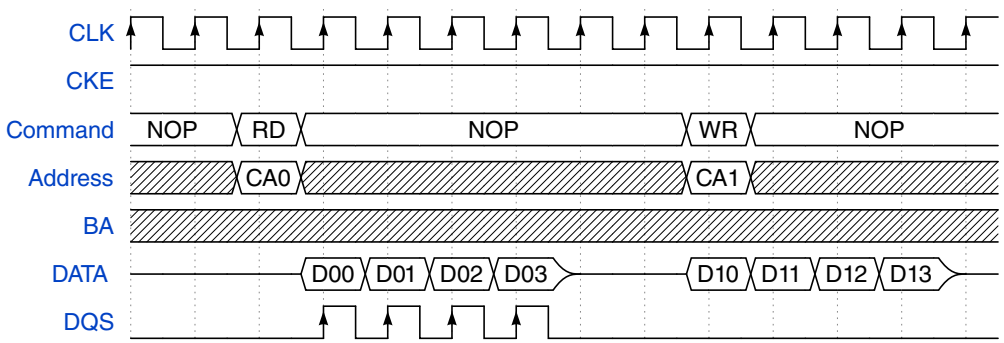

Figure 29-21. SDRAM Read-to-Write Access (CL=1)

Figure 29-26 shows SDRAM write-to-read access timing when CL=2.

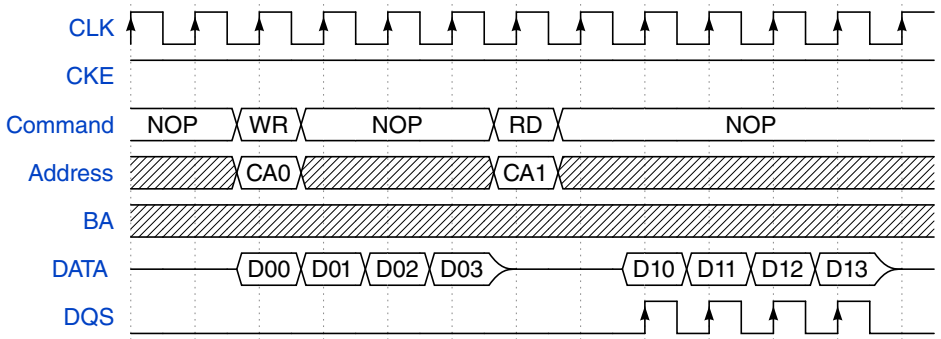

Figure 29-26. SDRAM Write-to-Read Access (CL=2)

Figure 29-27 shows SDRAM write-to-read access timing when CL=3.

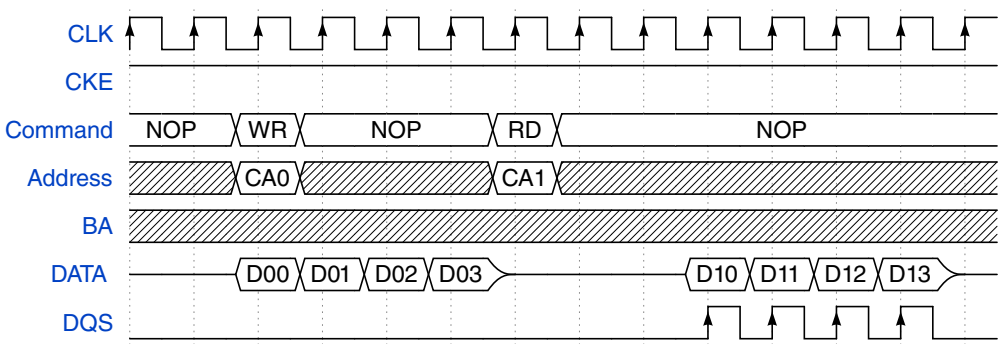

Figure 29-27. SDRAM Write-to-Read Access (CL=3)

29.3.1.4.4 Refresh Command - SDRAM AUTO REFRESH

When SDRAM refresh is enabled (SDRAMCR3[REN]=1), the SEMC will send an AUTO REFRESH command to all SDRAM devices whenever the refresh timer expires. Multiple AUTO REFRESH commands can be sent if refresh burst is not set to one (SDRAMCR3[REBL]!=0).

The refresh timer's count cycle is controlled by UT, RT and PRESCALE bits in SDRAMCR3.

Figure 29-28 shows the sequence of AUTO REFRESH Command.

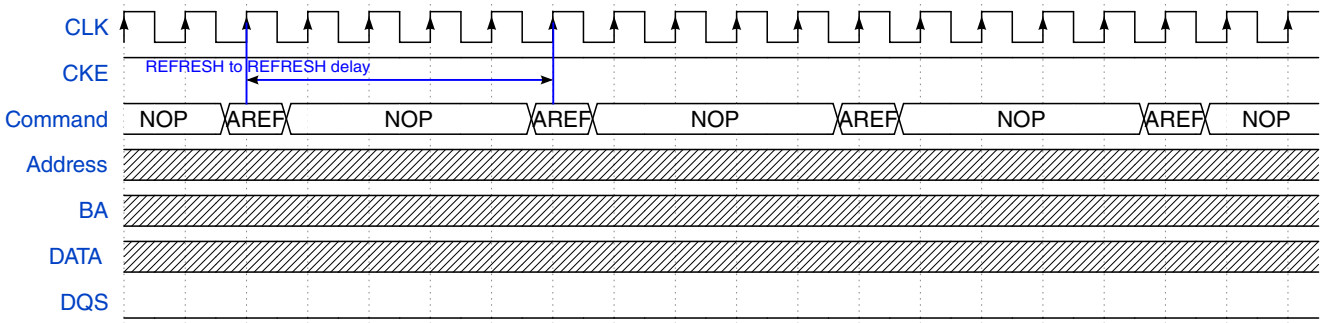

Figure 29-28. Refresh Command - SDRAM AUTO REFRESH

NOTE

- AUTO REFRESH command is sent to all devices.
- For this example:
  - Refresh to refresh delay is 5 clock cycles (SDRAMCR2[REF2REF]=4)
  - Refresh burst length is 4 (SDRAMCR3[REBL]=3)

29.3.1.4.5 SDRAM Low Power Feature

This section describes the low power feature that is implemented for SDRAM.

29.3.1.4.5.1 SDRAM Stop Mode

The SEMC puts SDRAM to self refresh mode automatically when the system enters STOP mode. The SEMC brings SDRAM out of self refresh mode when the system exits STOP mode.

Figure 29-29 shows the sequence of STOP mode entering and exiting.

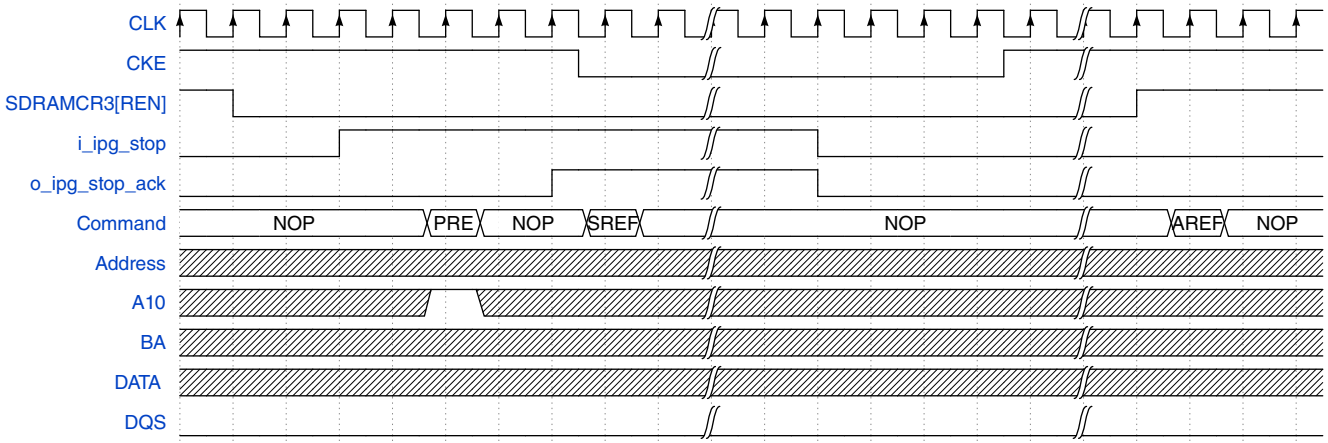

Figure 29-29. SDRAM Stop Mode Enter and Exit

NOTE

- The SEMC sends PRECHARGE ALL command to close any opened page on device before entering self refresh mode. There is no PRECHARGE ALL command if no page is opened at any device.
- SELF REFRESH command is sent to all devices.
- Disable the SEMC auto refresh bit (SDRAMCR3[REN]=0) before entering STOP mode, otherwise the SEMC may bring devices out of self refresh mode.

29.3.1.4.5.2 SDRAM Bus Idle

When there are no pending IP, AXI, or refresh commands, SDRAM interface will in the idle state. When the SDRAM interface bus idle timer expires, the SEMC closes all opened pages on all SDRAM devices. Refer to SDRAMCR2[ITO] for more information.

29.3.1.4.6 SDRAM Page Management

This section describes the SDRAM page management.

The SEMC will save row addresses for up to 8 opened pages: 4 pages for CS0/CS2 (4 banks), 4 pages for CS1/CS3 (4 banks). Device CS0 and CS2 pages are never opened at the same time. Before the SEMC opens pages on CS2, it closes all opened pages on CS0. This is similar for CS1/CS3.

The SEMC closes all pages on all CS by issuing a PRECHARGE ALL command in following cases:

1. SELF REFRESH triggered by IP command
2. SELF REFRESH triggered by stop mode entry

3. The idle time on AXI bus and SDRAM interface is longer than SDRAM idle timeout time (SDRAMCR2[ITO]).

NOTE

The SEMC will not send out PRECHARGE ALL command if there are no pages opened on any bank/CS.

The SEMC will close all pages on one CS in following cases:

1. PRECHARGE ALL command triggered by IP command
2. AUTO REFRESH command triggered by IP command
3. ACTIVE/WRITE/READ command triggered by IP command and CS miss
4. WRITE/READ command triggered by current AXI command and CS miss
5. WRITE/READ command triggered by next AXI command (not accepted yet), CS miss and not same CS as current AXI command

NOTE

One example for CS miss: current IP command access CS2 but there is page opened on CS0 already.

The SEMC will close one page on one CS in following cases:

1. PRECHARGE command triggered by IP command and this bank is opened
2. ACTIVE/READ/WRITE command triggered by IP command, this bank is opened and page missed.
3. WRITE/READ command triggered by current AXI command, this bank is opened and page missed.
4. WRITE/READ command triggered by next AXI command (not accepted yet), this bank is opened, page missed and different bank accessed with current AXI command.

NOTE

One example for page miss: current bank is opened but the opened page row address is different with current SDRAM command access.

The SEMC will open one page on one CS in following cases:

1. ACTIVE/READ/WRITE command triggered by IP command, this bank is not opened.
2. WRITE/READ command triggered by current AXI command, this bank is not opened.
3. WRITE/READ command triggered by next AXI command (not accepted yet), this bank is not opened and different bank accessed with current AXI command.

29.3.1.5 NAND Flash Controller Operations

This section describes the operations of NAND Flash controller.

29.3.1.5.1 NAND Flash Address Multiplexing

The NAND Flash controller uses a multiplexed address split into rows and columns. Figure 29-30 shows how the bits of the linear address sent to the SEMC are split up into the row and column addresses sent to the NAND Flash memory device.

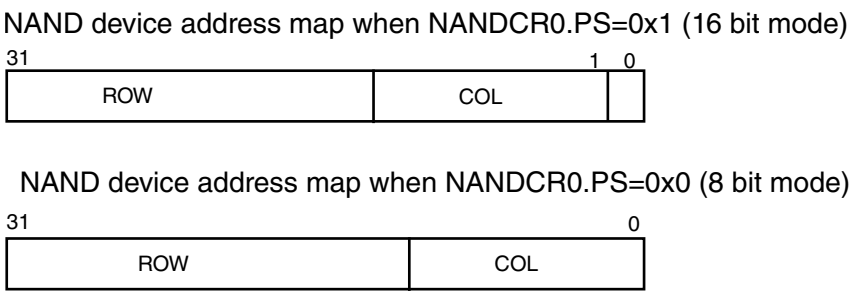

Figure 29-30. NAND Flash Address Multiplexing

NOTE

- NAND address bits consist of row and column address bits.
- Column address bits offset is bit 0 if NANDCR0[PS]=0, the offset is bit 1 if NANDCR0[PS]=1. Column address bit width is determined by NANDCR0[COL].
- Column bit number should cover all page size. For example, column bit number should be 14 if NAND Flash page size is 8192 + 448 (main + spare) bytes.
- Row address bits offset is determined by NANDCR0[PS] and NANDCR[COL].
- NAND device base address on SoC is configured by BR4 and BR8 registers.

29.3.1.5.2 NAND Flash Access Address Type

Table 29-3 lists the NAND address types that are triggered by IP commands.

Table 29-3. NAND Address Types

Address Type	IPCMD[7:4]
Five Bytes Row/Column Address	0x0
One Byte Column Address	0x1
Two Bytes Column Address	0x2
One Byte Row Address	0x3
Two Bytes Row Address	0x4
Three Bytes Row Address	0x5

For IP command, address type is determined by IPCMD register. For AXI command, address type is fixed to "Two Bytes Column Address" because AXI access is limited in opened NAND page.

29.3.1.5.2.1 Five Bytes Row/Column Address

Figure 29-31 shows the Five Bytes Row/Column Address type access timing.

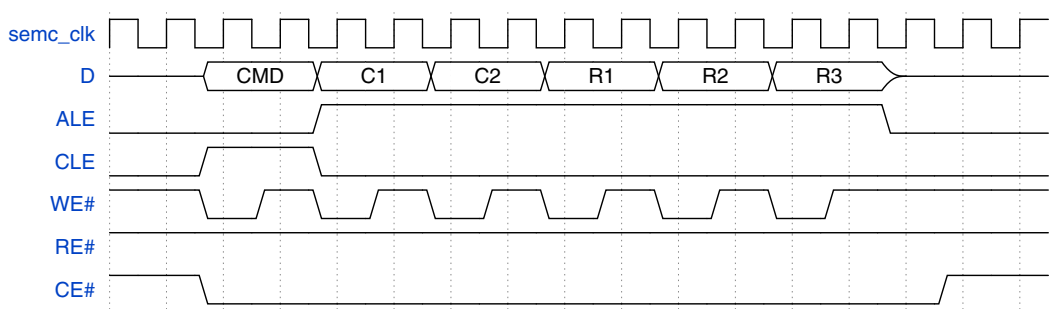

Figure 29-31. NAND Flash Access Address Type - Five Bytes Row/Column Address

There are some option bits to support different NAND address types in the Five Bytes Row/Column Address type. Table 29-4 lists all the combinations of address types.

Table 29-4. Address Bytes Order for five Bytes Row/Column Address Mode

NANDCR3[NDOPT3]	NANDCR3[NDOPT2]	NANDCR3[NDOPT1]	Address byte order
0	0	0	C1/C2/R1/R2/R3
0	0	1	C1/R1/R2/R3
0	1	0	C1/C2/R1/R2
0	1	1	C1/R1/R2
1	-	0	C1/C2/R1
1	-	1	C1/R1

29.3.1.5.2.2 One Byte Column Address

Figure 29-32 shows the One Byte Column Address type access timing.

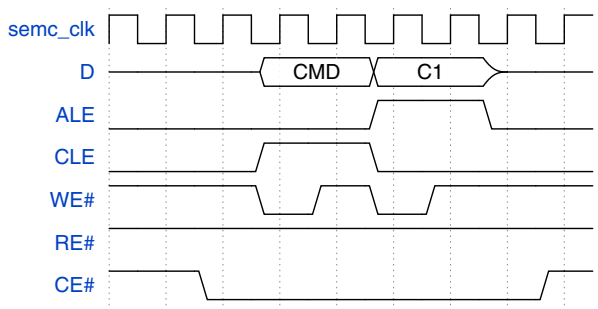

Figure 29-32. NAND Flash Access Address Type - One Byte Column Address

29.3.1.5.2.3 Two Bytes Column Address

Figure 29-33 shows the Two Bytes Column Address type access timing.

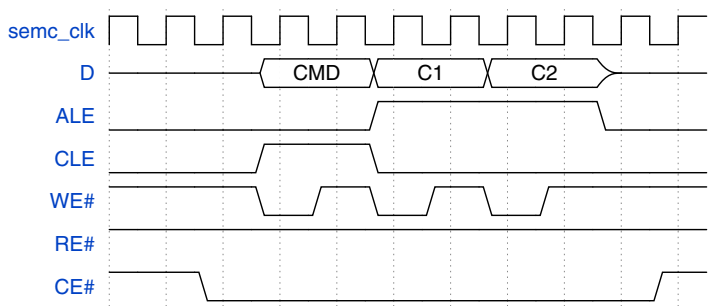

Figure 29-33. NAND Flash Access Address Type - Two Bytes Column Address

29.3.1.5.2.4 One Byte Row Address

Figure 29-34 shows the One Byte Row Address type access timing.

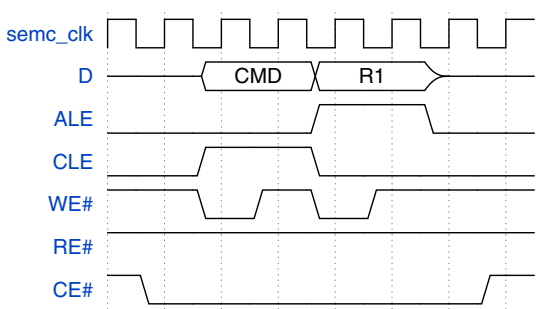

Figure 29-34. NAND Flash Access Address Type - One Byte Row Address

29.3.1.5.2.5 Two Bytes Row Address

Figure 29-35 shows the Two Bytes Row Address type access timing.

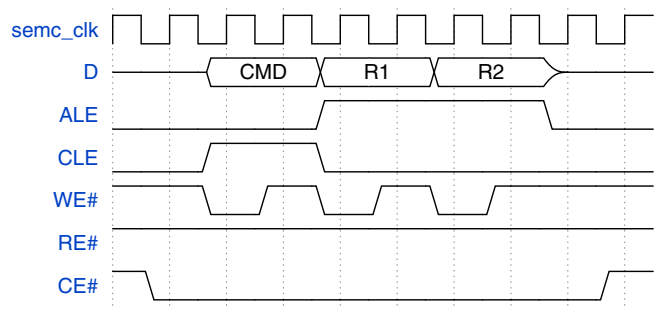

Figure 29-35. NAND Flash Access Address Type - Two Bytes Row Address

29.3.1.5.2.6 Three Bytes Row Address

Figure 29-36 shows the Three Bytes Row Address type access timing.

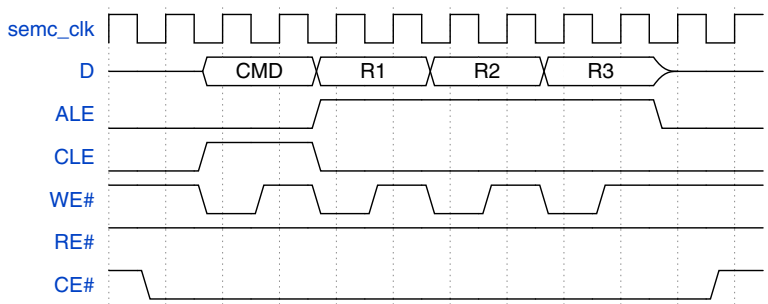

Figure 29-36. NAND Flash Access Address Type - Three Bytes Row Address

29.3.1.5.3 NAND Flash Access Command Type

NAND Flash access support following command types:

1. Command Phase
2. Command + Wait Phase
3. Command + Address Phase
4. Command + Address + Wait Phase
5. Command + Address + Read Phase
6. Command + Address + Write Phase (for IP command)
7. Command + Write Phase
8. Command + Read Phase
9. Write Phase
10. Read Phase
11. Command + Address + Command + Read Phase (for AXI command - Read)
12. Command + Address + Write Phase (for AXI command - Write)

29.3.1.5.3.1 Command Phase

Figure 29-37 shows the NAND Flash Command Phase access timing.

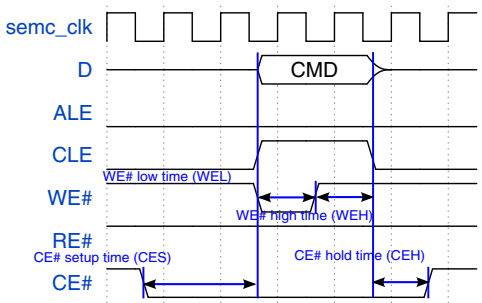

Figure 29-37. NAND Flash Access Command Type - Command Phase

NOTE

- semc_clk is the SEMC functional clock.
- For this example:
  - CE# setup time is 2 clock cycles (NANDCR1[CES]=1)
  - WE# low time is 1 clock cycle (NANDCR1[WEL]=0)
  - WE# high time is 1 clock cycle (NANDCR1[WEH]=0)
  - CE# hold time is 1 clock cycle (NANDCR1[CEH]=0)

29.3.1.5.3.2 Command + Wait Phase

Figure 29-38 shows NAND Flash Command + Wait Phase access timing

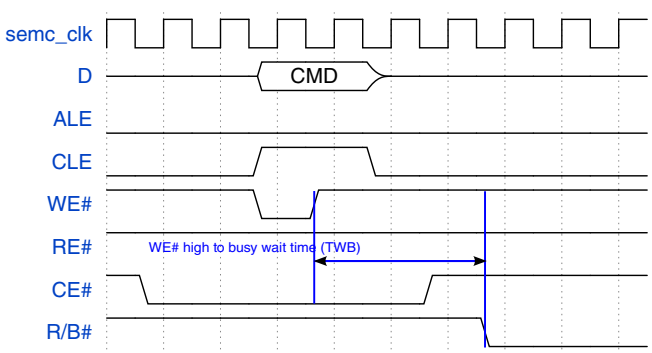

Figure 29-38. NAND Flash Access Command Type - Command + Wait Phase

NOTE

- For this example:
  - WE# high to busy time is 3 clock cycles (NANDCR1[TWB]=2)

29.3.1.5.3.3 Command + Address Phase

Figure 29-39 shows the NAND Flash Command + Address Phase access timing.

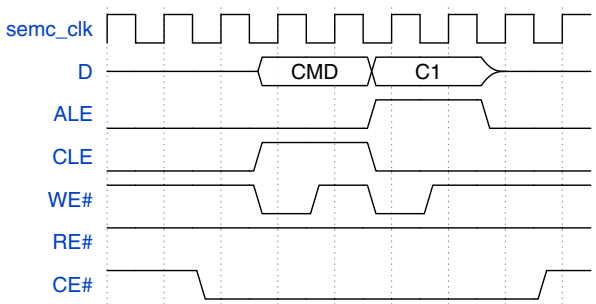

Figure 29-39. NAND Flash Access Command Type - Command + Address Phase

29.3.1.5.3.4 Command + Address + Wait Phase

Figure 29-40 shows NAND Flash Command + Address + Wait Phase access timing.

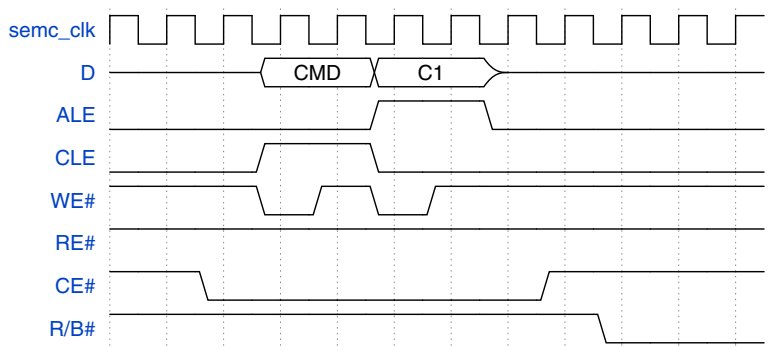

Figure 29-40. NAND Flash Access Command Type - Command + Address + Wait Phase

29.3.1.5.3.5 Command + Address + Read Phase

Figure 29-41 shows NAND Flash Command + Address + Read Phase access timing.

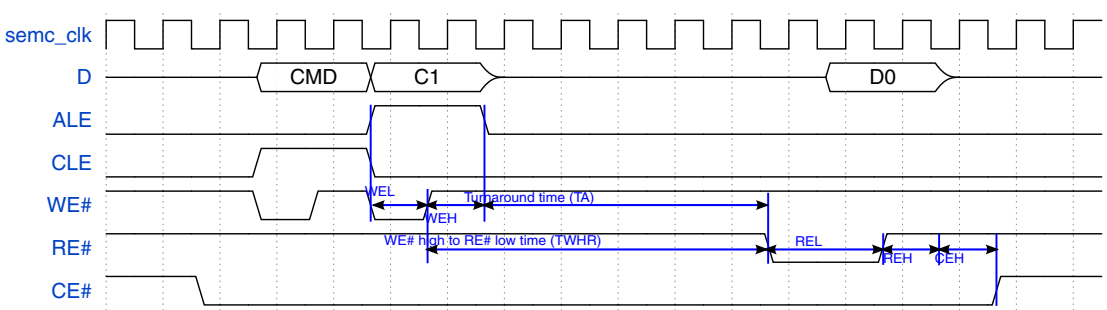

Figure 29-41. NAND Flash Access Command Type - Command + Address + Read Phase

NOTE

- For this example:
  - WE# low time is 1 clock cycle (NANDCR1[WEL]=0)
  - WE# high time is 1 clock cycle (NANDCR1[WEH]=0)
  - RE# low time is 2 clock cycles (NANDCR1[REL]=1)
  - RE# high time is 1 clock cycle (NANDCR1[REH]=0)
  - Turnaround time is 5 clock cycles (NANDCR1[TA]=4)
  - WE# high to RE# low time is 6 clock cycles (NANDCR2[TWHR]=5)
  - CE# hold time is 1 clock cycle (NANDCR1[CEH]=0)

29.3.1.5.3.6 Command + Address + Write Phase (for IP Command)

Figure 29-42 shows NAND Flash Command + Address + Write Phase access timing.

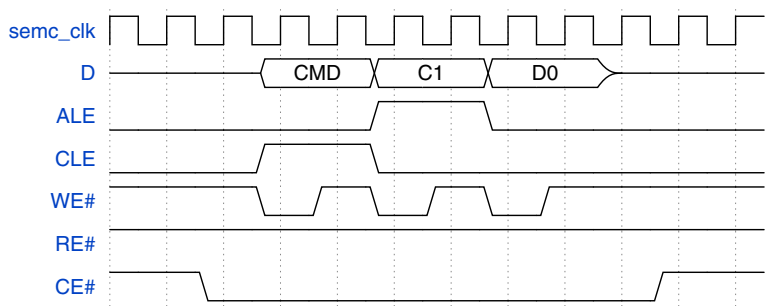

Figure 29-42. NAND Flash Access Command Type - Command + Address + Write Phase

29.3.1.5.3.7 Command + Read Phase

Figure 29-43 shows NAND Flash Command + Read Phase access timing.

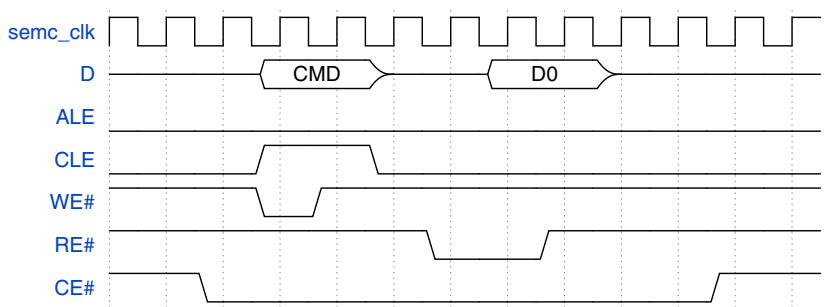

Figure 29-43. NAND Flash Access Command Type - Command + Read Phase

29.3.1.5.3.8 Command + Write Phase

Figure 29-44 shows NAND Flash Command + Write Phase access timing.

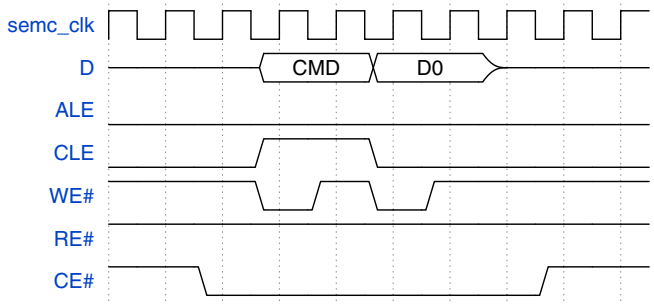

Figure 29-44. NAND Flash Access Command Type - Command + Write Phase

29.3.1.5.3.9 Read Phase

Figure 29-45 shows NAND Flash Read Phase access timing.

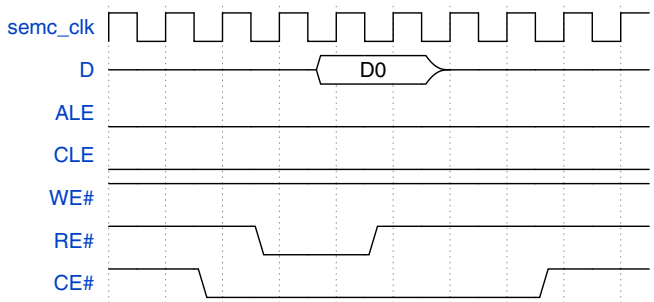

Figure 29-45. NAND Flash Access Command Type - Read Phase

29.3.1.5.3.10 Write Phase

Figure 29-46 shows the timing of NAND Flash Write Phase access.

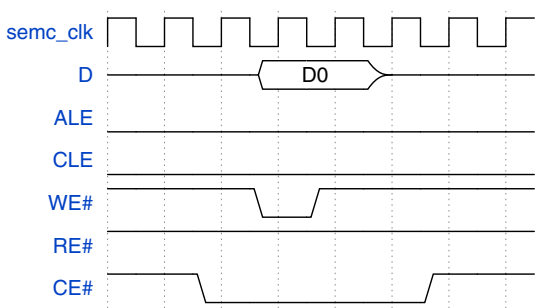

Figure 29-46. NAND Flash Access Command type - Write Phase

29.3.1.5.3.11 Command + Address + Command + Read Phase

Figure 29-47 shows the NAND Flash Command + Address + Command + Read Phase access timing.

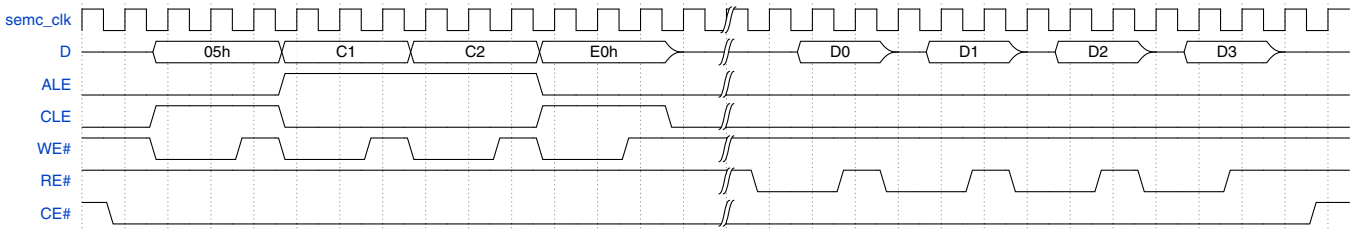

Figure 29-47. NAND Flash Access Command Type - Command + Address + Command + Read Phase

NOTE

- This command type is for AXI command only
- The command code in this command type is fixed value (Change Column Address) to support ONFI NAND device. The first byte command code is 05h, and second byte command code is E0h.
- The address type in this command type is fixed to two byte column address.

29.3.1.5.3.12 Command + Address + Write Phase (for AXI command)

Figure 29-48 shows the NAND Flash Command + Address + Write Phase access timing.

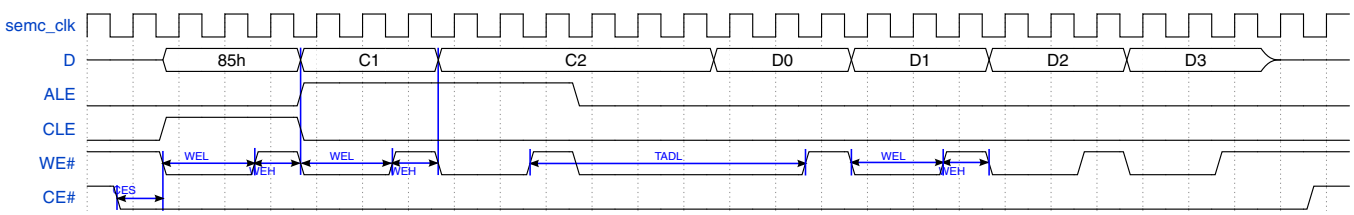

Figure 29-48. NAND Flash Access Command Type - Command + Address + Write Phase

NOTE

- This command type is for AXI command only
- The command code in this command type is fixed value (85h - Change Write Column Address) to support ONFI NAND device.
- The address type in this command type is fixed to two byte column address.
- For this example:
  - WE# low time is 2 clock cycles (NANDCR1[WEL]=1)
  - WE# high time is 1 clock cycle (NANDCR1[WEH]=0)
  - Address cycle to data loading time is 6 clock cycles (NANDCR2[TADL]=5)

29.3.1.5.4 NAND Flash Read Access in EDO and non-EDO Mode

NAND Flash support both EDO and non-EDO modes. Figure 29-49 shows the access timing of EDO mode.

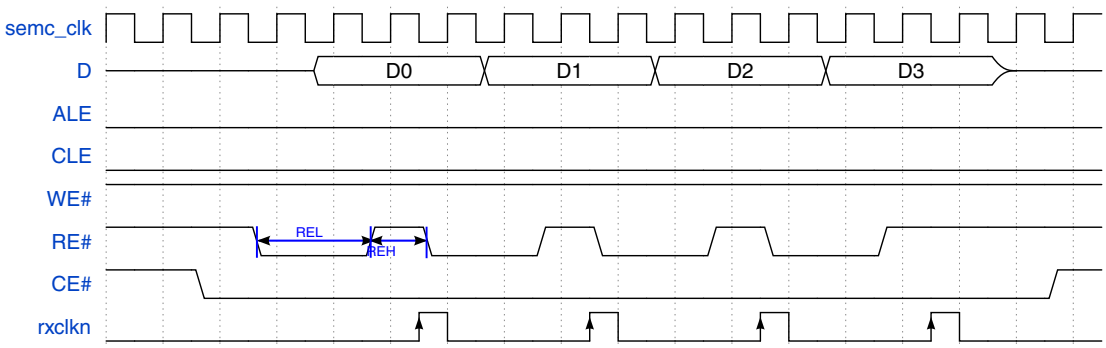

Figure 29-49. NAND Flash Read Access in EDO mode

NOTE

- rxclkn is the SEMC internal clock to sample read data. It is close to falling edge of RE#.
- For this example:
  - RE# low time is 2 clock cycles (NANDCR1[REL]=1)
  - RE# high time is 1 clock cycle (NANDCR1[REH]=0)

Figure 29-50 shows the access timing of non-EDO mode.

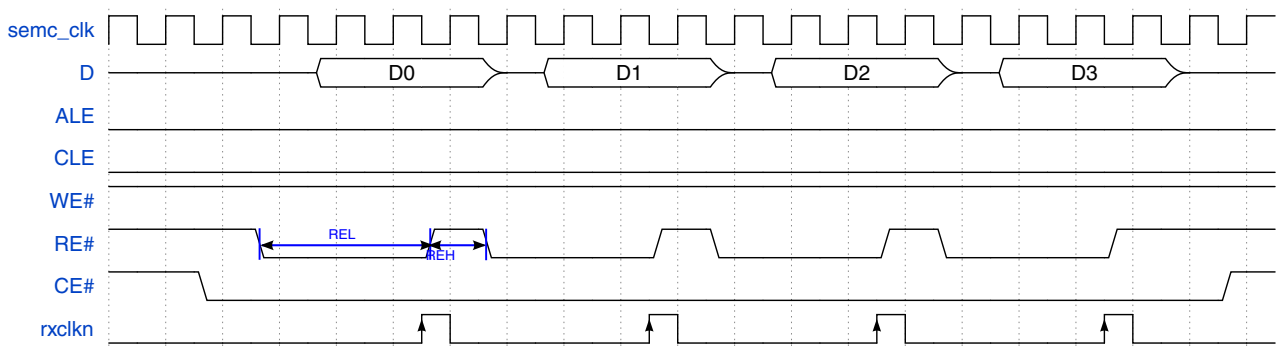

Figure 29-50. NAND Flash Read Access in non-EDO mode

NOTE

- rxclkn is the SEMC internal clock to sample read data. It is close to rising edge of RE#.
- For this example:
  - RE# low time is 3 clock cycles (NANDCR1[REL]=2)
  - RE# high time is 1 clock cycle (NANDCR1[REH]=0)

29.3.1.5.5 NAND Flash Access in SYNC Mode

NAND Flash supports SYNC mode, the following chapters describes the access timings.

29.3.1.5.5.1 NAND Command + Address + Command + Read Operation in SYNC Mode

Figure 29-51 shows NAND Command + Address + Command + Read operation in SYNC mode.

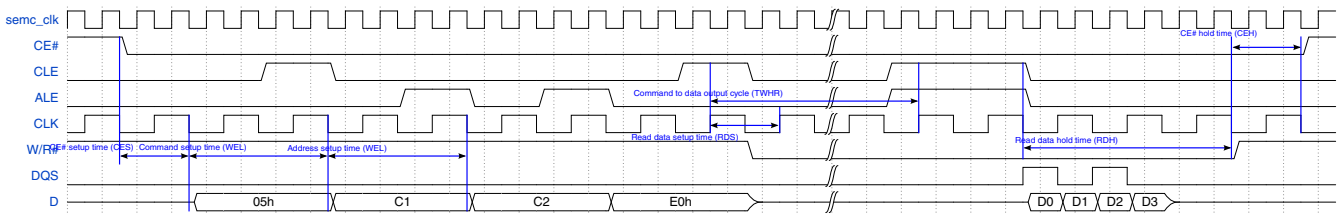

Figure 29-51. NAND Command + Address + Command + Read in SYNC Mode

NOTE

- semc_clk is the SEMC internal functional clock. CLK is the synchronous clock to latch command and address cycles. The frequency of CLK is half of semc_clk. For example, if semc_clk frequency is 200 MHz, the CLK frequency is 100 MHz.
- For this example:
  - CE# setup time is 2 clock cycles (NANDCR1[CES]=1)
  - Command/Address setup time is 4 clock cycles (NANDCR1[WEL]=2)
  - NANDCR3[RDS] and NANDCR2[TWHR] control the timing from command to data read phase. In general, NANDCR3[RDS] controls the minimum delay before data read phase. In this figure, NANDCR3[RDS]=0.
  - Read data hold time is 6 clock cycles (NANDCR3[RDH]=4)
  - CE# hold time is 2 clock cycles (NANDCR1[CEH]=1)

29.3.1.5.5.2 NAND Command + Address + Write Operation in SYNC Mode

Figure 29-52 shows NAND Command + Address + Write operation in SYNC mode.

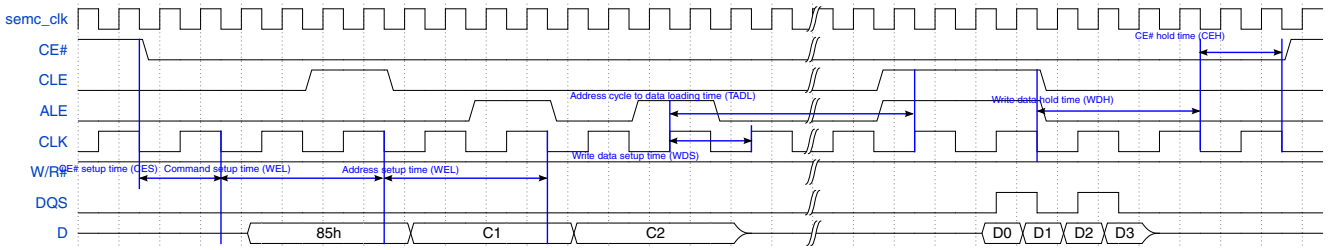

Figure 29-52. NAND Command + Address + Write in SYNC Mode

NOTE

- For this example:
  - CE# setup time is 2 clock cycles (NANDCR1[CES]=1)
  - Command/Address setup time is 4 clock cycles (NANDCR1[WEL]=2)
  - NANDCR3[WDS] and NANDCR2[TADL] control the timing from command to data write phase. In general, NANDCR3[WDS] controls the minimum delay before data write phase. In this figure, NANDCR3[WDS]=0.
  - Write data hold time is 4 clock cycles (NANDCR3[WDH]=2)
  - CE# hold time is 2 clock cycles (NANDCR1[CEH]=1)

29.3.1.6 NOR Flash Controller Operations

This section describes the operations of NOR Flash controller.

29.3.1.6.1 NOR Flash Address Multiplexing

NOR Flash use a multiplexed address split into rows and columns. Figure 29-53 shows how the bits of the linear address sent to the SEMC are split up into the row and column addresses sent to the NOR Flash memory device.

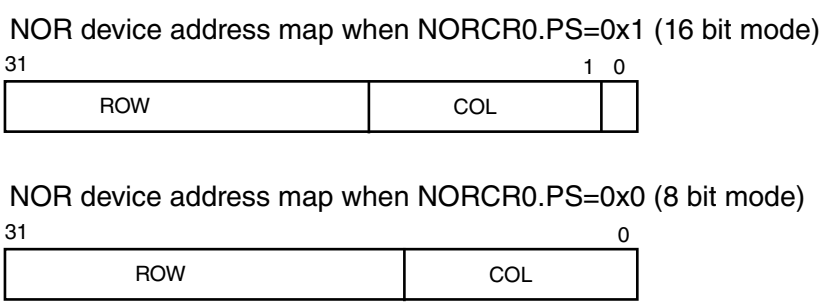

Figure 29-53. NOR Flash Address Multiplexing

NOTE

- NOR address bits consist of row and column address bits.
- Column address bits offset is bit 0 if NORCR0[PS]=0 and bit 1 if NORCR0[PS]=1. Column address bit width is determined by NORCR0[COL].
- Row address bits offset is determined by NORCR0[PS] and NORCR0[COL].
- NOR device base address on SoC is configured by BR5 register.
- Write data should be 16 bit aligned when connecting to 16 bit NOR device.

29.3.1.6.2 NOR Flash Read Operation in ASYNC Mode

NOR Flash controller supports following address modes, which setting by NORCR0[AM].

Figure 29-54 shows the ASYNC NOR Flash read in Non-ADMUX address mode.

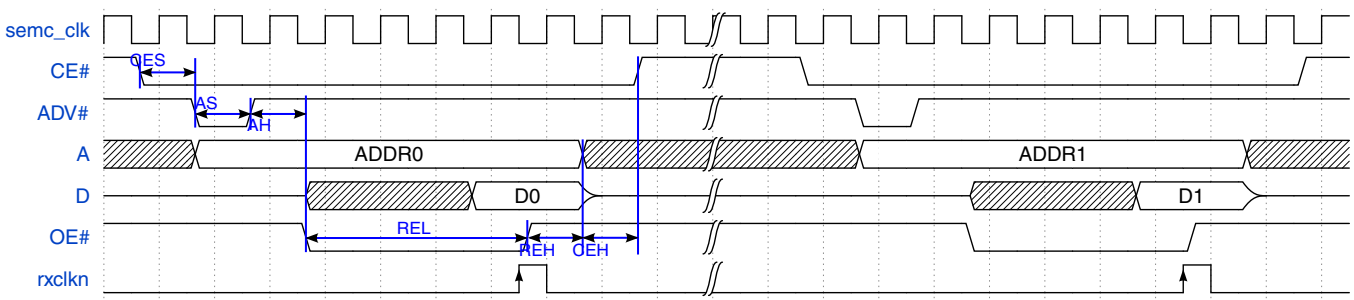

Figure 29-54. ASYNC NOR Flash Read in Non-ADMUX Address Mode

NOTE

- semc_clk and rxclkn are the internal signals. semc_clk is the SEMC functional clock. rxclkn is the clock to sample data from NOR Flash.
- For this example:
  - CE# setup time is 1 clock cycle (NORCR1[CES]=0)
  - Address setup time is 1 clock cycle (NORCR1[AS]=0)
  - Address hold time is 1 clock cycle (NORCR1[AH]=0)
  - OE# low time is 4 clock cycles (NORCR1[REL]=3)
  - OE# high time is 1 clock cycle (NORCR1[REH]=0)
  - CE# hold time is 1 clock cycle (NORCR1[CEH]=0)

Figure 29-55 shows the ASYNC NOR Flash read in ADMUX address mode.

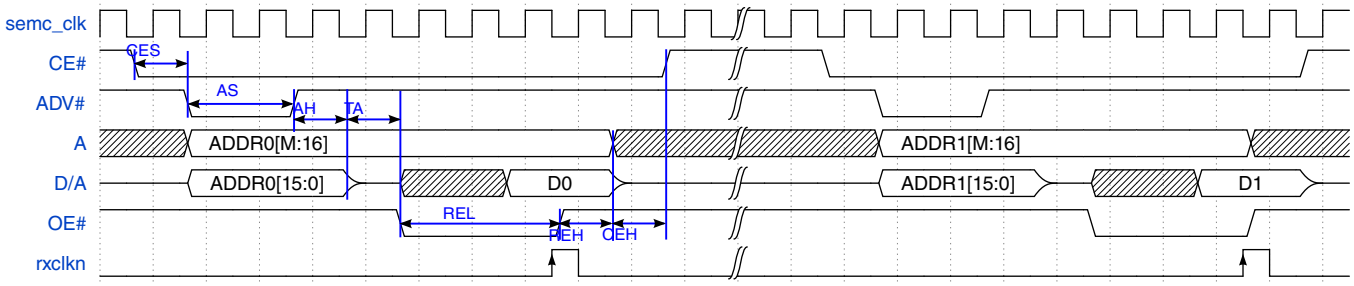

Figure 29-55. ASYNC NOR Flash Read in ADMUX Address Mode

NOTE

- semc_clk and rxclkn are the internal signals. semc_clk is the SEMC functional clock. rxclkn is the clock to sample data from NOR Flash.
- For this example:
  - CE# setup time is 1 clock cycle (NORCR1[CES]=0)
  - Address setup time is 2 clock cycles (NORCR1[AS]=1)
  - Address hold time is 1 clock cycle (NORCR1[AH]=0)
  - Turnaround time is 1 clock cycle (NORCR2[TA]=0)
  - OE# low time is 3 clock cycles (NORCR1[REL]=2)
  - OE# high time is 1 clock cycle (NORCR1[REH]=0)
  - CE# hold time is 1 clock cycle (NORCR1[CEH]=0)

Figure 29-56 shows the ASYNC NOR Flash read in AADM address mode.

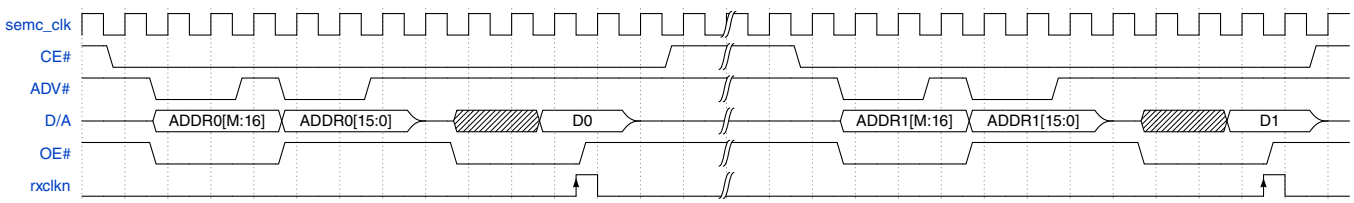

Figure 29-56. ASYNC NOR Flash Read in AADM Address Mode

29.3.1.6.3 NOR Flash Write Operation in ASYNC Mode

Figure 29-57 shows the ASYNC NOR Flash write in Non-ADMUX address mode.

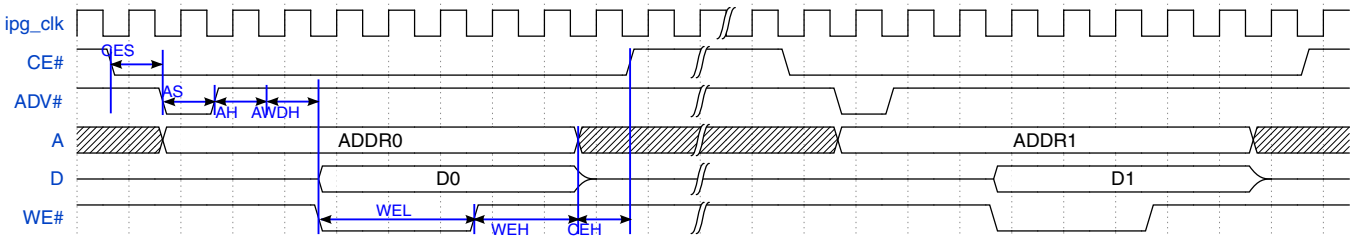

Figure 29-57. ASYNC NOR Flash Write in Non-ADMUX Address Mode

NOTE

- semc_clk is the SEMC functional clock.
- For this example:
  - CE# setup time is 1 clock cycle (NORCR1[CES]=0)
  - Address setup time is 1 clock cycle (NORCR1[AS]=0)
  - Address hold time is 1 clock cycle (NORCR1[AH]=0)
  - Address to write data hold time is 1 clock cycle (NORCR2[AWDH]=1)
  - WE# low time is 3 clock cycles (NORCR1[WEL]=2)
  - WE# high time is 2 clock cycles (NORCR1[WEH]=1)
  - CE# hold time is 1 clock cycle (NORCR1[CEH]=0)

Figure 29-58 shows the ASYNC NOR Flash write in ADMUX address mode.

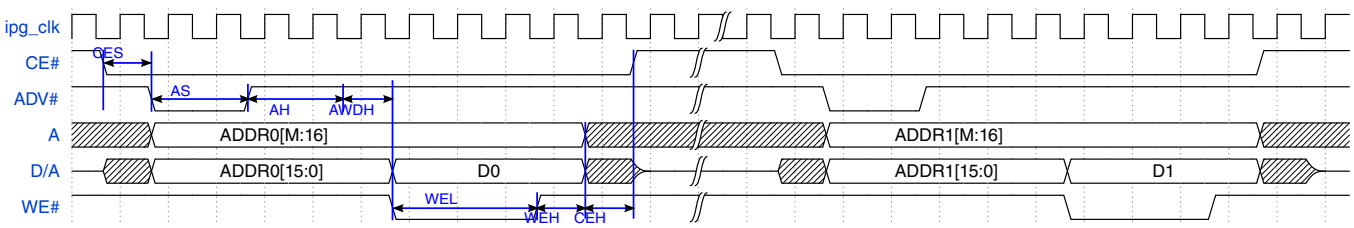

Figure 29-58. ASYNC NOR Flash Write in ADMUX Address Mode

NOTE

- semc_clk is the SEMC functional clock.
- For this example:
  - CE# setup time is 1 clock cycle (NORCR1[CES]=0)
  - Address setup time is 2 clock cycles (NORCR1[AS]=1)
  - Address hold time is 2 clock cycles (NORCR1[AH]=1)
  - Address to write data hold time is 1 clock cycle (NORCR2[AWDH]=1)
  - WE# low time is 3 clock cycles (NORCR1[WEL]=2)
  - WE# high time is 1 clock cycle (NORCR1[WEH]=0)
  - CE# hold time is 1 clock cycle (NORCR1[CEH]=0)

Figure 29-59 shows the ASYNC NOR Flash write in AADM address mode.

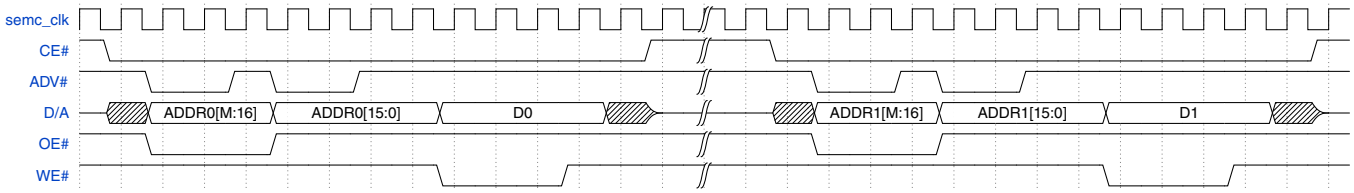

Figure 29-59. ASYNC NOR Flash Write in AADM Address Mode

29.3.1.6.4 NOR Flash Read Operation in SYNC Mode

Figure 29-60 shows the SYNC NOR Flash read in Non-ADMUX address mode.

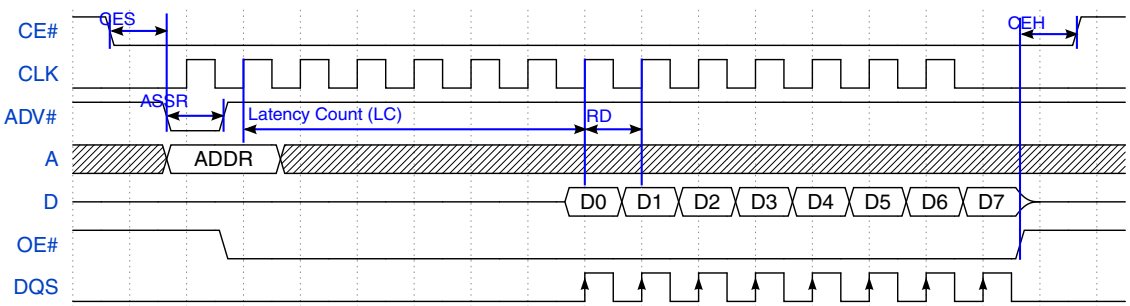

Figure 29-60. SYNC Flash Read in Non-ADMUX Address Mode

NOTE

- DQS is the clock to sample data from NOR Flash. It generally loops back from DQS pad.
- For this example:
  - CE# setup time is 1 clock cycle (NORCR1[CES]=0)
  - Address setup time is 1 clock cycle (NORCR3[ASSR]=0)
  - Latency count is 6 clock cycles (NORCR2[LC]=6)
  - Read time is 1 clock cycle (NORCR2[RD]=0)
  - CE# hold time is 1 clock cycle (NORCR1[CEH]=0)

Figure 29-61 shows the SYNC NOR Flash read in ADMUX address mode.

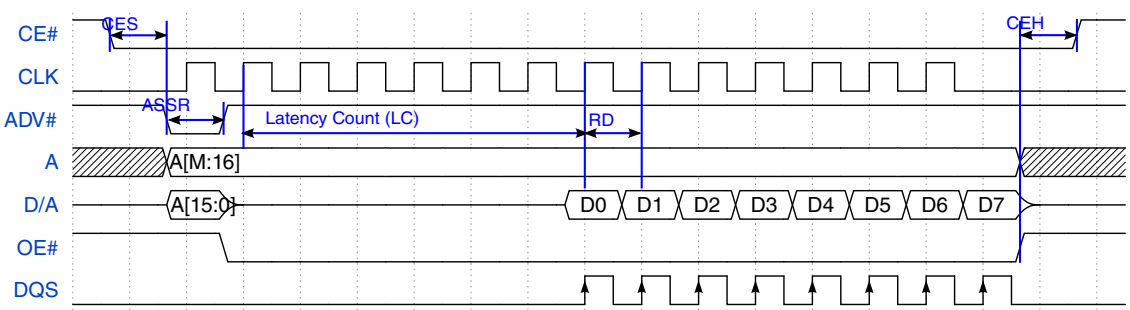

Figure 29-61. SYNC Flash Read in ADMUX Address Mode

NOTE

- DQS is the clock to sample data from NOR Flash. It generally loops back from DQS pad.
- For this example:
  - CE# setup time is 1 clock cycle (NORCR1[CES]=0)
  - Address setup time is 1 clock cycle (NORCR3[ASSR]=0)
  - Latency count is 6 clock cycles (NORCR2[LC]=6)
  - Read time is 1 clock cycle (NORCR2[RD]=0)
  - CE# hold time is 1 clock cycle (NORCR1[CEH]=0)

Figure 29-62 shows the SYNC NOR Flash read in AADM address mode.

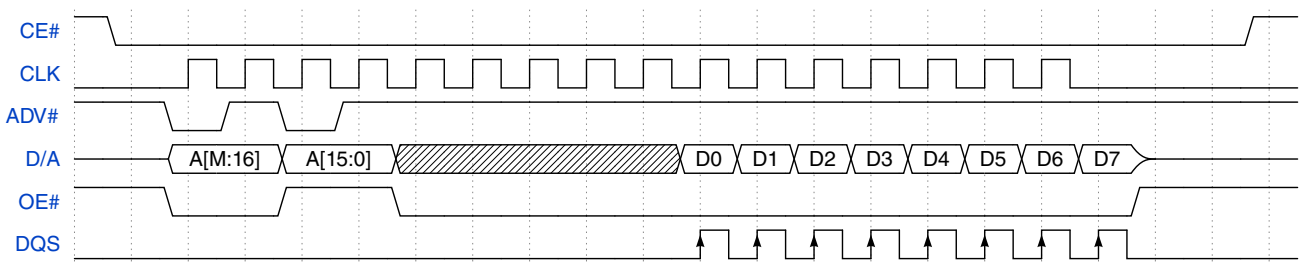

Figure 29-62. SYNC Flash Read in AADM Address Mode

29.3.1.6.5 NOR Flash Write Operation in SYNC Mode

Flash write operation in SYNC mode is same as asynchronous.

29.3.1.7 SRAM Controller Operations

This section describes the operations of SRAM controller.

29.3.1.7.1 SRAM Address Multiplexing

SRAM use a multiplexed address split into rows and columns. Figure 29-63 shows how the bits of the linear address sent to the SEMC are split up into the row and column addresses sent to the SRAM memory device.

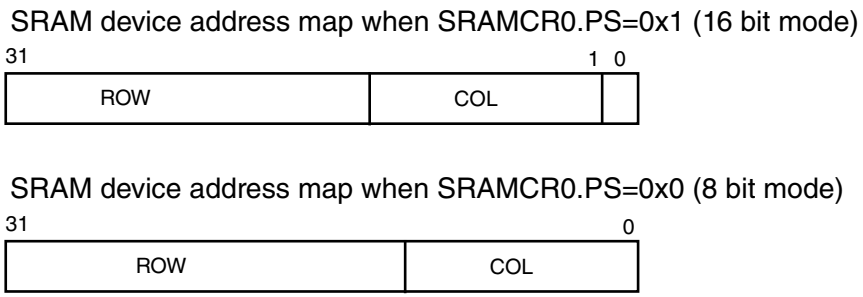

Figure 29-63. SRAM Address Multiplexing

NOTE

- SRAM address bits consist of row and column address bits.
- Column address bits offset is bit 0 if SRAMCR0[PS]=0, offset is bit 1 if SRAMCR0[PS]=1. Column address bit width is determined by SRAMCR0[COL].
- Row address bits offset is determined by SRAMCR0[PS] and SRAMCR0[COL].
- SRAM device base address on SoC is configured by BR6, BR9, BR10 and BR11 registers.

29.3.1.7.2 SRAM Read Operation in ASYNC Mode

Figure 29-64 shows the ASYNC SRAM read in Non-ADMUX address mode.

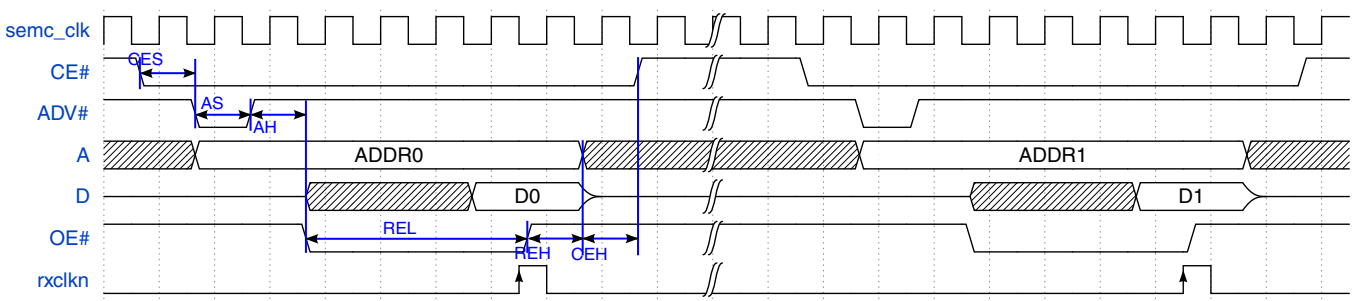

Figure 29-64. ASYNC SRAM Read in Non-ADMUX Address Mode

NOTE

- semc_clk and rxclkn are the internal signals. semc_clk is the SEMC functional clock. rxclkn is the clock to sample data from SRAM.
- For this example:
  - CE# setup time is 1 clock cycle (SRAMCR1[CES]=0)
  - Address setup time is 1 clock cycle (SRAMCR1[AS]=0)

- Address hold time is 1 clock cycle (SRAMCR1[AH]=0)
- OE# low time is 4 clock cycles (SRAMCR1[REL]=3)
- OE# high time is 1 clock cycle (SRAMCR1[REH]=0)
- CE# hold time is 1 clock cycle (SRAMCR1[CEH]=0)

Figure 29-65 shows the ASYNC SRAM read in ADMUX address mode.

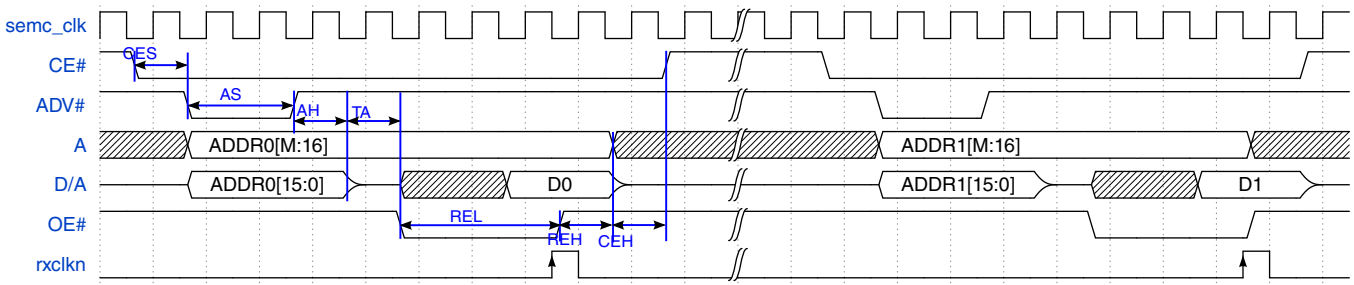

Figure 29-65. ASYNC SRAM Read in ADMUX Address Mode

NOTE

- semc_clk and rxclkn are the internal signals. semc_clk is the SEMC functional clock. rxclkn is the clock to sample data from SRAM.
- For this example:
  - CE# setup time is 1 clock cycle (SRAMCR1[CES]=0)
  - Address setup time is 2 clock cycles (SRAMCR1[AS]=1)
  - Address hold time is 1 clock cycle (SRAMCR1[AH]=0)
  - Turnaround time is 1 clock cycle (SRAMCR2[TA]=0)
  - OE# low time is 3 clock cycles (SRAMCR1[REL]=2)
  - OE# high time is 1 clock cycle (SRAMCR1[REH]=0)
  - CE# hold time is 1 clock cycle (SRAMCR1[CEH]=0)

Figure 29-66 shows the ASYNC SRAM read in AADM address mode.

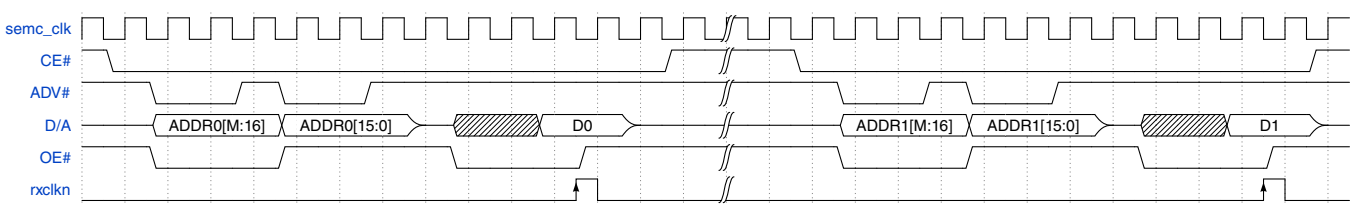

Figure 29-66. ASYNC SRAM Read in AADM Address Mode

29.3.1.7.3 SRAM Write Operation in ASYNC Mode

Figure 29-67 shows the ASYNC SRAM write in Non-ADMUX address mode.

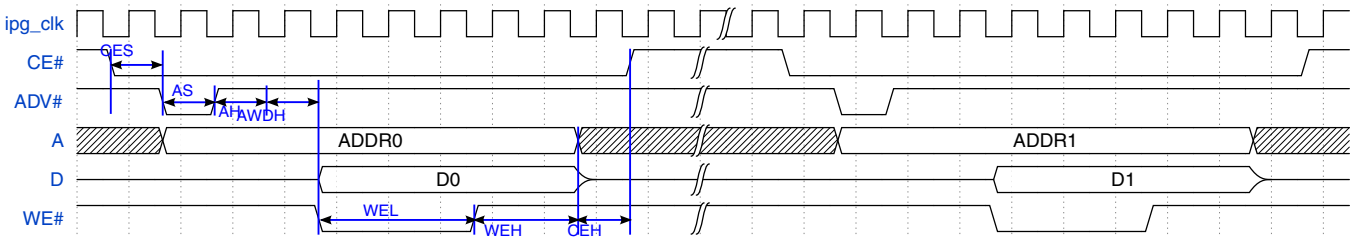

Figure 29-67. ASYNC SRAM Write in Non-ADMUX Address Mode

NOTE

- For this example:
  - CE# setup time is 1 clock cycle (SRAMCR1[CES]=0)
  - Address setup time is 1 clock cycle (SRAMCR1[AS]=0)
  - Address hold time is 1 clock cycle (SRAMCR1[AH]=0)
  - Address to write data hold time is 1 clock cycle (SRAMCR2[AWDH]=1)
  - WE# low time is 3 clock cycles (SRAMCR1[WEL]=2)
  - WE# high time is 2 clock cycles (SRAMCR1[WEH]=1)
  - CE# hold time is 1 clock cycle (SRAMCR1[CEH]=0)

Figure 29-68 shows the ASYNC SRAM write in ADMUX address mode.

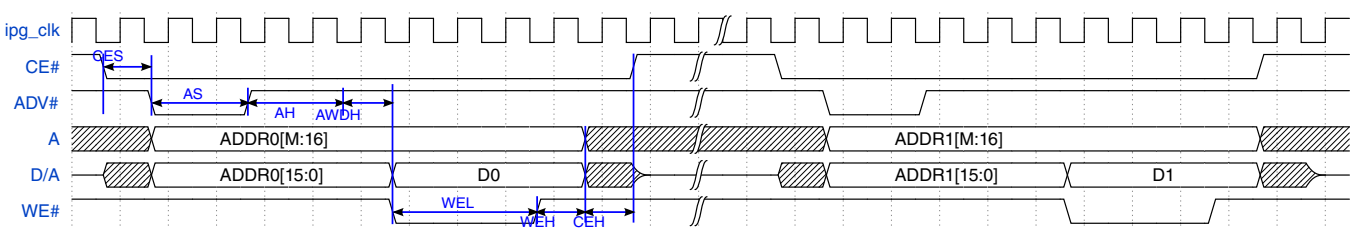

Figure 29-68. ASYNC SRAM Write in ADMUX Address Mode

NOTE

- For this example:
  - CE# setup time is 1 clock cycle (SRAMCR1[CES]=0)
  - Address setup time is 2 clock cycles (SRAMCR1[AS]=1)
  - Address hold time is 2 clock cycles (SRAMCR1[AH]=1)
  - Address to write data hold time is 1 clock cycle (SRAMCR2[AWDH]=1)

- WE# low time is 3 clock cycles (SRAMCR1[WEL]=2)
- WE# high time is 1 clock cycle (SRAMCR1[WEH]=0)
- CE# hold time is 1 clock cycle (SRAMCR1[CEH]=0)

Figure 29-69 shows the ASYNC SRAM write in AADM address mode.

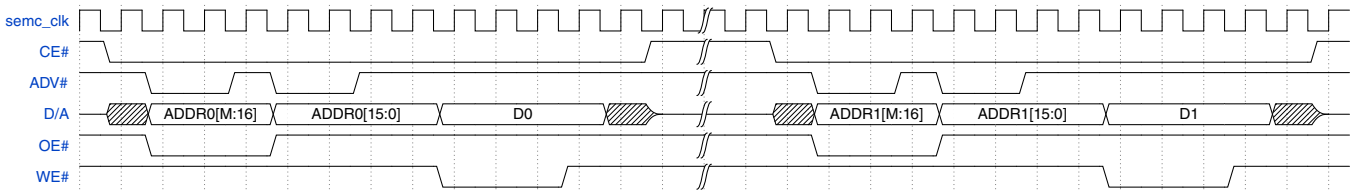

Figure 29-69. ASYNC SRAM Write in AADM Address Mode

29.3.1.7.4 SRAM Register Operation in ASYNC Mode

Figure 29-70 shows the ASYNC SRAM register access in ADMUX address mode.

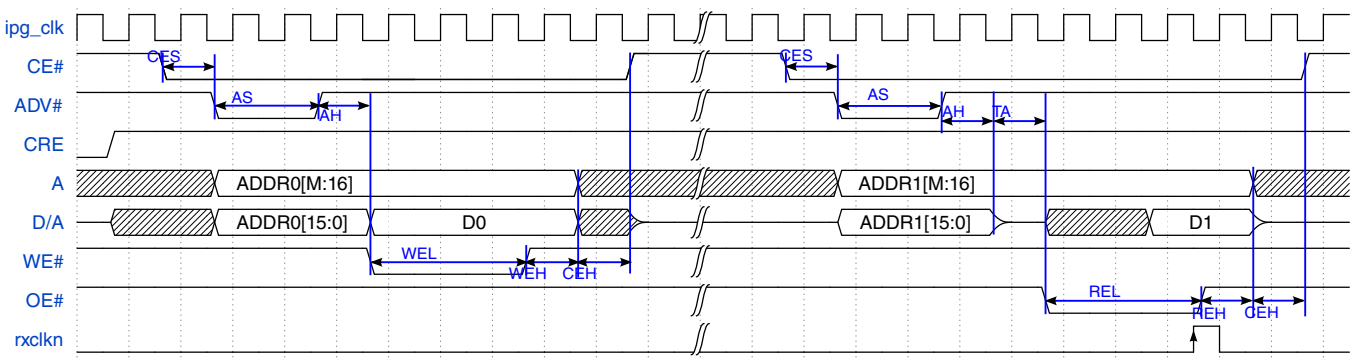

Figure 29-70. ASYNC SRAM Register Access in ADMUX Address Mode

NOTE

- For this example:
  - First operation is SRAM register write access. ADDR0[M:0] contains the value for writing to SRAM register. The value of D0 can be ignored.
  - Second operation is SRAM register read access. ADDR1[M:0] contains the value for choosing of SRAM register. D1 is the value that read from SRAM register.
  - The value of ADDR0/1 comes from IPCR0 register.

- If BR6[BA]=0x98000 and IPCR0=0x9810883E, ADDR0/1 is 0x8441F when port size is 16bit mode. The address is divided by 2 in 16bit mode.
- If BR6[BA]=0x98000 and IPCR0=0x9810883E, ADDR0/1 is 0x10883E when port size is 8bit mode.

- CE# setup time is 1 clock cycle (SRAMCR1[CES]=0)
- Address setup time is 2 clock cycles (SRAMCR1[AS]=1)
- Address hold time is 1 clock cycle (SRAMCR1[AH]=0)
- WE# low time is 3 clock cycles (SRAMCR1[WEL]=2)
- WE# high time is 1 clock cycle (SRAMCR1[WEH]=0)
- CE# hold time is 1 clock cycle (SRAMCR1[CEH]=0)
- Turnaround time is 1 clock cycle (SRAMCR2[TA]=0)
- OE# low time is 3 clock cycles (SRAMCR1[REL]=2)
- OE# high time is 1 clock cycle (SRAMCR1[REH]=0)

29.3.1.7.5 SRAM Read Operation in ASYNC Mode with Wait Pin

SRAM read operation in ASYNC mode with wait pin is indicated in following diagrams:

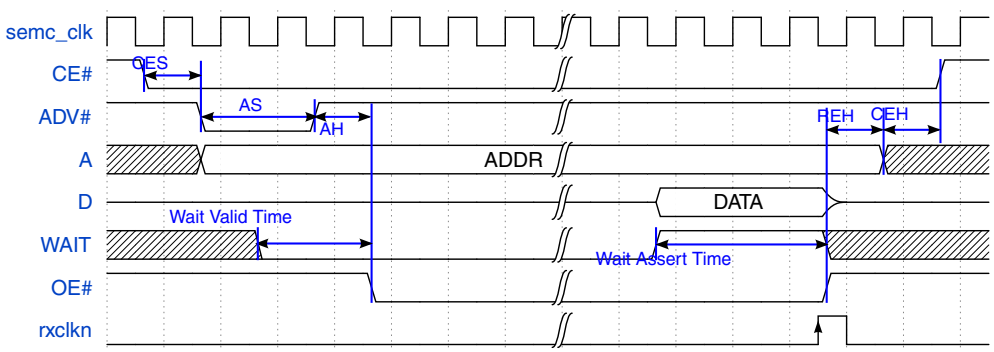

Figure 29-71. SRAM Read in ASYNC Mode (Non-ADMUX) with Wait Pin

NOTE

1. Wait Valid Time must be no less than 2 semc_clk cycles.
2. Wait and DATA must be valid till OE# high.
3. For this example:
   - SRAMCR0[WAITEN]=1
   - SRAMCR0[WAITSP]=1
   - MCR[WPOL0]=0

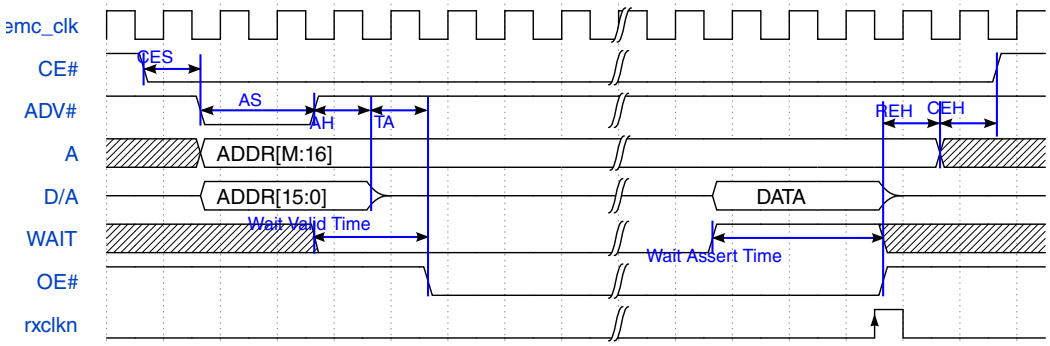

Figure 29-72. SRAM Read in ASYNC Mode (ADMUX) with Wait Pin

NOTE

1. Wait Valid Time must be no less than 2 semc_clk cycles.
2. Wait and DATA must be valid till OE# high.
3. For this example:
   - SRAMCR0[WAITEN]=1
   - SRAMCR0[WAITSP]=1
   - MCR[WPOL0]=0

29.3.1.7.6 SRAM Write Operation in ASYNC Mode with Wait Pin

SRAM write operation in ASYNC mode is indicated in following diagrams:

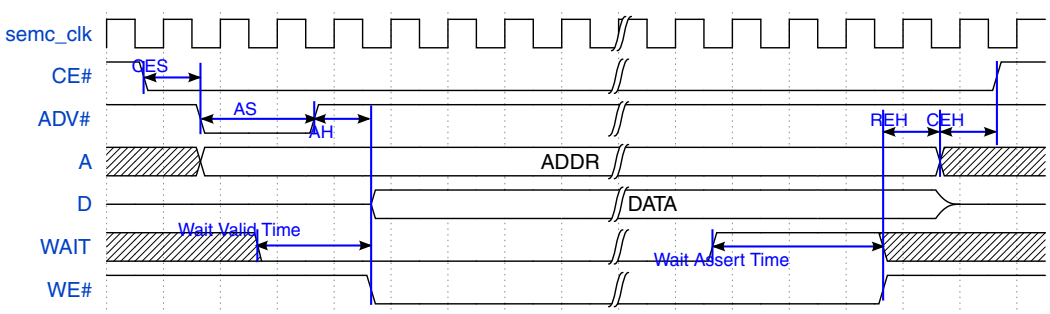

Figure 29-73. SRAM Write in ASYNC Mode (Non-ADMUX) with Wait Pin

NOTE

1. Wait Valid Time must be no less than 2 semc_clk cycles.
2. Wait must be valid till WE# high.
3. For this example:
   - SRAMCR0[WAITEN]=1
   - SRAMCR0[WAITSP]=1
   - MCR[WPOL0]=0

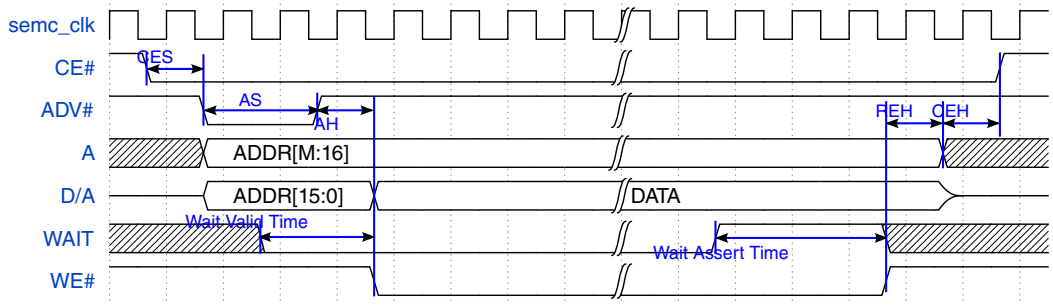

Figure 29-74. SRAM Write in ASYNC Mode (ADMUX) with Wait Pin

NOTE

1. Wait Valid Time must be no less than 2 semc_clk cycles.
2. Wait must be valid till WE# high.
3. For this example:
   - SRAMCR0[WAITEN]=1
   - SRAMCR0[WAITSP]=1
   - MCR[WPOL0]=0

29.3.1.7.7 SRAM Read Operation in SYNC Mode

Figure 29-75 shows the SYNC SRAM read in Non-ADMUX address mode.

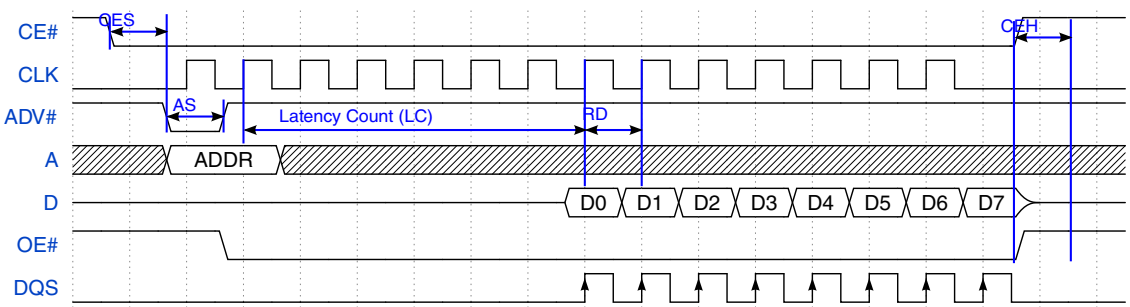

Figure 29-75. SYNC SRAM Read in Non-ADMUX Address Mode

NOTE

- DQS is the clock to sample data from SRAM. It generally loops back from DQS pad.
- For this example:
  - CE# setup time is 1 clock cycle (SRAMCR1[CES]=0)
  - Address setup time is 1 clock cycle (SRAMCR1[AS]=0)
  - Latency count is 6 clock cycles (SRAMCR2[LC]=6)
  - Read time is 1 clock cycle (SRAMCR2[RD]=0)
  - CE# hold time is 1 clock cycle (SRAMCR1[CEH]=0)

Figure 29-76 shows the SYNC SRAM read in ADMUX address mode.

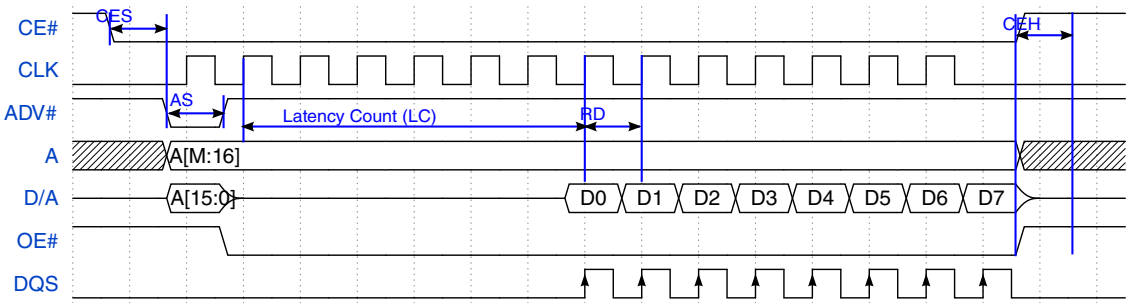

Figure 29-76. SYNC SRAM Read in ADMUX Address Mode

NOTE

- DQS is the clock to sample data from SRAM. It generally loops back from DQS pad.
- For this example:
  - CE# setup time is 1 clock cycle (SRAMCR1[CES]=0)
  - Address setup time is 1 clock cycle (SRAMCR1[AS]=0)
  - Latency count is 6 clock cycles (SRAMCR2[LC]=6)
  - Read time is 1 clock cycle (SRAMCR2[RD]=0)
  - CE# hold time is 1 clock cycle (SRAMCR1[CEH]=0)

29.3.1.7.8 SRAM Write Operation in SYNC Mode

Figure 29-77 shows the SYNC SRAM write in Non-ADMUX address mode.

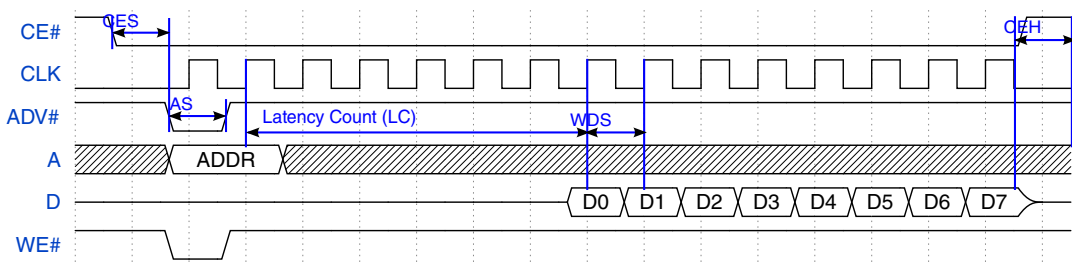

Figure 29-77. SRAM Write in SYNC Mode (Non-ADMUX)

NOTE

- For this example:
  - CE# setup time is 1 clock cycle (SRAMCR1[CES]=0)
  - Address setup time is 1 clock cycle (SRAMCR1[AS]=0)
  - Latency count is 6 clock cycles (SRAMCR2[LC]=6)

- Write data setup time is 1 clock cycle (SRAMCR2[WDS]=0)
- CE# hold time is 1 clock cycle (SRAMCR1[CEH]=0)

Figure 29-78 shows the SYNC SRAM write in ADMUX address mode.

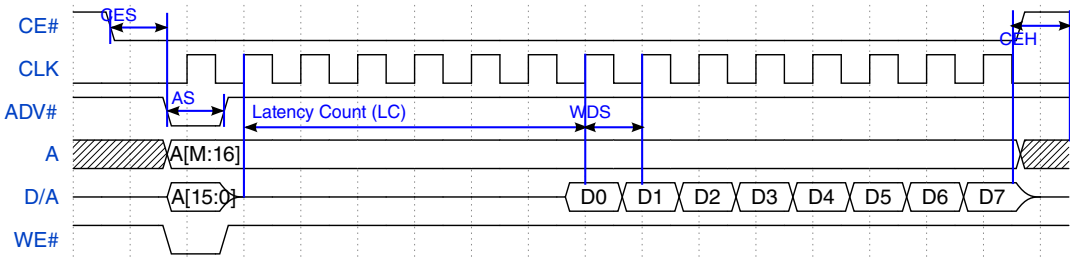

Figure 29-78. SRAM Write in SYNC Mode (ADMUX)

NOTE

- For this example:
  - CE# setup time is 1 clock cycle (SRAMCR1[CES]=0)
  - Address setup time is 1 clock cycle (SRAMCR1[AS]=0)
  - Latency count is 6 clock cycles (SRAMCR2[LC]=6)
  - Write data setup time is 1 clock cycle (SRAMCR2[WDS]=0)
  - CE# hold time is 1 clock cycle (SRAMCR1[CEH]=0)

29.3.1.8 Display Bus Interface Controller Operations

This section describes the operations of DBI controller.

DCX signal is controlled by write address. Write access to DBI is handled as DBI COMMAND WRITE transaction if address is higher than 0x10000 (DCX low). Otherwise, it is handled as DBI DATA WRITE transaction (DCX high).

For example, if BR7[BA]=0x9C000:

- An AXI write to address 0x9C010000 is treated as DBI COMMAND WRITE transaction.
- An AXI write to address 0x9C000000 is treated as DBI DATA WRITE transaction.

Figure 29-79 shows DBI write operation.

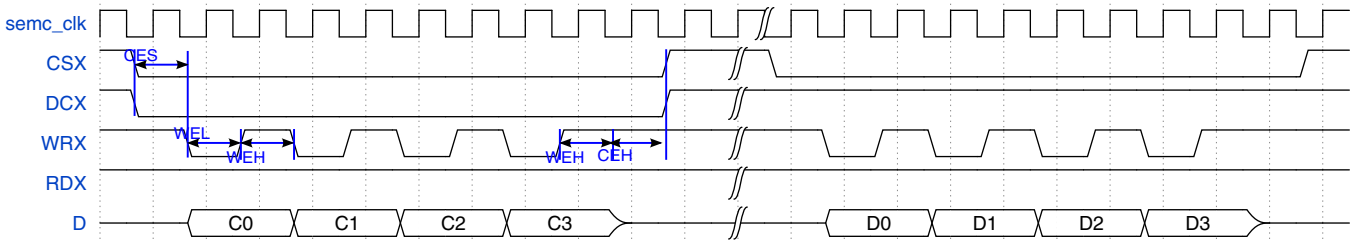

Figure 29-79. DBI Write Operation

NOTE

- DBI address is used to determine DBI COMMAND or DATA WRITE.
- DBI bus never send out address information for COMMAND and DATA WRITE.
- AXI WRAP write access to DBI is supported.
- DBI bus interface does not support WRITE mask feature.
- All write strobe in AXI write access to DBI must be valid. If AXI write strobe is invalid, the SEMC sends write data 0x00 instead of original write data.
- When DBI bus is 16 bit (DBICR0[PS]=1), AXI or IP command access start address to DBI bus must be 16 bit aligned. Otherwise the write data to DBI may be wrong. There is no bus error response or internal error status generated for this case.
- For this example:
  - CSX setup time is 1 clock cycle (DBICR1[CES]=0)
  - WRX low time is 1 clock cycle (DBICR1[WEL]=0)
  - WRX high time is 1 clock cycle (DBICR1[WEH]=0)
  - CSX hold time is 1 clock cycle (DBICR1[CEH]=0)

Figure 29-80 shows DBI read operation.

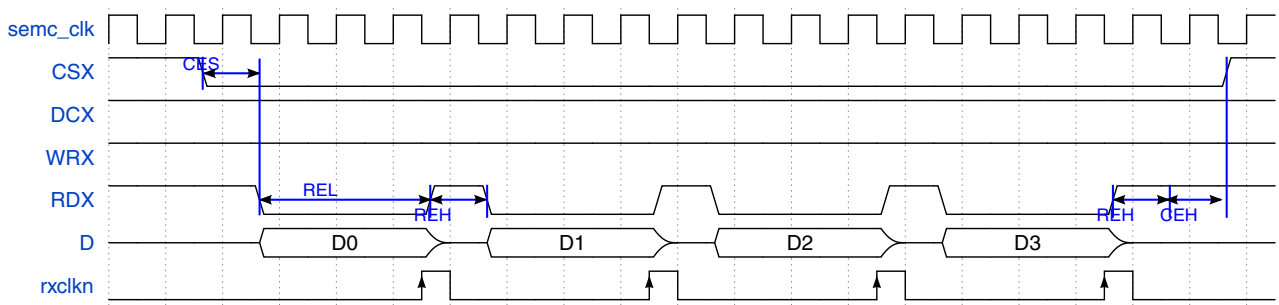

Figure 29-80. DBI Read Operation

NOTE

- Read access to DBI is always handled as DBI DATA READ transaction.
- DBI bus never sent out address information for DATA READ command.
- AXI WRAP read access to DBI is not supported except when the first beat address offset is zero in the burst.
- When DBI bus is 16 bit (DBICR0[PS]=1), AXI command or IP command access start address to DBI bus must be 16 bit aligned. Otherwise the read data is unknown. There is no bus error response or internal error status generated for this case.
- For this example:
  - CSX setup time is 1 clock cycle (DBICR1[CES]=0)
  - RDX low time is 3 clock cycles (DBICR1[REL]=2)
  - RDX high time is 1 clock cycle (DBICR1[REH]=0)
  - CSX hold time is 1 clock cycle (DBICR1[CEH]=0)

29.3.2 Clocks

There is one clock used for the SEMC AXI bus, IP bus, internal logic and external interface. It is shown as semc_clk in SEMC timing figures.

29.3.3 Reset

There is a hardware reset for the SEMC, which reset all the logic inside it. When set MCR[SWRST], there will be a software reset to reset all logic in the SEMC except configuration registers.

29.3.4 Interrupts

There is an interrupt output from the SEMC. It indicates the interrupt source that defined in INTR register. The interrupt source is enabled by INTEN register.

29.4 External Signals

Table 29-5 lists the SEMC module signals.

Table 29-5. SEMC Signals

Signal	Direction	Description
SEMC_DATA[31-00]	I/O	Data/Address Bits The SEMC has several controllers, and they share pins. SEMC_DATA works as data signal in SDRAM/NAND/8080 applications and works as data or address signal in NOR/SRAM applications. For detail pin mux information, refer to Pin Mux.
SEMC_DM[3-0]	O	Write Data Mask Bits
SEMC_ADDR[12-00]	O	Address Bits SEMC_ADDR08 can work as chip select pin in NAND/NOR/SRAM/ 8080 applications.
SEMC_BA[1-0]	O	Bank Address Bits SEMC_BA0 can work as WAIT in SRAM application. SEMC_BA1 can work as ALE/ADV#/DCX in NAND/NOR/SRAM/8080 applications.
SEMC_CAS	O	SDRAM Column Address Strobe
SEMC_RAS	O	SDRAM Row Address Strobe
SEMC_WE	O	SDRAM Write Enable
SEMC_CKE	O	SDRAM Clock enable
SEMC_CLK	O	SDRAM Clock
SEMC_CS0	O	SDRAM Chip Select 0
SEMC_CSX[3-0]	O	Configurable Chip Select bits
SEMC_RDY	I/O	Ready input pin for NAND It can also work as chip select pin in SDRAM/NOR/SRAM/8080 applications.
SEMC_DQS	I/O	DQS SEMC controller provides internal dummy read strobe for read data from SDRAM/NOR/SRAM. Higher read frequency can be achieved by looping back this dummy read strobe from pad. This pin can be floated or put some cap loads on board level to compensate DATA/CLK pins load.
SEMC_DQS4	I/O	DQS Data read strobe for NAND Flash.
SEMC_CLKX0	O	Configurable clock 0 for NOR/SRAM
SEMC_CLKX1	O	Configurable clock 1 for NOR/SRAM

29.4.1 Pin Mux

Table 29-6 lists the pin mux of the SEMC module.

Table 29-6. SEMC Pin Mux Overview

Signal	SDRAM	NAND	NOR (ADMUX 16bit)	SRAM (ADMUX 16bit)	DBI	Comment
SEMC_DATA00	D0	D0	D0/A0	D0/A0	D0	Hardware MUX The SEMC determines the pin function according to its internal state

SEMC_CLKX0	-	-	CLK	CLK	-	Configured by IOCR[MUX_CLKX0]
SEMC_CLKX1	-	-	CLK	CLK	-	Configured by IOCR[MUX_CLKX1]

NOTE

- IOCR configuration should be static. Dynamic remapping of pin muxing controlled by IOCR is not supported.
- NOR and SRAM pins are configured as 16 bit ADMUX mode in above table. It is the recommended configuration.

Table 29-7 lists the different configurations for NOR and SRAM pin mux of the SEMC module.

Table 29-7. SEMC Pin Mux for NOR and SRAM

Signal	NOR (Non-ADMUX)	NOR (ADMUX 8bit)	NOR (ADMUX 16bit)	NOR (AADM 16bit)	SRAM (Non-ADMUX)	SRAM (ADMUX 8bit)	SRAM (ADMUX 16bit)	SRAM (AADM 16bit)

29.5 Initialization

To initialize the block:

- Ensure the clock for the SEMC is enabled.
- Configure corresponding pin MUX for the SEMC external signals.
- Configure registers of the SEMC properly, according to the applications.
- Configure the Module Control Register and clear MCR[MDIS] bit to enable the SEMC module.
- Reset SEMC optionally by setting the MCR[SWRST] bit.

29.6 Application Information

This section describes applications supported by the SEMC module.

29.6.1 SDRAM Application

This section provides the example sequences for SDRAM device.

- Configure MCR[DQSMD] bit to select the read clock source. Suggest to set it with 0x1 to reach high clock frequency.
- Configure IOCR register to choose chip select pins.
- Configure BMCR0/1 registers to adjust AXI bus access efficiency scheme.
- Configure Base Register 0/1/2/3 with base address, memory size and valid information.
- Configure INTEN and INTR registers if need to generate interrupt.
- Configure SDRAM Control Registers with valid settings that matches SDRAM device.
- Initialize SDRAM device by IP command registers (IPCR0/1/2, IPCMD and IPTXDAT).
- Write and read operations can be triggered by AXI or IP command. However, AXI command is suggested.

29.6.2 NAND Application

This section provides the example sequences for NAND device.

- Configure IOCR register to choose chip select pins.
- Configure BMCR0/1 registers to adjust AXI bus access efficiency scheme.
- Configure Base Register 4/8 with base address, memory size and valid information.
- Configure INTEN and INTR registers if need to generate interrupt.
- Configure NAND Control Registers with valid settings that matches NAND device.
- Configure DLL Control Register for synchronous mode.
- Initialize NAND device by IP command registers (IPCR0/1/2, IPCMD and IPTXDAT).
- For programming operation, need to open page by IP command. Then you can write data to the NAND buffer by IP or AXI bus.
- For read operation, need to open page by IP command. Then you can read data from the NAND buffer by IP or AXI bus.
- For erase operation, you should do it by IP command.

29.6.3 NOR Application

This section provides the example sequences for NOR device.

- Configure MCR[DQSMD] bit to select the read clock source for synchronous mode. Suggest to set it with 0x1 to reach high clock frequency.
- Configure IOCR register to choose chip select pins.
- Configure BMCR0/1 registers to adjust AXI bus access efficiency scheme.
- Configure Base Register 5 with base address, memory size and valid information.
- Configure INTEN and INTR registers if need to generate interrupt.
- Configure NOR Control Registers with valid settings that matches NOR device.
- Initialize NOR device by IP command registers (IPCR0/1/2, IPCMD and IPTXDAT) if needed.
- Programming operation can be triggered by IP command only.
- Read operation can be triggered by AXI or IP command.

29.6.4 SRAM Application

This section provides the example sequences for SRAM device.

- Configure MCR[DQSMD] bit to select the read clock source for synchronous mode. Suggest to set it with 0x1 to reach high clock frequency.
- Configure IOCR register to choose chip select pins.
- Configure BMCR0/1 registers to adjust AXI bus access efficiency scheme.

- Configure Base Register 6/9/10/11 with base address, memory size and valid information.
- Configure INTEN and INTR registers if need to generate interrupt.
- Configure SRAM Control Registers with valid settings that matches SRAM device.
- Initialize SRAM device by IP command registers (IPCR0/1/2, IPCMD and IPTXDAT) if needed.
- Write and read operations can be triggered by AXI or IP command.

29.6.5 DBI Application

This section provides the example sequences for Display Bus Interface.

- Configure IOCR register to choose chip select pins.
- Configure BMCR0/1 registers to adjust AXI bus access efficiency scheme.
- Configure Base Register 7 with base address, memory size and valid information.
- Configure INTEN and INTR registers if need to generate interrupt.
- Configure DBI Control Registers with valid settings that matches DBI device.
- Write and read operations can be triggered by AXI or IP command.

29.7 Memory Map and Register Definition

This section includes the SEMC module memory map and detailed descriptions of all registers.

29.7.1 SEMC register descriptions

29.7.1.1 SEMC memory map

SEMC base address: 400D_4000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Module Control Register (MCR)	32	RW	1000_0002h
4h	IO MUX Control Register (IOCR)	32	RW	0000_0000h
8h	Bus (AXI) Master Control Register 0 (BMCR0)	32	RW	0000_0000h

Table continues on the next page...

Offset	Register	Width (In bits)	Access	Reset value
Ch	Bus (AXI) Master Control Register 1 (BMCR1)	32	RW	0000_0000h
10h - 30h	Base Register n (BR0 - BR8)	32	RW	0000_0000h
34h	DLL Control Register (DLLCR)	32	RW	0000_0100h
38h	Interrupt Enable Register (INTEN)	32	RW	0000_0000h
3Ch	Interrupt Register (INTR)	32	RW	0000_0000h
40h	SDRAM Control Register 0 (SDRAMCR0)	32	RW	0000_0C26h
44h	SDRAM Control Register 1 (SDRAMCR1)	32	RW	0099_4934h
48h	SDRAM Control Register 2 (SDRAMCR2)	32	RW	8000_0EEEh
4Ch	SDRAM Control Register 3 (SDRAMCR3)	32	RW	4080_8000h

29.7.1.2 Module Control Register (MCR)

29.7.1.2.1 Offset

Register	Offset
MCR	0h

29.7.1.2.2 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	Reserved			BTO					CTO							
Reset	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	Reserved								WPOL1	WPOL0	Reserved			DQSMD	MDIS	SWRST
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0

29.7.1.2.3 Fields

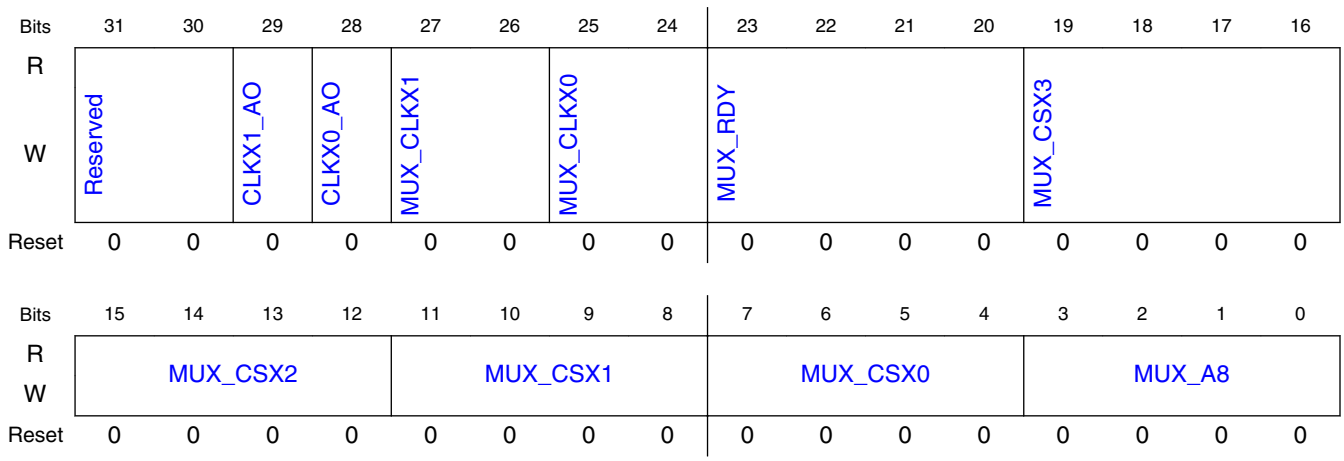
Field	Function
31-29 —	Reserved
28-24 BTO	Bus timeout cycles The SEMC monitors AXI transactions in the queue. When it exceeds the timeout cycles, an AXIBUSERR interrupt is generated. The AXI Bus timeout is 255*2^{BTO} clock cycles. 0_0000b - 255*1 0_0001b - 255*2 1_1111b - 255*2^31
23-16 CTO	Command Execution timeout cycles When Command Execution time exceeds the timeout cycles, an IPCMDERR or AXICMDERR interrupt is generated. When CTO is set to zero, timeout cycles is 256*1024 cycle. Otherwise timeout cycles is CTO*1024 cycle.
15-8 —	Reserved
7 WPOL1	R/B# polarity for NAND device This bit configures the expected polarity of R/B# signal from NAND device. 0b - R/B# polarity is not changed. 1b - R/B# polarity is inverted.
6 WPOL0	WAIT/RDY polarity for SRAM/NOR This bit configures the expected polarity of WAIT/RDY signal from SRAM and NOR devices. 0b - WAIT/RDY polarity is not changed. 1b - WAIT/RDY polarity is inverted.
5-3 —	Reserved
2 DQSMD	DQS (read strobe) mode DQSMD controls the read clock source of SDRAM, NOR and SRAM in synchronous mode. When it set, the read clock is loopbacked from DQS pad, it benefits the read path timing, and can get high read clock frequency. Delay Chain Control Register (DCCR) register can slightly adjust the DQS timing if DQS is faster than read data in sample phase. 0b - Dummy read strobe loopbacked internally 1b - Dummy read strobe loopbacked from DQS pad
1 MDIS	Module Disable When this bit set, the SEMC internal clock is stopped, and no function is available except register access. 0b - Module enabled 1b - Module disabled
0 SWRST	Software Reset Reset all internal logic in the SEMC except configuration registers. It is an auto clear bit. 0b - No reset 1b - Reset

29.7.1.3 IO MUX Control Register (IOCR)

29.7.1.3.1 Offset

Register	Offset
IOCR	4h

29.7.1.3.2 Diagram



29.7.1.3.3 Fields

Field	Function
31-30 —	Reserved
29 CLKX1_AO	SEMC_CLKX1 Always On This field controls the clock gating of SEMC_CLKX1 signal. 0b - SEMC_CLKX1 is controlled by MUX_CLKX1 1b - SEMC_CLKX1 is always on
28 CLKX0_AO	SEMC_CLKX0 Always On This field controls the clock gating of SEMC_CLKX0 signal. 0b - SEMC_CLKX0 is controlled by MUX_CLKX0 1b - SEMC_CLKX0 is always on
27-26 MUX_CLKX1	SEMC_CLKX1 function selection This field controls the clock source of SEMC_CLKX1 signal. 00b - Keep low 01b - NOR clock 10b - SRAM clock 11b - NOR and SRAM clock, suitable for Multi-Chip Product package
25-24 MUX_CLKX0	SEMC_CLKX0 function selection This field controls the clock source of SEMC_CLKX0 signal. 00b - Keep low 01b - NOR clock

Table continues on the next page...

Field	Function
	10b - SRAM clock 11b - NOR and SRAM clock, suitable for Multi-Chip Product package
23-20 MUX_RDY	SEMC_RDY function selection This field controls the function of SEMC_RDY signal. 0000b - NAND R/B# input 0001b - SDRAM CS1 0010b - SDRAM CS2 0011b - SDRAM CS3 0100b - NOR/SRAM Address bit 27 (A27) in Non-ADMUX mode 0101b - NOR CE# 0110b - SRAM CE# 0 0111b - DBI CSX 1000b - SRAM CE# 1 1001b - SRAM CE# 2 1010b - SRAM CE# 3 1011b-1111b - NOR/SRAM Address bit 27 in Non-ADMUX mode
19-16 MUX_CSX3	SEMC_CSX3 output selection This field controls the function of SEMC_CSX3 signal. 0000b - NOR/SRAM Address bit 27 (A27) in Non-ADMUX mode 0001b - SDRAM CS1 0010b - SDRAM CS2 0011b - SDRAM CS3 0100b - NAND CE# 0101b - NOR CE# 0110b - SRAM CE# 0 0111b - DBI CSX 1000b - SRAM CE# 1 1001b - SRAM CE# 2 1010b - SRAM CE# 3 1011b-1111b - NOR/SRAM Address bit 27 (A27) in Non-ADMUX mode
15-12 MUX_CSX2	SEMC_CSX2 output selection This field controls the function of SEMC_CSX2 signal. 0000b - NOR/SRAM Address bit 26 (A26) in Non-ADMUX mode 0001b - SDRAM CS1 0010b - SDRAM CS2 0011b - SDRAM CS3 0100b - NAND CE# 0101b - NOR CE# 0110b - SRAM CE# 0 0111b - DBI CSX 1000b - SRAM CE# 1 1001b - SRAM CE# 2 1010b - SRAM CE# 3 1011b-1111b - NOR/SRAM Address bit 26 (A26) in Non-ADMUX mode
11-8 MUX_CSX1	SEMC_CSX1 output selection This field controls the function of SEMC_CSX1 signal. 0000b - NOR/SRAM Address bit 25 (A25) in Non-ADMUX mode 0001b - SDRAM CS1 0010b - SDRAM CS2 0011b - SDRAM CS3 0100b - NAND CE# 0101b - NOR CE# 0110b - SRAM CE# 0 0111b - DBI CSX

Table continues on the next page...

Field	Function
	1000b - SRAM CE# 1 1001b - SRAM CE# 2 1010b - SRAM CE# 3 1011b-1111b - NOR/SRAM Address bit 25 (A25) in Non-ADMUX mode
7-4 MUX_CSX0	SEMC_CSX0 output selection This field controls the function of SEMC_CSX0 signal. 0000b - NOR/SRAM Address bit 24 (A24) in Non-ADMUX mode 0001b - SDRAM CS1 0010b - SDRAM CS2 0011b - SDRAM CS3 0100b - NAND CE# 0101b - NOR CE# 0110b - SRAM CE# 0 0111b - DBI CSX 1000b - SRAM CE# 1 1001b - SRAM CE# 2 1010b - SRAM CE# 3 1011b-1111b - NOR/SRAM Address bit 24 (A24) in Non-ADMUX mode
3-0 MUX_A8	SEMC_ADDR08 output selection This field controls the function of SEMC_ADDR08 signal. 0000b-0011b - SDRAM Address bit 8 (A8) or NOR/SRAM Address bit 24 (A24) in ADMUX 16bit mode 0100b - NAND CE# 0101b - NOR CE# 0110b - SRAM CE# 0 0111b - DBI CSX 1000b - SRAM CE# 1 1001b - SRAM CE# 2 1010b - SRAM CE# 3 1011b-1111b - SDRAM Address bit 8 (A8) or NOR/SRAM Address bit 24 (A24) in ADMUX 16bit mode

29.7.1.4 Bus (AXI) Master Control Register 0 (BMCR0)

29.7.1.4.1 Offset

Register	Offset
BMCR0	8h

29.7.1.4.2 Function

Queue A weight settings for AXI bus access to SDRAM, NAND, NOR, SRAM and DBI slaves.

NOTE

Please refer to BMCR0 Register Configuration

29.7.1.4.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	Reserved								WRWS							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	WSH								WAGE				WQOS			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

29.7.1.4.4 Fields

Field	Function
31-24 —	Reserved
23-16 WRWS	Weight of slave hit with Read/Write Switch This weight score is valid when the queue command's slave is same as current executing command with read/write operation switch.
15-8 WSH	Weight of Slave Hit without read/write switch This weight score is valid when queue command's slave is the same as current executing command without read/write operation switch.
7-4 WAGE	Weight of AGE Each command in queue has an age score to indicate its wait period. The age score is multiplied by WAGE to get the weight score. Recommend to use non-zero value.
3-0 WQOS	Weight of QOS AXI bus access has AxQOS signal set, which is used as a priority indicator for the associated write or read transaction. A higher value indicates a higher priority transaction. AxQOS is multiplied by WQOS to get the weight score.

29.7.1.5 Bus (AXI) Master Control Register 1 (BMCR1)

29.7.1.5.1 Offset

Register	Offset
BMCR1	Ch

29.7.1.5.2 Function

Queue B weight settings for AXI bus access to SDRAM slave.

NOTE

Please refer to BMCR1 Register Configuration

29.7.1.5.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	WBR								WRWS							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	WPH								WAGE				WQOS			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

29.7.1.5.4 Fields

Field	Function
31-24 WBR	Weight of Bank Rotation This weight score is valid when queue command's bank is not same as current executing command.
23-16 WRWS	Weight of slave hit without Read/Write Switch This weight score is valid when queue command's read/write operation is same as current executing command.
15-8 WPH	Weight of Page Hit This weight score is valid when queue command's page hits current executing command.
7-4 WAGE	Weight of AGE Each command in queue has an age signal to indicate its wait period. It is multiplied by WAGE to get the weight score. Recommend to use non-zero value.
3-0 WQOS	Weight of QOS AXI bus access has AxQOS signal set, which is used as a priority indicator for the associated write or read transaction. A higher value indicates a higher priority transaction. AxQOS is multiplied by WQOS to get the weight score.

29.7.1.6 Base Register n (BR0 - BR8)

29.7.1.6.1 Offset

For n = 0 to 8:

Register	Offset
BRn	10h + (n × 4h)

29.7.1.6.2 Function

Table 29-8 shows the detail information about the Base Registers.

Table 29-8. Base Register Information

Register	Reset Value	Purpose	Comments
BR0	0x8000001D	For SDRAM CS0	For AXI and IP commands
BR1	0x8400001C	For SDRAM CS1	For AXI and IP commands
BR2	0x8800001C	For SDRAM CS2	For AXI and IP commands
BR3	0x8C00001C	For SDRAM CS3	For AXI and IP commands
BR4	0x9E00001A	For NAND	For AXI command only
BR5	0x90000018	For NOR	For AXI and IP commands
BR6	0x98000018	For SRAM CS0	For AXI and IP commands
BR7	0x9C00001A	For DBI-B	For AXI and IP commands
BR8	0x00000026	For NAND	For IP command only

NOTE

Base Register 9 (BR9), Base Register 10 (BR10) and Base Register 11 (BR11) show Base Registers for other SRAM devices.

29.7.1.6.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	BA

R W	BA				Reserved						MS					VLD
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

29.7.1.6.4 Fields

Field	Function
31-12 BA	Base Address This field determines high position 20 bits of SoC level base address. The low position 12 bits of the address are all zero. The base address must be within the SEMC range defined for the device memory map.
11-6 —	Reserved
5-1 MS	Memory size It defines the size of the memory. Memory size must be aligned with base address. Memory regions should be configured to avoid overlapping areas. Overlapping regions will cause bus errors. 0_0000b - 4KB 0_0001b - 8KB 0_0010b - 16KB 0_0011b - 32KB 0_0100b - 64KB 0_0101b - 128KB 0_0110b - 256KB 0_0111b - 512KB 0_1000b - 1MB 0_1001b - 2MB 0_1010b - 4MB 0_1011b - 8MB 0_1100b - 16MB 0_1101b - 32MB 0_1110b - 64MB 0_1111b - 128MB 1_0000b - 256MB 1_0001b - 512MB 1_0010b - 1GB 1_0011b - 2GB 1_0100b-1_1111b - 4GB
0 VLD	Valid This bit controls whether the memory is valid or not. 0b - The memory is invalid, can not be accessed. 1b - The memory is valid, can be accessed.

29.7.1.7 DLL Control Register (DLLCR)

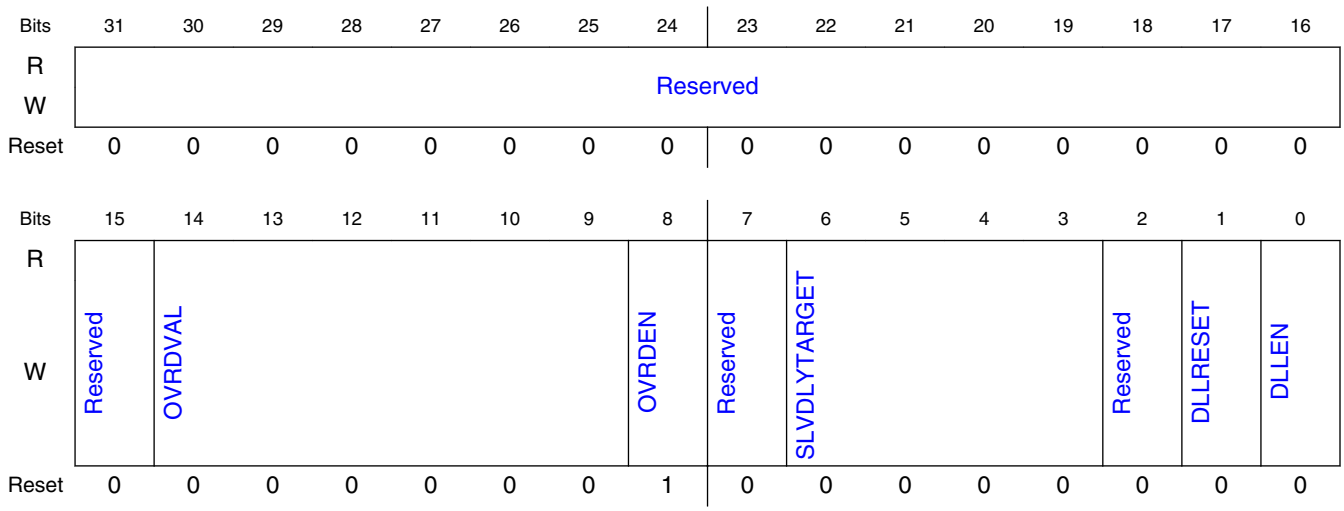
29.7.1.7.1 Offset

Register	Offset
DLLCR	34h

29.7.1.7.2 Function

This register provides the configuration fields for sample clock from DLL. It is for NAND only.

29.7.1.7.3 Diagram



29.7.1.7.4 Fields

Field	Function
31-15 —	Reserved
14-9 OVRDVAL	Override Value When OVRDEN is set, the delay cell number is OVRDVAL+1 for slave clock delay line.
8 OVRDEN	Override Enable Slave clock delay line delay cell number selection override enable. 0b - The delay cell number is not overridden. 1b - The delay cell number is overridden.
7 —	Reserved
6-3 SLVDLYTARGET	Delay Target for Slave The delay target for slave delay line is: ((SLVDLYTARGET+1) * 1/32 * clock cycle of reference clock (ipgclock).
2 —	Reserved
1 DLLRESET	DLL Reset Software can force a reset on DLL by setting this field to 0x1. This causes the DLL to lose lock and re-calibrate to detect an ref_clock half period phase shift. The reset action is edge triggered, so software need to clear this bit after setting this bit (no delay limitation).

Table continues on the next page...

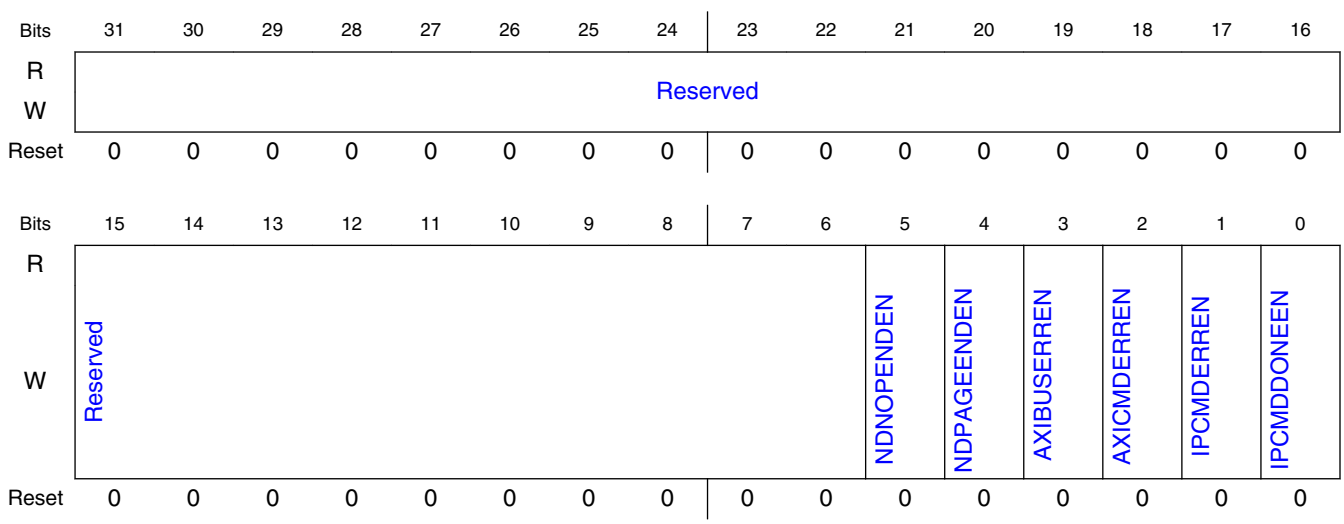
Field	Function
	0b - DLL is not reset. 1b - DLL is reset.
0 DLLEN	DLL calibration enable When this bit is cleared, DLL calibration is disabled and the delay cell number in slave delay line is always 1. Please note that SLV delay line is overridden when OVRDEN bit is set and this bit field setting is ignored. 0b - DLL calibration is disabled. 1b - DLL calibration is enabled.

29.7.1.8 Interrupt Enable Register (INTEN)

29.7.1.8.1 Offset

Register	Offset
INTEN	38h

29.7.1.8.2 Diagram



29.7.1.8.3 Fields

Field	Function
31-6 —	Reserved

Table continues on the next page...

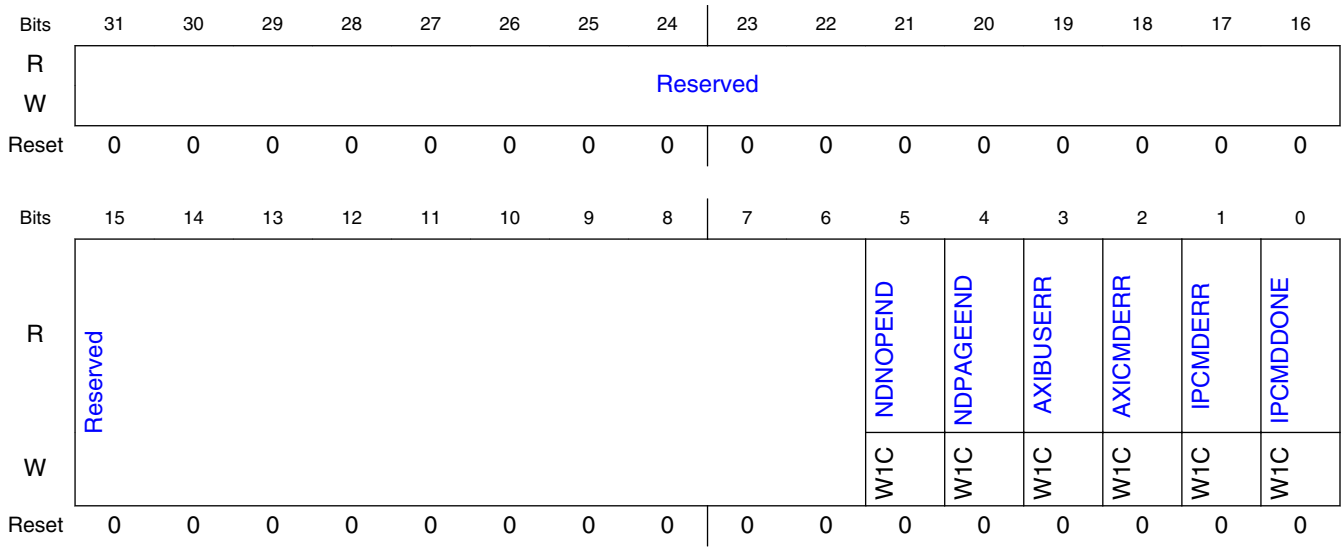
Field	Function
5 NDNOPENDEN	NAND no pending AXI access interrupt enable This bit enable/disable the NDNOPEND interrupt generation. 0b - Interrupt is disabled 1b - Interrupt is enabled
4 NDPAGEENDEN	NAND page end interrupt enable This bit enable/disable the NDPAGEEND interrupt generation. 0b - Interrupt is disabled 1b - Interrupt is enabled
3 AXIBUSERREN	AXI bus error interrupt enable 0b - Interrupt is disabled 1b - Interrupt is enabled
2 AXICMDERREN	AXI command error interrupt enable 0b - Interrupt is disabled 1b - Interrupt is enabled
1 IPCMDERREN	IP command error interrupt enable 0b - Interrupt is disabled 1b - Interrupt is enabled
0 IPCMDDONEEN	IP command done interrupt enable 0b - Interrupt is disabled 1b - Interrupt is enabled

29.7.1.9 Interrupt Register (INTR)

29.7.1.9.1 Offset

Register	Offset
INTR	3Ch

29.7.1.9.2 Diagram



29.7.1.9.3 Fields

Field	Function
31-6 —	Reserved
5 NDNOPEND	NAND no pending AXI write transaction interrupt This interrupt is generated when all pending AXI write transactions to NAND are finished. 0b - At least one NAND AXI write transaction is pending or no NAND write transaction is sent to the queue. 1b - All NAND AXI write pending transactions are finished.
4 NDPAGEEND	NAND page end interrupt This interrupt is generated when the last address of one page in NAND device is written by AXI command. 0b - The last address of main space in the NAND is not written by AXI command. 1b - The last address of main space in the NAND is written by AXI command.
3 AXIBUSERR	AXI bus error interrupt AXI Bus error interrupt is generated in following cases: • AXI address is invalid • AXI write to NOR Flash • AXI 8-bit write to 16-bit NAND Flash • AXI 8-bit or 16-bit WRAP write/read 0b - No AXI bus error. 1b - AXI bus error occurs.
2 AXICMDERR	AXI command error interrupt AXI command error interrupt is generated when AXI command execution times out. 0b - No AXI command error. 1b - AXI command error occurs.
1	IP command error done interrupt

Table continues on the next page...

Field	Function
IPCMDERR	IP command error interrupt is generated in following cases: • IP Command Address target invalid device space • IP Command Code unsupported • IP Command triggered when previous command not finished yet • IP Command Execution timeout 0b - No IP command error. 1b - IP command error occurs.
0 IPCMDDONE	IP command normal done interrupt It monitors whether IP command is done or not. 0b - IP command is not done. 1b - IP command is done.

29.7.1.10 SDRAM Control Register 0 (SDRAMCR0)

29.7.1.10.1 Offset

Register	Offset
SDRAMCR0	40h

29.7.1.11.3 Fields

Field	Function
31-24 —	Reserved
23-20 ACT2PRE	ACTIVE to PRECHARGE minimum time The SEMC promises ACT2PRE+1 clock cycles delay between ACTIVE command to PRECHARGE/ PRECHARGE ALL command. It helps to meet tRAS timing requirement by SDRAM device.
19-16 CKEOFF	CKE off minimum time The SEMC promises at least CKEOFF+1 clock cycles in self refresh mode. It helps to meet the minimum period request to remain in self refresh mode.
15-13 WRC	WRITE recovery time The SEMC promises WRC+1 clock cycles delay between WRITE command to PRECHARGE/ PRECHARGE ALL command. It helps to meet tWR timing requirement by SDRAM device.
12-8 RFRC	REFRESH recovery time The SEMC promises RFRC+1 clock cycles delay between AUTO REFRESH command to ACTIVE command. It helps to meet tRFC timing requirement by SDRAM device.
7-4 ACT2RW	ACTIVE to READ/WRITE delay The SEMC promises ACT2RW+1 clock cycles delay between ACTIVE command to READ/WRITE command. It helps to meet tRCD timing requirement by SDRAM device.
3-0 PRE2ACT	PRECHARGE to ACTIVE/REFRESH command wait time The SEMC promises PRE2ACT+1 clock cycles delay between PRECHARGE/PRECHARGE ALL command to ACTIVE/REFRESH command. It helps to meet tRP timing requirement by SDRAM device.

29.7.1.12 SDRAM Control Register 2 (SDRAMCR2)

29.7.1.12.1 Offset

Reset	0	0	0	0	1	1	1	0	1	1	1	0	1	1	1	0

29.7.1.12.3 Fields

Field	Function
31-24 ITO	SDRAM idle timeout The SEMC closes all opened pages if the SDRAM idle time lasts more than idle timeout period. SDRAM is considered idle when there is no AXI Bus transfer and no SDRAM command pending. 0000_0000b - IDLE timeout period is 256*Prescale period. 0000_0001b-1111_1111b - IDLE timeout period is ITO*Prescale period.
23-16 ACT2ACT	ACTIVE to ACTIVE delay The SEMC promises ACT2ACT+1 clock cycles delay between ACTIVE command to ACTIVE command. It helps to meet tRRD timing requirement by SDRAM device.
15-8 REF2REF	REFRESH to REFRESH delay The SEMC promises REF2REF+1 clock cycles delay between REFRESH command to REFRESH command. It helps to meet tRFC timing requirement by SDRAM device.
7-0 SRRC	SELF REFRESH recovery time The SEMC promises SRRC+1 clock cycles delay between SELF REFRESH command to any subsequent command. SDRAM device may have limitation on self refresh recovery time. It help to meet the wait time from exiting self refresh mode to sending new command to device.

29.7.1.13 SDRAM Control Register 3 (SDRAMCR3)

29.7.1.13.1 Offset

R W	UT								RT							
Reset	0	1	0	0	0	0	0	0	1	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	PRESCALE								Reserved				REBL			REN
Reset	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

29.7.1.13.3 Fields

Field	Function
31-24 UT	Urgent refresh threshold Urgent refresh threshold is used to handle urgent refresh request. Urgent refresh timer starts to count when normal refresh request is asserted but not handled by the controller yet. When the urgent refresh timer count up to the threshold, urgent refresh request is sent to the controller. The priority of urgent refresh is higher than any pending AXI or IP command to SDRAM, so it can be handled by the controller at the first time. **NOTE:** Refresh request is considered as urgent refresh request when urgent threshold is no less than refresh period. 0000_0000b - 256*(Prescaler period) 0000_0001b-1111_1111b - UT*(Prescaler period)
23-16 RT	Refresh timer period Refresh timer period is the threshold for SDRAM normal refresh request. The normal refresh request is sent to the controller when the refresh timer count up to it. The priority of normal refresh request is lower than any pending AXI or IP command to SDRAM. 0000_0000b - (256+1)*(Prescaler period) 0000_0001b-1111_1111b - (RT+1)*(Prescaler period)
15-8 PRESCALE	Prescaler period Prescaler period is used as a clock cycle count unit for refresh and bus idle timer period.

Table continues on the next page...

Field	Function
	0000_0000b - (256*16+1) clock cycles 0000_0001b-1111_1111b - (PRESCALE*16+1) clock cycles
7-4 —	Reserved
3-1 REBL	Refresh burst length The SEMC can send multiple AUTO REFRESH commands in one burst when REBL is set to non-zero. The number of AUTO REFRESH command in one burst is listed below. 000b - 1 001b - 2 010b - 3 011b - 4 100b - 5 101b - 6 110b - 7 111b - 8
0 REN	Refresh enable The SEMC sends AUTO REFRESH command automatically when REN bit is set. The AUTO REFRESH command interval is decided by UT, RT and PRESCALE bits. 0b - The SEMC does not send AUTO REFRESH command automatically 1b - The SEMC sends AUTO REFRESH command automatically

29.7.1.14 NAND Control Register 0 (NANDCR0)

29.7.1.15.3 Fields

Field	Function
31-28 CEITV	CE# interval time CE# interval minimum time is CEITV+1 clock cycles.
27-24 TA	Turnaround time Turnaround time is TA+1 clock cycles. Both the SEMC and Device do not drive Data Lines to avoid bus confliction. This field applied to ASYNC mode only.
23-20 REH	RE# high time RE# high time is REH+1 clock cycles. This field applied to ASYNC mode only.
19-16 REL	RE# low time RE# low time is REL+1 clock cycles. This field applied to ASYNC mode only.
15-12 WEH	WE# high time WE# high time is WEH+1 clock cycles in ASYNC mode. It is used as command and address hold time in SYNC mode. WEH must be even number in SYNC mode, and command/address hold time is WEH clock cycles.
11-8 WEL	WE# low time WE# low time is WEL+1 clock cycles in ASYNC mode. It is used as command and address setup time in SYNC mode. WEL must be even number in SYNC mode, and command/address setup time is WEL+2 clock cycles.
7-4 CEH	CE# hold time CE# hold minimum time is CEH+1 clock cycles. CEH must be odd number in SYNC mode. CE# hold time may be larger than this time to wait all read data sampled.
3-0	CE# setup time

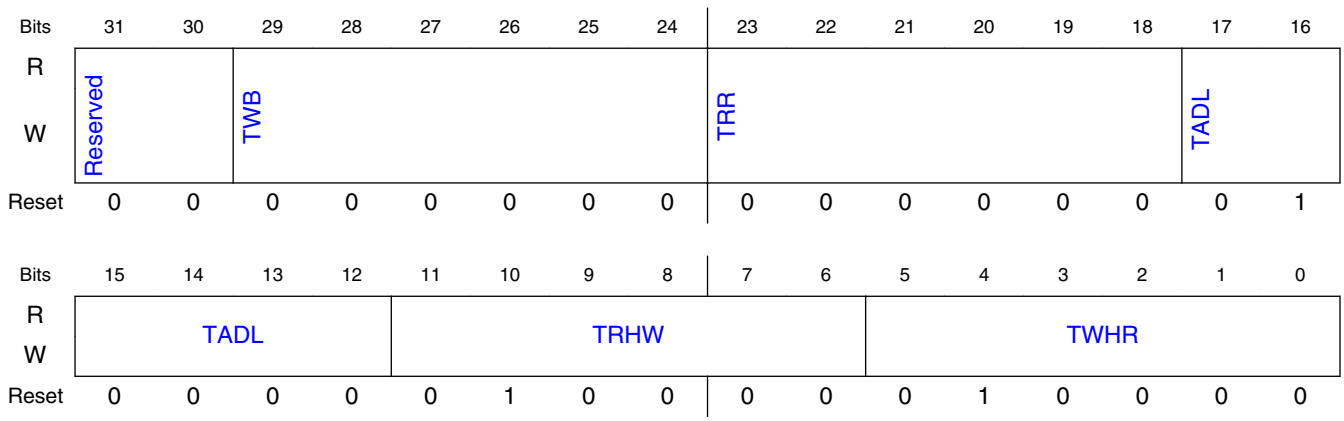
Field	Function
CES	CE# setup time is CES+1 clock cycles. CES must be odd number in SYNC mode.

29.7.1.16 NAND Control Register 2 (NANDCR2)

29.7.1.16.1 Offset

Register	Offset
NANDCR2	58h

29.7.1.16.2 Diagram



29.7.1.16.3 Fields

Field	Function
31-30 —	Reserved
29-24 TWB	WE# high to busy time WE# high to busy time is TWB+1 clock cycles
23-18 TRR	Ready to RE# low time Ready to RE# low minimum time is TRR+1 clock cycles. Actual time may be 1 or 2 clock cycles more than this because of synchronizer logic. This field applied to ASYNC mode only.
17-12 TADL	Address cycle to data loading time Address to data loading time is TADL+1 clock cycles. Timing for TADL begins in the address cycle on the final rising edge of WE#, and ends with the first rising edge of WE# for data input.

Table continues on the next page...

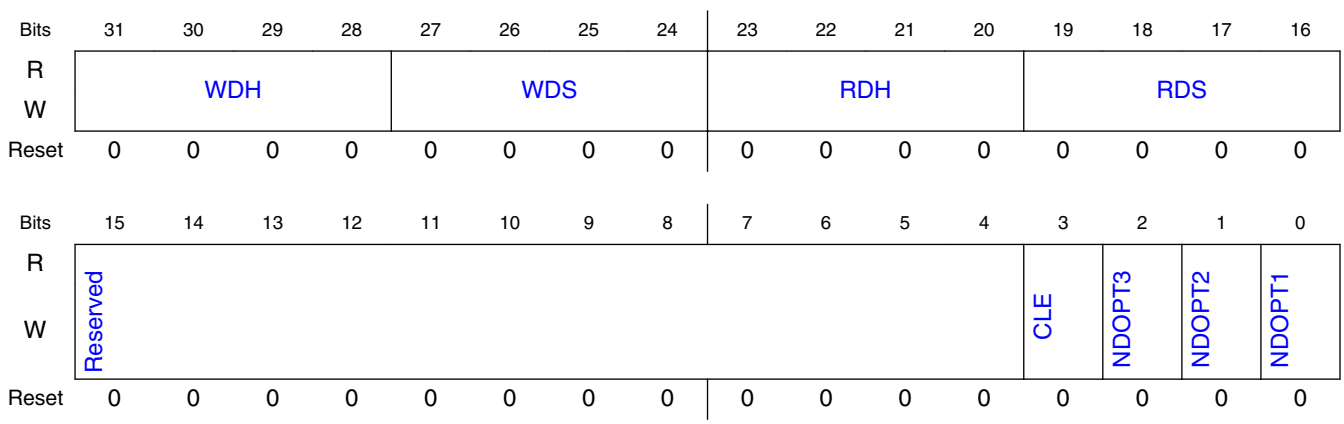
Field	Function
11-6 TRHW	RE# high to WE# low time RE# high to WE# low time is TRHW+1 clock cycles
5-0 TWHR	WE# high to RE# low time WE# high to RE# low time is TWHR+1 clock cycles in ASYNC mode. TWHR represents command, address or data input cycle to data output clock cycles in SYNC mode. The delay is TWHR+2 clock cycles and TWHR must be even.

29.7.1.17 NAND Control Register 3 (NANDCR3)

29.7.1.17.1 Offset

Register	Offset
NANDCR3	5Ch

29.7.1.17.2 Diagram



29.7.1.17.3 Fields

Field	Function
31-28 WDH	Write Data Hold time Write data hold time is WDH+2 clock cycles, and WDH must be even number. This field applied to SYNC mode only.
27-24 WDS	Write Data Setup time Write data setup time is WDS+2 clock cycles, and WDS must be even number. This field applied to SYNC mode only.

Table continues on the next page...

Field	Function
23-20 RDH	Read Data Hold time Read data hold time is RDH+2 clock cycles, and RDH must be even number. This field applied to SYNC mode only.
19-16 RDS	Read Data Setup time Read data setup time is RDS+2 clock cycles, and RDS must be even number. It provides the minimum timing control before data output phase. This field applied to SYNC mode only.
15-4 —	Reserved
3 CLE	NAND CLE Option This bit is intended to add a CLE valid clock cycle before WE# valid clock cycle for ASYNC mode.
2 NDOPT3	NAND option bit 3 This bit is intended to bypass row address byte #1 for address mode 0x0 - Column and Row address(5 Byte-CA0/CA1/RA0/RA1/RA2).
1 NDOPT2	NAND option bit 2 This bit is intended to bypass row address byte #2 for address mode 0x0 - Column and Row address(5 Byte-CA0/CA1/RA0/RA1/RA2).
0 NDOPT1	NAND option bit 1 This bit is intended to bypass column address byte #1 for address mode 0x0 - Column and Row address(5 Byte-CA0/CA1/RA0/RA1/RA2). **NOTE:** Please refer to NAND Flash Access Address Type

23-22 —	Reserved
21-17 SRAM0VAL	Clock delay line delay cell number selection value for SRAM device 0. When SRAM0EN is set, the delay cell number in delay chain is SRAM0VAL+1.
16 SRAM0EN	Delay chain insertion enable for SRAM device 0. 0b - Delay chain is not inserted. 1b - Delay chain is inserted.
15-14 —	Reserved
13-9 NORVAL	Clock delay line delay cell number selection value for NOR device. When NOREN is set, the delay cell number in delay chain is NORVAL+1.
8 NOREN	Delay chain insertion enable for NOR device. 0b - Delay chain is not inserted. 1b - Delay chain is inserted.
7-6 —	Reserved

Table continues on the next page...

Field	Function
5-1 SDRAMVAL	Clock delay line delay cell number selection value for SDRAM device. When SDRAMEN is set, the delay cell number in delay chain is SDRAMVAL+1.
0 SDRAMEN	Delay chain insertion enable for SRAM device. 0b - Delay chain is not inserted. 1b - Delay chain is inserted.

Chapter 30
FlexSPI Controller (FLEXSPI)

30.1 Chip-specific FlexSPI information

Table 30-1. Reference links to related information

Topic	Related module(s)	Reference
System memory map	-	System Memory Map
Clocking	CCM	Clock Management Clock Control Module (CCM)
Power management	PMU	Power Management Power Management Unit
Signal multiplexing	IOMUX	External Signals and Pin Multiplexing IOMUX
Interrupts, DMA Events and XBAR Assignments	-	Interrupts, DMA Events and XBAR Assignments

NOTE

- The soft reset bit (MCR_SWRESET) should be set, to enable the inverted clock, after setting the SCKBDIFFOPT bit.
- For Octal mode support, refer to Table 30-4.
- ARM AXIM access to FlexSPI is converted to AHB command access of FlexSPI, on this device.

30.1.1 AHB Memory Map Address Ranges

The table below shows the address range calculations for the various instances of FlexSPI:

Table 30-2. Memory Map Address Range Calculations

Description	FlexSPI1	FlexSPI2
address range is mapped for AHB read access to IP RX FIFO:	- 0x2FC0_0000 – 0x2FC0_00FF	- 0x7FC0_0000 – 0x7FC0_00FF
address range is mapped for AHB write access to IP TX FIFO:	- 0x2F80_0000 – 0x2F80_00FF	- 0x7F80_0000 – 0x7F80_00FF
AHB Memory Map for Serial Flash memory access	- 0x3000_0000	- 0x6000_0000
Total AHB RX Buffer size:	- 4 KBytes	- 4 KBytes
AHB TX Buffer size:	- 64 Bytes	- 64 Bytes
IP Bus memory space access:	- 0x2FC0_0000 – 0x2FC0_00FF	- 0x7FC0_0000 – 0x7FC0_00FF
AHB bus memory space access:	- 0x3000_0000 – 0x3FFF_FFFF	- 0x6000_0000 – 0x6FFF_FFFF

30.1.2 Master ID allocation

To enable FlexSPI to view different IDs from different masters, follow the steps shown below:

- Set AHBCR[HMSTRIDREMAP] =1 to enable master ID mapping
- Configure HMSTRxCR[MSTRID] using the table below (The “x” should be masked by the mask value. Other bits can be selectively masked to group some masters into one AHB buffer region):

Table 30-3. Master IDs

Module	Master ID
CM7	xxxx xxxx xxxx x000
eDMA	xxxx_xxxx_xxxx_x101
CM4	xxxx_xxxx_xxxx_x100
EDMA_LPSR	xxxx_xxxx_xxxx_x100
CAAM	xxxx_xxxx_x0000_011
ENET_1G TX	xxxx_xxxx_x0001_011
ENET_1G RX	xxxx_xxxx_x0010_011
USB	xxxx_xxxx_x0100_011
ENET	xxxx_xxxx_x0011_011
USDHC1	xxxx_xxxx_x0101_011

Table continues on the next page...

Table 30-3. Master IDs (continued)

Module	Master ID
USDHC2	xxxx_xxxx_x0110_011
ENET QOS	xxxx_xxxx_x1000_011
GPU	xxxx_xxxx_xx000_001
PXP	xxxx_xxxx_xx001_001
ELCDIF	xxxx_xxxx_xx001_010
LCDIFv2	xxxx_xxxx_xx010_010
CSI	xxxx_xxxx_xx011_010

NOTE

- After reset, the FlexSPI sees all masters IDs as zero

30.1.3 FlexSPI connection modes

The table below shows details about the Parallel, Individual, and Combination modes for Flash memory.

Table 30-4. Relation between Modes and Bus size for FlexSPI instances

Mode	Instance	Effective Bus Size	Data Signals	Function	Devices Attached to Bus	Chip Selects
INDIVIDUAL	FLEXSPI1	4 bit	A_DATA0 - A_DATA3	Single QSPI chip support (1b, 2b,4b)	Up to 2	A_SS0_B, A_SS1_B
INDIVIDUAL	FLEXSPI1	4 bit	B_DATA0 - B_DATA3	Single QSPI chip support (1b, 2b,4b)	Up to 2	B_SS0_B, B_SS1_B
INDIVIDUAL	FLEXSPI2	4 bit	A_DATA0 - A_DATA3	Single QSPI chip support (1b, 2b,4b)	Up to 2	A_SS0_B, A_SS1_B
INDIVIDUAL	FLEXSPI2	4 bit	B_DATA0 - B_DATA3	Single QSPI chip support (1b, 2b,4b)	Up to 2	B_SS0_B, B_SS1_B
INDIVIDUAL	FLEXSPI2	8 bit	A_DATA0 - A_DATA7	Single Octal/ Hyperbus/ Xccela chip support (1x8b)	Up to 2	A_SS0_B, A_SS1_B
INDIVIDUAL	FLEXSPI2	8 bit	B_DATA0 - B_DATA7	Single Octal/ Hyperbus/ Xccela chip support (1x8b)	Up to 2	B_SS0_B, B_SS1_B

Table continues on the next page...

Table 30-4. Relation between Modes and Bus size for FlexSPI instances (continued)

COMBINE	FLEXSPI1	8 bit	A_DATA0 - A_DATA3 | B_DATA0 - B_DATA3	Single Octal/ Hyperbus/ Xccela chip support (1x8b)	Up to 2	A_SS0_B, A_SS1_B
PARALLEL	FLEXSPI1	8 bit	A_DATA0 - A_DATA3 | B_DATA0 - B_DATA3	Two QSPI chips in parallel (2x4b)	2 parallel chips x 2 = up to 4	(A_SS0_B | B_SS0_B), (A_SS1_B | B_SS1_B)
PARALLEL	FLEXSPI2	8 bit	A_DATA0 - A_DATA3 | B_DATA0 - B_DATA3	Two QSPI chips in parallel (2x4b)	2 parallel chips x 2 = up to 4	(A_SS0_B | B_SS0_B), (A_SS1_B | B_SS1_B)

30.1.4 FlexSPI memory details

The table below shows the FlexSPI memory details

Table 30-5. FlexSPI memory details

Start address	End address	Size(kB)	Description
3000_0000	3FFF_FFFF	256MB	FlexSPI1/ FlexSPI1 cipher text
6000_0000	7F7F_FFFF	504MB	FlexSPI2/ FlexSPI2 ciphertext

30.2 Overview

FlexSPI supports two SPI channels and up to four external devices. Each channel supports Single/Dual/Quad/Octal mode data transfer (1/2/4/8 bidirectional data lines).

The FlexSPI configuration depends on the chip configuration. See the system-level section for boot information and pinmux for chip-specific information regarding the modes and number of devices supported.

FlexSPI supports communication with both serial flash memory and serial RAM devices. While many of the descriptions, registers, and fields specifically reference flash memory, almost all information can also be applied to serial RAM. Flash memory is used as an example in the tables and figures in this chapter.

NOTE

Terminology in this chapter has been updated to align with JEDEC standard *EXpanded Serial Peripheral Interface (xSPI) for Non Volatile Memory Devices, Version 1.0*.

Table 30-6. Updated terms

Updated term	Deprecated term
Controller	Master
Target	Slave

30.2.1 Block diagram

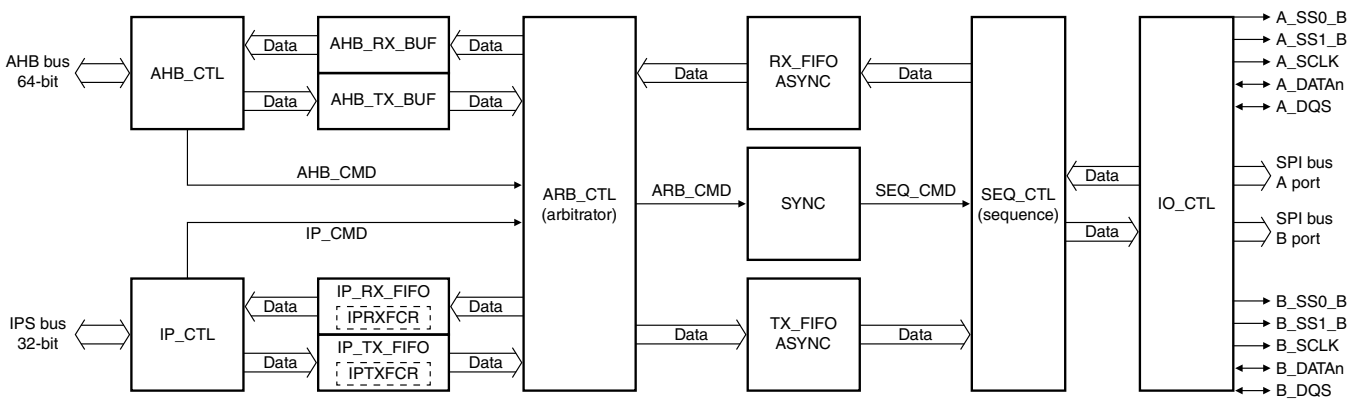

Figure 30-1. Block diagram

30.2.2 Features

FlexSPI supports:

- Flexible sequence engine (lookup table) to support various vendor devices
  - Serial NOR flash memory and other devices with SPI protocol similar to serial NOR flash memory
  - Serial NAND flash memory
  - HyperBus devices (HyperFlash/HyperRAM)
  - XCCELA devices
  - FPGA devices
- Flash memory access modes
  - Single, Dual, Quad, Octal mode
  - Single Data Transfer Rate (SDR) and Double Data Transfer Rate (DDR) mode
  - Individual/Parallel mode
- Sampling clock mode
  - Internal dummy read strobe looped back internally
  - Internal dummy read strobe looped back from pad
  - Flash-memory-provided read strobe

- Memory mapped read and write access by AHB bus
  - AHB receive buffer implemented to reduce read latency. See the chip-specific section for AHB buffer size.
  - 16 AHB controllers with programmable priority for read access from each
  - 8 flexible and configurable buffers in AHB receive buffer
  - AHB transmit buffer implemented to buffer all write data from one AHB burst. See the chip-specific section for AHB buffer size.

Note

All AHB controllers share this AHB transmit buffer. There is no AHB controller number limitation for write access.

- Software-triggered flash memory read and write access by IP bus
  - IP receive FIFO implemented to buffer all read data from external devices. FIFO size: 256 bytes
  - IP transmit FIFO implemented to buffer all write data to external devices. FIFO size: 256 bytes
  - DMA support to read IP receive FIFO
  - DMA support to fill IP transmit FIFO
  - SCLK stops when IP receive FIFO is full during reading flash memory data
  - SCLK stops when IP transmit FIFO is empty during writing flash memory data

30.3 Functional description

30.3.1 Flash connection

There are two FlexSPI interface ports (port A and port B). Each port supports up to two flash devices by providing two chip select outputs.

NOTE

FlexSPI configuration depends on the chip configuration. See the chip-specific FlexSPI information regarding the number of devices supported.

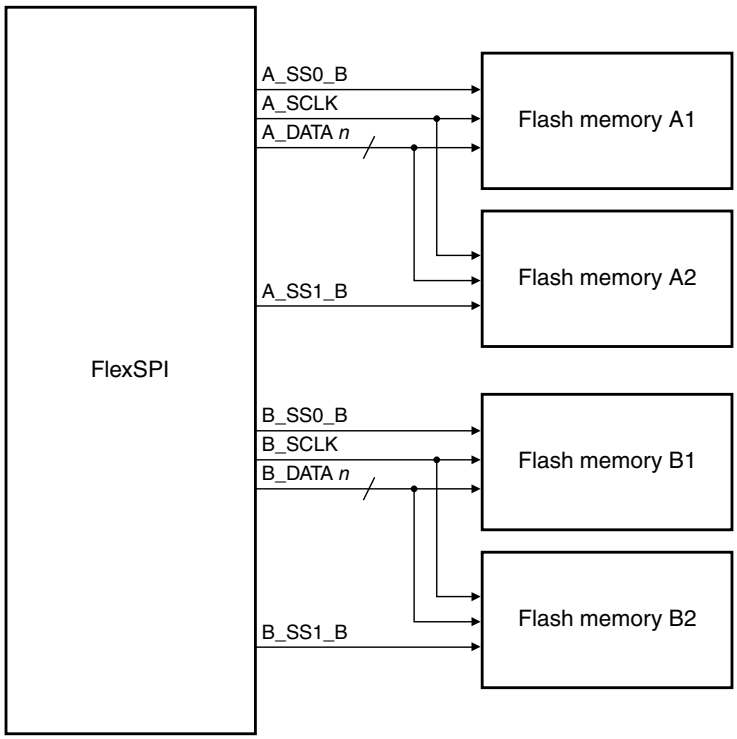

Figure 30-2. FlexSPI connection diagram with four devices

NOTE

- Flash A1 and Flash A2 can be two flash chip packages or two flash dies in the same package. There is no difference to FlexSPI. This statement is also true for Flash B1 and Flash B2.
- Flash A1 and Flash B1 can be accessed in parallel, using parallel mode. FlexSPI merges or splits the flash read and program data automatically. This statement is also true for Flash A2 and Flash B2.
- In parallel mode, Flash A1 and Flash A2 cannot be accessed at the same time. This statement is also true for Flash B1 and Flash B2.
- In individual mode, flash devices cannot be accessed at the same time. But these four devices can be accessed separately.

There is a combination mode (MCR0[COMBINATIONEN] = 1) used to provide octal flash memory support by combining Port A (A_DATA[3:0]) and Port B (B_DATA[3:0]) together. Normal mode can also support Octal mode by using all eight data lines from Port A or Port B.Figure 30-3 shows the connection diagram for combination mode.

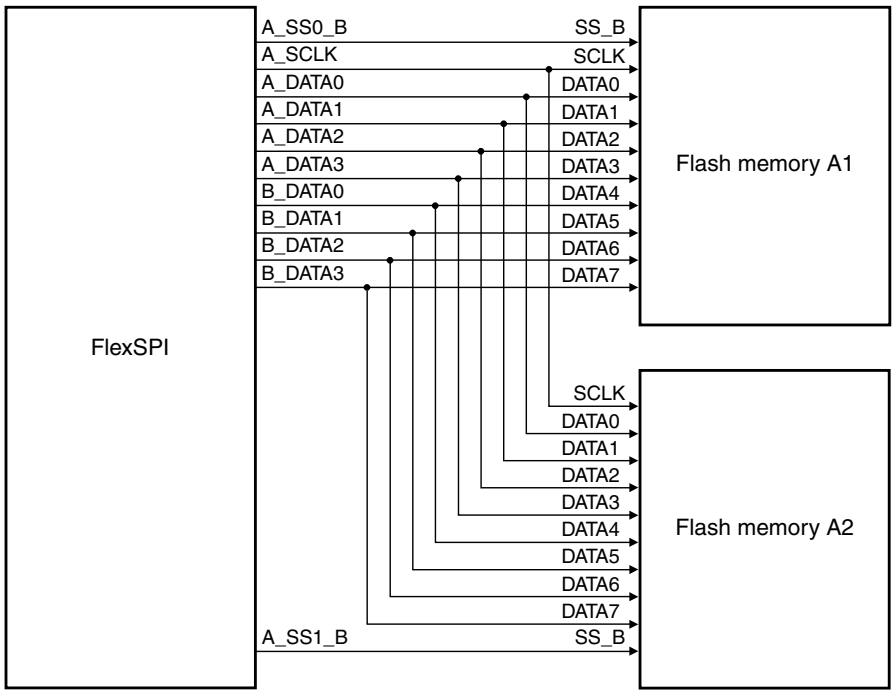

Figure 30-3. FlexSPI connection diagram for combination mode

30.3.2 Flash memory access mode

30.3.2.1 SPI clock mode

FlexSPI only supports SPI clock mode 0: clock polarity (CPOL) = 0 and clock phase (CPHA) = 0. When the SPI bus is idle, SCLK stays at a logic low state.

30.3.2.2 Individual mode and Parallel mode

In individual mode, read and write data are received and transmitted on port A or port B.

In parallel mode, read and write data are received and transmitted on port A and port B in parallel. FlexSPI merges or splits the read and program data automatically (READ/WRITE instruction). Only read and program data is merged or split (READ/WRITE instruction). For other instructions (such as Command, Address, Mode, and Data size), the same associated information is transmitted to the devices connected to port A and port B. For more details, see Executing instructions on SPI interface.

IPCR1[IPAREN] (for IP command) or AHBCR[APAREN] (for AHB command) statistically determines Individual and Parallel mode.

NOTE

FlexSPI does not support 16-bit read and write for the SPI interface.

30.3.2.3 SDR mode and DDR mode

In SDR mode, flash memory receives data on the rising edge of SCLK and transmits data on the falling edge of SCLK.

In DDR mode, flash memory receives and transmits data on both the rising and falling edges of SCLK.

The instruction (opcode) in the LUT sequence dynamically determines SDR and DDR modes. There is no static configuration register field setting for SDR and DDR modes. See FlexSPI input timing and FlexSPI output timing for details about input and output timing.

30.3.2.4 Single, Dual, Quad, and Octal mode

In Single mode, FlexSPI transmits and receives data on one data pin (DATA0 for transmitting, DATA1 for receiving).

In Dual mode, FlexSPI transmits and receives data on two data pins (DATA0–DATA1 for both transmitting and receiving).

In Quad mode, FlexSPI transmits and receives data on four data pins (DATA0–DATA3 for both transmitting and receiving).

In Octal mode, FlexSPI transmits and receives data on eight data pins (DATA0–DATA7 for both transmitting and receiving).

Instruction (num_pads) in the LUT sequence dynamically determine Single, Dual, Quad, and Octal modes. There is no static configuration register field setting for Single, Dual, Quad, and Octal modes.

30.3.3 Modes of operation

FlexSPI operates with these modes.

Table 30-7. Operating modes

Mode	Description
Module Disable	This mode is a low-power mode for FlexSPI. In Module Disable mode, the AHB clock and serial clock domains are gated off internally, but the IPS bus clock domain is not gated off. Read and write access to the control and status register are available, but the LUT, IP receive FIFO, and IP transmit FIFO cannot be accessed. Serial memory access is also not available. Write 1 to MCR0[MDIS] to enter this mode. Write 0 to MCR0[MDIS] to exit this mode.
Doze	This mode is a low-power mode for the chip. When the chip requires FlexSPI to enter Doze mode and MCR0[DOZEEN] = 1, FlexSPI enters Doze mode after all transactions are completed (STS0[ARBIDLE] = 1). In Doze mode, the AHB clock and serial clock domains are gated off internally, but the IPS bus clock is not gated off. Read and write access to the control and status register are available, but the LUT, IP receive FIFO, the IP transmit FIFO cannot be accessed. Serial memory access is also not available. This mode is entered via system request, and exited by deasserting this system request.
Stop	This mode is a low-power mode for the chip. When the chip requires the FlexSPI to enter Stop mode, FlexSPI waits for all transactions to complete (STS0[ARBIDLE] = 1) and return ACK handshake to the system. After the ACK handshake is returned, FlexSPI gates off the AHB clock and serial clock domains internally. The system can gate off the AHB bus clock, IPS bus clock, and serial clock at the system level. This mode is entered via system request. This mode is exited by deasserting this system request, and the ACK handshake message is also deasserted immediately.
Normal	No clock is gated off internally. Normal register access and serial memory access are available.

30.3.4 AHB access memory map

FlexSPI allocates AHB memory space for each memory device starting from the FlexSPI region base address of the system memory map. The FLSHxCR0[FLSHSZ] field determines the amount of memory allocated for each memory device in KB, Fx_SIZE. The memory is then allocated sequentially and contiguously.

NOTE

See the chip-specific section for the maximum flash size supported.

When MCR2[SAMEDEVICEEN] = 1:

- FA1_SIZE = FLSHA1CR0[FLSHSZ] × 1 KB
- FA2_SIZE = FLSHA1CR0[FLSHSZ] × 1 KB
- FB1_SIZE = FLSHA1CR0[FLSHSZ] × 1 KB
- FB2_SIZE = FLSHA1CR0[FLSHSZ] × 1 KB

When MCR2[SAMEDEVICEEN] = 0:

- FA1_SIZE = FLSHSZ × 1 KB

- FA2_SIZE = FLSHA2CR0[FLSHSZ] × 1 KB
- FB1_SIZE = FLSHB1CR0[FLSHSZ] × 1 KB
- FB2_SIZE = FLSHB2CR0[FLSHSZ] × 1 KB

Flash B1 and Flash B2 size settings are ignored in parallel mode (FLSHB1CR0[FLSHSZ], FLSHB2CR0[FLSHSZ]). To execute in parallel mode, Flash B1 should be the same device as Flash A1, and Flash B2 should be the same device as Flash A2.

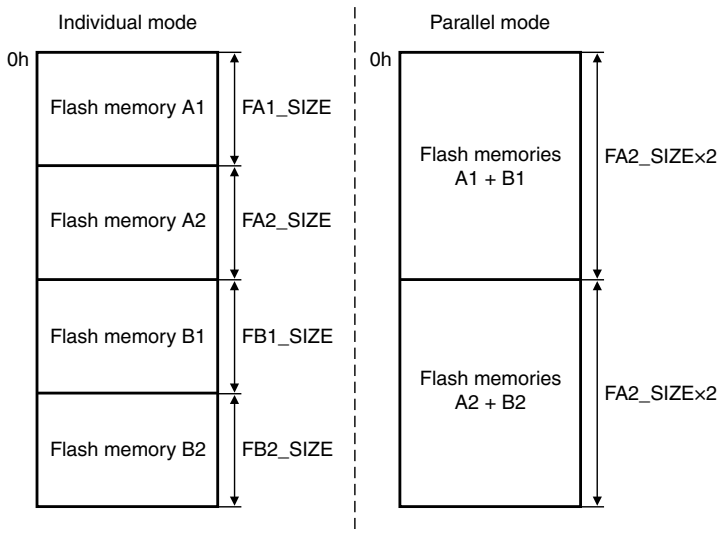

Figure 30-4. AHB access memory map in individual and parallel mode

AHB access memory map in individual mode:

- Flash A1 address range: 0000_0000h to FA1_SIZE
- Flash A2 address range: FA1_SIZE to (FA1_SIZE + FA2_SIZE)
- Flash B1 address range: (FA1_SIZE + FA2_SIZE) to (FA1_SIZE + FA2_SIZE + FB1_SIZE)
- Flash B2 address range: (FA1_SIZE + FA2_SIZE + FB1_SIZE) to (FA1_SIZE + FA2_SIZE + FB1_SIZE + FB2_SIZE)

AHB access memory map in parallel mode:

- Flash A1+B1 address range: 0000_0000h to FA1_SIZE × 2
- Flash A2+B2 address range: FA1_SIZE × 2 to (FA1_SIZE × 2 + FA2_SIZE × 2)

NOTE

The address used in Figure 30-4 and equations in this topic is the address presented to the memory. The base address for FlexSPI in the system memory map has already been removed, so it not used or shown here.

30.3.4.1 Dual image use case using HADDRSTART, HADDREND, and HADDROFFSET registers

The FlexSPI controller has a remap feature that supports the storage of dual images in memory. The HADDRSTART and HADDREND registers can be used to configure an address range to which an offset (that the HADDROFFSET register configures) is applied. This feature allows a single system bus address range to be mapped to two different memory ranges: the range that is remapped or the range that is not remapped. You can enable and disable the remapping to switch between accessing the two images at the same system memory address. This feature is used for booting.

NOTE

- Remapping in this table includes the REMAP register (HADDRSTART[0]) and SWAP register (HADDRSTART[2]).
- The swap function impacts both the AHB and IPS address remapping with the same mechanism. The remap function only impacts the AHB address.

Table 30-8. FlexSPI address translation

	AHB or IPS address	Memory address	Description
Enable remap			
AHB WR	ADDR	ADDR + OFFSET	The remap function is available if HADDRSTART <= ADDR < HADDREND, otherwise no change in address.
AHB RD	ADDR	ADDR + OFFSET	The remap function is available if HADDRSTART <= ADDR <HADDREND, otherwise no change in address.
Disable remap			
AHB WR	ADDR	ADDR	No change in address.
AHB RD	ADDR	ADDR	No change in address.

NOTE

- HADDRSTART[0] is used to enable the remap feature.
- The ADDR above is the address from the IPS or AHB interface. The OFFSET is same as the HADDROFFSET register.

30.3.4.2 Flash address sent to flash memory devices

The AHB address (AHB command) or IPCR0[SFAR] (IP command) determines the flash memory access start address. See Flash memory access via AHB command and Flash memory access via IP command for more details.

For AHB commands, the FlexSPI controller removes the flash memory base address automatically when sending flash addresses to flash devices. The flash address is sent to devices in two parts: row address and column address. For flash devices that do not support the column address, set FLSHxCR1[CAS] to 0. This setting causes all flash address bits to be sent to flash devices as row addresses.

For word-addressable flash devices, the last bit of the address is not needed, because flash memory is read and programmed in terms of two bytes. For parallel mode, Flash A1 and Flash B1 (or Flash A2 and Flash B2) are accessed in parallel. As a result, the flash memory address sent to flash devices should be divided by 2. Table 30-9 indicates the relationship of row address, column address, and flash address (FA).

Table 30-9. Flash address, row address, and column address

Parallel mode	Word-addressable	Row address	Column address	Comment
0	0	FA[31:CAS]	FA[CAS-1:0]	There is no limitation on FA and data size alignment.
0	1	FA[31:CAS+1]	FA[CAS:1]	FA and data size should be two-byte aligned.
1	0	FA[31:CAS+1]	FA[CAS:1]	FA and data size should be two-byte aligned.
1	1	FA[31:CAS+2]	FA[CAS+1:2]	FA and data size should be four-byte aligned.

NOTE

- FA is the flash address without base address.
- If the bit number of the row or column flash address is more than the valid value, the high position bits are supplemented with zero. See Programmable sequence engine for details about row or column address instructions.

When parallel mode is enabled or word-addressable flash memory is used, there are limitations on the flash memory start address and data size. You can address this requirement by aligning the AHB bus access address (for AHB command) or IP command address IPCR0[SFAR] (for IP command) in software. There are two ways to avoid these limitations in the specified case.

1. For AHB Read Command only:

   When AHBCR[READADDROPT] and AHBCR[PREFETCHEN] are both 1, or OTFAD is enabled, FlexSPI guarantees the start address and data size for the flash memory access are eight-byte aligned by hardware.

   When AHBCR[READADDROPT] is 1, or OTFAD is enabled, FlexSPI fetches redundant data to guarantee the flash memory start address is eight-byte aligned. When prefetch is enabled (AHBCR[PREFETCHEN] is 1), the size of the eight-byte-aligned AHB receive buffer determines the flash memory read data size.

2. For AHB Write Command and Individual Mode only:

   By default, FlexSPI guarantees the flash memory write access start address and data size are two-byte aligned when using DQS as write mask (FLSHCR4[WMENB or WMENA] = 1).

   This feature is not applied in parallel mode and must be used if the external device supports write mask feature.

30.3.5 Lookup table (LUT)

The LUT is an internal memory that preserves a number of preprogrammed sequences. Each sequence consists of up to eight instructions which are executed sequentially. When an IP command or an AHB command triggers a flash memory access, the FlexSPI controller:

1. Fetches the sequence from LUT (sequence index or number).
2. Executes the flash memory access to generate a valid flash transaction on the SPI interface.

Figure 30-5 shows the LUT structures, sequences, and instructions.

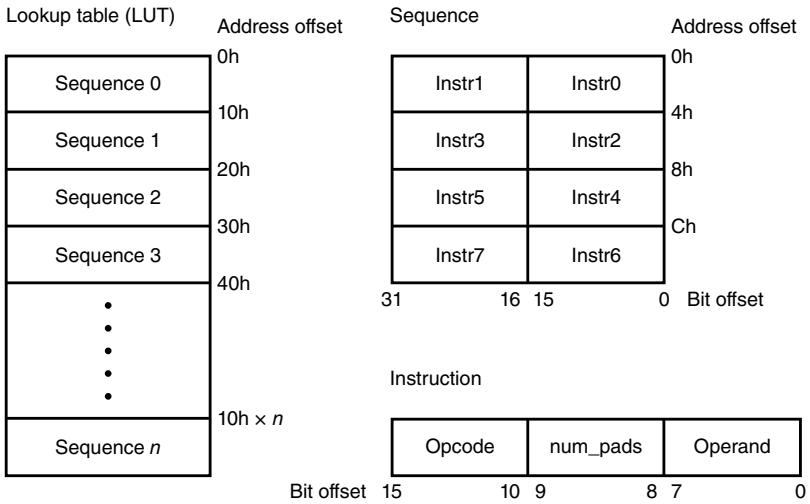

Figure 30-5. LUT structure, sequences, and instructions

NOTE

If the number of instructions needed for a flash transaction is less than eight, the STOP instruction (code 0000_0000h) must be programmed for unneeded instructions.

For IP and AHB write commands, the FlexSPI controller always executes from instruction pointer 0. For AHB read commands, the FlexSPI controller executes from a saved instruction start pointer. The FlexSPI controller saves the instruction start pointers separately for each flash device. All these saved instruction pointers are zero before the JMP_ON_CS instruction is executed. When the JMP_ON_CS instruction is executed, the operand in the JMP_ON_CS instruction is saved as instruction start pointer. See Execute-In-Place (XIP) enhanced mode.

The reset value of the LUT is unknown because it is implemented as internal memory. The LUT must be programmed according to the connected device. To protect its contents during a code runover, the LUT can be locked or unlocked to prevent unwanted changes after the LUT has been configured. The key to lock or unlock the LUT is **5AF05AF0h**.

To lock the LUT:

1. Write the key (5AF05AF0h) to LUT Key (LUTKEY).
2. Write 1 to LUTCR[LOCK] and write 0 to LUTCR[UNLOCK]. When there is another register write access to FlexSPI between these two write accesses, this LUT is not successfully locked.

To unlock the LUT:

1. Write the key (5AF05AF0h) to the LUT Key Register LUT Key (LUTKEY).

2. Write 0 to LUTCR[LOCK] and write 1 to LUTCR[UNLOCK]. When there is another register write access to FlexSPI between these two write accesses, this LUT is not successfully locked.

The lock status of the LUT can be read from LUTCR[LOCK] and LUTCR[UNLOCK].

30.3.6 Programmable sequence engine

The FlexSPI controller implements a programmable sequence engine that executes the sequence from the LUT. The FlexSPI controller executes the instructions sequentially, and generates flash transactions on the SPI interface accordingly. Table 30-10 is a complete list of the supported instructions.

Table 30-10. Instruction set

Name	Opcode	num_pads	Action on SPI interface	Transmit data	Bits/bytes/cycle number
CMD_SDR	00_0001h	00h - one pad (Single mode) 01h - two pads (Dual mode) 02h - four pads (Quad mode) 03h - eight pads (Octal mode)	Transmit command code to flash memory	Command code: Operand[7:0]	Bit number: 8
CMD_DDR	00_0021h				
RADDR_SDR	00_0002h		Transmit row address to flash memory See Flash address sent to flash memory devices	Row_Address[31:0] Row_Address comes from AHB bus (AHB command) or IPCR0[SFAR] (IP command).	Bit number: operand[7:0] Value of operand determines number of bits sent in Row_Address.
RADDR_DDR	00_0022h				
CADDR_SDR	00_0003h		Transmit column address to flash memory. See Flash address sent to flash memory devices.	Column_Address[31:0] Column_Address comes from AHB bus (AHB command) or IPCR0[SFAR] (IP command).	Bit number: operand[7:0] Value of operand determines number of bits sent in Column_Address.
CADDR_DDR	00_0023h				
MODE1_SDR	00_0004h		Transmit mode bits to flash memory	Mode bits: Operand[0]	Bit number: 1
MODE1_DDR	00_0024h				
MODE2_SDR	00_0005h			Mode bits: Operand[1:0]	Bit number: 2
MODE2_DDR	00_0025h				
MODE4_SDR	00_0006h			Mode bits: Operand[3:0]	Bit number: 4
MODE4_DDR	00_0026h				
MODE8_SDR	00_0007h			Mode bits: Operand[7:0]	Bit number: 8
MODE8_DDR	00_0027h				
WRITE_SDR	00_0008h		Transmit program data to flash device	Program data in IP_TX_FIFO or AHB_TX_BUF	AHB burst size and burst type (AHB command) or IPCR1[IDATSZ] (IP
WRITE_DDR	00_0028h				

Table continues on the next page...

Table 30-10. Instruction set (continued)

Name	Opcode	num_pads	Action on SPI interface	Transmit data	Bits/bytes/cycle number
READ_SDR	00_0009h		Receive read data from flash device Read data is put into AHB_RX_BUF or IP_RX_FIFO.	-	command) determines byte number (data size). For details about flash read or program data size, see Flash memory access via AHB command and Flash memory access via IP command.
READ_DDR	00_0029h				
DATSZ_SDR	00_000Bh		Transmit read or program data size (byte number) to flash device	Internal logic Read or program data size for current command sequence	Bit number: operand[7:0] Never set operand to zero or greater than 64 for DATSZ instruction.
DATSZ_DDR	00_002Bh				
DUMMY_SDR	00_000Ch		Leave data lines undriven by FlexSPI controller. Turnaround cycles are provided from host driving to device driving. num_pads determines number of pads in input mode.	-	Dummy cycle number (in serial root clock): Operand[7:0] Dummy cycle (N), described in data sheet of flash device, is in number of SCLK cycles. This number may be configurable. In SDR mode, SCLK cycle is same as serial root clock. Operand value must be set to N. In DDR mode, SCLK cycle is double serial root clock cycle. Operand value must be set to 2N, 2N-1 or 2N+1 depending on definition of dummy in data sheet of flash device. See Flash memory access sequence examples and dummy cycle definition in data sheet of external memory.
DUMMY_DDR	00_002Ch				
DUMMY_RWDS_SDR	00_000Dh		Similar to DUMMY_SDR/ DUMMY_DDR instruction. Difference is in dummy cycle number. DQS pin is called RWDS in HyperBus specification. See Dummy instruction for details. **Set operand to "Latency count" for HyperBus devices.**	-	For read command, dummy cycle number (in serial root clock): (operand[7:0] × 4 - 1) if RWDS (DQS pin) is high; (operand[7:0] × 2 - 1) if RWDS (DQS pin) is low; For write command, dummy cycle number (in serial root clock): (operand[7:0] × 4 - 2) if RWDS (DQS pin) is high; (operand[7:0] × 2 - 2) if RWDS (DQS pin) is low;
DUMMY_RWDS_DDR	00_002Dh				

Table continues on the next page...

Table 30-10. Instruction set (continued)

Name	Opcode	num_pads	Action on SPI interface	Transmit data	Bits/bytes/cycle number
JMP_ON_CS	00_001Fh	Num_pads setting ignored.	Stop execution, deassert CS and save operand[7:0] as instruction start pointer for next sequence. Normally this instruction is used to support Execute-In-Place enhanced mode. See Execute-In-Place (XIP) enhanced mode. This instruction is only allowed for AHB read commands. When using this instruction in IP command or AHB write command, interrupt status flag set (INTR[IPCMDERR] or INTR[AHBCMDERR]).	-	No transaction on SPI interface.
STOP	00_0000h		Stop execution and deassert CS. Next command sequence (to same flash device) starts from instruction pointer 0.	-	

The programmable sequence engine allows configuration of the LUT according to the connected external serial device. The flexible LUT structure easily adapts to new command or protocol changes from different vendors.

The DDR sequence is a flash memory access sequence that contains DDR instructions other than DUMMY_DDR, and may contain SDR instructions. The output and input timing on FlexSPI differs for SDR and DDR sequences. When included as part of a DDR sequence, SDR instructions execute differently from SDR instructions in an SDR sequence. See FlexSPI input timing and FlexSPI output timing.

30.3.6.1 Executing instructions on SPI interface

This section describes the execution of instructions on the SPI interface. For all instructions that receive bits from or transmit bits to flash devices:

- The bit order in one byte is higher on DATA3 than DATA0.
- The bit order is higher on port B than port A.

This order is shown in Figure 30-6.

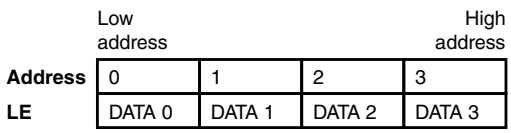

Figure 30-6. Bus bit order

Table 30-11. SPI instructions

Instructions	Description
Command (CMD_SDR, CMD_DDR)	Normally used to transmit a command code to the external device. The command code is the 8-bit operand in the instructions. Command code is sent to both port A and port B in parallel mode. See Flash memory access sequence examples.
Address (RADDR_SDR, RADDR_DDR, CADDR_SDR, CADDR_DDR)	Normally used to send the flash memory access start address (row address or column address) to an external device. FlexSPI determines the bits of the row address or column address according to the AHB access address or IP command address. See Flash address sent to flash memory devices. The operand value in the instruction code represents the number of address bits to send. The bits in the row address or column address are sent to both port A and port B in parallel mode. For example, when NUM_PADSn = 8, a memory reading the flash memory address on four SCK edges requires the sum of bits in CADDR and RADDR instructions to be 32. Otherwise, FlexSPI does not generate four SCK edges of address phase. See Flash memory access sequence examples.
Mode (MODEx_SDR, MODEx_DDR)	Normally used to send mode bits to external devices. Mode bits are the lower bits of an operand. For example, the bit number is 1 for MODE1_SDR and MODE1_DDR, 2 for MODE2_SDR and MODE2_DDR, 4 for MODE4_SDR and MODE4_DDR, and 8 for MODE8_SDR and MODE8_DDR. The pad number should not be greater than the mode bit number. For example, you cannot set NUM_PADSn to 11b (Octal mode) for MODE4_* instructions. Mode bits are sent to both port A and port B in parallel mode. See Flash memory access sequence examples for more details.
Data Size (DATSZ_SDR, DATSZ_DDR)	Used to send the size of program data or read data (byte number) to external devices. This instruction is normally used in FPGA applications where the memory space in external device acts like a FIFO. The external device requires data size information to determine how much data are popped from or pushed into the internal FIFO. The operation value in the data size instructions is the bit number. Data size is sent to both port A and port B in parallel mode. See Flash memory access sequence examples.
Write (WRITE_SDR, WRITE_DDR)	Normally used to send program data to external device. Programming data is fetched from IP_TX_FIFO (IP Command) or AHB_TX_Buffer (AHB command). For details about flash program data size, see Flash memory access via AHB command and Flash memory access via IP command. The byte order for program data is always from low to high. Odd bytes are sent on port A and even bytes are sent on port B in parallel mode. See Flash memory access sequence examples for more details.

Table continues on the next page...

Table 30-11. SPI instructions (continued)

Instructions	Description
Read (READ_SDR, READ_DDR)	Normally used to receive flash memory data from external devices. Received data is put into IP_RX_FIFO (IP Command) or AHB_RX_Buffer (AHB command). For information about flash memory read data size, see Flash memory access via AHB command and Flash memory access via IP command. The byte order for reading data is always from low to high. Odd bytes are received from port A and even bytes are received from port B in parallel mode. See Flash memory access sequence examples.
Dummy (DUMMY_SDR, DUMMY_DDR, DUMMY_RWDS_SDR, DUMMY_RWDS_DDR)	Used to provide turnaround cycles on the SPI interface. During dummy instruction, the FlexSPI controller and external devices do not drive the SPI interface. See Programmable sequence engine for details about dummy cycle number. DUMMY_RWDS_DDR can be used for a HyperBus device that uses RWDS pin to indicate whether extra latency is needed. DUMMY_RWDS_SDR is reserved. The FlexSPI controller checks the DQS pin input level at the fourth cycle after SCLK output toggling is enabled. The DQS pin is called RWDS in HyperBus specification. See Flash memory access sequence examples. **NOTE:** FlexSPI releases the bus after at least one cycle. To avoid data contention, the NUM_PADSn value for the dummy commands should be configured to match the number of data lines used for the external memory.

30.3.6.2 Flash memory access sequence examples

Diagrams below all assume MCR0[SERCLKDIV] = 0.

Figure 30-7 shows an example SDR single I/O read sequence (Cypress Serial Nor Flash S25FS512S) in individual mode.

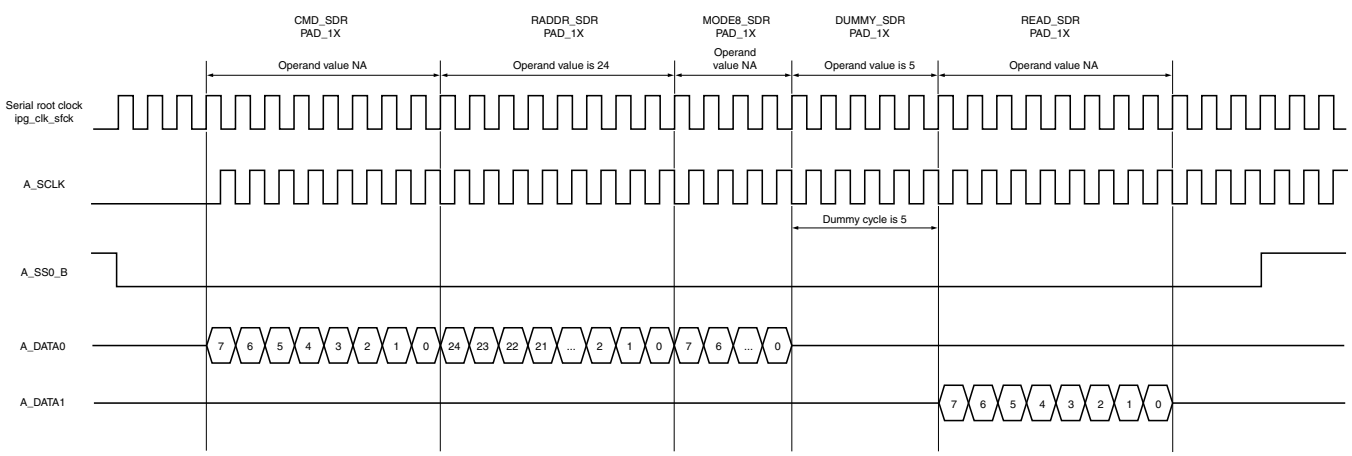

Figure 30-7. Flash memory access sequence example (SDR single I/O read sequence)

NOTE

- FlexSPI dummy instruction starts and ends at the rising edge of serial root clock.
- Device dummy cycle starts and ends at the falling edge of SCLK (on Cypress S25FS512S data sheet).

Figure 30-8 shows an example SDR quad I/O read sequence (Cypress Serial Nor Flash S25FS512S) in individual mode.

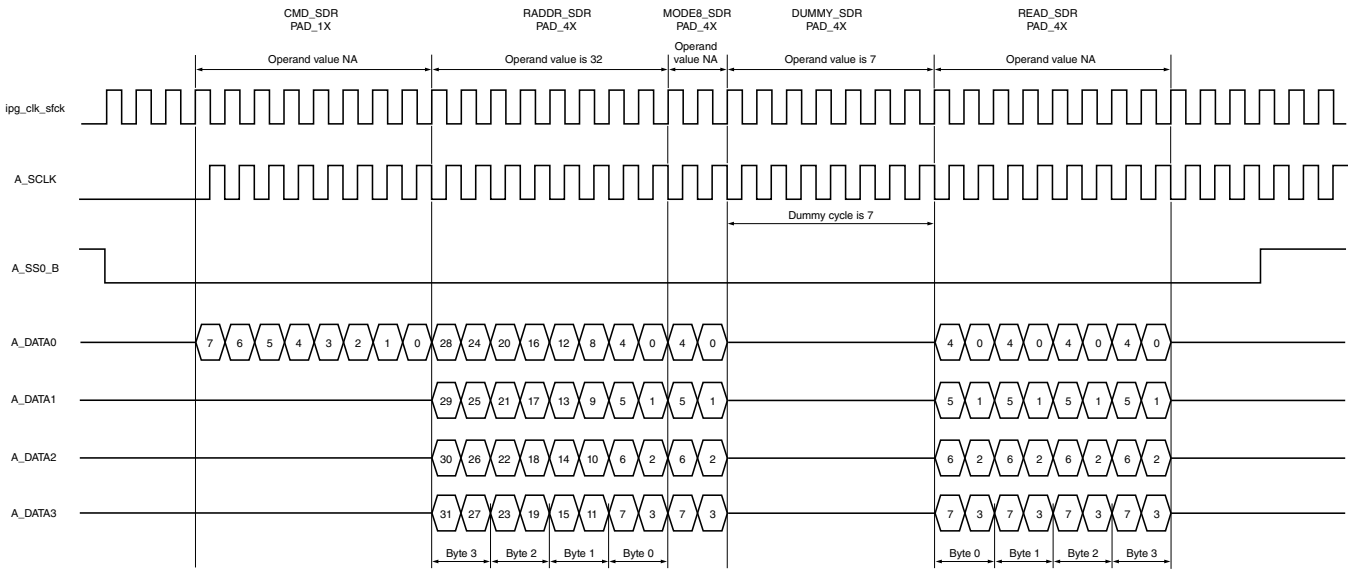

Figure 30-8. Flash memory access sequence example (SDR quad I/O read sequence)

NOTE

- FlexSPI dummy instruction starts and ends at the rising edge of serial root clock.
- Device dummy cycle starts and ends at the falling edge of SCLK (on Cypress S25FS512S data sheet).

Figure 30-9 shows an example DDR quad I/O read sequence (Cypress Serial Nor Flash S25FS512S) in parallel mode.

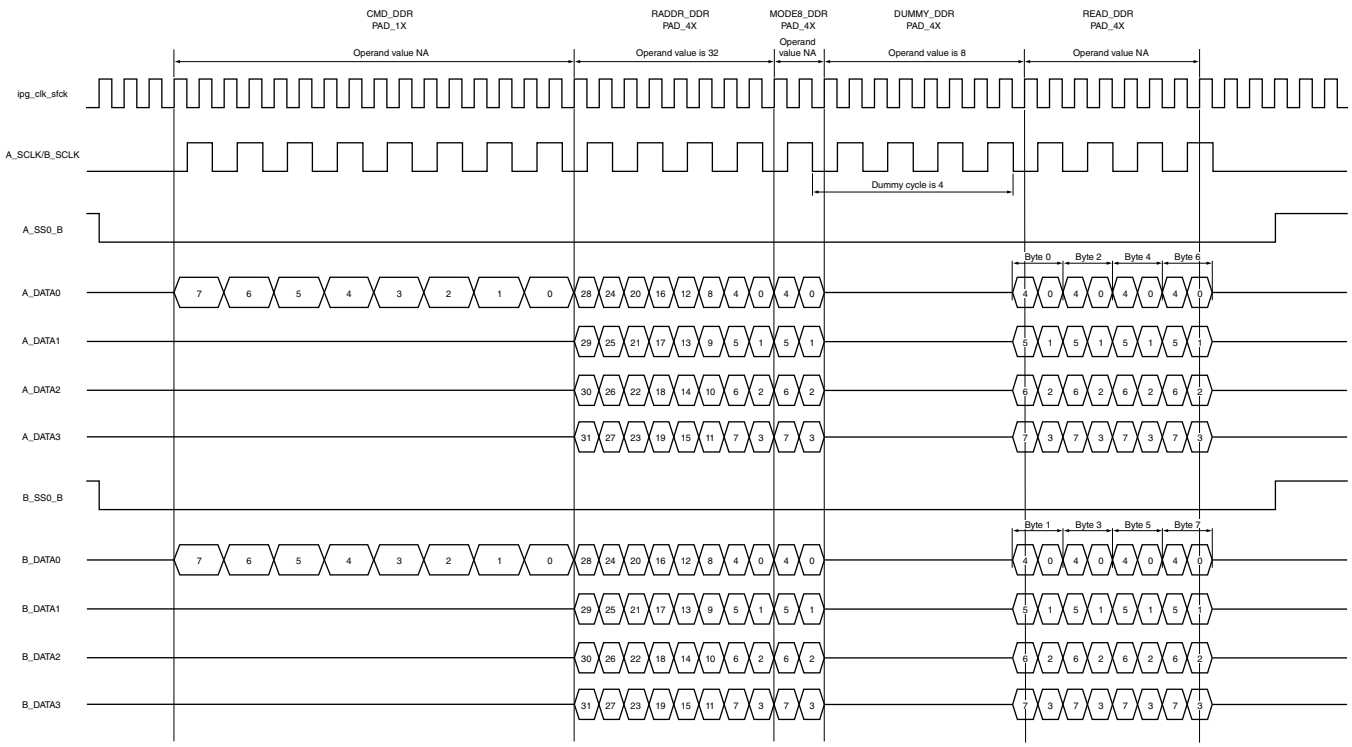

Figure 30-9. Flash memory access sequence example (DDR quad I/O read sequence)

Figure 30-10 shows an example HyperBus device read transaction (single latency count) in individual mode.

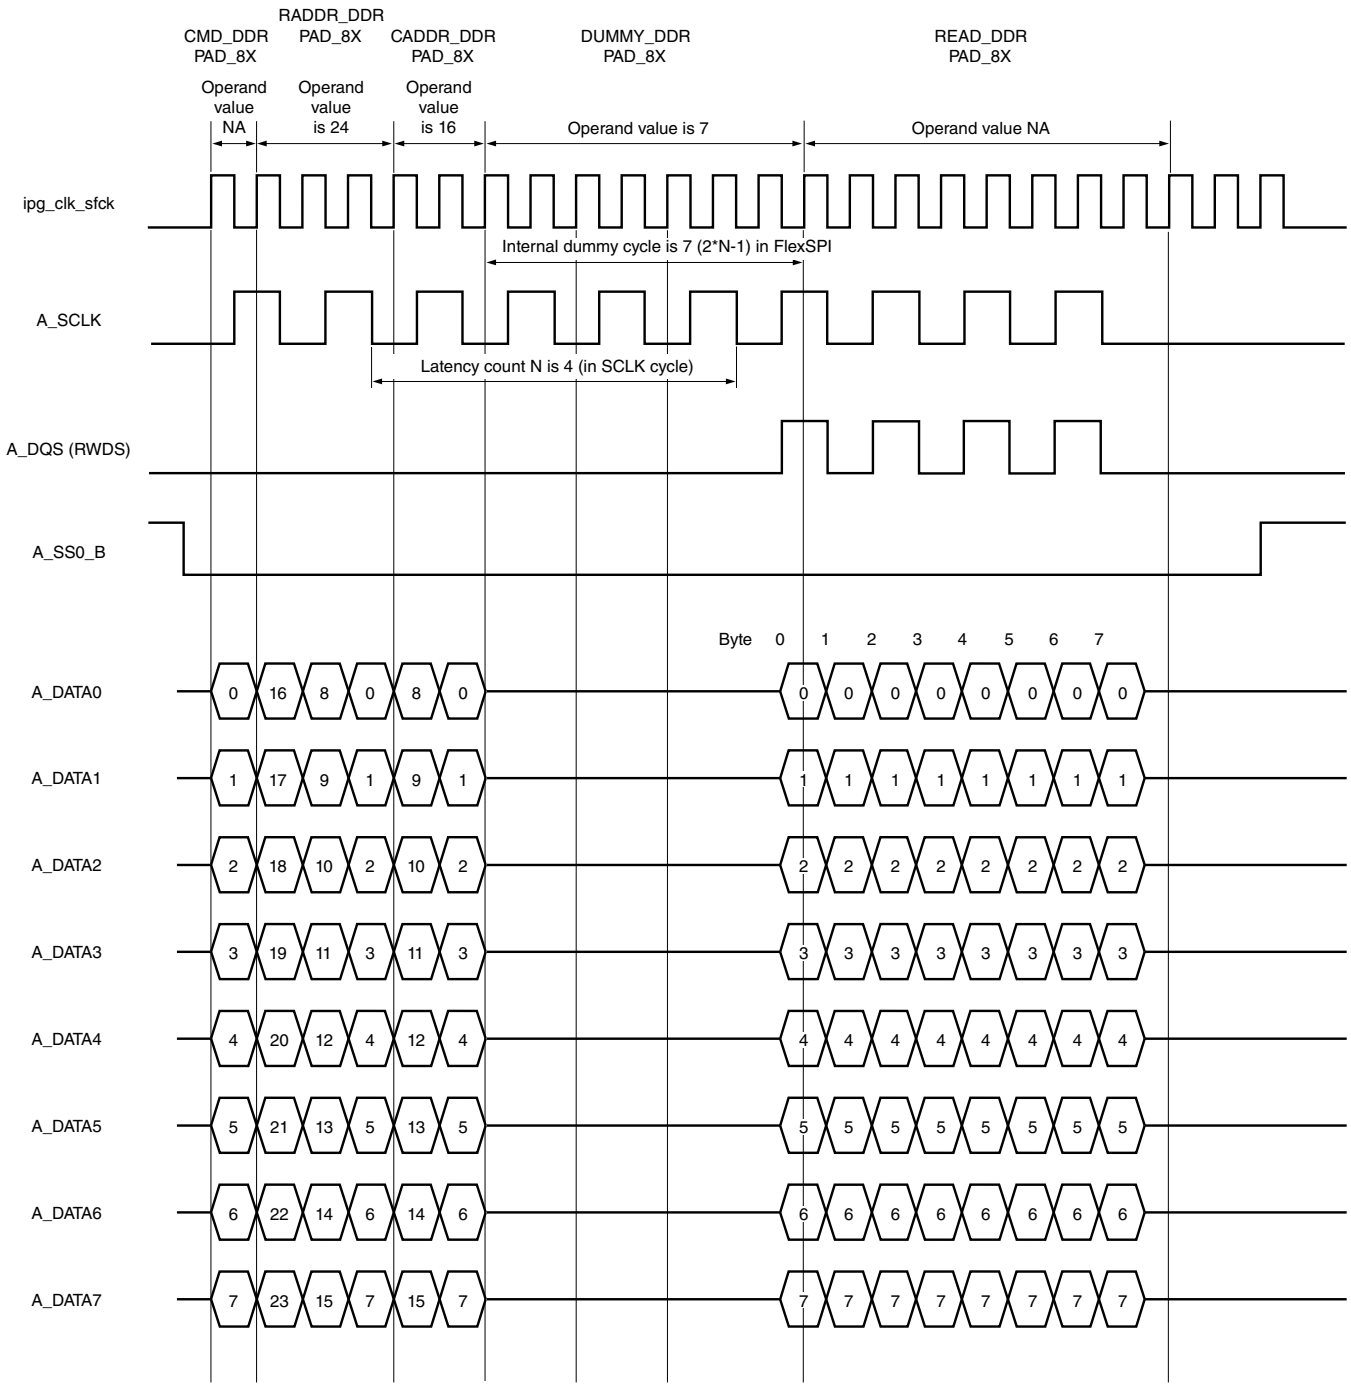

Figure 30-10. HyperBus device read transaction with single latency count

NOTE

FlexSPI continues to drive the clock until it has latched all of the read data it is expecting. On-chip delay for the data to reach FlexSPI can increase the number of SCK clock pulses.

Figure 30-11 shows an example HyperBus device read transaction (additional latency count) in individual mode.

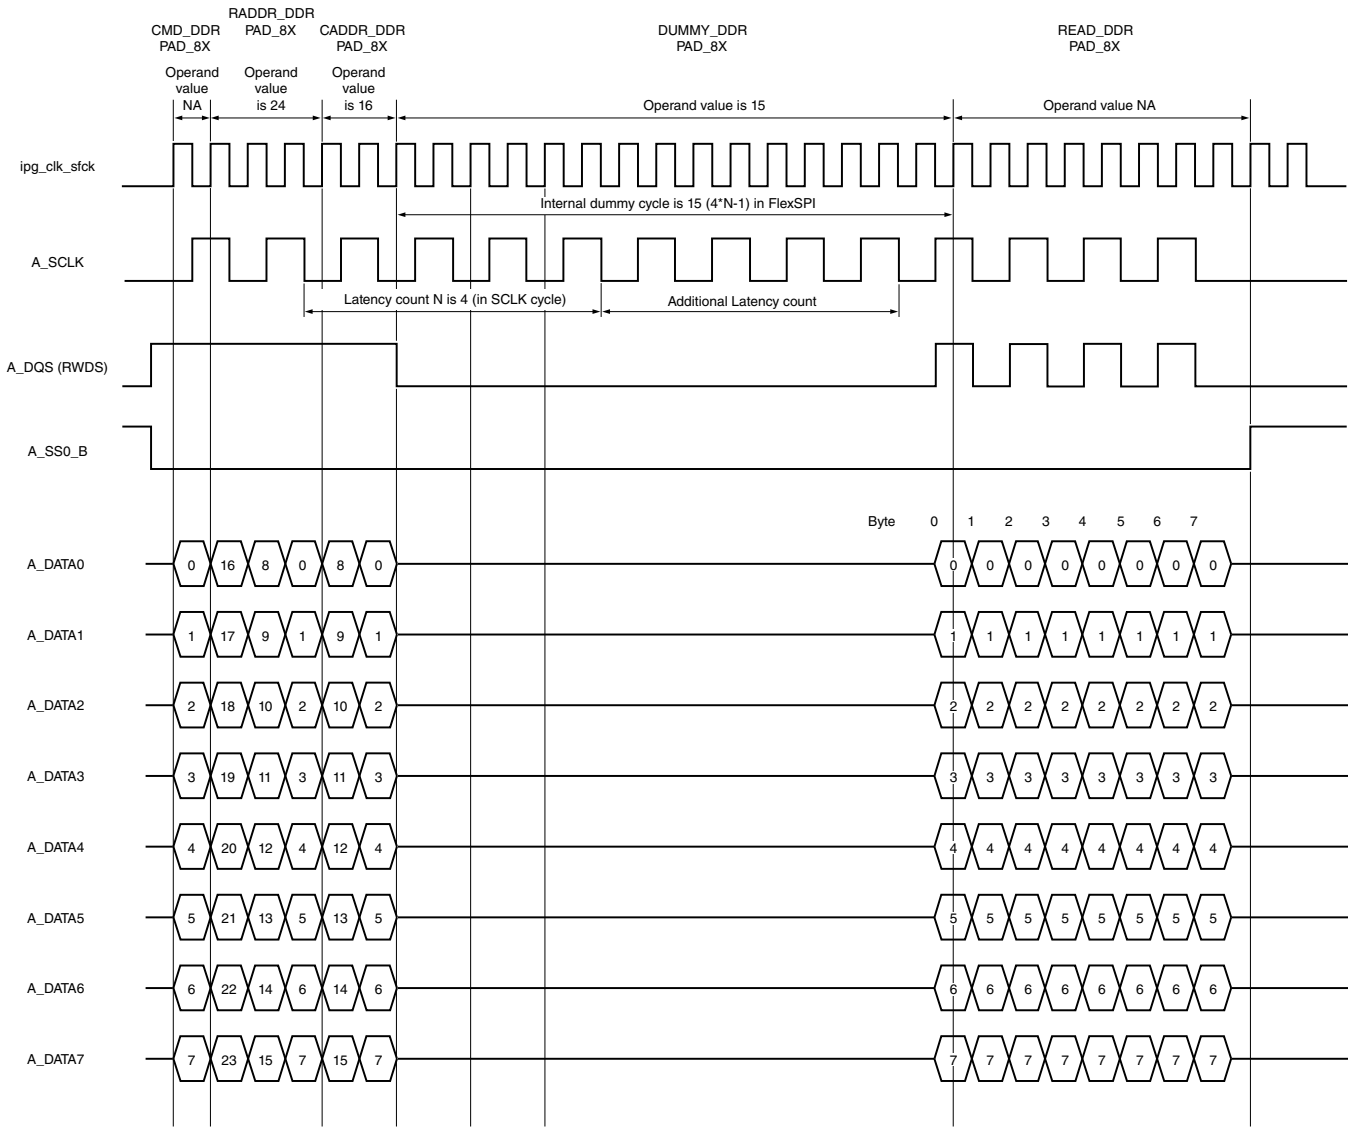

Figure 30-11. HyperBus device read transaction with additional latency count

Figure 30-12 shows an example HyperBus device write transaction (single latency count) in individual mode.

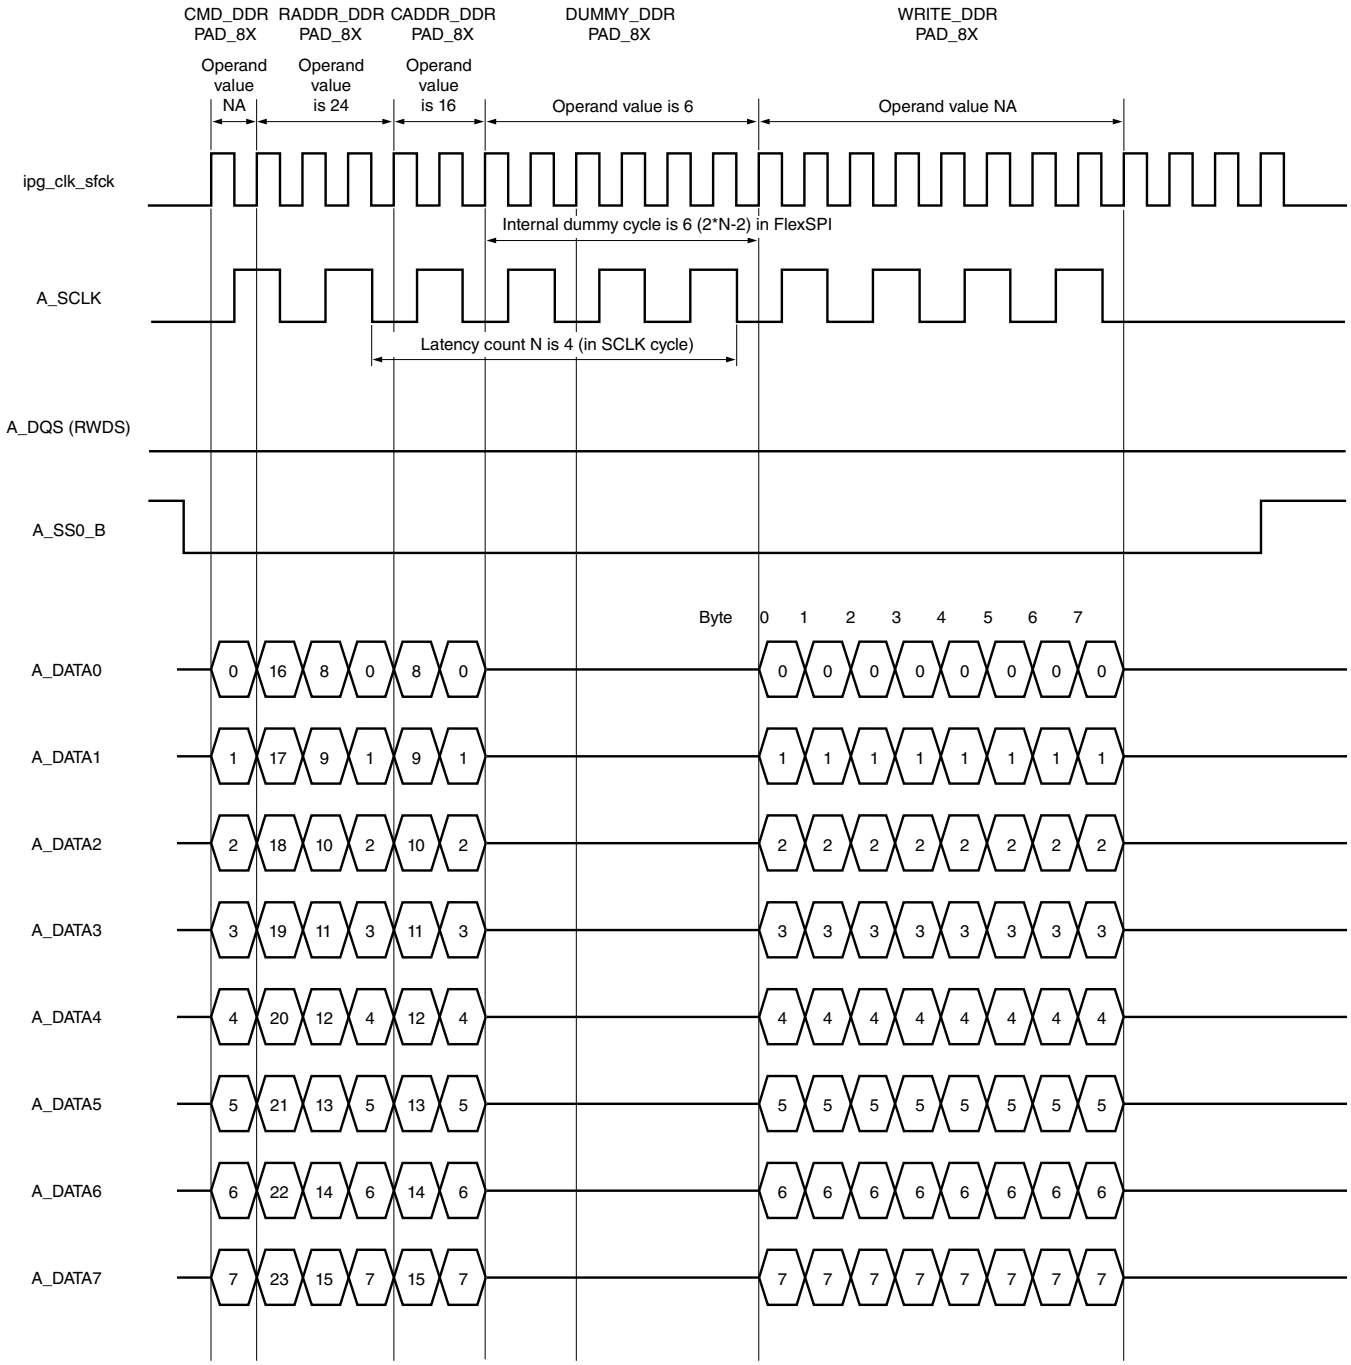

Figure 30-12. HyperBus device write transaction with single latency count

Figure 30-13 shows an example HyperBus device write transaction (additional latency count) in individual mode.

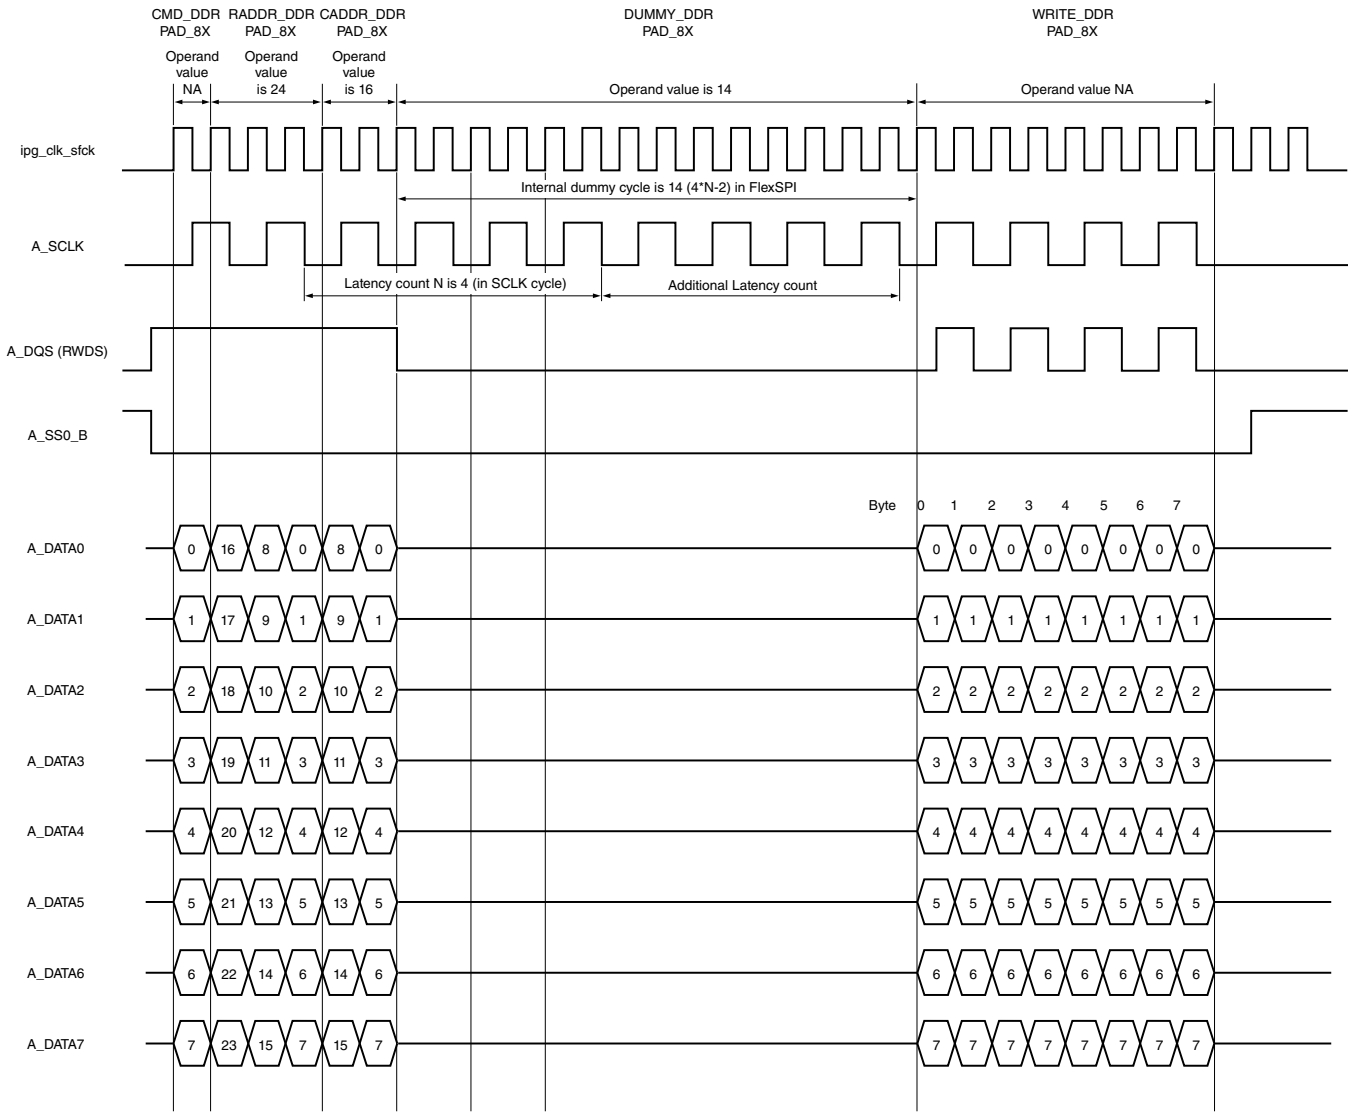

Figure 30-13. HyperBus device write transaction with additional latency count

30.3.7 Clocking

This section describes FlexSPI clocks and special clocking requirements.

Table 30-12. Clock usage

Clock name	Description	Comment
serial clock root (ipg_clk_sfck)	Root clock for Serial domain	FlexSPI core clock, used to generate the serial clock output. The clock is optionally divided using MCR0[SERCLKDIV] to obtain the SCLK.

Table continues on the next page...

Table 30-12. Clock usage (continued)

Clock name	Description	Comment
		Its frequency is same as SPI SCK frequency in SDR mode if MCR0[SERCLKDIV] = 0.
ahb clock (hclk)	AHB bus clock	hclk frequency is higher than 1/4 of serial root clock, so internal async FIFO is never full. This clock is used for internal logic in FlexSPI.
ipg clock (ipg_clk)	IPS bus clock	Register access clock. ipg_clk must be equal to hclk or an integer division of hclk. For example, ipg_clk = hclk/2.
SCLK	FlexSPI serial clock. Output clock on SCLK pin	Half clock frequency of serial clock root in DDR mode, and same frequency as serial clock root in SDR mode. Clock output toggles during the entire flash memory access sequence.
DQS_OUT	Dummy Read Strobe output	Same frequency as SCLK. Clock output toggles during READ and LEARN instructions. The DQS ensures that the data can be strobed correctly. It is only used for data strobe, instead of command or address strobe. The data includes useful read data and data learning patterns.
DQS_IN	Sample clock for receive data	Same frequency as SCLK. Sample clock comes from looped-back dummy read strobe, looped-back SCLK, or flash-memory-provided read strobe.

30.3.8 Interrupts

Table 30-13 describes all interrupts that FlexSPI generates.

Table 30-13. Flash memory address, row address, and column address

Interrupt	Enable	Condition
IP command done	INTEN[IPCMDDONEEN]	An IP command is finished.
IP command grant error	INTEN[IPCMDGEEN]	An IP command grant timeout occurs (bus not granted after MCR0[IPGRANTWAIT] × 1024 AHB clock cycles). See Overview of error categories, flags, and triggered sources.
AHB command grant error	INTEN[AHBCMDGEEN]	An AHB command grant timeout occurs (bus not granted after MCR0[AHBGRANTWAIT] × 1024 AHB clock cycles). See Overview of error categories, flags, and triggered sources.

Table continues on the next page...

Table 30-13. Flash memory address, row address, and column address (continued)

IP command error	INTEN[IPCMDERREN]	A command check error or a command execution error for an IP command occurs. See Overview of error categories, flags, and triggered sources.
AHB command error	INTEN[AHBCMDERREN]	A command check error or a command execution error for AHB command occurs. See Overview of error categories, flags, and triggered sources.
IP_RX_FIFO watermark available	INTEN[IPRXWAEN]	The fill level of IP_RX_FIFO reaches the watermark level (IPRXFCR[RXWMRK]).
IP_TX_FIFO watermark empty	INTEN[IPTXWEEN]	The empty level of IP_TX_FIFO reaches the watermark level (IPTXFCR[TXWMRK]).
Sequence execution timeout	INTEN[SEQTIMEOUTEN]	A sequence execution time exceeds the timeout wait time (MCR1[SEQWAIT]). For example, the following flash memory read command sequence lasts about 800_0000h cycles (ipg_clk_sfck). If SEQWAIT is set to FFFFh, a sequence timeout interrupt is generated. • IP command triggers timeout. • Flash memory read data size is 100_0000h bytes. • Flash memory accesses in single mode and SDR mode.
AHB bus error	INTEN[AHBBUSERROREN]	AHB bus response timeout occurs, or AHB read access occurs while OTFAD is enabled and FlexSPI is still fetching the key blob. For example, AHB read sequence is not configured properly in LUT (such as without a READ instruction). No data is read from the external device. As a result, FlexSPI cannot reach the read data in AHB_RX_Buffers for the AHB read command.
Write command stops SCLK	INTEN[SCKSTOPBYWREN]	IP_TX_FIFO is empty while executing a write command sequence. FlexSPI stops SCLK output clock toggling and waits for write data filling.
Read command stops SCLK	INTEN[SCKSTOPBYRDEN]	IP_RX_FIFO is full while executing a read command sequence. FlexSPI stops SCLK output clock toggling and waits to read the data from IP_RX_FIFO.
Key done	INTEN[KEYDONEEN]	OTFAD is enabled and key blob processing is enabled, key blob processing is done, and no error is detected.
Key error	INTEN[KEYERROREN]	OTFAD is enabled and key blob processing is enabled, and an error occurs during key blob processing. Once

Table continues on the next page...

Table 30-13. Flash memory address, row address, and column address (continued)

		this interrupt is set, only reset can clear it.
ECC multibit error	INTEN[ECCMULTIERREN]	ECC is enabled, the current AHB read data has a multibit ECC error, and the ECC engine cannot correct this error.
ECC single-bit error	INTEN[ECCSINGLEERREN]	ECC is enabled, and the current AHB read data has a single-bit error

30.3.9 On-The-Fly AES Decryption (OTFAD) support

After power-up, if OTFAD and key fetches are enabled in the system, FlexSPI automatically starts fetching the key blobs from location 0 of flash A1. The key fetches continue until OTFAD receives and processes all key blobs. During the fetch operation, any AHB access causes an error response, and INTR[AHBBUSERROR] is set. No IPS access is allowed during the fetching of key blobs. INTR[KEYDONE] or INTR[KEYERROR] represents the key blob processing result.

After OTFAD processes all key blobs, the OTFAD engine decrypts any reads from FlexSPI and returns them on the AHB bus. When OTFAD is enabled, FlexSPI always enables prefetch; only AHBCR[READSZALIGN] can disable the prefetch. The Read Resume function is also disabled. All read access addresses are eight-byte-aligned automatically, regardless the setting of AHBCR[READADDROPT]. If OTFAD is enabled, the prefetch never crosses the 1 KB boundary.

30.3.10 AHB read ECC support

The purpose of ECC is to protect data transactions between the chip and external memory. When AHBCR[ECCEN] = 1:

- All data that the AHB bus reads from flash memory conducts ECC checking.
- Prefetch and address alignment are enabled.
- The resume function is disabled.

FlexSPI supports two wdata formats: swap wdata and raw wdata.

- When wdata is raw data, AHBCR[ECCSWAPEN] should be 0.
- When wdata is swap data, AHBCR[ECCSWAPEN] should be 1.

If the chip does not have an automatic ECC write data generation circuit, software should follow these steps to generate the write data:

1. To convert wdata to wdata_swap, perform a bit swap.

Table 30-14. wdata to wdata_swap

Bit Offset of Packed data	Byte 0	Byte 1	Byte 2	Byte 3
7	B3[7]	B0[7]	B1[7]	B2[7]
6	B2[6]	B3[6]	B0[6]	B1[6]
5	B1[5]	B2[5]	B3[5]	B0[5]
4	B0[4]	B1[4]	B2[4]	B3[4]
3	B3[3]	B0[3]	B1[3]	B2[3]
2	B2[2]	B3[2]	B0[2]	B1[2]
1	B1[1]	B2[1]	B3[1]	B0[1]
0	B0[0]	B1[0]	B2[0]	B3[0]

2. To convert 32 bits of wdata_swap into wdata_ECC, use the matrix shown below. wdata_swap[3:0] becomes wdata_ECC[3:0], wdata_swap[7:4] becomes wdata_ECC[7:4], and so on.

   0 1 1 1

   1 0 1 1

   1 1 0 1

   1 1 1 0

3. To convert wdata_ECC into wdata_ECC_swap, perform a nibble swap.

Table 30-15. wdata_ECC to wdata_ECC_swap

Bit offset of packed data	Byte 0	Byte 1	Byte 2	Byte 3
7	B0[3]	B1[3]	B2[3]	B3[3]
6	B0[2]	B1[2]	B2[2]	B3[2]
5	B0[1]	B1[1]	B2[1]	B3[1]
4	B0[0]	B1[0]	B2[0]	B3[0]
3	B0[7]	B1[7]	B1[7]	B2[7]
2	B0[6]	B1[6]	B2[6]	B3[6]
1	B0[5]	B1[5]	B2[5]	B3[5]
0	B0[4]	B1[4]	B2[4]	B3[4]

4. Write wdata_ECC_swap and wdata to memory.

For a read operation, FlexSPI uses the above steps in reverse.

Every 32 bits of actual data have one ECC single-bit error indication bit and one ECC multibit error indication bit. Therefore, every 64 bits of data have four bits of ECC information. 68 bits of data are stored in the AHB receive buffer for every 64 bits of data read from an external device.

When the AHB receive buffer read data indicates an ECC error in the current data, FlexSPI asserts a multibit error or single-bit error interrupt (if the corresponding interrupt is enabled).

In ECC single-bit error interrupt service, you can check Miscellaneous Control 5 (MISCCR5) and Miscellaneous Control 6 (MISCCR6). MISCCR5 and MISCCR6 store the information for the first ECC single bit-error that FlexSPI encountered since the last ECC single-bit error interrupt was served or reset. Before exiting service, toggle AHBCR[ECCSINGLEERRCLR] to clear the valid bit of MISCCR6.

In ECC multi error interrupt service, you can check Misc Control 4 (MISCCR4) and Miscellaneous Control 7 (MISCCR7). MISCCR4 and MISCCR7 store the information for the first ECC multibit error that FlexSPI encountered since the last ECC multibit error interrupt was served or reset. Before leaving service, software should toggle AHBCR[ECCMULTIERRCLR] to clear the valid bit of MISCCR7. Software can assert AHBCR[CLRAHBRXBUF] to clear the AHB receive buffer. FlexSPI then rereads the data from the external flash memory.

30.3.11 AHB transaction split

When AHBCR[SPLITEN] = 1, and FLSHxCR0[SPLITWREN] = 1 or FLSHxCR0[SPLITRDEN] = 1 , and the corresponding flash memory is accessed, all read and write transactions to external memory devices are split into subtransactions. This feature is used for RAM devices with a self-refresh limit that has a maximum chip select assertion time interval requirement. If FlexSPI operates at a low frequency, a single AHB burst can violate this timing requirement.

Consider an example where a DDR RAM with SCK = 20 MHz has only one data line. If an AHB burst is 128 bytes long, FlexSPI requires about 26 µs to finish the whole data reading. If the timing interval is 6 µs, this read operation violates the RAM refresh limitation. The RAM cannot refresh the data during the read operation, which may cause data corruption. The situation is similar for AHB write operations. This feature can be enabled to reduce the chip select assertion time.

NOTE

When this feature is enabled and the corresponding flash memory is accessed, FlexSPI splits one single burst into smaller

bursts based on AHBCR[SPLIT_LIMIT]. A long read burst is aligned to the next eight-byte-aligned data size. Prefetch is disabled.

Consider an example where the AHB read burst length = 42 bytes and AHCBR[SPLIT_LIMIT] = 00b. The 42-byte AHB read is aligned to 48 bytes, with an extra six bytes fetched. The entire burst is split into six subbursts of eight bytes each (8-8-8-8-8-8). The chip select signal to the external device asserts and deasserts six times.

Consider another example where the AHB write burst length = 42 bytes and AHCBR[SPLIT_LIMIT] = 00b. In this case, there is no burst size modification. The long write burst is split into five subbursts of eight bytes, and one subburst of two bytes (8-8-8-8-8-2).

NOTE

This feature is transparent to software and it significantly impacts performance, so enable it only when necessary. Base your decision on the maximum supported AHB burst size of the current chip, the clock frequency, and the refresh limitation of external RAM.

30.3.12 Flash memory access via IP command

Follow these steps to trigger a flash memory access via IP command.

1. If this command is a programing command, fill the IP transmit FIFO with programming data (for instance, programming flash data and flash memory status registers.)
2. Write the flash memory access start address to IPCR0[SFAR].
3. Write the read or program data size to IPCR1[IDATSZ]. Write the sequence index to IPCR1[ISEQID]. Write the sequence number to IPCR1[ISEQNUM].
4. Write 1 to IPCMD[TRG] to trigger a flash memory access command.
5. Wait for the INTR[IPCMDDONE] flag to set or for the IP command done interrupt to fire, indicating the command has completed on the FlexSPI interface.

NOTE

- The IP transmit FIFO can be filled before or after writing the IPCR0, IPCR1, and IPCMD registers. If the SFM command starts with the IP transmit FIFO empty, FlexSPI stops SCLK toggling to wait for transmit data ready automatically.
- The IPCMD register must be written after writing the IPCR0 and IPCR1 registers.

- One IP command can issue up to eight command sequences.
- You cannot issue another IP command before the previous IP command is finished. Performing this action results in unknown behavior.

If this command is a read command, all read data from flash memory is put into the IP receive FIFO. Software must read data from the IP receive FIFO via AHB bus or IP bus. When the IP receive FIFO is full and the flash device still contains data to read, FlexSPI stops SCLK toggling until the FIFO has free space. See SCLK stop.

A triggered serial flash command contains:

- A flash memory access start address. IPCR0[SFAR] determines this address.
- A flash chip select. The flash memory access address and flash memory size setting (FLSHxCR0[FLSHSZ]) determine the chip select.
- A flash command sequence index and sequence number. FlexSPI sequentially executes the sequences indexed from IPCR1[ISEQID] to (IPCR1[ISEQID] + IPCR1[ISEQNUM]) in LUT.
- Flash individual/parallel memory access mode:

  Determined by IPCR1[IPAREN].

- The flash memory read or program data size, in bytes.
  - If the value of IPCR1[IDATSZ] is nonzero, the data size is IPCR1[IDATSZ].
  - If the value of IPCR1[IDATSZ] is zero, the operand value in the read or write instruction determines the data size.

NOTE

- Software must ensure that the last sequence index never exceeds the LUT sequence number. That is, IPCR1[ISEQID] + IPCR1[ISEQNUM] must be less than 16.
- For sequence numbers greater than one, the data size is applied to every command sequence.
- If there is no write or read instruction in the command sequence, the data size is ignored.

The IP command request is sent to the arbitrator after software triggers it. It is not executed on the FlexSPI interface until the arbitrator grants it. See Command arbitration.

30.3.12.1 Reading data from IP receive FIFO

FlexSPI puts read data from the external device into the IP receive FIFO for IP commands.

The data stored in the IP receive FIFO can be read using IPS and register or system and AHB bus transactions:

- Via IP bus
- Via AHB bus

If MCR0[ARDFEN] = 1, only the AHB bus can read the read data in the IP receive FIFO. Read access to the IP receive FIFO using IP bus always returns with data zero, and no bus error occurs.

If MCR0[ARDFEN] = 0, only the IPS bus can read the read data in the IP receive FIFO. Read access to the IP receive FIFO using the AHB bus triggers a bus error.

FlexSPI pushes read data into the IP receive FIFO in sets of 64 bits each time it receives 64 bits of data from an external device. When the number of read data bits is not 64-bit-aligned, FlexSPI pushes additional zero bits into the IP receive FIFO for the last push.

The processor or DMA can read the IP receive FIFO.

30.3.12.1.1 Reading via processor

To read data from the IP receive FIFO via processor, configure the items below.

- Write 0 to IPRXFCR[RXDMAEN].
- Write the watermark level to IPRXFCR[RXWMRK]. The watermark level is (IPRXFCR[RXWMRK] + 1) × 8 bytes.
- Write 1 to INTEN[IPRXWAEN] to enable the IP receive FIFO watermark available interrupt (optional).

The processor must poll INTR[IPRXWA] or wait for the IP receive FIFO watermark available interrupt before reading data from the FIFO. Waiting ensures that a watermark level amount of data is filled in the IP receive FIFO before reading.

After reading a watermark level amount of data from the FIFO, software must set the INTR[IPRXWA] flag to pop that data from the FIFO.

Figure 30-14 shows the reading flow from the IP receive FIFO via processor.

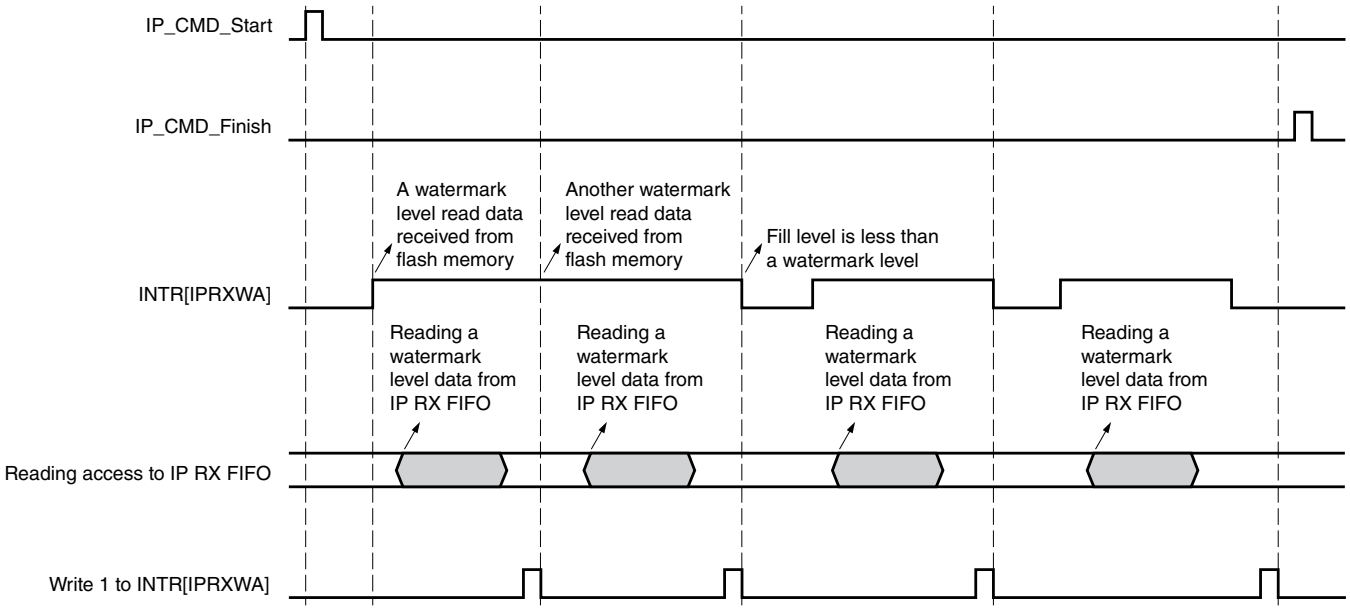

Figure 30-14. Reading IP receive FIFO via processor

NOTE

- The processor must read a watermark level of data from the IP receive FIFO before setting the INTR[IPRXWA] flag.
- The total flash read or program data size is not required to be a multiple of the watermark level. When the reading data size from the FIFO is less than a watermark level for the last time, software polls IPRXFSTS[FILL], not INTR[IPRXWA]. After all data from the FIFO are copied and all command sequences to flash memory are finished (INTR[IPCMDDONE] = 1), software sets IPRXFCR[CLRIPRXF] to clear the FIFO. If the FIFO is not cleared, the reading data will be incorrect for the next reading command to flash memory.
- Setting the INTR[IPRXWA] flag pops the IP receive FIFO data. Each read access to the FIFO does not pop the data.

30.3.12.1.2 Reading via DMA

To read data from the IP receive FIFO via DMA, configure the items below.

- Write 1 to IPRXFCR[RXDMAEN].
- Write the watermark level to IPRXFCR[RXWMRK]. The watermark level is (IPRXFCR[RXWMRK] + 1) × 8 bytes.
- Configure the DMA transfer minor loop size to match the watermark level.

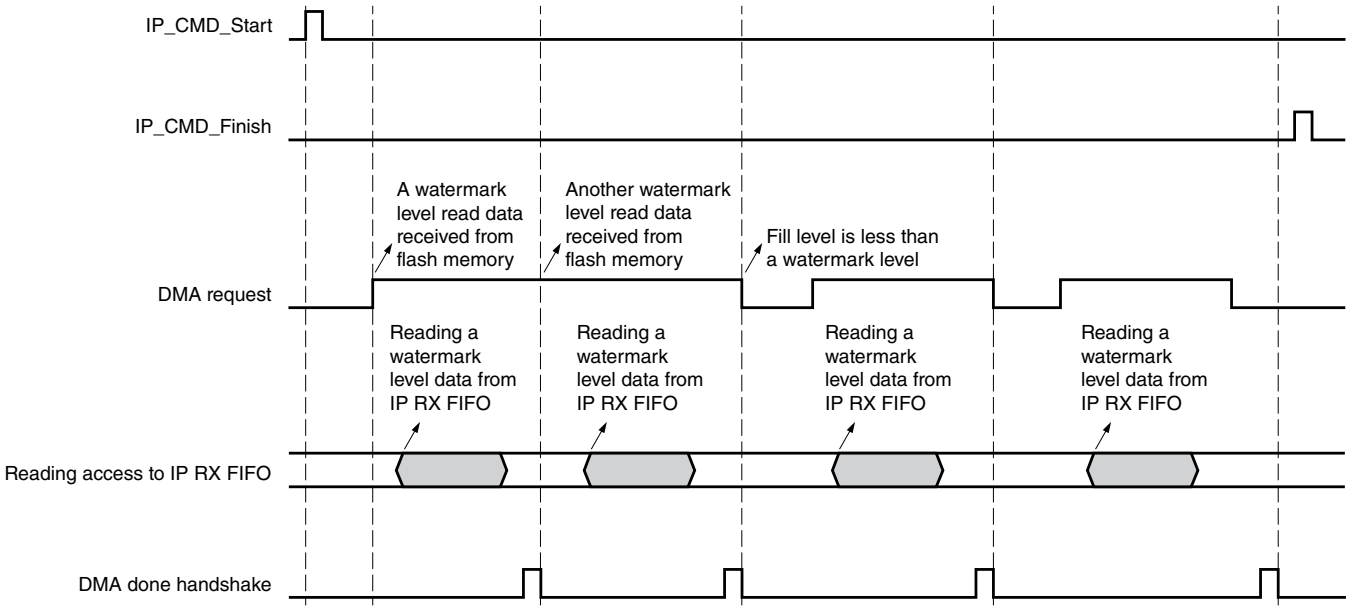

Figure 30-15. Reading from IP receive FIFO via DMA

NOTE

- When the fill level of the FIFO meets or exceeds the watermark level, a DMA request is generated. This request is level-valid, not pulse-valid.
- DMA reads a watermark level amount of data from the IP receive FIFO each time. (Configure the minor loop size to match the watermark level).
- DMA must return a done handshake (pulse valid) to FlexSPI each time it finishes reading a watermark level amount of data.
- The DMA done handshake (not each read access) pops the IP receive FIFO data.
- The total read and write data size (major loop size) must be a multiple of the watermark level. The DMA does not know when the data is ready for the last reading. When the data size is not a multiple of the watermark level, it is too complex for the DMA driver to poll IPRXFSTS[FILL].

30.3.12.2 Writing data to IP transmit FIFO

The programming data is put into the IP transmit FIFO, then FlexSPI transmits it to the flash memory. IPS or AHB access can write it:

- Via IP bus
- Via AHB bus

To write the programming data into the IP transmit FIFO via AHB bus, write 1 to MCR0[ATDFEN]. The IP bus write access to the FIFO is ignored, but no bus error occurs.

To write the programming data into the IP transmit FIFO via IP bus, write 0 to MCR0[ATDFEN]. The AHB bus write access to the FIFO returns a bus error.

When FlexSPI fetches data to transmit, 64 bits of data from the IP transmit FIFO are popped. If the programming data size is not a multiple of 64 bits, the number of last popped valid bits is less than 64 bits. No error occurs; these invalid bits are not transmitted to the flash memory.

The processor or DMA can fill the IP transmit FIFO with programming data.

30.3.12.2.1 Writing via processor

To write data into the IP transmit FIFO via processor, configure the items below.

- Write 0 to IPTXFCR[TXDMAEN].
- Write the watermark level to IPTXFCR[TXWMRK]. The watermark level is (IPTXFCR[TXWMRK] + 1) × 8 bytes.
- Write 1 to INTEN[IPTXWEEN] to enable the IP transmit FIFO watermark available interrupt (optional).

The processor must poll INTR[IPTXWE] or wait for the IP transmit FIFO watermark empty interrupt before writing data to the FIFO. Waiting ensures that a watermark level amount of data is available in the IP transmit FIFO before writing.

After writing a watermark level amount of data to the FIFO, software must set the INTR[IPTXWE] flag to push that data into the FIFO. (The write pointer is incremented.)

NOTE

Setting the INTR[IPTXWE] flag pushes the IP transmit FIFO data. Each write access to the FIFO does not push the data.

Figure 30-16 shows the writing flow to the IP transmit FIFO via processor.

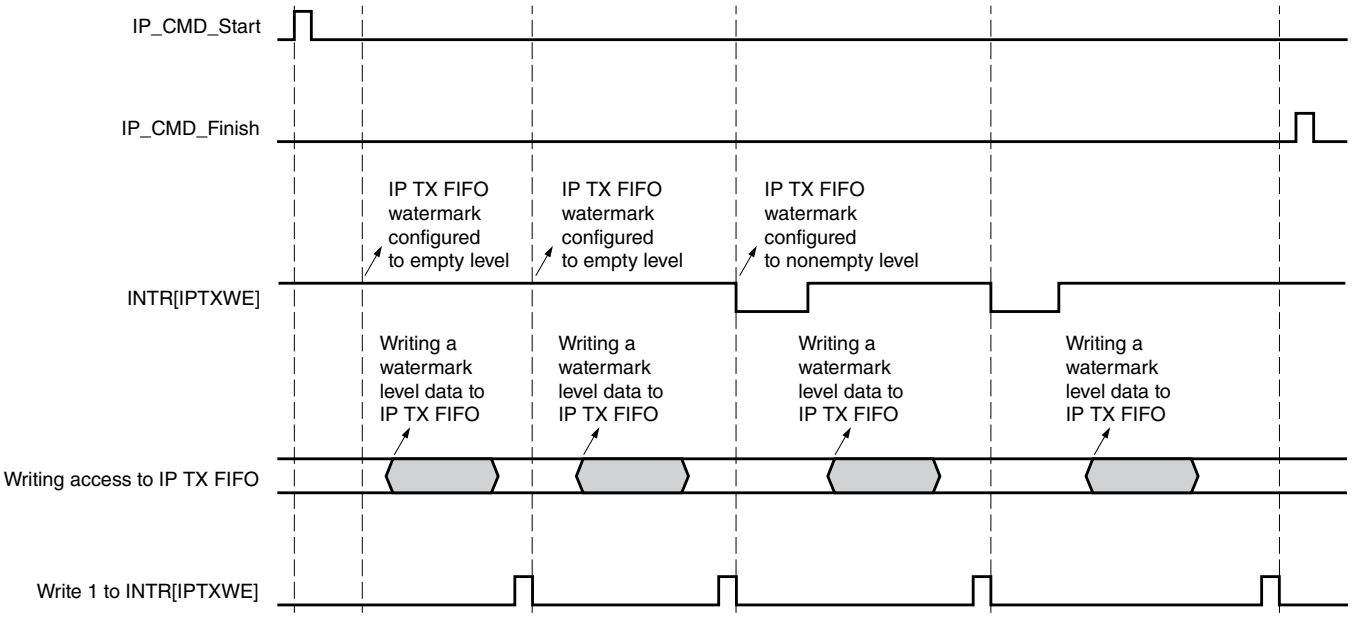

Figure 30-16. Writing to IP transmit FIFO via processor

NOTE

- The processor must write a watermark level amount of data into the IP transmit FIFO each time.
- The total flash write data size is not required to be a multiple of the watermark level. In this case, the writing data size to the FIFO is less than a watermark level for the last time. After all data to the FIFO are written and all command sequences to flash memory are finished (INTR[IPCMDDONE] = 1), the processor sets IPTXFCR[CLRIPTXF] to clear the FIFO. If the FIFO is not cleared, the programming data will be incorrect for the next programming command to flash memory.

30.3.12.2.2 Writing via DMA

To write data into the IP transmit FIFO via DMA, configure the items below.

- Write 1 to IPTXFCR[TXDMAEN].
- Write the watermark level to IPTXFCR[TXWMRK]. The watermark level is (IPTXFCR[TXWMRK] + 1) × 8 bytes.
- Configure the DMA transfer minor loop size to match the watermark level.

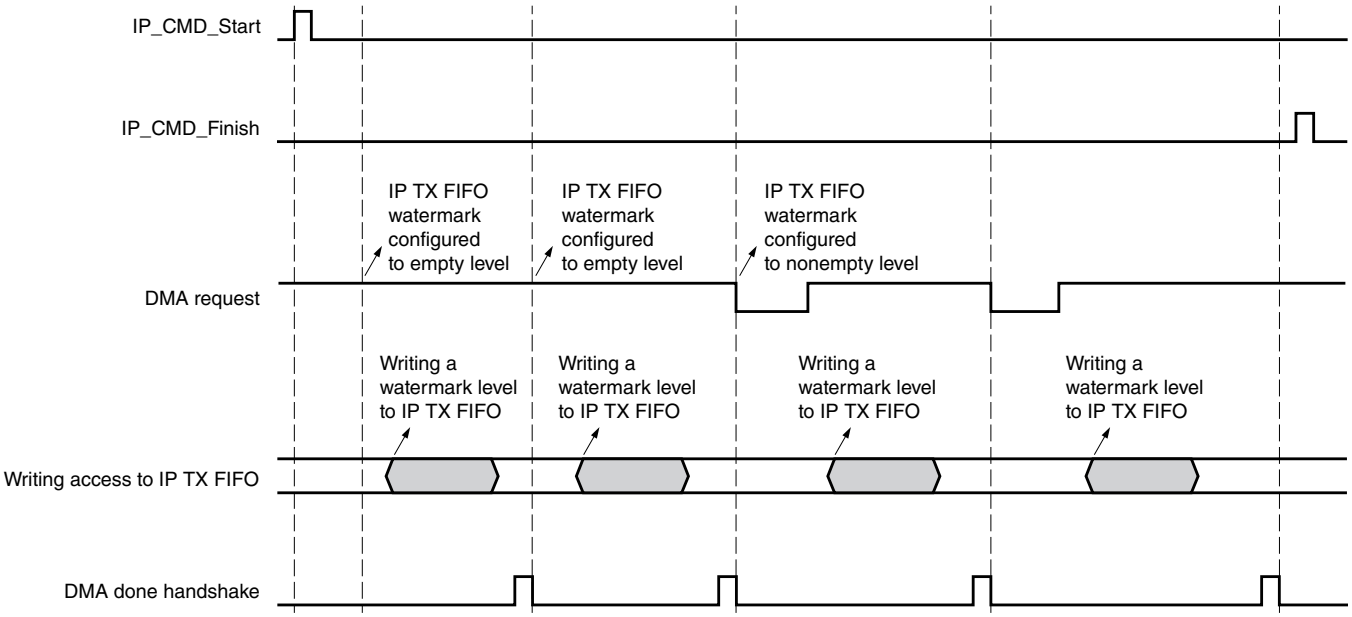

Figure 30-17. Writing into IP transfer FIFO via DMA

NOTE

- When there is empty space in the IP transmit FIFO greater than the watermark level, a DMA request is generated. This request is level-valid, not pulse-valid.
- DMA writes a watermark level amount of data into the FIFO each time. (Configure the minor loop size to match the watermark level.
- DMA returns a done handshake (pulse valid) to FlexSPI each time it finishes writing a watermark level amount of data.
- The DMA done handshake (not each write access) pushes the IP transmit FIFO data.
- The total program data size (major loop size) is not required to be a multiple of the watermark level. After writing all data into the IP transmit FIFO and all command sequences to flash memory are finished (INTR[IPCMDDONE] = 1), write 1 to IPTXFCR[CLRIPTXF] to clear the FIFO. Failure to clear the FIFO results in incorrect programming data for the next programming command to flash memory.

30.3.13 Flash memory access via AHB command

Flash memory can be accessed via AHB bus directly on the AHB address space. This address space is mapped to serial flash memory in FlexSPI. AHB bus accesses to this address space trigger flash memory access command sequences as needed.

For AHB read access to serial flash memory, FlexSPI fetches data from flash memory into the AHB receive buffer, then returns the data on the AHB bus. For AHB write access to serial flash memory, FlexSPI buffers AHB bus write data into the AHB transmit buffer, then transmits the data to serial flash memory.

No software configuration or polling is needed for AHB commands, except for FlexSPI initialization. As with a normal AHB target, the AHB controller accesses the external flash device transparently.

AHB commands are normally used to access serial flash memory space. IP commands must be used to access the control and status registers or other spaces, such as a one-time programmable (OTP) space in an external flash device.

The AHB commands for read and write access are discussed in detail below.

30.3.13.1 AHB write access to flash memory

For AHB write access to flash memory, FlexSPI buffers the write data from the AHB bus into the internal AHB transmit buffer. FlexSPI then transmits the data to flash memory. FlexSPI only buffers write data for one AHB burst. Figure 30-18 shows the hardware operation in response to an AHB write access to flash memory.

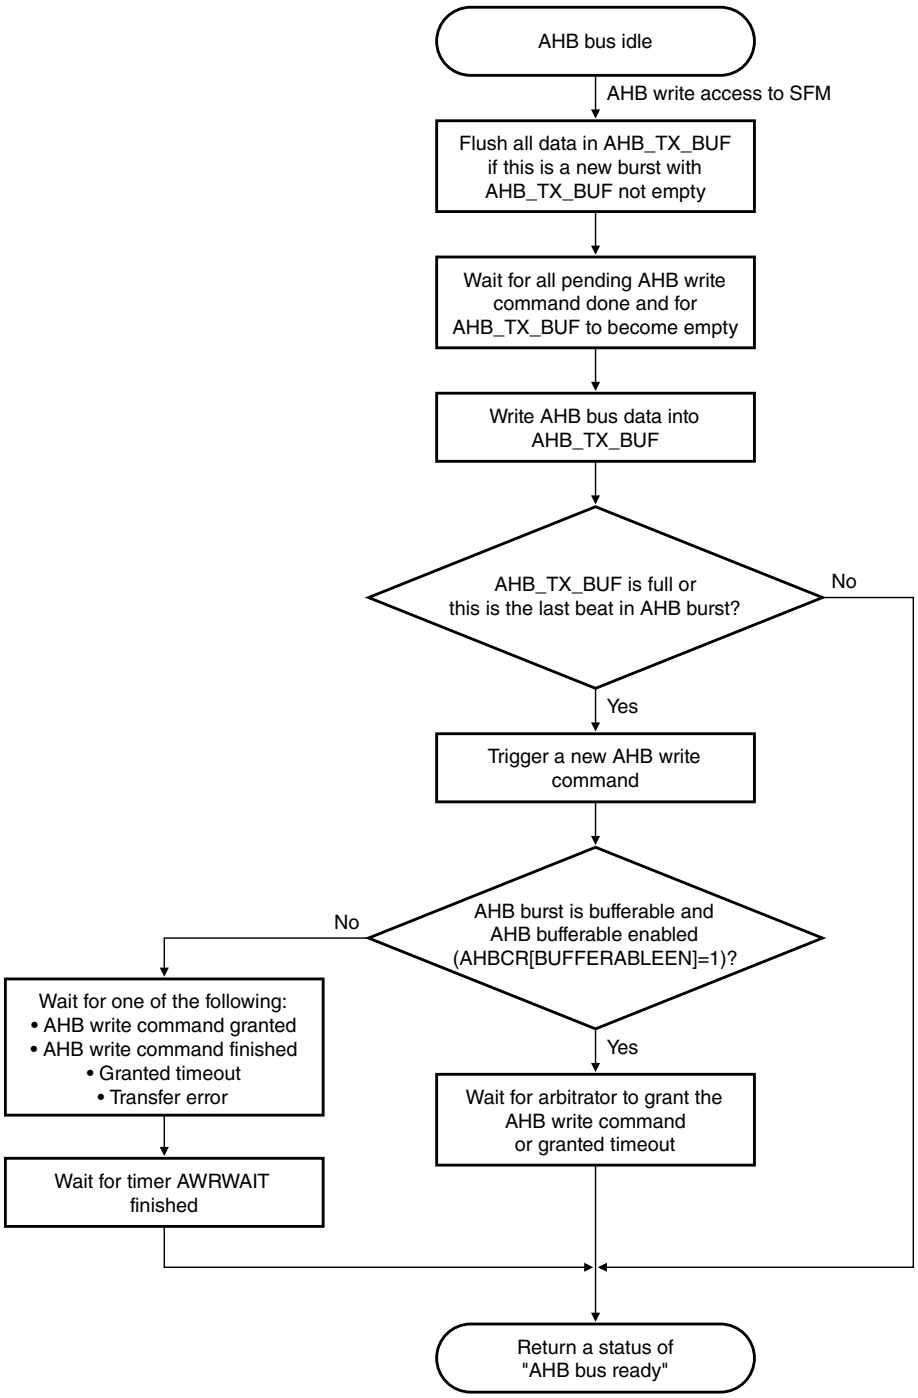

Figure 30-18. Hardware operation in response to AHB write access to flash memory

NOTE

1. If previous AHB burst is INCR write burst, AHB transmit buffer may not be empty when AHB bus is idle or new burst arrives. A new AHB write command is triggered to flush all data in AHB transmit buffer to external flash device. The new burst is held until this AHB write command finishes.

2. If the current access is bufferable, when the AHB write command is triggered, AHB ready is returned after the write command is granted. If the current access is non-bufferable, AHB ready is returned after the write command finishes.

FlexSPI triggers a new AHB write command in these cases:

- This beat is the last one in the current AHB burst, for any burst type except INCR.
- AHB transmit buffer is full after the current beat data is buffered.
- AHB bus becomes idle or a new burst arrives with the AHB transmit buffer not empty.

Table 30-16 describes the details of a triggered AHB write command.

Table 30-16. Triggered AHB write command

Item	Description
Flash memory access start address	Determined by AHB burst address. FlexSPI records the start address for the data in AHB transmit buffer, which is used as flash memory access start address.
Flash memory chip select	FlexSPI uses the settings of the flash memory access start address and flash memory size to determine the chip selection.
Flash memory command sequence index	Determined by FLSHxCR2[AWRSEQID].
Flash memory command sequence number	Determined by FLSHxCR2[AWRSEQNUM]. If AWRSEQNUM is not zero, multiple flash memory access command sequences are triggered every time for an AHB write command. The sequences indexed from AWRSEQID to (AWRSEQID + AWRSEQNUM) in LUT are executed sequentially.
Flash memory access mode (Individual/ Parallel)	Determined by AHBCR[APAREN].
Flash memory data size	Determined by byte number of buffered data in AHB transmit buffer.

The following examples indicate internal logic for AHB write access to flash memory, where AHB_TX_BUF is 64 bytes :

- AHB INCR 64-bit bufferable burst with address sequence 8h, 10h, 18h, 20h, ..., 50h (10 beats total).

  Two AHB write commands are triggered: the first command with flash memory start address 8h and data size 40h; the second command with flash memory start address 48h and data size 10h. See Figure 30-19.

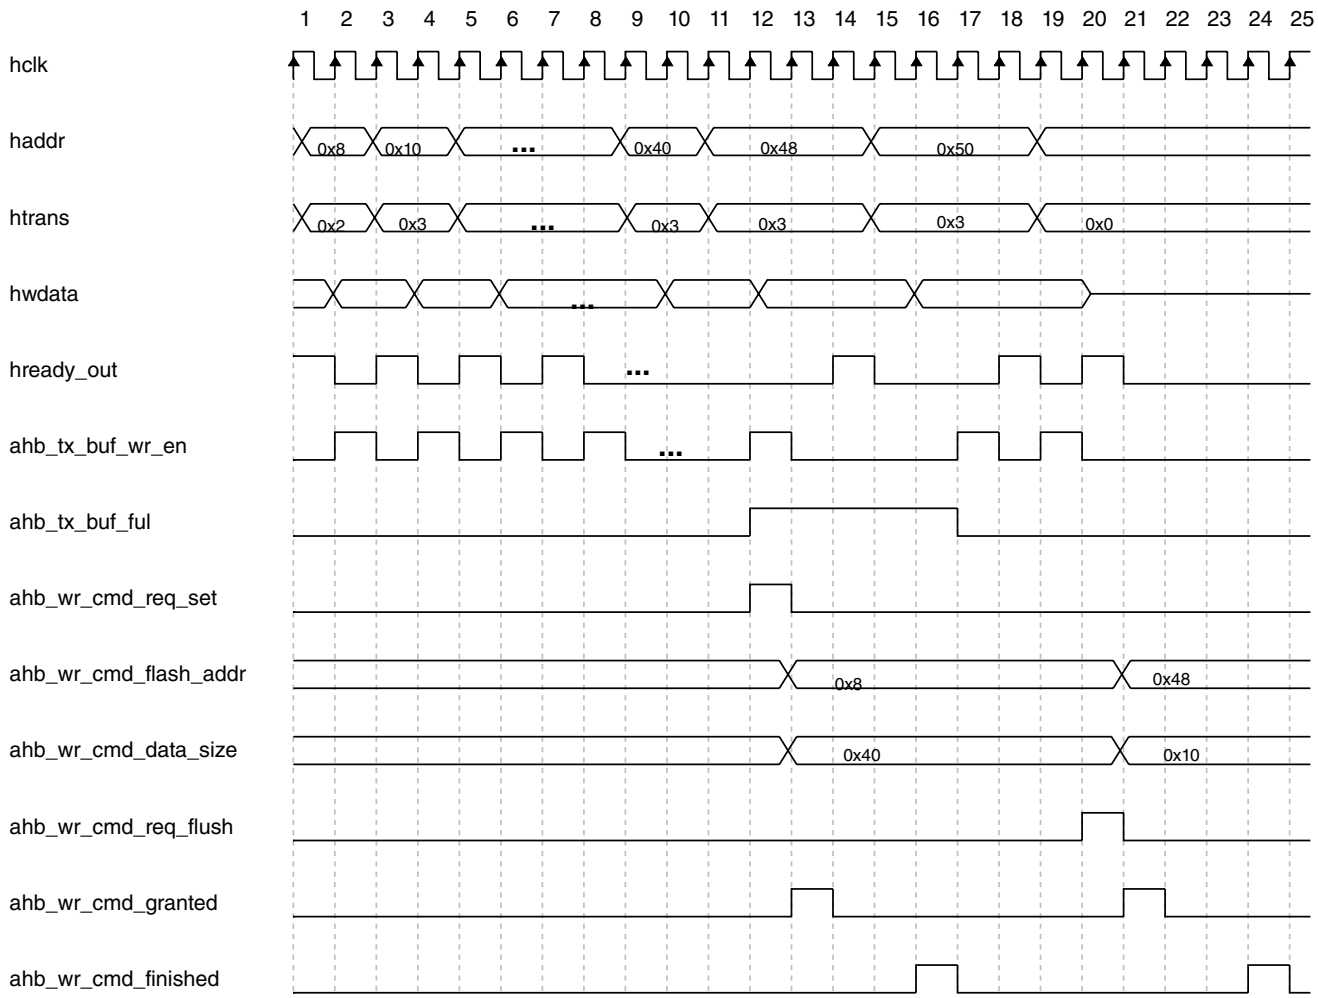

Figure 30-19. AHB write access (INCR, 64-bit, bufferable)

- AHB WRAP8 64-bit bufferable burst with address sequence 28h, 30h, 38h, 0h, 8h, 10h, 18h, 20h.

  One AHB write command is triggered with flash memory start address 0h and data size 40h. See Figure 30-20.

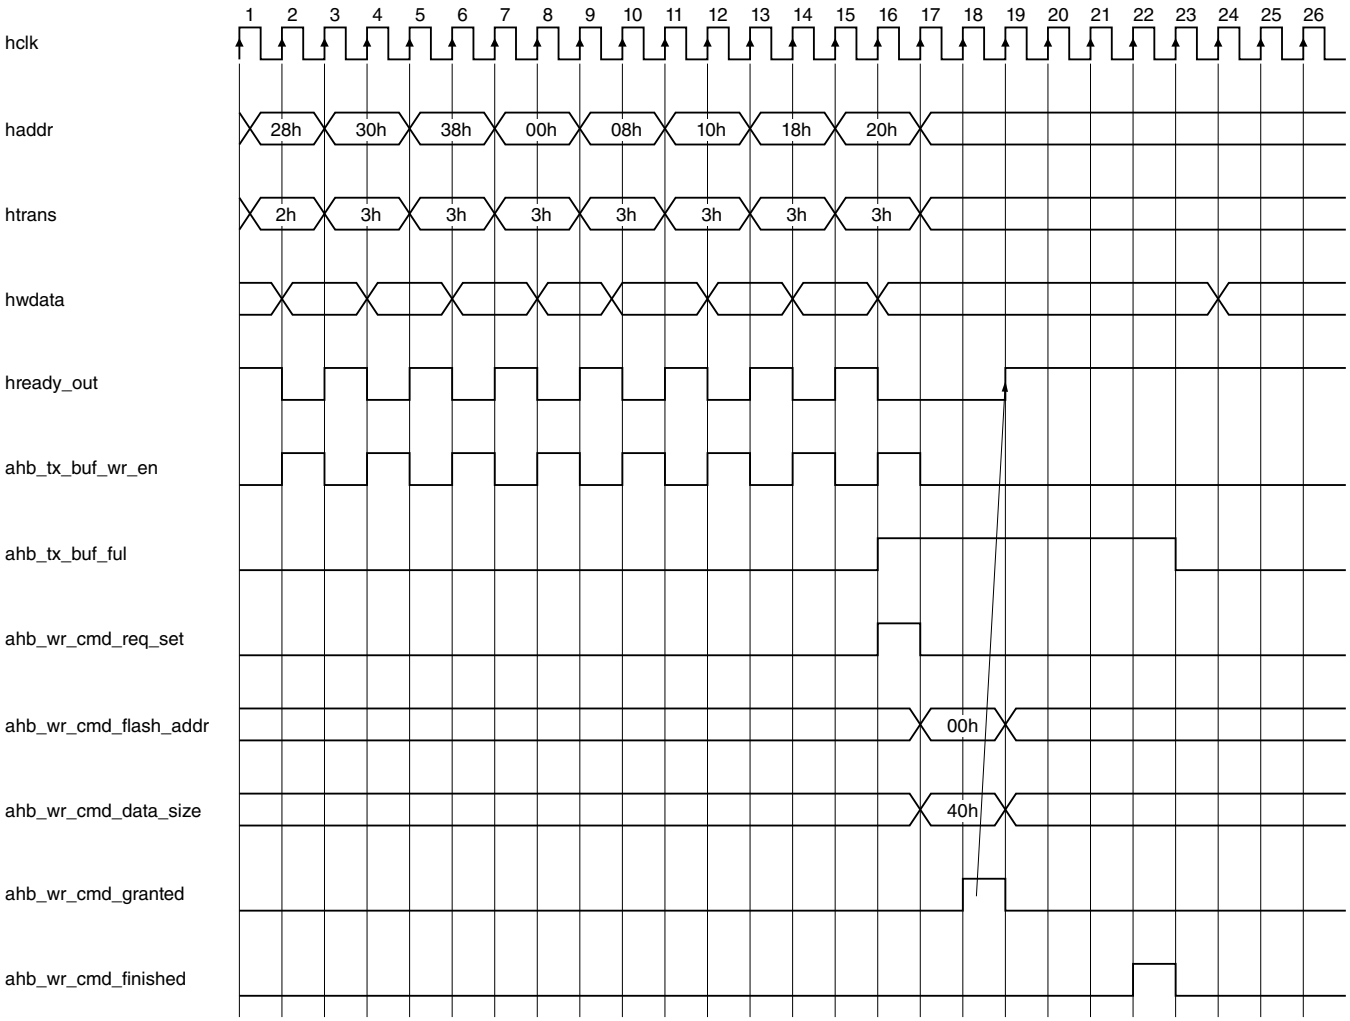

Figure 30-20. AHB write access (WRAP8, 64-bit, bufferable)

- AHB WRAP8 64-bit non-bufferable burst with address sequence 28h, 30h, 38h, 0h, 8h, 10h, 18h, 20h.

  One AHB write command is triggered with flash memory start address 0h and data size 40h.

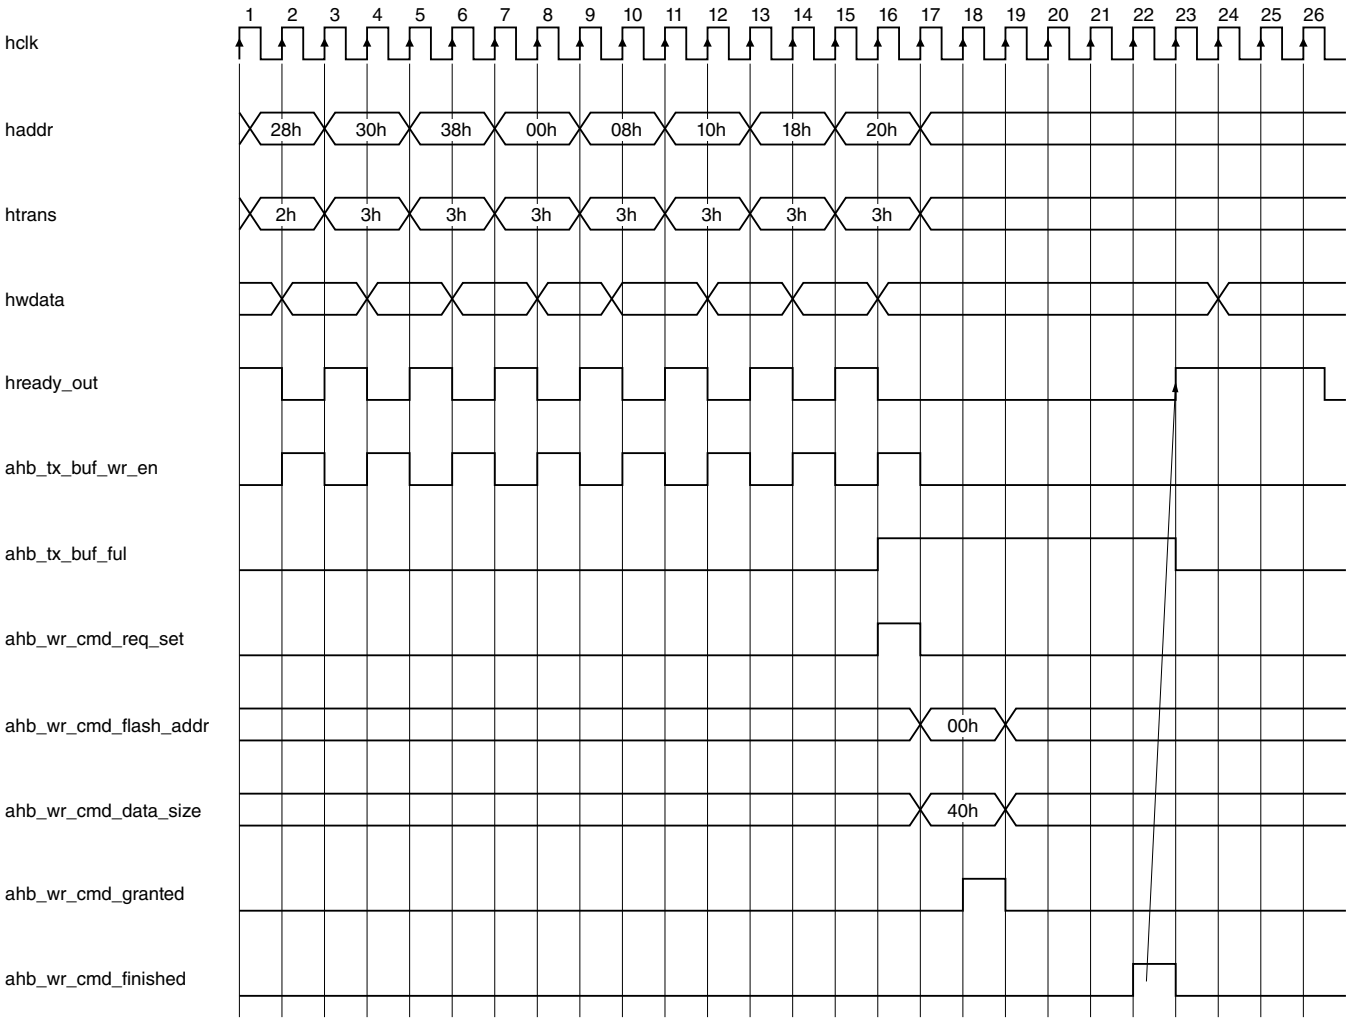

Figure 30-21. AHB write access (WRAP8, 64-bit, non-bufferable)

NOTE

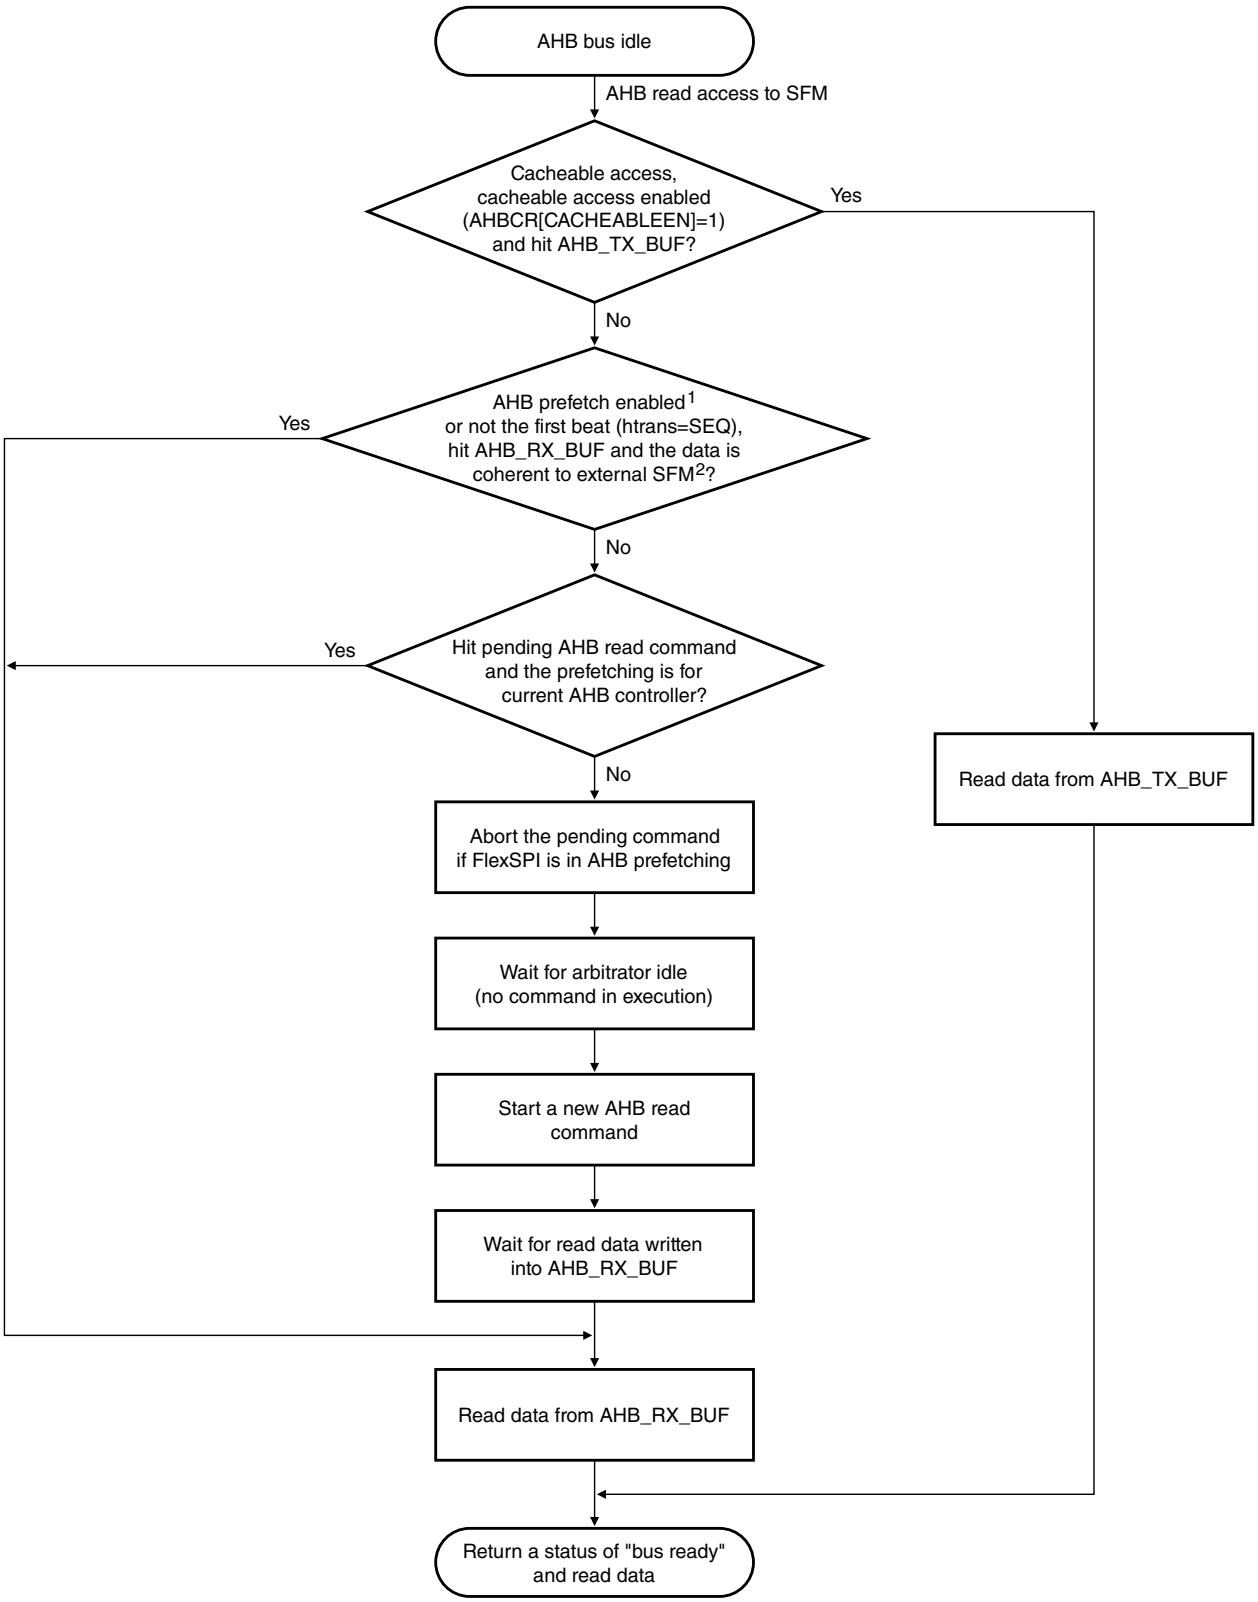
If the burst data size (in bytes) is greater than the AHB transmit buffer size, wrapper burst is not supported. For example, if AHB_TX_BUF is 64 bytes, AHB WRAP16 (16 × 64 bits = 128 bytes) write burst access is not supported.

30.3.13.2 AHB read access to flash memory

For AHB read access to flash memory, FlexSPI checks the burst access type and register setting to determine whether to access these locations:

- The AHB transmit buffer
- The AHB receive buffer
- A pending AHB read command

If all of these options are missed, FlexSPI triggers a new AHB read command to fetch data from flash memory. Figure 30-22 shows the hardware operation in response to AHB read access to flash memory.



Notes:
1) AHB prefetch is enabled when both AHBCR[PREFETCHEN]=1 and AHBRXBUFxCR0[PREFETCHEN]=1 (x is the AHB RX buffer ID for the current AHB controller) or OTFAD is enabled.
2) The AHB RX buffer holds the data read from flash memory. This data may become incoherent if AHB writes to the same flash-memory address.

Figure 30-22. Hardware operation in response to AHB read access to flash memory

Table 30-17 describes the details of a triggered AHB read command.

Table 30-17. Triggered AHB read command

Item	Description
Flash memory access start address and data size	Determined by AHB address, burst type, and burst size. FlexSPI fetches read data from the start address for the current burst or beat. See Table 30-18 for details.
Flash memory chip select	FlexSPI uses the settings of the flash memory access start address and flash memory size to determine the chip select.
Flash memory command sequence index	Determined by FLSHxCR2[AWRSEQID].
Flash memory command sequence number	Determined by FLSHxCR2[AWRSEQNUM]. If AWRSEQNUM is not zero, multiple flash memory access command sequences are triggered every time for an AHB read command. The sequences indexed from AWRSEQID to (AWRSEQID + AWRSEQNUM) in LUT are executed sequentially.
Flash memory access mode (Individual/ Parallel)	Determined by AHBCR[APAREN].

NOTE

- FlexSPI automatically determines which ARDSEQNUM and ARDSEQID fields that the flash device uses as sequence ID for chip selection. See MCR2[SAMEDEVICEEN].
- FlexSPI determines which AHB receive buffer to use for the current AHB read access by controller ID. For details about the AHB receive buffer ID and AHB controller ID mapping, see AHB receive buffer management.
- You cannot allocate the size of the AHB receive buffer to be less than the AHB Burst size. This allocation results in unknown behavior.

Table 30-18. AHB read command flash memory start address and data size

Prefetch enable	Cross flash boundary	Burst type	Flash memory start address [27:0]	Data size
0	Never cross flash boundary, because AHB burst never crosses 1 KB boundary.	SINGLE, INCR4, INCR8, INCR16	hbeat_start_address	(hburst_end_address-hbeat_start_address)
		INCR	hbeat_start_address	byte size of current beat For INCR burst with prefetch disabled, each beat is handled same as SINGLE burst.
		WRAP4, WRAP8, WRAP16	hburst_start_address	(hburst_end_address-hburst_start_address)

Table continues on the next page...

Table 30-18. AHB read command flash memory start address and data size (continued)

Prefetch enable	Cross flash boundary	Burst type	Flash memory start address [27:0]	Data size
1	No	INCR, SINGLE, INCR4, INCR8, INCR16	hbeat_start_address	ahb_rx_buf_sz
	No	WRAP4, WRAP8, WRAP16	hburst_start_address	ahb_rx_buf_sz
	Yes	INCR, SINGLE, INCR4, INCR8, INCR16	hbeat_start_address	(flash_top_address-hbeat_start_address)
	Yes	WRAP4, WRAP8, WRAP16	hburst_start_address	(flash_top_address-hburst_start_address)

NOTE

- hbeat_start_address is HADDR input from the AHB controller for current beat.
- hburst_start_address (for example 00h) is the lowest address for current burst. hburst_end_address (for example 10h) is the highest address in current burst plus 1. For example, WRAP4 burst with HADDR 8h, Ch, 0h, 4h.
- ahb_rx_buf_sz is the buffer size in bytes of AHB receive buffer that the current AHB controller uses.
- flash_top_address is the top address of currently accessed flash memory.

30.3.13.3 AHB receive buffer management

There are 8 buffers (Buffer 0–7) in the AHB receive buffer. These buffers are transparent to AHB controllers. FlexSPI fetches flash memory data and returns it on the AHB bus automatically. No status register polling is needed for AHB read access to Serial Flash Memory (SFM).

See the chip-specific section for AHB buffer size.Use AHBRXBUF0CR0[BUFSZ]–AHBRXBUFCR7[BUFSZ] to configure the buffer size of each AHB receive buffer. The buffer size for Buffer 0 to Buffer 7 could be set to 0. If the buffer size is set to 0, FlexSPI ignores the related setting of AHBRXBUFxCR0[MSTRID]. Buffer 7 is used for all AHB controllers not assigned to Buffer 0–6. FlexSPI ignores the Buffer 7 size setting field (AHBRXBUF7CR0[BUFSZ]). Its buffer size is: (AHB receive buffer total size) - (the sum of the sizes of Buffer 0–6).

When an AHB read access to serial flash memory occurs, FlexSPI determines which buffer to use via this method:

1. If the controller ID equals AHBRXBUF0CR0[MSTRID] and AHBRXBUF0CR0[BUFSZ] is not zero, Buffer 0 is used.
2. If the controller ID equals AHBRXBUF1CR0[MSTRID] and AHBRXBUF1CR0[BUFSZ] is not zero, Buffer 1 is used.
3. If the controller ID equals AHBRXBUF2CR0[MSTRID] and AHBRXBUF2CR0[BUFSZ] is not zero, Buffer 2 is used.
4. If the controller ID equals AHBRXBUF3CR0[MSTRID] and AHBRXBUF3CR0[BUFSZ] is not zero, Buffer 3 is used.
5. If the controller ID equals AHBRXBUF4CR0[MSTRID] and AHBRXBUF4CR0[BUFSZ] is not zero, Buffer 4 is used.
6. If the controller ID equals AHBRXBUF5CR0[MSTRID] and AHBRXBUF5CR0[BUFSZ] is not zero, Buffer 5 is used.
7. If the controller ID equals AHBRXBUF6CR0[MSTRID] and AHBRXBUF6CR0[BUFSZ] is not zero, Buffer 6 is used.
8. If all the above cases are not met, Buffer 7 is used.

NOTE

- Software must ensure that the size of each buffer is not less than the maximum burst size of an AHB read access from the AHB controller using this buffer. Otherwise, the behavior is undefined. The minimum buffer size request depends on the chip implementation. For example, if the capability of the chip to send out a maximum burst is 64 bytes, the minimum AHB receive buffer is 64 bytes.
- Assigning multiple buffers to a single AHB controller is not supported, unless the prefetch buffer enhancement feature is being used.
- When AHB read prefetch is enabled (AHBCR[PREFETCHEN] = 1), the size of the buffer determines the prefetch data size. If it does not cross the flash boundary, FlexSPI fetches data from the external flash device with that buffer size.
- The priority setting of AHB controller (AHBRXBUFxCR0[PRIORITY] = 1) is used only for suspending control of AHB prefetching. See Command abort and suspend.

30.3.13.4 AHB controller ID remapping

The AHB controller uses AHB user bits instead of HMASTER to support multiple AHB receive buffers on one AHB controller. For example, a single AHB controller with two sub threads can be distinguished by using different AHB user bits to access FLEXSPI. The controller ID remapping feature is designed to support such user cases.

The related AHB user bits mask and expected controller value are defined in HMSTRnCR0-7. The function enable is AHBCR[HMSTRIDREMAP]

When there is an AHB read access to serial flash memory, FlexSPI remaps the controller ID as shown below.

1. If AHBCR[HMSTRIDREMAP] = 0, the remapping function is disabled and bus signal HMASTER[3:0] is used directly.
2. If AHBCR[HMSTRIDREMAP] = 1, AHB user bits [15:0] are ANDed with HMSTRCR0~7's bits [15:0], which is a masking field. This combining results in eight new user bits (for example, masked_user[15:0]_0-7_).
3. If masked_user[15:0]_0_ = HMSTRCR0[31:16], controller ID is mapped to 0h internally, which is compared to AHBRXBUFxCR0[MSTRID].
4. If masked_user[15:0]_1_ = HMSTRCR1[31:16], controller ID is mapped to 1h internally, which is compared to AHBRXBUFxCR0[MSTRID].
5. If masked_user[15:0]_2_ = HMSTRCR2[31:16], controller ID is mapped to 2h internally, which is compared to AHBRXBUFxCR0[MSTRID].
6. If masked_user[15:0]_3_ = HMSTRCR3[31:16], controller ID is mapped to 3h internally, which is compared to AHBRXBUFxCR0[MSTRID].
7. If masked_user[15:0]_4_ = HMSTRCR4[31:16], controller ID is mapped to 4h internally, which is compared to AHBRXBUFxCR0[MSTRID].
8. If masked_user[15:0]_5_ = HMSTRCR5[31:16], controller ID is mapped to 5h internally, which is compared to AHBRXBUFxCR0[MSTRID].
9. If masked_user[15:0]_6_ = HMSTRCR6[31:16], controller ID is mapped to 6h internally, which is compared to AHBRXBUFxCR0[MSTRID].
10. If none of the above listed cases are met, Buffer 7 is used.

30.3.14 Command arbitration

There are four flash memory access command sources:

1. AHB command, that AHB write access to serial flash memory space triggers
2. AHB command, that AHB read access to serial flash memory space triggers
3. IP command, that writing IPCMD[TRG] triggers
4. Suspended command, an AHB read prefetch sequence which is suspended

An AHB bus access never triggers a write command and a read command at the same time.

The AHB prefetch sequence is an AHB command sequence triggered via AHB read access when AHB prefetch is enabled. After all read data is fetched for the current AHB read burst, FlexSPI prefetches more data to reduce read latency for the next AHB read access. An AHB command for a read operation is never aborted while fetching read data for the current AHB read burst. However, a new IP command or AHB command request while prefetching data (not for the current read burst) can abort an AHB read command.

When the arbitrator is idle (STS0[ARBIDLE] = 1), the granted priority of these command sources is:

1. AHB command (read or write)
2. IP command
3. Suspended command

NOTE

When the arbitrator is idle and there is no AHB or IP command request, a suspended command is not granted immediately. The arbitrator waits MCR2[RESUMEWAIT] AHB clock cycle idle states before resuming the suspended command to avoid AHB prefetch sequence being resumed and suspended frequently.

If the arbitrator is busy executing AHB or IP commands (not suspended commands), no new command requests are granted. If the grant times out, an AHB or IP command granted error occurs.

If a new AHB or IP command request comes while arbitrator is executing AHB read prefetch sequence, AHB read prefetch sequence is aborted (but not immediately). Arbitrator grants the AHB or IP command request after AHB read prefetch sequence is aborted on the FlexSPI interface and saved all internal data pointers.

30.3.14.1 Command abort and suspend

Table 30-19 describes the command abort and suspend mechanism.

Table 30-19. Command abort and suspend

Action	Description
Aborting a command	As mentioned above, if a new AHB or IP command request arrives, an AHB read prefetch sequence can be aborted.
Suspending a command	When an AHB read prefetch sequence is aborted on the FlexSPI interface, FlexSPI saves this suspended sequence in the cases listed below. FlexSPI resumes this sequence after the arbitrator has been idle for enough time.

Table continues on the next page...

Table 30-19. Command abort and suspend (continued)

Action	Description
	• There is no valid suspended command (AHBSPNDSTS[ACTIVE] = 0). This condition can occur when no command is suspended or when the suspended command is resumed. • The priority of aborted AHB read prefetch sequence is higher than the active suspend sequence. **NOTE:** FlexSPI ignores and never resumes the original suspended sequence.
Activating a suspended command	The suspended command (internal status) becomes active when an AHB prefetch command is aborted and suspended. It becomes inactive in the following cases: • The arbitrator resumes the suspended command. • The AHB controller triggers a new AHB read command request using the same AHB receive buffer (buffer ID).

Figure 30-23 shows an example of the flow of command abort, suspend, or resume.

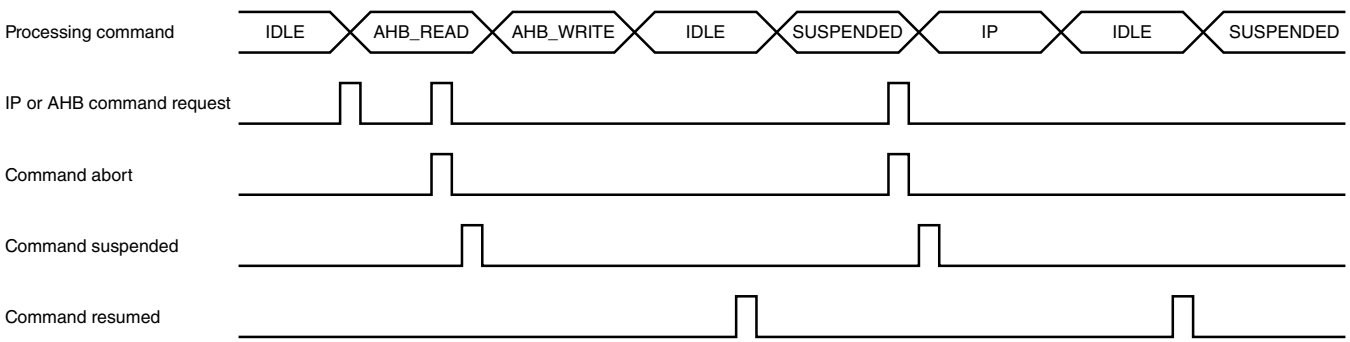


Figure 30-23. Command instruction execution on FlexSPI interface

NOTE

- The AHB prefetch sequence is aborted, suspended, or resumed twice in Figure 30-23. A new AHB write command request aborts the sequence the first time, and a new IP command request aborts the sequence the second time.
- The suspended sequence is resumed after a wait time of idle state. If there are frequent IP or AHB command requests and the wait time is not set reasonably, the suspend and resume activities may be triggered frequently.

30.3.15 SCLK stop

FlexSPI stops SCLK output toggling:

- When programming data is not ready for a programming command sequence.
- When an internal FIFO has no space to receive data for reading command sequence.

Certain devices may not support the stopping of SCLK during a command sequence (chip select is valid). SCLK stopping can be avoided via the methods described below.

- For flash memory reading that an IP command triggers:
  - Never trigger a read command with data size larger than IP receive FIFO size.
  - Internal asynchronous FIFO for flash memory reading should never be full.

    FlexSPI pops 64 bits of data per AHB clock cycle from this FIFO, and receives data from FlexSPI interface on the serial root clock. The flash memory access mode (Single, Dual, Quad, or Octal mode and Individual or Parallel mode) determines the receiving speed. For example, in Octal mode and Parallel mode, FlexSPI receives 16 bits per serial root clock cycle. If the AHB clock frequency is faster than 1/4 of the serial root clock, this asynchronous FIFO is never full.

- For flash memory programming that an IP command triggers:
  - Never trigger a program command with data size larger than the IP transmit FIFO size. Write all programming data into the IP transmit FIFO before triggering the IP command.
  - The internal asynchronous FIFO for flash memory programming must never be empty.

    FlexSPI fetches 64 bits of programming data per AHB clock cycle into this FIFO, and transmits data to the FlexSPI interface on the serial root clock. The flash memory access mode (Single, Dual, Quad, or Octal mode and Individual or Parallel mode) determines the transmitting speed. For example, in Octal mode and Parallel mode, FlexSPI transmits 16 bits per serial root clock cycle. If the AHB clock frequency is faster than 1/4 of the serial root clock, this asynchronous FIFO is never empty.

- For flash memory reading or programming that an AHB command triggers:
  - The internal asynchronous FIFO for flash memory reading and programming must never be full or empty. The frequency ratio limitation is same as it is for flash memory reading or flash memory programming that an IP command triggers.

NOTE

- FlexSPI never triggers an AHB read command with data size larger than the internal AHB receive buffer size.

- FlexSPI never triggers an AHB program command with data size larger than the internal AHB transmit buffer size.
- All programming data is buffered into the AHB transmit buffer before triggering an AHB program command in FlexSPI.

30.3.16 FlexSPI output timing

30.3.16.1 Output timing between data and SCLK

This section describes the output timing relationship of data (on A_DATA and B_DATA) and SCLK. There are three cases.

- **SDR instruction in SDR sequence**
  An SDR sequence contains only SDR instructions. In this case, all data bits last one serial root clock cycle on the FlexSPI interface. Figure 30-24 shows the relationship between the serial root clock, data, and SCLK:

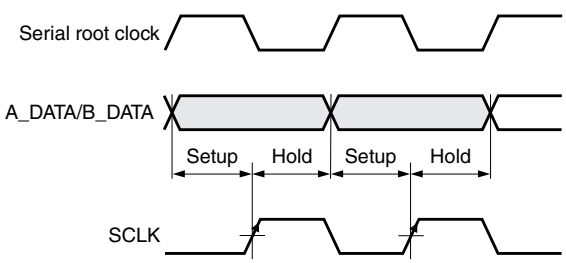

Figure 30-24. SDR instruction in SDR sequence

- **SDR instructions in a DDR sequence**

  A DDR sequence is a flash memory access command sequence that contains DDR instructions other than DUMMY_DDR. It may contain SDR instructions. If there are SDR instructions in a DDR sequence, all data bits last for two serial root clock cycles on the FlexSPI interface. Figure 30-25 shows the relationships between the serial root clock, data, and SCLK.

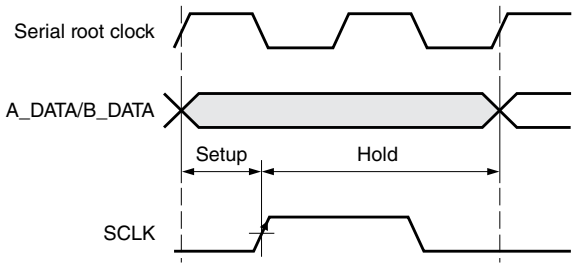

Figure 30-25. SDR instruction in DDR sequence

- **DDR instructions in a DDR sequence**

  For DDR instructions in a DDR sequence, all data bits last one serial root clock cycle on the FlexSPI interface. Figure 30-26 shows the relationships between the serial root clock, data, and SCLK.

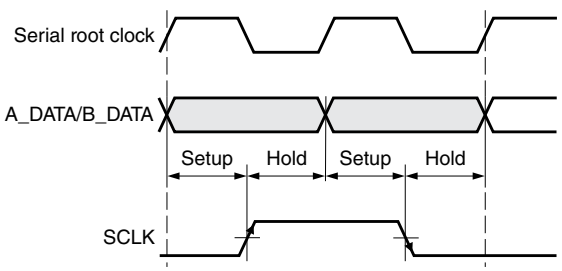

Figure 30-26. DDR instruction in DDR sequence

30.3.16.2 Output timing between chip select and SCLK

This section describes the output timing relationship between chip select (on A_SS0_B, A_SS1_B, B_SS0_B, and B_SS1_B) and SCLK. The timing relationship for the SDR sequence differs a little from the timing relationship for the DDR sequence.

- **Chip select timing in SDR sequence**

  For an SDR sequence, the delay from chip select assertion to the SCLK rising edge is (FLSHxCR1[TCSS] + 0.5) cycles of the serial root clock. The delay from SCLK falling edge to chip select deassertion is FLSHxCR1[TCSH] cycles of serial root clock. Figure 30-27 shows the timing relationship between the chip select and SCLK.

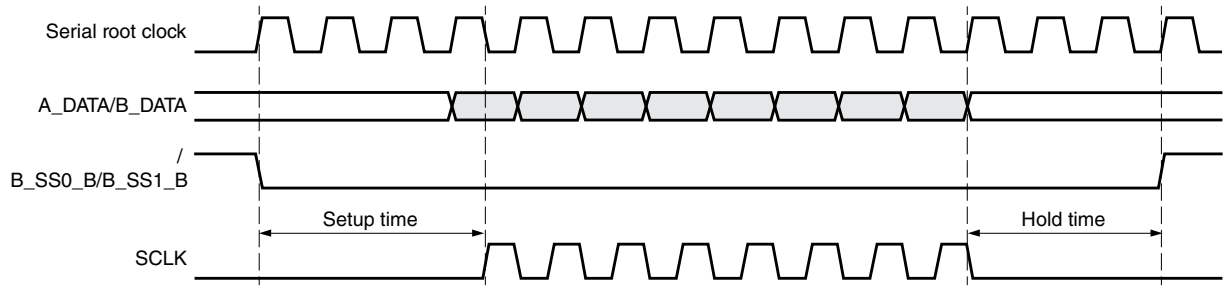

Figure 30-27. Chip select output timing for SDR sequence

- **Chip select timing in DDR sequence**

  For a DDR sequence, the delay from chip select assertion to the SCLK rising edge is **(FLSHxCR1[TCSS] + 0.5)** cycles of the serial root clock. The delay from the SCLK falling edge to chip select deassertion is **(FLSHxCR1[TCSH] + 0.5)** cycles of serial root clock.

  NOTE

  When AHB receive prefetch is enabled, and prefetch can be aborted, configure TCSH to 1 or greater. Configuring TCSH in this way guarantees a positive chip select hold time after the SCLK falling edge.

  Figure 30-28 shows the timing relationship between chip select and SCLK.

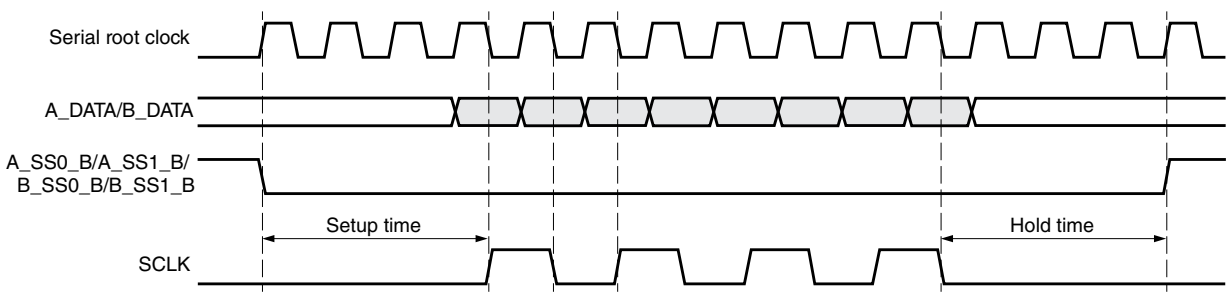

Figure 30-28. Chip select output timing for DDR sequence

For devices such as an FPGA device, a minimum chip select negation time (time between two chip select assertions) may be required. If the value of FLSHxCR1[CSINTERVAL] is nonzero, FlexSPI ensures a delay between chip select valid assertions. The delay time is CSINTERVAL × 256 cycles of serial root clock for an SDR or DDR sequence. If the external device has no limitation, configure the value of this field to zero. Figure 30-29 shows the timing of the chip select interval.

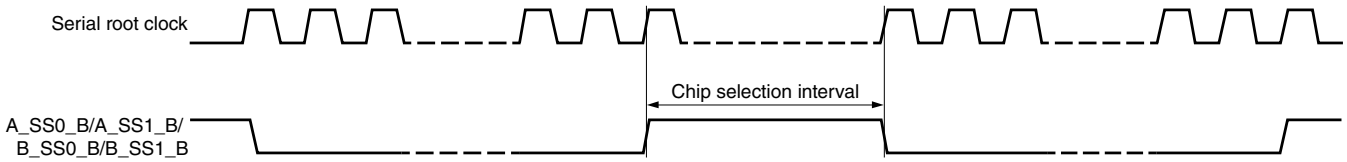

Figure 30-29. Chip select valid interval

30.3.17 FlexSPI input timing

This section describes the input timing of FlexSPI.

30.3.17.1 Receiving block

This section describes the receiving block in FlexSPI.

FlexSPI decodes instruction code to determine SDR mode or DDR mode. It also determines whether both the rising and falling edges are used for flash data sampling. FlexSPI samples the data line for learn instructions and read instructions.

MCR0[RXCLKSRC] selects the clock source from these four sources for the sampling clock:

- Internal dummy read strobe and looped back internally
- Internal dummy read strobe and looped back from DQS pad
- SCK output and looped back from SCK pad
- Flash-memory-provided read strobe

For details about DLL configuration, see DLL configuration for sampling.

Figure 30-30 shows the sampling block in FlexSPI.

FlexSPI uses both rising and falling edges to sample data from flash_A and flash_B. Two muxes with four clock source inputs generate the signals ipp_ind_io_fa, ipp_ind_io_fb. See Receive clock source features. ipp_ind_io_fa_int and ipp_ind_io_fb_int are reversed from ipp_ind_io_fa and ipp_ind_io_fb. Both sampling flip-flops are used when FlexSPI is in DDR mode. Only the falling edge sampling flip-flop is used in SDR mode.

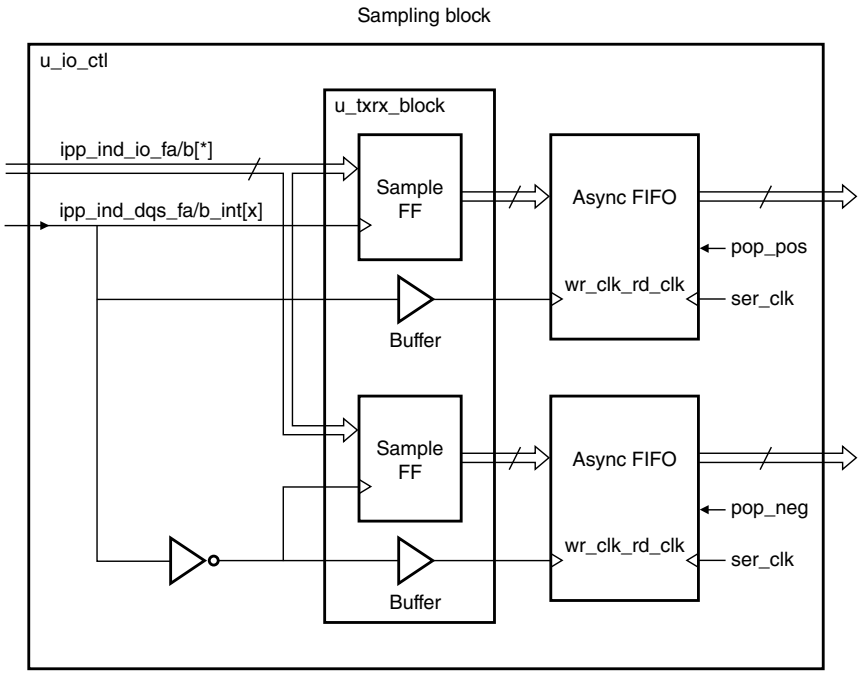

Figure 30-30. Sampling block in FlexSPI

There are 1 clock phases for sampling data. An internal delay chain delays the clock phases.

FlexSPI does not support read operations with a zero-turnaround cycle for direction switching on I/O pins. This read operation often occurs in QuadSPI configuration register reads. In Figure 30-31 and Figure 30-32, SIO[3:0] is an output from FlexSPI in the CMD phase, and is an input to FlexSPI in the DATA phase. No time remains for FlexSPI to switch the direction. This kind of read is not supported. FlexSPI and flash memory drive the I/O pins at the same time, which may cause a problem. To avoid this behavior on I/O pins, using SPI mode or reading with dummy cycles is required.

NOTE

The cycle numbers are not accurate in the examples below. See the device spec for accurate cycle numbers.

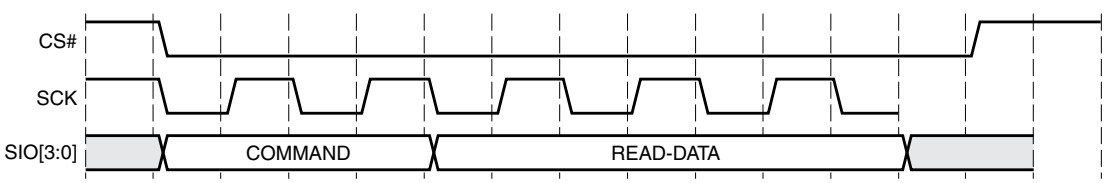

Figure 30-31. Unsupported read behavior

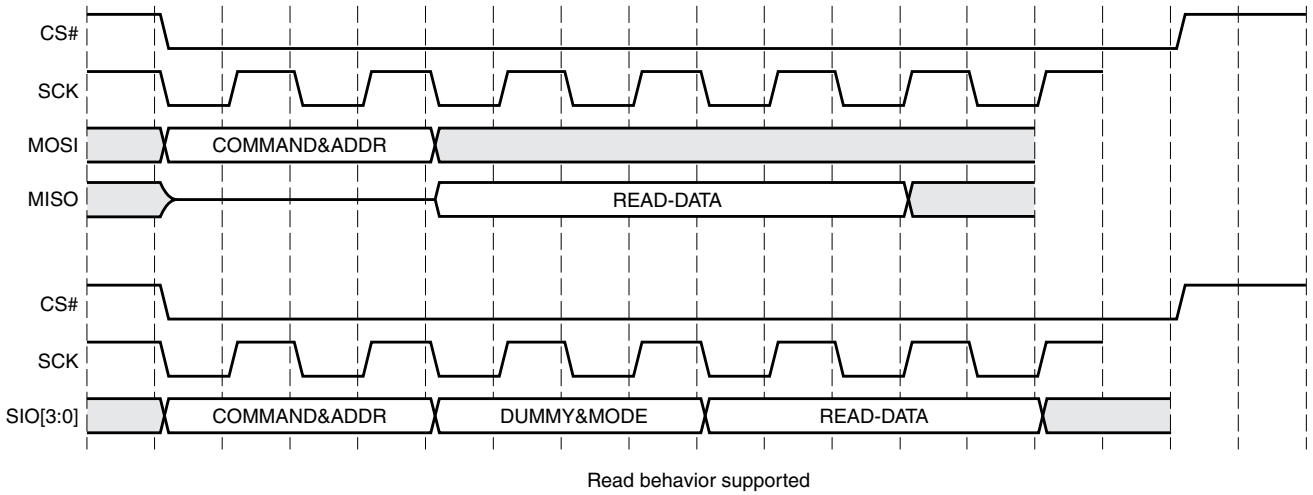

Figure 30-32. Supported read behavior

30.3.17.2 Receive clock source features

FlexSPI uses a read strobe to sample incoming data. There are several options for generating the read clock strobe that MCR0[RXCLKSRC] selects. Using the receive clock source method has implications for the board connections and can affect the maximum frequency that the interface supports. See the device data sheet for details on the maximum frequency supported for each RXCLKSRC option.

Table 30-20. RXCLKSRC options

MCR0[RXCLKSRC]	Description	Board connection	Max Frequency
0	Internal dummy read strobe and internal loopback	DQS pin is not used. The DQS pin can be configured for an alternate signal function.	Lowest
1	Internal dummy read strobe and loopback from DQS pad	FlexSPI uses the DQS pin, and it must be configured for its FlexSPI function. The internally generated read strobe is sent to the DQS pin and is sampled at the pin to match more closely the data pin timings. The DQS pin is typically left floating. External capacitance can be added to adjust timing.	Medium
3	Flash-memory-provided read strobe	DQS pin is connected to the DQS or RWDS signal that the memory provides.	Highest

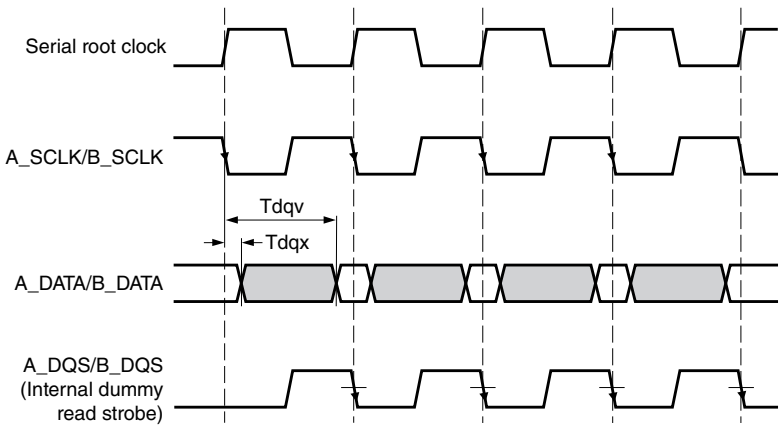
30.3.17.3 Input timing for sampling with dummy read strobe

This section describes the input timing when sampling with the internal dummy read strobe (MCR0[RXCLKSRC] = 0 or 1). The timing for sampling with an internal dummy read strobe loopback is very similar to the timing for loopback from pad. Sampling with a dummy read strobe loopback from the DQS pad can achieve a higher read frequency. It compensates for the delay of the SCLK output path and data pin input path.

The input timing is different for SDR mode and DDR mode.

- **Input timing for sampling with dummy read strobe in SDR mode**

  For SDR read or learn instructions, FlexSPI samples input data pins with the falling edge of the dummy read strobe. Figure 30-33 shows the input timing for sampling with dummy read strobe in SDR mode.



Tdqv is the setup time from SCLK to the next valid data.
Tdqx is the hold time from SCLK to the current valid data.

Figure 30-33. Input timing for sampling with dummy read strobe in SDR mode

- **Input timing for sampling with dummy read strobe in DDR mode**

  For DDR read or learn instructions, FlexSPI samples input data pins on rising and falling edges of the dummy read strobe. Figure 30-34 shows the input timing for sampling with dummy read strobe in DDR mode.

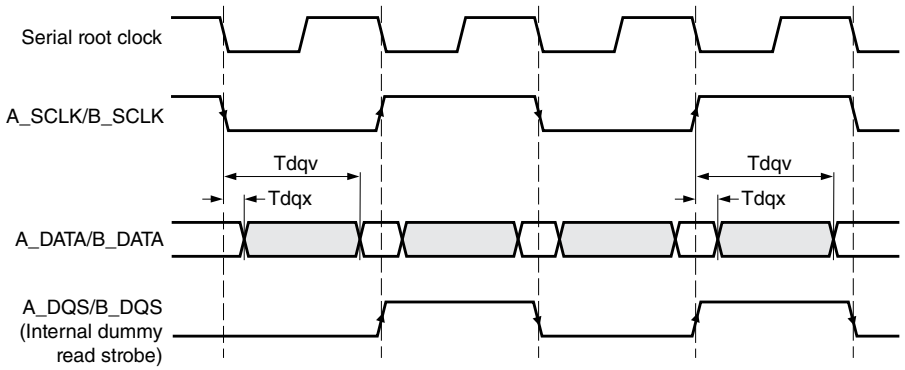


Figure 30-34. Input timing for sampling with dummy read strobe in DDR mode

30.3.17.4 Input timing for sampling with flash-memory-provided read strobe

This section describes the input timing when sampling with flash-memory-provided read strobe (MCR0[RXCLKSRC] = 3). The input timing is different for SDR mode and DDR mode.

NOTE

There are no known devices that provide a read strobe and support SDR mode operation.

- **Flash-memory-provided read strobe with SCLK**

  Certain flash devices provide both read data and read strobes with SCLK. Then the read strobe edge is aligned with the read data change. The FlexSPI controller delays the read strobe for one half cycle of the serial root clock (with DLL), then samples read data with the delayed strobe. See DLL configuration for sampling. Figure 30-35 and Figure 30-36 show the input timing for sampling with flash memory read strobe in SDR mode and DDR mode.

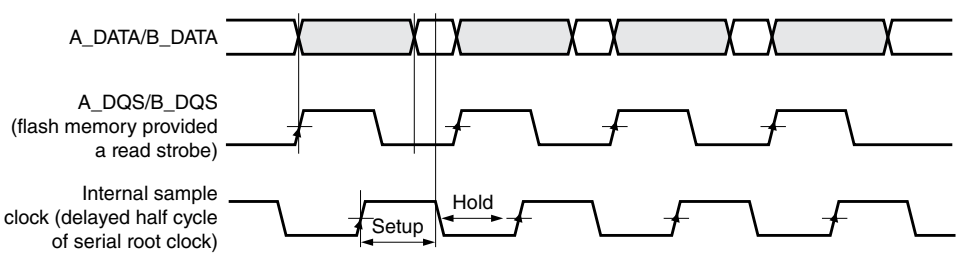

Figure 30-35. Input timing 2 for flash-memory-provided read strobe in SDR mode

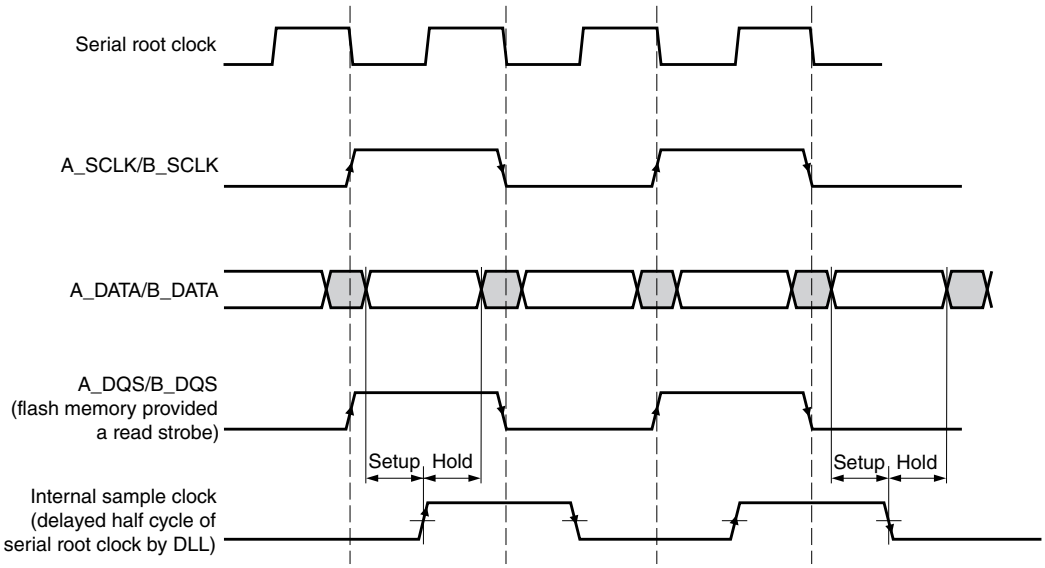

Figure 30-36. Input timing 2 for flash-memory-provided read strobe in DDR mode

30.3.17.5 DLL configuration for sampling

For the four sampling clock sources described previously, the input timing differs depending on the DLLxCR register configuration, according to the sampling clock source mode. The DLL is a delay-line chain that can be set to a fixed number of delay cells. It can also be auto-adjusted to lock on a certain phase delay to the reference clock.

- DLLxCR must be set to 0000_0100h (one fixed delay cell in DLL delay chain) in the following cases:
  - Sampling data with dummy read strobe looped back internally (MCR0[RXCLKSRC] = 0h)
  - Sampling data with dummy read strobe looped back from DQS pad (MCR0[RXCLKSRC] = 1h)
- When data is sampled with a flash-memory-provided read strobe (MCR0[RXCLKSRC] = 3h) and flash memory provides the read strobe with SCLK, DLL must be configured as follows. These settings ensure a lock of the reference clock (serial root clock).
  - DLLxCR[SLVDLYTARGET] is up to flash parameters used.
  - DLLxCR[REFPHASEGAP] = 2h
  - DLLxCR[DLLEN] = 1h
  - DLLxCR[OVRDEN] = 0h
  - Other fields in DLLxCR must be kept at their reset values (all zeroes).

NOTE

If the serial root clock is slower than 100 MHz, DLL cannot lock on a half cycle of serial root clock. The delay cell number is limited in the delay chain. DLL must be configured as follows instead:

- DLLxCR[OVRDEN] = 1
- DLLxCR[OVRDVAL] = N

  Each delay cell in DLL is about 75 ps to 225 ps. The delay of DLL delay chain is (N × Delay_cell_delay). N is set based on the maximum DDR frequency (N ≤ equation). This value is calculated based on the MAX_DDR_FREQ parameter. N = 18. This value is a recommended value. If a failure occurs, the value might require adjustment in a real application.

- Other fields in DLLxCR must be kept at their reset values (all zeroes).

30.3.18 Execute-In-Place (XIP) enhanced mode

FlexSPI always supports XIP, regardless of whether external devices provide XIP enhanced mode. To support XIP, put program codes on an external device, then read or execute these codes directly via AHB read access to serial flash memory space. There is no configuration or status polling needed during AHB read access to the memory of the external device. The AHB receive buffer is fully transparent to software.

Certain devices provide XIP enhanced mode to improve code execution. In this mode, the command code is only sent in the first read instruction. It saves many cycles for command instructions and improves code execution. Devices enter or exit XIP enhanced mode via a special sequence that external devices specify. See the external device data sheet for more details.

Normally, a device enters XIP enhanced mode via this sequence:

1. Enable XIP enhanced mode in external flash device via IP command.
2. Send the first read sequence to external flash device with correct mode bits. Command code is included in this read sequence.
3. Send the subsequent read sequences to external flash device with correct mode bits. Command code is not included in these read sequences. Mode bits must be sent according to the flash specified; otherwise, the flash exits XIP enhanced mode.

The instruction JMP_ON_CS in FlexSPI must be used to support XIP enhanced mode in external devices. This instruction is only allowed in the AHB read command; otherwise, the instruction generates an IPCMDERR or AHBCDMERR interrupt (when the interrupt is enabled). When external devices do not support XIP enhanced mode, JMP_ON_CS must never be used. To support XIP enhanced mode:

- The first instruction in the read sequence must be the command instruction.
- The last valid instruction must be JMP_ON_CS (with operand 1h).

For the first AHB read command triggered, FlexSPI executes the instructions from the instruction pointer 0 in the sequence (which is the command instruction). After this sequence is executed, FlexSPI saves the operand in the JMP_ON_CS instruction as the start pointer for the next command to current device internally. For the next AHB read command triggered, FlexSPI executes from the instruction pointer 1h, bypassing the command instruction.

After XIP enhanced mode is started, it is possible to access flash via other commands like program commands. You must, however, use a special sequence to exit enhanced XIP mode before you can run a different command. Figure 30-37 indicates XIP operation with Flash XIP enhanced mode.

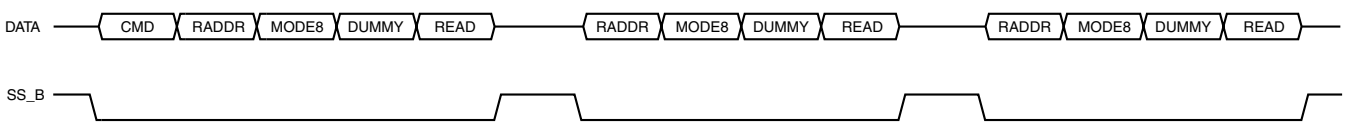

Figure 30-37. XIP Enhanced Mode Operation

30.4 External signals

This section provides the external signal information for the FlexSPI module.

Table 30-21. External Signal List

Signal name	Function	Direction	Description
A_SS0_B	Peripheral Chip Select Flash A1	O	Chip select for the serial flash device A1
A_SS1_B	Peripheral Chip Select Flash A2	O	Chip select for the serial flash device A2
B_SS0_B	Peripheral Chip Select Flash B1	O	Chip select for the serial flash device B1
B_SS1_B	Peripheral Chip Select Flash B2	O	Chip select for the serial flash device B2
A_SCLK	Serial Clock Flash A	O	Serial clock output to the serial flash device A.

Table continues on the next page...

Table 30-21. External Signal List (continued)

Signal name	Function	Direction	Description
			This clock runs at half the frequency of serial clock root in DDR mode, and at the same frequency as serial clock root in SDR mode. Clock output toggles during the entire flash memory access sequence.
B_SCLK	Serial Clock Flash B	O	Serial clock output to the serial flash device B. This clock runs at half the frequency of serial clock root in DDR mode, and at the same frequency as serial clock root in SDR mode. Clock output toggles during the entire flash memory access sequence. **NOTE:** B_SCLK may be used as the differential clock output of A_SCLK by writing 1 to MCR2[SCKBDIFFOPT].
A_DATAn	Serial I/O Flash A	I/O	Data I/O lines to and from the serial flash device A
B_DATAn	Serial I/O Flash B	I/O	Data I/O lines to and from the serial flash device B
A_DQS	Data Strobe Signal Flash A	I/O	Data strobe signal for port A. This signal has three functions: • Driven with read strobe by external device. Some flash devices provide the read strobe signal together with read data. In this case, if the external device drives this pad only when reading flash memory data, this pad may require a **pull-down** resistor. • Driven with latency information by external device. Some devices use this pin to indicate the dummy cycles needed (before program or read data transfer) such as HyperRAM or HyperFlash. • Loopback dummy read strobe. The FlexSPI controller provides internal dummy read strobe for flash memory read data. Higher read frequency can be achieved by looping back this dummy read strobe from the pad. This pin can be floated or have some capacitive load added at the board level to compensate for load on DATA or SCLK pins.
B_DQS	Data Strobe Signal Flash B	I/O	Similar to A_DQS

30.5 Initialization

The FlexSPI controller initialization sequence is:

1. Enable controller clocks (AHB clock, IP bus clock, or serial root clock) at system level.
2. To enter module stop mode, write 1 to MCR0[MDIS].
3. Configure module control registers: MCR0, MCR1, and MCR2. Do not change MCR0[MDIS].
4. When AHB commands are used, configure AHB Bus Control (AHBCR) and AHB Receive Buffer Control (AHBRXBUFxCR0) registers.
5. Configure flash control registers (FLSHxCR0, FLSHxCR1, or FLSHxCR2) according to external device type.
6. Configure DLL control register (DLLxCR) according to sample clock source selection.
7. To exit module stop mode, write 0 to MCR0[MDIS].
8. Configure LUT as needed for AHB command or IP command.
9. Optionally, to reset controller, write 1 to MCR0[SWRESET].

External devices must be configured via IP command normally after initialization. For example, the WRITE STATUS command performs device configuration for most serial NOR flash memory.

30.6 Application information

This section describes applications that FlexSPI supports.

30.6.1 Application on serial NOR flash device

This section provides the example LUT instruction sequences for serial NOR flash device (Cypress Flash S25FS128S).

30.6.1.1 Write enable command

Table 30-22 shows the WRITE ENABLE command sequence.

Table 30-22. WRITE ENABLE command

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0h	06h	Command name: WREN
1-7	STOP (00h)	0h	00h	

30.6.1.2 Write registers command

Table 30-23 shows the Write Registers command sequence.

Table 30-23. Write Registers command

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0h (Single)	01h	Command name: WRR
1	WRITE_SDR	0h (Single)	1h or 2h	Data size is 1 byte or 2 bytes. Byte 0 is write data for Status Register 1; Byte 1 is write data for Configuration Register 1. IPCR1[IDATSZ] can override this value.
2-7	STOP (00h)	0h	00h	

30.6.1.3 Page Program command

Table 30-24 shows Page Program command sequence.

Table 30-24. PAGE PROGRAM command (Cypress serial NOR flash)

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0h (Single)	02h or 12h	Command name: PP or 4PP PP is 3-byte address mode. 4PP is 4-byte address mode.
1	ADDR_SDR	0h (Single)	18h or 20h	Address bit number (operand value) should be 24 in 3-byte address mode and 32 in 4-byte address mode.
2	WRITE_SDR	0h (Single)	Any nonzero value	If IPCR1[IDATSZ] is zero, this operand value can be used as default programming data size. This value is ignored for AHB command.
3-7	STOP (00h)	0h	00h	

Table 30-25 shows Page Program command sequence (QPI mode).

Table 30-25. PAGE PROGRAM (QPI mode) command (Cypress serial NOR flash)

				data size. This value is ignored for AHB command.
3-7	STOP (00h)	0h	00h	

30.6.1.6 Fast Read command

Table 30-28 shows Fast Read command sequence. This table shows Cypress SPI Configuration Register bits CR2V[7] = 0, CR2V[3:0] = 8h.

Table 30-28. FAST_READ command

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0h (Single)	0Bh or 0Ch	Command name: FAST_READ or 4FAST_READ FAST_READ is 3-byte address mode. 4FAST_READ is 4-byte address mode.
1	ADDR_SDR	0h (Single)	18h or 20h	Address bit number (operand value) should be 24 in 3-byte address mode and 32 in 4-byte address mode.
2	DUMMY_SDR	0h (Single)	08h	Dummy cycle is 8 (in serial root clock) as CR2V[3:0] = 8h.
3	READ_SDR	0h (Single)	Any nonzero value	If IPCR1[IDATSZ] is zero, this operand value can be used as default reading data size. This value is ignored for AHB command.
4-7	STOP (00h)	0h	00h	

30.6.1.7 Dual IO Fast Read command

Table 30-29 shows Dual IO FAST_READ command sequence. This table shows Cypress SPI Configuration Register bits CR2V[7] = 0, CR2V[3:0] = 8h, Continuous Read mode.

Table 30-29. Dual IO FAST_READ command (Continuous Read mode)

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0h (Single)	BBh or BCh	Command name: DIOR or 4DIOR DIOR is 3-byte address mode.

Table continues on the next page...

Table 30-29. Dual IO FAST_READ command (Continuous Read mode) (continued)

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
				4DIOR is 4-byte address mode.
1	ADDR_SDR	1h (Dual)	18h or 20h	Address bit number (operand value) should be 24 in 3-byte address mode and 32 in 4-byte address mode.
2	MODE8_SDR	1h (Dual)	Axh	Enter continuous read mode or remain in continuous read mode.
3	DUMMY_SDR	1h (Dual)	08h	Dummy cycle is 8 (in serial root clock) as CR2V[3:0] = 8h.
4	READ_SDR	1h (Dual)	Any nonzero value	If IPCR1[IDATSZ] is zero, this operand value can be used as default reading data size. This value is ignored for AHB command.
5	JMP_ON_CS	0h (or Don't care)	01h	CMD instruction is bypassed after the first read access.
6-7	STOP (00h)	0h	00h	

Table 30-30 shows Dual IO FAST_READ command sequence. This table shows Cypress SPI Configuration Register bits CR2V[7] = 0, CR2V[3:0] = 8h, Noncontinuous Read mode.

Table 30-30. Dual IO FAST_READ command (Noncontinuous Read mode)

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0h (Single)	BBh or BCh	Command name: DIOR or 4DIOR DIOR is 3-byte address mode. 4DIOR is 4-byte address mode.
1	ADDR_SDR	1h (Dual)	18h or 20h	Address bit number (operand value) should be 24 in 3-byte address mode and 32 in 4-byte address mode.
2	MODE8_SDR	1h (Dual)	Any value other than Axh	Exit continuous read mode or remain in noncontinuous read mode.
3	DUMMY_SDR	1h (Dual)	08h	Dummy cycle is 8 (in serial root clock) as CR2V[3:0] = 8h.
4	READ_SDR	1h (Dual)	Any nonzero value	If IPCR1[IDATSZ] is zero, this operand value can be used as default reading data size. This value is ignored for AHB command.
5-7	STOP (00h)	0h	00h	

30.6.1.8 Quad IO Fast Read command

Table 30-31 shows Quad IO FAST_READ command sequence. This table shows Cypress SPI Configuration Register bits CR2V[7] = 0, CR2V[6] = 0, CR2V[3:0] = 8h, Non-QPI mode, Noncontinuous read mode.

Table 30-31. Quad IO FAST_READ command (Non-QPI mode, Noncontinuous read mode)

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0h (Single)	EBh or ECh	Command name: QIOR or 4QIOR QIOR is 3-byte address mode. 4QIOR is 4-byte address mode.
1	ADDR_SDR	2h (Quad)	18h or 20h	Address bit number (operand value) should be 24 in 3-byte address mode and 32 in 4-byte address mode.
2	MODE8_SDR	2h (Quad)	Any value other than Axh	Exit continuous read mode or remain in noncontinuous read mode.
3	DUMMY_SDR	2h (Quad)	08h	Dummy cycle is 8 (in serial root clock) as CR2V[3:0] = 8h.
4	READ_SDR	2h (Quad)	Any nonzero value	If IPCR1[IDATSZ] is zero, this operand value can be used as default reading data size. This value is ignored for AHB command.
5-7	STOP (00h)	0h	00h	

Table 30-32 shows Quad IO FAST_READ command sequence. This table shows Cypress SPI Configuration Register bits CR2V[7] = 0, CR2V[6] = 0, CR2V[3:0] = 8h, Non-QPI mode, Continuous read mode.

Table 30-32. Quad IO FAST_READ command (Non-QPI mode, Continuous read mode)

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0h (Single)	EBh or ECh	Command name: QIOR or 4QIOR QIOR is 3-byte address mode. 4QIOR is 4-byte address mode.
1	ADDR_SDR	2h (Quad)	18h or 20h	Address bit number (operand value) should be 24 in 3-byte address mode and 32 in 4-byte address mode.
2	MODE8_SDR	2h (Quad)	A0h	Enter continuous read mode or remain in continuous read mode.
3	DUMMY_SDR	2h (Quad)	08h	Dummy cycle is 8 (in serial root clock) as CR2V[3:0] = 8h.
4	READ_SDR	2h (Quad)	Any nonzero value	If IPCR1[IDATSZ] is zero, this operand value can be used as default reading data size. This value is ignored for AHB command.

5-7	STOP (00h)	0h	00h	

30.6.3 Application on Serial NAND flash device

This section provides example LUT instruction sequences for serial NAND flash device (Micron Flash MT29 series). The operation of serial NAND flash is similar to serial NOR flash.

The read operation sequence is:

- Page read. Transfer the data from the NAND flash array to the cache register.
- Get feature to read the status.
- Random data read

Table 30-42 shows the page read command sequence.

Table 30-42. Page Read command

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	1h (Single)	13h	Command code: 13h

Table 30-44 shows Random Data Read command sequence.

Table 30-44. Read from Cache x4 command

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	1h (Single)	6Bh	Command code: 6Bh
1	MODE4_SDR	1h (Single)	0h or 1h	If plane selection is one, software should decode the flash address and write 1h to mode bits. If plane selection is zero, software should write 0h to mode bits.

Table continues on the next page...

Table 30-44. Read from Cache x4 command (continued)

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
				Plane selection bit is 18th bit of flash address. If NAND flash size is less than 4 Gbit, plane selection is always zero.
2	CADDR_SDR	1h (Single)	0Ch	Column address: 12 bit
3	DUMMY_SDR	2h (Quad)	08h	Dummy cycle number: 8 (serial root clock)
4	READ_SDR	2h (Quad)	Any nonzero value	If IPCR1[IDATSZ] is zero, this operand value can be used as default reading data size.
5-7	STOP (0x0)	0x0	0x00	

The program operation sequence is:

- Write enable
- Program Load. Transfer the write data to the cache register.
- Program Execute
- Get Feature to read the status.

Table 30-45 shows Program Load command sequence.

Table 30-45. Program Load command

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	1h (Single)	02h	Command code: 02h
1	MODE4_SDR	1h (Single)	0h or 1h	If plane selection is one, software should decode the flash address and write 1h to mode bits. If plane selection is zero, software should write 0h to mode bits. Plane selection bit is 18th bit of flash address. If NAND flash size is less than 4 Gbit, plane selection is always zero.
2	CADDR_SDR	1h (Single)	0Ch	Column address: 12 bit
3	WRITE_SDR	1h (Single)	Any nonzero value	If IPCR1[IDATSZ] is zero, this operand value can be used as default writing data size.
4-7	STOP (0h)	0h	00h	

Table 30-46 shows Program Execute command sequence.

Table 30-46. Program Execute command

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	1h (Single)	10h	Command code: 10h
1	RADDR_SDR	1h (Single)	18h	Row Address: 24 bit
2-7	STOP (0h)	0h	00h	

30.6.4 Application on FPGA device

An FPGA device must be accessed via AHB command. All AHB accesses to FPGA are transparent to the software driver (no software intervention). An FPGA device may have some special requirements.

Table 30-47. Special requirements for FPGA devices

Condition	How to manage the condition
Device type may be different on A1, A2, B1, or B2.	Write 0 to MCR2[SAMEDEVICEEN] and configure the FLSHxCR0 and FLSHxCR1 registers separately for up to four external devices.
Device requires different wait cycle for programming.	The AHB write wait cycle number can be set separately for these four external devices (via FLSHxCR2[AWRWAIT]). Software can configure the sequences in LUT with different dummy instructions (operand determines dummy cycle). FlexSPI holds the AHB bus ready for this wait time; AHB bus performance may decrease when this wait time is very long.
Device requires different wait cycle for reading.	The AHB read sequence index and sequence number can be set separately for these four external devices (via FLSHxCR2[ARDSEQID] and FLSHxCR2[ARDSEQNUM]). Software can configure the sequences in LUT with different dummy instructions (operand determines dummy cycle).
Device may be sensitive to read instruction clock cycle number.	If its internal memory is implemented similar to a FIFO, the device is sensitive to the read instruction clock cycle number. Software can send the data size information to the external device via DATSZ instruction. The FPGA device decodes the data size information and determines how many data bytes must be popped.
Device may require interval time between chip select valid.	This interval can be managed via FLSHxCR1[CSINTERVAL].
Device may use SCLK as reference clock for its internal PLL.	SCLK must be free-running and the clock frequency must be stable. To achieve this configuration, write 1 to MCR0[SCKFREERUNEN] and only use SDR sequences.

30.6.5 Overview of error categories, flags, and triggered sources

Table 30-48 provides an overview of the categories, flags, and triggered sources of errors in FlexSPI.

Table 30-48. Error category, triggered sources, and flags

Error Category	Triggered Sources	Description	Error Flags
Command grant error	AHB write command	Command grant timeout	INTR[AHBCMDGE] is set. AHB bus error response
	AHB read command		INTR[AHBCMDGE] is set. AHB bus error response
	IP command		INTR[IPCMDGE] is set.
Command check error	AHB write command	• AHB write command with JMP_ON_CS instruction used in the sequence • Unknown instruction opcode in the sequence. • Instruction DUMMY_SDR or DUMMY_RWDS_SDR used in DDR sequence. • Instruction DUMMY_DDR or DUMMY_RWDS_DDR used in SDR sequence.	INTR[AHBCMDERR] is set. Command is not executed when an error is detected in command check
	AHB read command	• Unknown instruction opcode in the sequence. • Instruction DUMMY_SDR or DUMMY_RWDS_SDR used in DDR sequence. • Instruction DUMMY_DDR or DUMMY_RWDS_DDR used in SDR sequence.	INTR[AHBCMDERR] is set. Command is not executed when an error is detected in command check
	IP command	• IP command with JMP_ON_CS instruction used in the sequence. • Unknown instruction opcode in the sequence • Instruction DUMMY_SDR or DUMMY_RWDS_SDR used in DDR sequence. • Instruction DUMMY_DDR or DUMMY_RWDS_DDR used in SDR sequence. • Flash boundary across	INTR[IPCMDERR] is set. Command is not executed when an error is detected in command check.
Command execution error	AHB write command	Command timeout during execution	INTR[AHBCMDERR] is set. INTR[SEQTIMEOUT] is set. An AHB bus error response occurs, except in following cases: • Flush triggers AHB write command (INCR

Table continues on the next page...

Table 30-48. Error category, triggered sources, and flags (continued)

Error Category	Triggered Sources	Description	Error Flags
			burst ended with AHB_TX_BUF not empty). • AHB bufferable write access and bufferable enabled (AHBCR[BUFFERABLEEN] = 1).
	AHB read command		INTR[AHBCMDERR] is set. INTR[SEQTIMEOUT] is set. AHB bus error response
	IP command		INTR[IPCMDERR] is set. INTR[SEQTIMEOUT] is set.
AHB bus timeout	AHB write command	AHB bus timeout (no bus ready return)	AHB bus error response
	AHB read command		

30.7 Memory map and register definition

This section includes the FlexSPI module memory map and detailed descriptions of all registers.

30.7.1 Register access

All registers can be accessed with 8-bit, 16-bit, and 32-bit width operations. Never change the values of reserved fields in control registers. Changing the values of reserved fields may impact the normal functioning of the controller.

NOTE

When FlexSPI can access sensitive memory contents, the FlexSPI controller should protect those contents using resource isolation such as XRDC. Ensure that only trusted software is allowed to access the FlexSPI controller register interface.

30.7.2 FlexSPI register descriptions

30.7.2.1 FlexSPI memory map

FLEXSPI1 base address: 400C_C000h

FLEXSPI2 base address: 400D_0000h

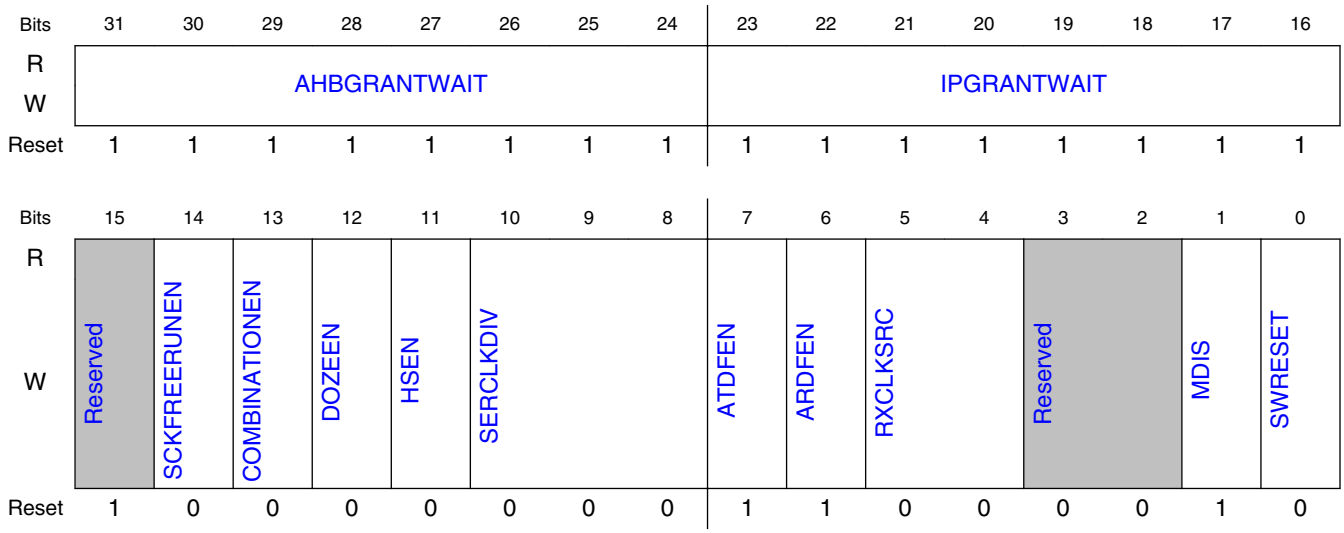
30.7.2.2.1 Offset

Register	Offset
MCR0	0h

30.7.2.2.2 Function

Controls basic functions of FlexSPI module

30.7.2.2.3 Diagram



30.7.2.2.4 Fields

Field	Function
31-24 AHBGRANTWAIT	Timeouts Wait Cycle for AHB command Grant Sets duration of timeout wait cycle for AHB commands. If the arbitrator does not grant the AHB-triggered command, it times out after (AHBGRANTTIMEOUT × 1024) AHB clock cycles. When the pending command sequence is IP-triggered and the read or write data size is too large, this grant timeout may occur. When an AHB command grant timeout occurs, an INTR[AHBCMDGE] interrupt is generated. When INTEN[AHBCMDGEEN] = 1, the arbitrator ignores AHB commands. **NOTE:** This field is for debugging only. Do not change the value from its default.
23-16 IPGRANTWAIT	Timeout Wait Cycle for IP Command Grant Sets duration of timeout wait cycle for IP commands. If the arbitrator does not grant the IP-triggered command, it times out after (IPGRANTTIMEOUT × 1024) AHB clock cycles. When the pending command sequence is AHB-triggered and the read or write data size is too large, this grant timeout may occur. When IP command grant timeout occurs, an INTR[IPCMDGE] interrupt is generated. When INTEN[IPCMDGEEN] = 1, the arbitrator ignores IP commands. **NOTE:** This field is for debugging only. Do not change the value from its default.
15 —	Reserved
14 SCKFREERUNEN	SCLK Free-running Enable Enables free-running SCLK output. For FPGA applications, the external device may use SCLK as a reference clock to its internal PLL. 0b - Disable 1b - Enable
13 COMBINATIONEN	Combination Mode Enable Enables combination mode, which supports flash Octal mode access. When Port A and Port B data are four bits wide, this mode combines Port A and B Data pins (A_DATA[3:0] and B_DATA[3:0]). When Port A and Port B data are eight bits wide, combination mode is not supported; write 0 to this field in this case.

Table continues on the next page...

Field	Function
	0b - Disable 1b - Enable
12 DOZEEN	Doze Mode Enable Enables Doze mode. When enabled, AHB clock and serial clock are gated off when there is a Doze-mode request from the system. 0b - Disable 1b - Enable
11 HSEN	Half Speed Serial Flash Memory Access Enable Enables the clock divider to provide a half-speed clock to external serial flash devices (A_SCLK/B_SCLK) for all commands in SDR and DDR mode. Write 1 to MCR0[MDIS] before changing the value of this field. Failure to do so may cause issues in the internal logic or state machine. 0b - Disable 1b - Enable
10-8 SERCLKDIV	Serial Root Clock Divider Sets divider value for serial root clock. The serial root clock can be divided inside FlexSPI . See Clocking. **NOTE:** Do not modify this field while FlexSPI is active (MCR0[MDIS] = 0). 000b - Divided by 1 001b - Divided by 2 010b - Divided by 3 011b - Divided by 4 100b - Divided by 5 101b - Divided by 6 110b - Divided by 7 111b - Divided by 8
7 ATDFEN	AHB Write Access to IP Transmit FIFO Enable Enables AHB write access to IP transmit FIFO. See Writing data to IP transmit FIFO. 0b - AHB write access disabled. IP bus writes to IP transmit FIFO. AHB bus write access to IP transmit FIFO memory space produces bus error. 1b - AHB write access enabled. AHB bus writes to IP transmit FIFO. IP Bus write access to IP transmit FIFO memory space is ignored and causes no bus error.
6 ARDFEN	AHB Read Access to IP Receive FIFO Enable Enables AHB read access to IP receive FIFO. See Reading data from IP receive FIFO. 0b - AHB read access disabled. IP bus reads IP receive FIFO. AHB Bus read access to IP receive FIFO memory space produces bus error. 1b - AHB read access enabled. AHB bus reads IP receive FIFO. IP Bus read access to IP receive FIFO memory space returns data zero and causes no bus error.
5-4 RXCLKSRC	Sample Clock Source for Flash Reading Selects sampling clock source for flash memory reading. See Receive clock source features. 00b - Dummy Read strobe that FlexSPI generates, looped back internally 01b - Dummy Read strobe that FlexSPI generates, looped back from DQS pad 10b - Reserved 11b - Flash-memory-provided read strobe and input from DQS pad
3-2 —	Reserved
1 MDIS	Module Disable Disables FlexSPI module. When the module is disabled, AHB and serial clock are gated off internally to save power. Only register access is allowed, except for the LUT, IP receive FIFO, and IP transmit FIFO. 0b - No impact

Table continues on the next page...

Field	Function
	1b - Module disable
0 SWRESET	Software Reset Resets the internal FlexSPI state machine and aborts any transactions in progress. Hardware automatically writes 0 to this field after software reset is done. Configuration registers are not reset. 0b - No impact 1b - Software reset

8-0 —	Reserved

30.7.2.5 AHB Bus Control (AHBCR)

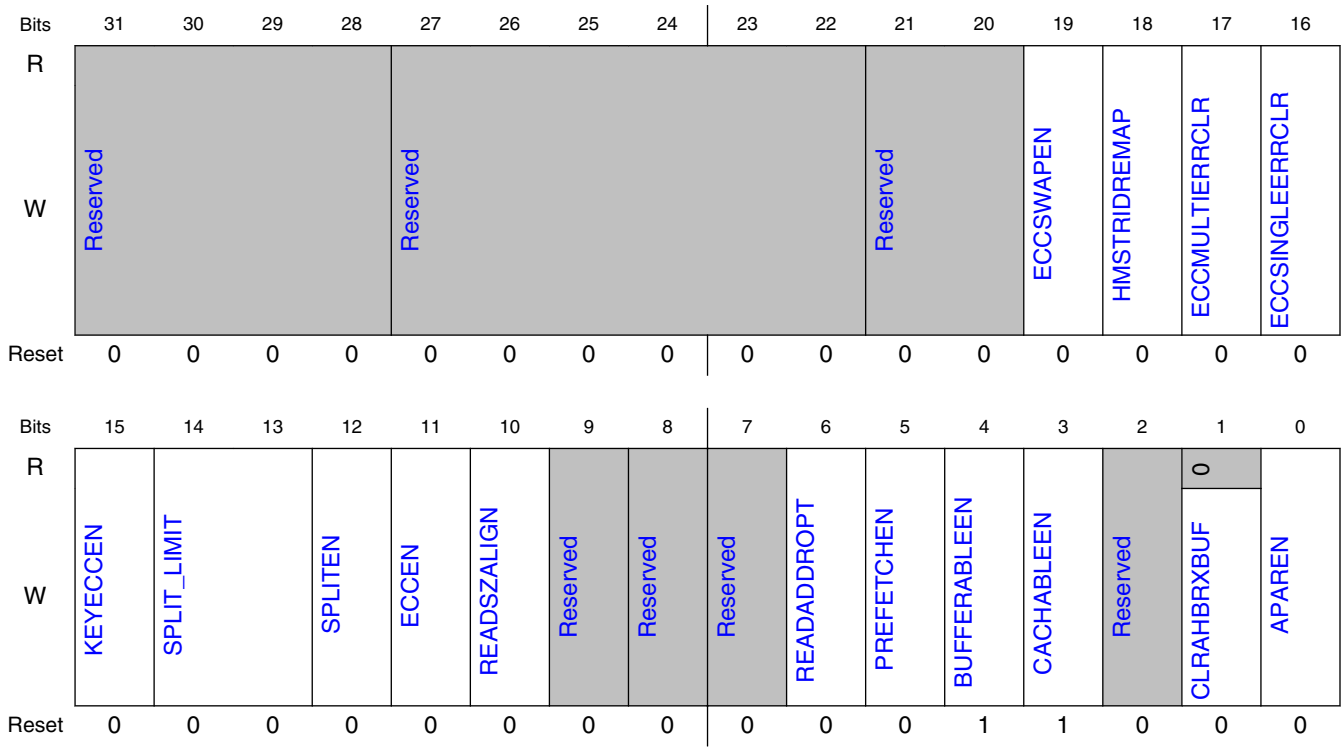
30.7.2.5.1 Offset

Register	Offset
AHBCR	Ch

30.7.2.5.2 Function

Controls AHB bus interface functions.

30.7.2.5.3 Diagram



30.7.2.5.4 Fields

Field	Function
31-28 —	Reserved
27-22 —	Reserved
21-20 —	Reserved
19 ECCSWAPEN	ECC Read Data Swap Enable Enables ECC data swapping when read data is sent to an ECC check. If write data swapping is enabled, read data swapping must also be enabled. Otherwise, ECC function fails. For swap methodology, see AHB read ECC support. 0b - Disable 1b - Enable
18 HMSTRIDREMAP	AHB Controller ID Remapping Enable Enables AHB controller ID remapping. See AHB controller ID remapping. 0b - Disable 1b - Enable
17	AHB ECC Multibit Error Clear

Table continues on the next page...

Field	Function
ECCMULTIERRCLR	Clears the valid bit in ECC multibit error information registers. Do not toggle this field during interrupt service; otherwise, ECC multibit error information is not updated. 0b - No function 1b - Clear
16 ECCSINGLEERRCLR	AHB ECC Single-Bit Error Clear Clears the valid bit in ECC single-bit error information registers. Do not toggle this field during interrupt service; otherwise, ECC single-bit error information is not updated. 0b - No function 1b - Clear
15 KEYECCEN	OTFAD Key Blob ECC Enable Enables ECC checking on OTFAD key blob. 0b - Disable 1b - Enable
14-13 SPLIT_LIMIT	AHB Split Limit Size Configures the AHB Split Size when AHBCR[SPLITEN] = 1. See AHB transaction split. 00b - 8 bytes 01b - 16 bytes 10b - 32 bytes 11b - 64 bytes
12 SPLITEN	AHB Transaction Split Enable Enables the AHB transaction split feature. When enabled, all AHB read and write bursts are split into smaller transactions on the flash SPI bus side. This function is used for RAM devices with a self-refresh limit. See AHB transaction split. 0b - Disable 1b - Enable
11 ECCEN	AHB Read ECC Enable Enables ECC checks for AHB read operations. When enabled, AHB read operations perform ECC checking. All ECC-related logic and registers are activated. Prefetching is enabled by default. Address fetches are eight-bytes aligned. The prefetching resume function is disabled. 0b - Disable 1b - Enable
10 READSZALIGN	AHB Read Size Alignment Configures how AHB read size is determined. See Table 30-18. **NOTE:** When 1, data prefetching is disabled regardless of other field settings such as PREFETCH_EN and OTFAD_EN. Read size is rounded up to the nearest eight-byte multiple. For example, if current AHB read size is 12 bytes, it is aligned to 16 bytes. When the fetch size must be eight-byte aligned but no speculative fetching is wanted, write 1 to this field. 0b - Register settings such as PREFETCH_EN and OTFAD_EN determine AHB read size. 1b - AHB read size to up size to 8 bytes aligned, no prefetching
9 —	Reserved
8 —	Reserved
7 —	Reserved
6	AHB Read Address Option

Table continues on the next page...

Field	Function
READADDROPT	Removes AHB burst start address alignment limitation. When the FlexSPI controller is used for FPGA application, this field may be required for FlexSPI to fetch the exact byte number as an AHB burst. In this case, FPGA device should be non-word-addressable and this field must be 0. **NOTE:** When OTFAD is enabled, FlexSPI functions as it does when READADDROPT = 1 regardless the value of this field. 0b - AHB read burst start address alignment is limited when flash memory is accessed in parallel mode or flash is word-addressable. 1b - AHB read burst start address alignment is not limited. FlexSPI fetches more data than the AHB burst requires for address alignment.
5 PREFETCHEN	AHB Read Prefetch Enable Enables AHB read prefetch. When enabled, FlexSPI fetches more flash read data than the current AHB burst requires. This action reduces the read latency for next AHB read access. **NOTE:** When OTFAD is enabled, the AHB prefetch function is enabled regardless of the value of this field. **NOTE:** AHB read prefetch is enabled only when both this field and AHBRXBUFnCR0[PREFETCHEN] are 1. 0b - Disable 1b - Enable
4 BUFFERABLEEN	Bufferable Write Access Enable Enables AHB bus bufferable write access. This field affects the last beat of an AHB write access. See AHB write access to flash memory. 0b - Disabled. For all AHB write accesses (bufferable or nonbufferable), FlexSPI returns AHB Bus Ready after transmitting all data and finishing command. 1b - Enabled. For AHB bufferable write access, FlexSPI returns AHB Bus Ready when the arbitrator grants the AHB command. FlexSPI does not wait for the AHB command to finish.
3 CACHABLEEN	Cacheable Read Access Enable Enables AHB bus cacheable read access. 0b - Disabled. When an AHB bus cacheable read access occurs, FlexSPI does not check whether it hit the AHB transmit buffer. 1b - Enabled. When an AHB bus cacheable read access occurs, FlexSPI first checks whether the access hit the AHB transmit buffer.
2 —	Reserved
1 CLRAHBRXBUF	Clear AHB Receive Buffer Clears status and pointers of AHB receive buffer. When the clear operation completes, this field clears automatically, so it always reads as 0. 0b - No impact. 1b - Enable clear operation.
0 APAREN	AHB Parallel Mode Enable Enables Parallel mode for AHB-triggered read and write commands. 0b - Flash is accessed in Individual mode. 1b - Flash is accessed in Parallel mode.

30.7.2.6 Interrupt Enable (INTEN)

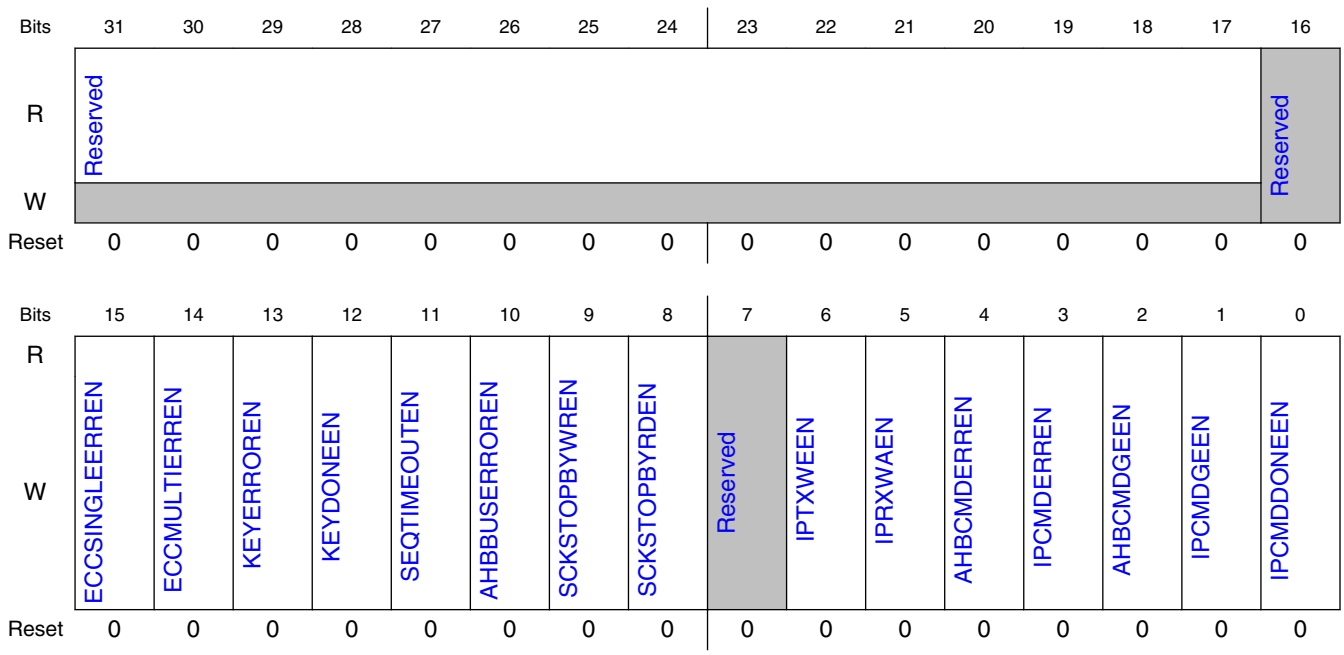
30.7.2.6.1 Offset

Register	Offset
INTEN	10h

30.7.2.6.2 Function

Includes AHB error response, IPS error response, and ECC error interrupt enables. See Interrupts.

30.7.2.6.3 Diagram



30.7.2.6.4 Fields

Field	Function
31-17 —	Reserved
16 —	Reserved
15 ECCSINGLEERREN	ECC Single-Bit Error Interrupt Enable 0b - Disable interrupt or no impact 1b - Enable interrupt
14	ECC Multibit Error Interrupt Enable

Table continues on the next page...

Field	Function
ECCMULTIERREN	0b - Disable interrupt or no impact 1b - Enable interrupt
13 KEYERROREN	OTFAD Key Blob Processing Error Interrupt Enable 0b - Disable interrupt or no impact 1b - Enable interrupt
12 KEYDONEEN	OTFAD Key Blob Processing Done Interrupt Enable 0b - Disable interrupt or no impact 1b - Enable interrupt
11 SEQTIMEOUTEN	Sequence execution Timeout Interrupt Enable 0b - Disable interrupt or no impact 1b - Enable interrupt
10 AHBBUSERROREN	AHB Bus Error Interrupt Enable 0b - Disable interrupt or no impact 1b - Enable interrupt
9 SCKSTOPBYWREN	SCLK Stopped By Write Interrupt Enable Enables interrupt that indicates SCLK is stopped during command sequence because asynchronous transmit FIFO is empty. 0b - Disable interrupt or no impact 1b - Enable interrupt
8 SCKSTOPBYRDEN	SCLK Stopped By Read Interrupt Enable Enables interrupt that indicates SCLK is stopped during command sequence because asynchronous receive FIFO is full. 0b - Disable interrupt or no impact 1b - Enable interrupt
7 —	Reserved
6 IPTXWEEN	IP Transmit FIFO Watermark Empty Interrupt Enable Enables interrupt that indicates IP transmit FIFO contains more empty space than watermark level. 0b - Disable interrupt or no impact 1b - Enable interrupt
5 IPRXWAEN	IP Receive FIFO Watermark Available Interrupt Enable Enables interrupt that indicates IP receive FIFO contains more valid data than the watermark level. 0b - Disable interrupt or no impact 1b - Enable interrupt
4 AHBCMDERREN	AHB-Triggered Command Sequences Error Detected Interrupt Enable 0b - Disable interrupt or no impact 1b - Enable interrupt
3 IPCMDERREN	IP-Triggered Command Sequences Error Detected Interrupt Enable 0b - Disable interrupt or no impact 1b - Enable interrupt
2 AHBCMDGEEN	AHB-Triggered Command Sequences Grant Timeout Interrupt Enable. 0b - Disable interrupt or no impact 1b - Enable interrupt
1 IPCMDGEEN	IP-Triggered Command Sequences Grant Timeout Interrupt Enable 0b - Disable interrupt or no impact 1b - Enable interrupt
0	IP-Triggered Command Sequences Execution Finished Interrupt Enable 0b - Disable interrupt or no impact

Field	Function
IPCMDDONEEN	1b - Enable interrupt

30.7.2.7 Interrupt (INTR)

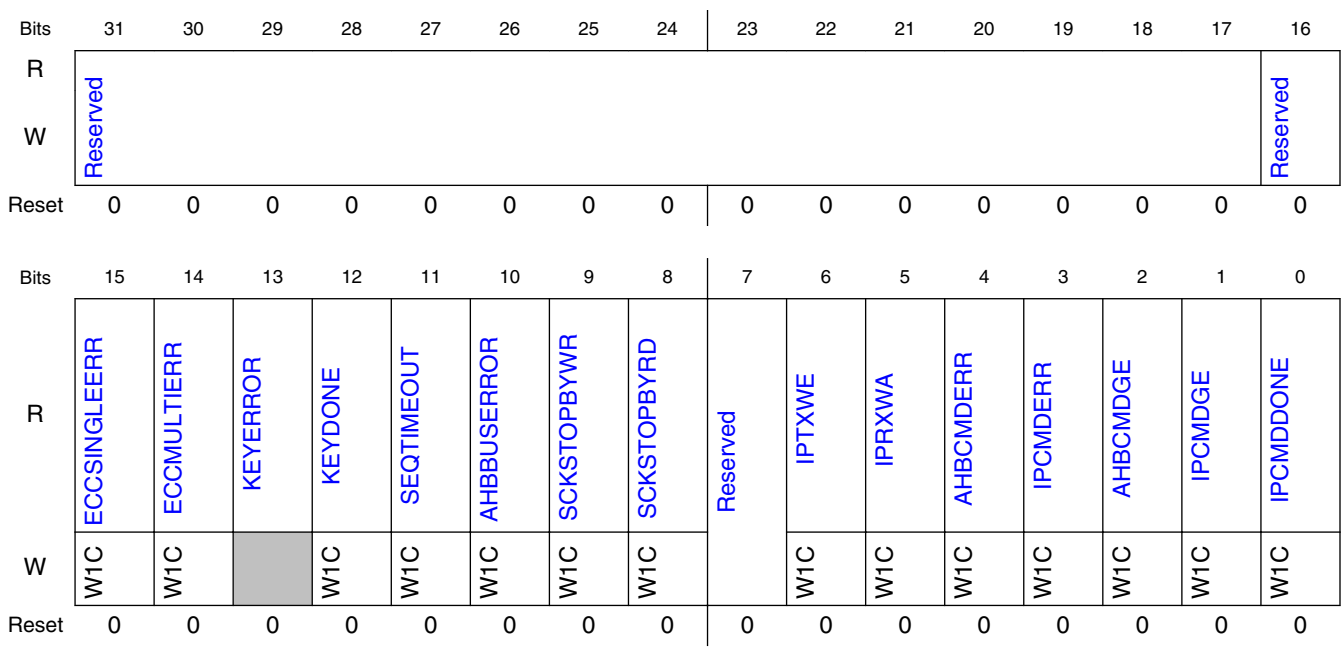
30.7.2.7.1 Offset

Register	Offset
INTR	14h

30.7.2.7.2 Function

Includes AHB error response, IPS error response, and ECC error interrupts. See Interrupts.

30.7.2.7.3 Diagram



30.7.2.7.4 Fields

Field	Function
31-17	Reserved

Table continues on the next page...

Field	Function
—	
16 —	Reserved
15 ECCSINGLEERR	ECC Single-Bit Error **NOTE:** This field behaves differently for read and write operations. When reading 0b - Interrupt condition has not occurred 1b - Interrupt condition has occurred When writing 0b - No effect 1b - Clear the flag
14 ECCMULTIERR	ECC Multibit Error **NOTE:** This field behaves differently for read and write operations. When reading 0b - Interrupt condition has not occurred 1b - Interrupt condition has occurred When writing 0b - No effect 1b - Clear the flag
13 KEYERROR	OTFAD Key Blob Processing Error **NOTE:** This field behaves differently for read and write operations. When reading 0b - Interrupt condition has not occurred 1b - Interrupt condition has occurred When writing 0b - No effect 1b - Clear the flag
12 KEYDONE	OTFAD key blob processing done interrupt.
11 SEQTIMEOUT	Sequence Execution Timeout **NOTE:** This field behaves differently for read and write operations. When reading 0b - Interrupt condition has not occurred 1b - Interrupt condition has occurred When writing 0b - No effect 1b - Clear the flag
10 AHBBUSERROR	AHB Bus Error Generated upon an AHB bus timeout or an AHB bus illegal access to flash during OTFAD key blob processing.

Table continues on the next page...

Field	Function
	NOTE: This field behaves differently for read and write operations. When reading 0b - Interrupt condition has not occurred 1b - Interrupt condition has occurred When writing 0b - No effect 1b - Clear the flag
9 SCKSTOPBYWR	SCLK Stopped Due To Empty Transmit FIFO Generated when SCLK is stopped during command sequence because the asynchronous transmit FIFO is empty. **NOTE:** This field behaves differently for read and write operations. When reading 0b - Interrupt condition has not occurred 1b - Interrupt condition has occurred When writing 0b - No effect 1b - Clear the flag
8 SCKSTOPBYRD	SCLK Stopped Due To Full Receive FIFO Generated when SCLK is stopped during command sequence because the asynchronous receive FIFO is full. **NOTE:** This field behaves differently for read and write operations. When reading 0b - Interrupt condition has not occurred 1b - Interrupt condition has occurred When writing 0b - No effect 1b - Clear the flag
7 —	Reserved
6 IPTXWE	IP Transmit FIFO Watermark Empty Generated when the IP transmit FIFO contains more empty space than the watermark level. **NOTE:** This field behaves differently for read and write operations. When reading 0b - Interrupt condition has not occurred 1b - Interrupt condition has occurred When writing 0b - No effect 1b - Clear the flag
5 IPRXWA	IP Receive FIFO Watermark Available Generated when the IP receive FIFO contains more valid data than the watermark level.

Table continues on the next page...

Field	Function
	NOTE: This field behaves differently for read and write operations. When reading 0b - Interrupt condition has not occurred 1b - Interrupt condition has occurred When writing 0b - No effect 1b - Clear the flag
4 AHBCMDERR	AHB-Triggered Command Sequences Error Generated upon an AHB-triggered command sequence error. When an error is detected for an AHB command, the command is ignored and not executed. **NOTE:** This field behaves differently for read and write operations. When reading 0b - Interrupt condition has not occurred 1b - Interrupt condition has occurred When writing 0b - No effect 1b - Clear the flag
3 IPCMDERR	IP-Triggered Command Sequences Error Generated upon an IP-triggered command sequence error. When an error is detected for an IP command, the command is ignored and not executed. **NOTE:** This field behaves differently for read and write operations. When reading 0b - Interrupt condition has not occurred 1b - Interrupt condition has occurred When writing 0b - No effect 1b - Clear the flag
2 AHBCMDGE	AHB-Triggered Command Sequences Grant Timeout **NOTE:** This field behaves differently for read and write operations. When reading 0b - Interrupt condition has not occurred 1b - Interrupt condition has occurred When writing 0b - No effect 1b - Clear the flag
1 IPCMDGE	IP-Triggered Command Sequences Grant Timeout **NOTE:** This field behaves differently for read and write operations. When reading 0b - Interrupt condition has not occurred 1b - Interrupt condition has occurred

Table continues on the next page...

Field	Function
	When writing 0b - No effect 1b - Clear the flag
0 IPCMDDONE	IP-Triggered Command Sequences Execution Finished Generated upon completion of an IP-triggered command sequence. Also generated when IPCMDGE or IPCMDERR interrupt is generated **NOTE:** This field behaves differently for read and write operations. When reading 0b - Interrupt condition has not occurred 1b - Interrupt condition has occurred When writing 0b - No effect 1b - Clear the flag

30.7.2.8 LUT Key (LUTKEY)

30.7.2.8.1 Offset

Register	Offset
LUTKEY	18h

30.7.2.8.2 Function

Contains the key to lock and unlock LUT. See Lookup table (LUT).

30.7.2.8.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

30.7.2.8.4 Fields

Field	Function
31-0 KEY	LUT Key Contains key to lock or unlock LUT. The key is 5AF05AF0h. Read value is always 5AF05AF0h.

30.7.2.9 LUT Control (LUTCR)

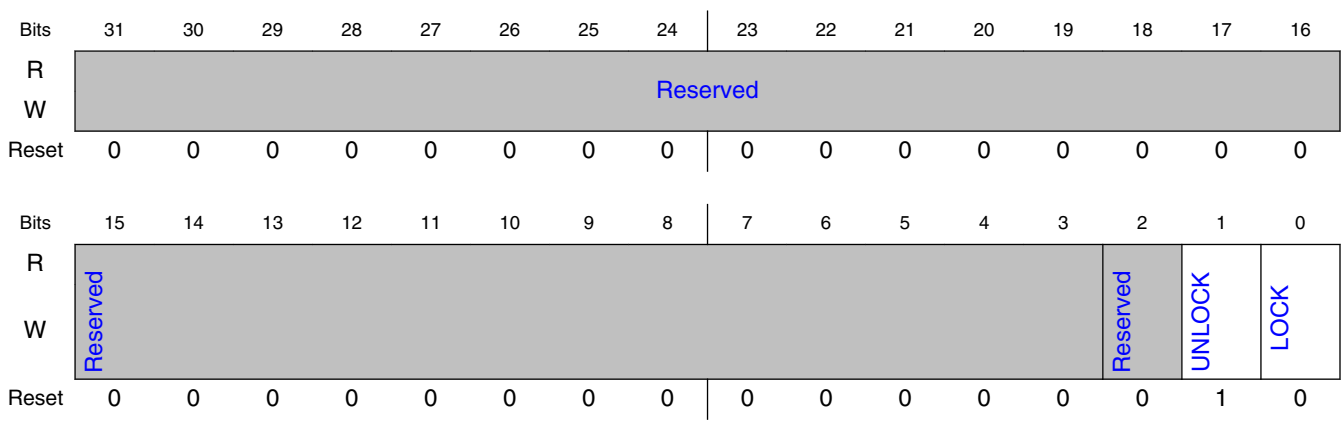
30.7.2.9.1 Offset

Register	Offset
LUTCR	1Ch

30.7.2.9.2 Function

Used with LUTKEY register to lock or unlock LUT. For the lock or unlock operation to be successful, this register must be written immediately after writing 5AF05AF0h to the LUTKEY register. See Lookup table (LUT) for details on locking and unlocking LUT. You cannot write 00 or 11 to the LOCK and UNLOCK fields.

30.7.2.9.3 Diagram



30.7.2.9.4 Fields

Field	Function
31-3	Reserved

Table continues on the next page...

Field	Function
—	
2 —	Reserved
1 UNLOCK	Unlock LUT 0b - LUT is locked (LUTCR[LOCK] must be 1) 1b - LUT is unlocked and can be written
0 LOCK	Lock LUT 0b - LUT is unlocked (LUTCR[UNLOCK] must be 1) 1b - LUT is locked and cannot be written

30.7.2.10 AHB Receive Buffer n Control 0 (AHBRXBUF0CR0 - AHBRXBUF7CR0)

30.7.2.10.1 Offset

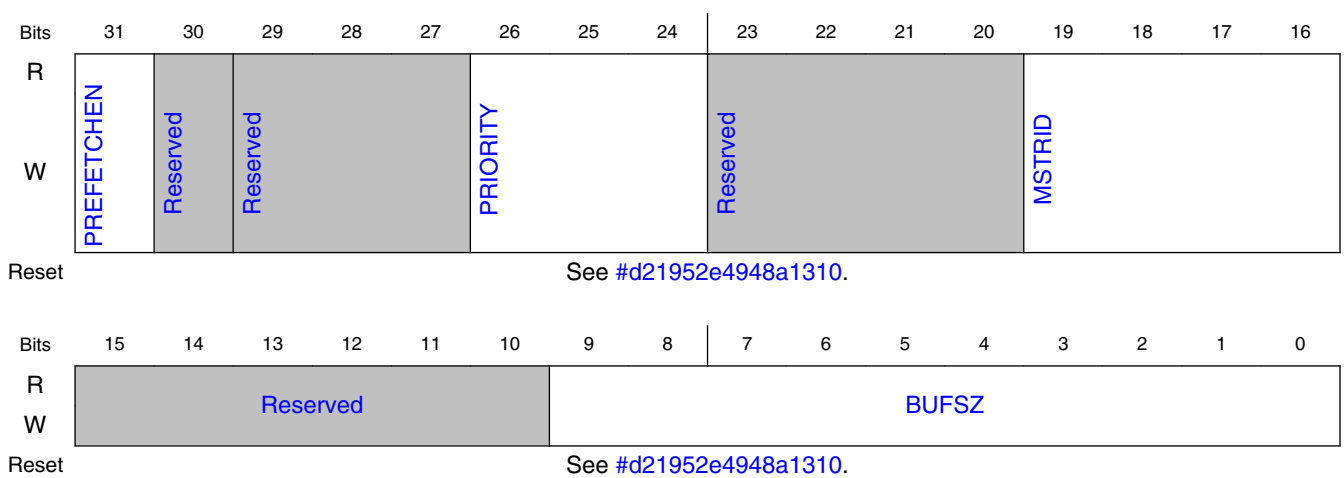
For n = 0 to 7:

Register	Offset
AHBRXBUFnCR0	20h + (n × 4h)

30.7.2.10.2 Function

Stores the read data from the SPI interface.

30.7.2.10.3 Diagram



30.7.2.10.4 Register reset values

Register	Reset value
AHBRXBUF0CR0	FLEXSPI1,FLEXSPI2: 8000_0040h
AHBRXBUF1CR0	FLEXSPI1,FLEXSPI2: 8001_0040h
AHBRXBUF2CR0	FLEXSPI1,FLEXSPI2: 8002_0040h
AHBRXBUF3CR0	FLEXSPI1,FLEXSPI2: 8003_0040h
AHBRXBUF4CR0	FLEXSPI1,FLEXSPI2: 8004_0040h
AHBRXBUF5CR0	FLEXSPI1,FLEXSPI2: 8005_0040h
AHBRXBUF6CR0	FLEXSPI1,FLEXSPI2: 8006_0040h
AHBRXBUF7CR0	FLEXSPI1,FLEXSPI2: 8007_0040h

30.7.2.10.5 Fields

Field	Function
31 PREFETCHEN	AHB Read Prefetch Enable Enables AHB read prefetch for the controller corresponding to the current AHB receive buffer. The prefetch feature is disabled when AHBCR[PREFETCHEN] is 0. You can use this field to enable or disable prefetch separately for each controller. 0b - Disabled 1b - Enabled when AHBCR[PREFETCHEN] is enabled.
30 —	Reserved
29-27 —	Reserved
26-24 PRIORITY	AHB Controller Read Priority Configure the priority for the AHB Controller Read to which this AHB receive buffer is assigned. 7 is the highest priority, 0 the lowest. See Command abort and suspend.
23-20 —	Reserved
19-16 MSTRID	AHB Controller ID Configures the ID of the AHB controller to which this AHB receive buffer is assigned. See AHB receive buffer management.
15-10 —	Reserved
9-0 BUFSZ	AHB Receive Buffer Size Configures the size of the AHB receive buffer in multiples of 64 bits. See AHB receive buffer management.

30.7.2.11 Flash Control 0 (FLSHA1CR0 - FLSHB2CR0)

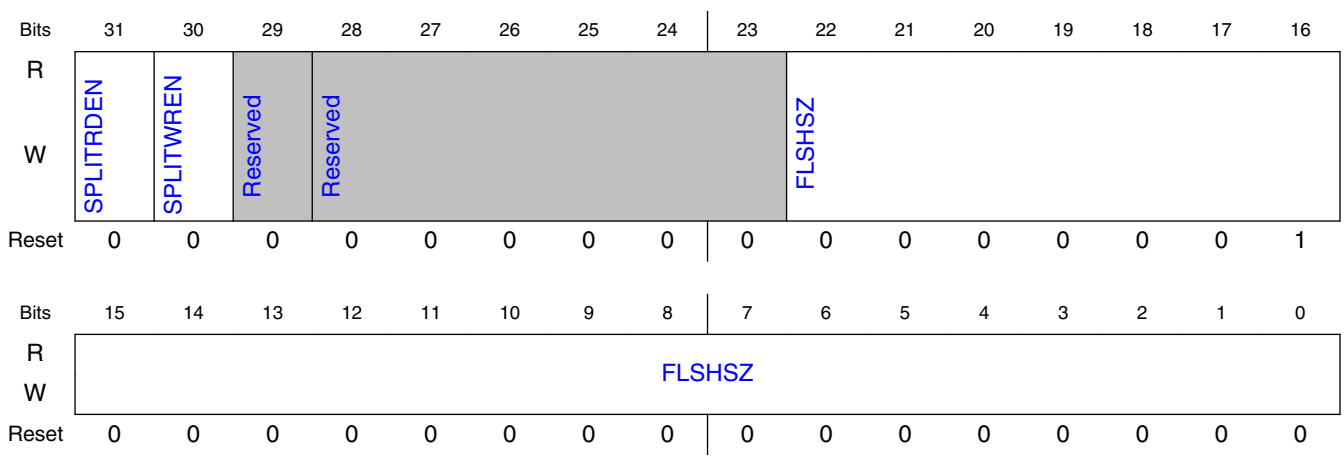
30.7.2.11.1 Offset

Register	Offset
FLSHA1CR0	60h
FLSHA2CR0	64h
FLSHB1CR0	68h
FLSHB2CR0	6Ch

30.7.2.11.2 Function

Contains flash memory size setting. FlexSPI determines which device is accessed (Chip Select) via this register.

30.7.2.11.3 Diagram



30.7.2.11.4 Fields

Field	Function
31 SPLITRDEN	AHB Read Access Split Function Enable Combined with AHBCR[SPLITEN], used to control the split function enable and disable, based on which flash is accessed. See AHB transaction split. 0b - Disable 1b - Enable

Table continues on the next page...

Field	Function
30 SPLITWREN	AHB Write Access Split Function Enable Combined with AHBCR[SPLITEN], used to control the split function enable and disable, based on which flash memory is accessed. See AHB transaction split 0b - Disable 1b - Enable
29 —	Reserved
28-23 —	Reserved
22-0 FLSHSZ	Flash Size in KB Configures the maximum flash memory size. See the chip-specific section for the maximum flash size supported. When the value of this field is greater than the maximum size, the device flash size is interpreted as the maximum. The maximum flash size is the largest flash size supported for a single device. It is also the maximum total flash size supported for all devices (up to four). If the total flash size is larger than the maximum size, only the maximum flash size address space is accessible.

30.7.2.12 Flash Control 1 (FLSHA1CR1 - FLSHB2CR1)

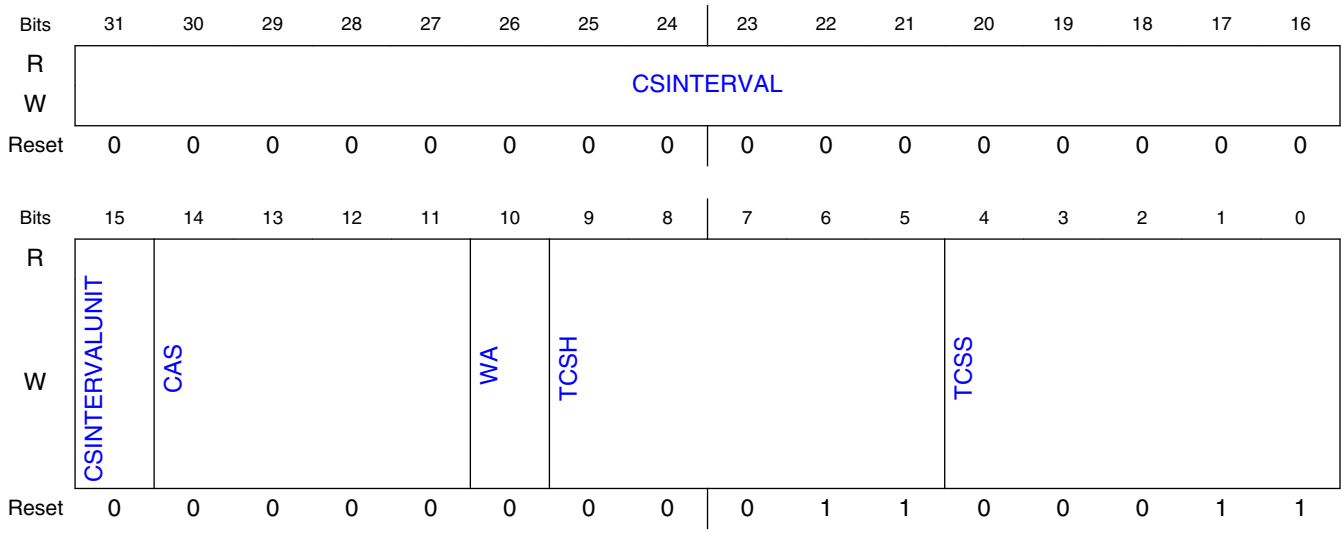
30.7.2.12.1 Offset

Register	Offset
FLSHA1CR1	70h
FLSHA2CR1	74h
FLSHB1CR1	78h
FLSHB2CR1	7Ch

30.7.2.12.2 Function

Contains settings for flash device-specific timings and flash internal address space.

30.7.2.12.3 Diagram



30.7.2.12.4 Fields

Field	Function
31-16 CSINTERVAL	Chip Select Interval Configures the minimum interval between flash device chip select deassertion and chip select assertion. If the external flash device has a limitation on the interval between command sequences, configure this field accordingly. If there is no limitation, write 0h to this field. When CSINTERVALUNIT = 0, the chip select invalid interval is: CSINTERVAL × 1 serial clock cycle; When CSINTERVALUNIT = 1, the chip select invalid interval is: CSINTERVAL × 256 serial clock cycles. **NOTE:** The minimum chip select interval is 2 cycles, even when the value of CSINTERVAL is less than 2.
15 CSINTERVALUNIT	Chip Select Interval Unit Configures the interval unit for chip select. 0b - 1 serial clock cycle 1b - 256 serial clock cycles
14-11 CAS	Column Address Size When external flash memory has a separate address field for rows and columns, this field configures the flash column address bit width. FlexSPI automatically splits a flash-mapped address into row address and column address according to the values of this field and the WA field. When the external flash memory does not support column address, write 0 to this field. FlexSPI transmits all flash address bits as Row address. For flash address mapping, see Flash address sent to flash memory devices.
10 WA	Word-Addressable Configures whether external flash memory is word-addressable or byte-addressable. If flash memory is word-addressable, it should be accessed in multiples of 16 bits. Currently, FlexSPI does not transmit flash address bit 0 to external flash memory. For flash address mapping, see Flash address sent to flash memory devices. 0b - Byte-addressable 1b - Word-addressable

Table continues on the next page...

Field	Function
9-5 TCSH	Serial Flash CS Hold Time Used to meet flash TCSH timing requirement. Serial flash CS Hold time that FlexSPI promises is: (TCSH + 1/2) serial clock cycles for DDR mode, and TCSH serial clock cycles for SDR mode. See Output timing between chip select and SCLK.
4-0 TCSS	Serial Flash CS Setup Time Used to meet flash TCSS timing requirement. Serial flash CS Setup time that FlexSPI promises is: (TCSS + 1/2) serial root clock cycles for SDR and DDR mode. See Output timing between chip select and SCLK.

30.7.2.13 Flash Control 2 (FLSHA1CR2 - FLSHB2CR2)

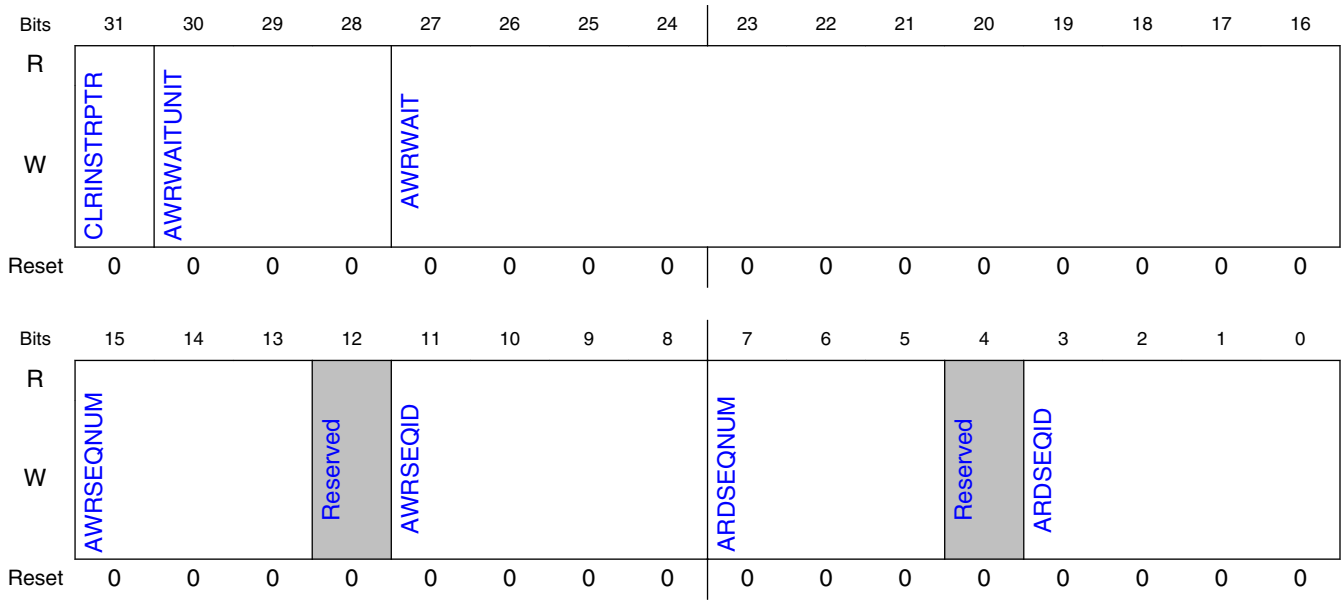
30.7.2.13.1 Offset

Register	Offset
FLSHA1CR2	80h
FLSHA2CR2	84h
FLSHB1CR2	88h
FLSHB2CR2	8Ch

30.7.2.13.2 Function

Contains fields to configure AHB bus access. If the four external devices are different types, AHB read and write commands may use different command sequences; AHB bus ready wait time may also differ.

30.7.2.13.3 Diagram



30.7.2.13.4 Fields

Field	Function
31 CLRINSTRPTR	
30-28 AWRWAITUNIT	AWRWAIT Unit Configures the unit of AHB write wait time, as the value of AWRWAIT determines, in terms of AHB clock cycles. 000b - 2 001b - 8 010b - 32 011b - 128 100b - 512 101b - 2048 110b - 8192 111b - 32768
27-16 AWRWAIT	AHB Write Wait Configures AHB write wait time, with the AWRWAITUNIT field. Certain devices (such as FPGA) require time to write data into internal memory after the command sequences finished on the FlexSPI interface. If another read command sequence arrives before the current programming finishes internally, the read data may be wrong. This field is used to hold the AHB bus ready for AHB write access, waiting until the programming is finished in the external device. This hold ensures that no AHB read command is triggered before the programming finishes in the external device. The wait cycle between an AHB-triggered command sequence finishing on FlexSPI and the AHB return bus being ready is: AWRWAIT × AWRWAITUNIT.
15-13 AWRSEQNUM	Sequence Number for AHB Write-Triggered Command

Table continues on the next page...

Field	Function
	Configures the sequence number of an AHB read-triggered command. For certain flash devices (for example, HyperFlash, HyperRam, and Serial NAND flash), a flash programming access is done via several command sequences. An AHB write command triggers (AWRSEQNUM + 1) command sequences to external flash memory each time. FlexSPI executes the sequences in LUT incrementally. **NOTE:** • Software should ensure that the last sequence index never exceeds LUT sequence numbers: AWRSEQID + AWRSEQNUM < 16 • Software must ensure that the AWRSEQNUM and LUT fields are configured correctly according to the external device specification. FlexSPI does not check the sequence; it executes the sequences one by one.
12 —	Reserved
11-8 AWRSEQID	Sequence Index for AHB Write-Triggered Command
7-5 ARDSEQNUM	Sequence Number for AHB Read-Triggered Command Configures the sequence number of an AHB read-triggered command in the lookup table. For certain flash devices (for example, HyperFlash, HyperRam, and Serial NAND flash), a flash read access is done via several command sequences. An AHB read command triggers (ARDSEQNUM + 1) command sequences to external flash memory each time. FlexSPI executes the sequences in LUT incrementally. **NOTE:** • Software should ensure that the last sequence index never exceeds LUT sequence numbers: ARDSEQID + ARDSEQNUM ≤ 16. • Software must ensure that the ARDSEQNUM and LUT fields are configured correctly according to the external device specification. FlexSPI does not check the sequence; it executes the sequences one by one.
4 —	Reserved
3-0 ARDSEQID	Sequence Index for AHB Read-Triggered Command in LUT

30.7.2.14 Flash Control 4 (FLSHCR4)

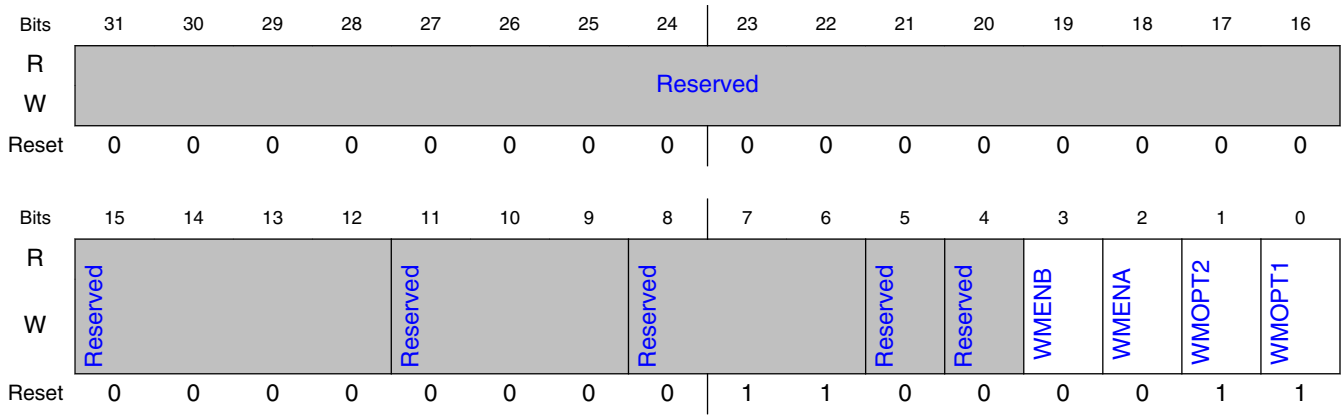
30.7.2.14.1 Offset

Register	Offset
FLSHCR4	94h

30.7.2.14.2 Function

Provides configuration for all external devices.

30.7.2.14.3 Diagram



30.7.2.14.4 Fields

Field	Function
31-12 —	Reserved
11-9 —	Reserved
8-6 —	Reserved
5 —	Reserved
4 —	Reserved
3 WMENB	Write Mask Enable for Port B Enables write mask for flash device on port B. 0b - Disabled. When writing to external device, DQS(RWDS) pin is not driven. 1b - Enabled. When writing to external device, FlexSPI drives DQS(RWDS) pin as write mask output.
2 WMENA	Write Mask Enable for Port A Enables write mask for flash device on port A. 0b - Disabled. When writing to external device, DQS(RWDS) pin is not driven. 1b - Enabled. When writing to external device, FlexSPI drives DQS(RWDS) pin as write mask output.
1 WMOPT2	Write Mask Option 2 When using AP memory, used to remove AHB or IP write burst minimum length limitation. When using this field, FLSHCR4[WMOPT1] should be 1. 0b - When writing to an external device, DQS pin is used as write mask. When flash memory is accessed in individual mode, AHB or IP write burst length is not limited. 1b - When writing to an external device, DQS pin is not used as write mask. When flash memory is accessed in individual mode, AHB or IP write burst length is limited. The minimum write burst length should be 4.

Table continues on the next page...

Field	Function
0 WMOPT1	Write Mask Option 1 Used to remove AHB and IP write burst start address alignment limitation. 0b - When writing to an external device, DQS pin is used as write mask. When flash memory is accessed in individual mode, AHB or IP write burst start address alignment is not limited. 1b - When writing to an external device, DQS pin is not used as write mask. When flash memory is accessed in individual mode, AHB or IP write burst start address alignment is limited.

30.7.2.15 IP Control 0 (IPCR0)

30.7.2.15.1 Offset

Register	Offset
IPCR0	A0h

30.7.2.15.2 Function

Provides all configuration required for IP commands. Provides the start address for the flash device, instead of the chip address, to be accessed for IP command. FlexSPI determines the chip select automatically according to this start address.

NOTE

- You cannot issue an IP command that crosses flash device boundaries. If you do so, it generates an IPCMDERR interrupt.
- Configure this register before an IP command is triggered.
- Do not change the values in this register while an IP command is in progress.

30.7.2.15.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

30.7.2.15.4 Fields

Field	Function
31-0 SFAR	Serial Flash Address Configures the serial flash address for IP commands. The address should be the address of the flash device without the base address.

30.7.2.16 IP Control 1 (IPCR1)

30.7.2.16.1 Offset

Register	Offset
IPCR1	A4h

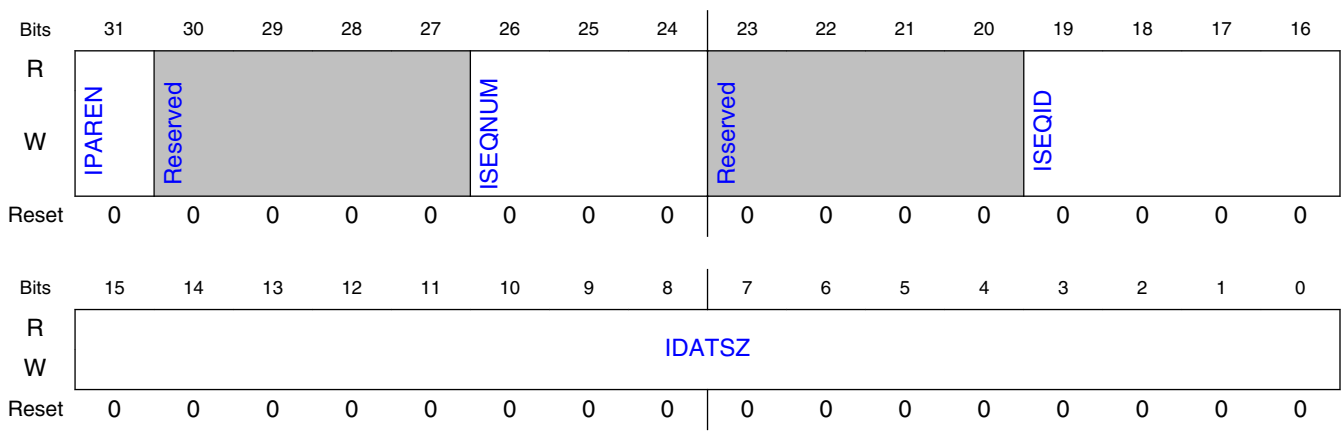
30.7.2.16.2 Function

Provides all configuration required for IP commands. Provides the flash read and program data size, sequence index in LUT, sequence number and individual/parallel mode settings for IP commands.

NOTE

- Configure this register before an IP command is triggered.
- Do not change the values in this register while an IP command is in progress.

30.7.2.16.3 Diagram



30.7.2.16.4 Fields

Field	Function
31 IPAREN	Parallel Mode Enable for IP Commands 0b - Disabled. Flash memory is accessed in Individual mode. 1b - Enabled. Flash memory is accessed in Parallel mode.
30-27 —	Reserved
26-24 ISEQNUM	Sequence Number for IP command: ISEQNUM+1.
23-20 —	Reserved
19-16 ISEQID	Sequence Index in LUT for IP command.
15-0 IDATSZ	Flash Read/Program Data Size (in bytes) for IP command.

30.7.2.17 IP Command (IPCMD)

30.7.2.17.1 Offset

Register	Offset
IPCMD	B0h

30.7.2.17.2 Function

Used to trigger an IP command to access external flash device. When the arbitrator grants the IP command, the command is executed on the FlexSPI interface.

30.7.2.17.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	Reserved

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved															0
W																TRG
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

30.7.2.17.4 Fields

Field	Function
31-1 —	Reserved
0 TRG	Command Trigger Triggers an IP command. This field clears automatically after it has been written and always reads as 0. **NOTE:** You cannot trigger another IP command before the previous IP command finishes on the FlexSPI interface. Software must poll INTR[IPCMDDONE] or wait for this interrupt. 0b - No action 1b - Start the IP command that the IPCR0 and IPCR1 registers define.

30.7.2.18 IP Receive FIFO Control (IPRXFCR)

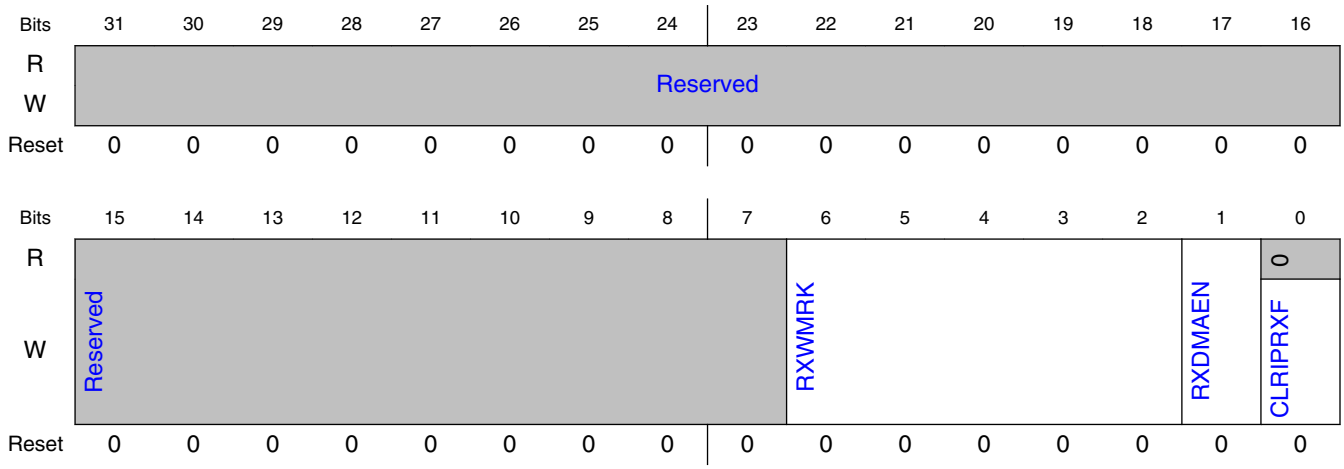
30.7.2.18.1 Offset

Register	Offset
IPRXFCR	B8h

30.7.2.18.2 Function

Provides the configuration fields for IP receive FIFO management.

30.7.2.18.3 Diagram



30.7.2.18.4 Fields

Field	Function
31-7 —	Reserved
6-2 RXWMRK	IP Receive FIFO Watermark Level Configures the watermark level for the IP receive FIFO. The watermark level is (RXWMRK + 1) × 64 bits. The INTR[IPRXWA] interrupt is set when FlexSPI fills the IP receive FIFO ≥ the watermark level. A DMA request occurs when the fill level is ≥ the watermark level and IPRXFCR[RXDMAEN] = 1. When the fill level is ≥ the watermark level and INTEN[IPRXWAEN] = 1, an INTR[IPRXWA] interrupt is generated. **NOTE:** After writing 1 to INTR[IPRXWA] to clear it, the read address should be rolled back to the start address (memory mapped). If the IP bus reads the IP receive FIFO, the read address should roll back to RFDR0. If the AHB bus reads the IP receive FIFO, the read address should roll back to ARDF_BASE.
1 RXDMAEN	IP Receive FIFO Reading by DMA Enable 0b - Disabled. The processor reads the FIFO. 1b - Enabled. DMA reads the FIFO.
0 CLRIPRXF	Clear IP Receive FIFO Clears all valid data entries in IP receive FIFO. Resets the read and write pointers in IP receive FIFO. 0b - No function 1b - A clock cycle pulse clears all valid data entries in IP receive FIFO.

30.7.2.19 IP Transmit FIFO Control (IPTXFCR)

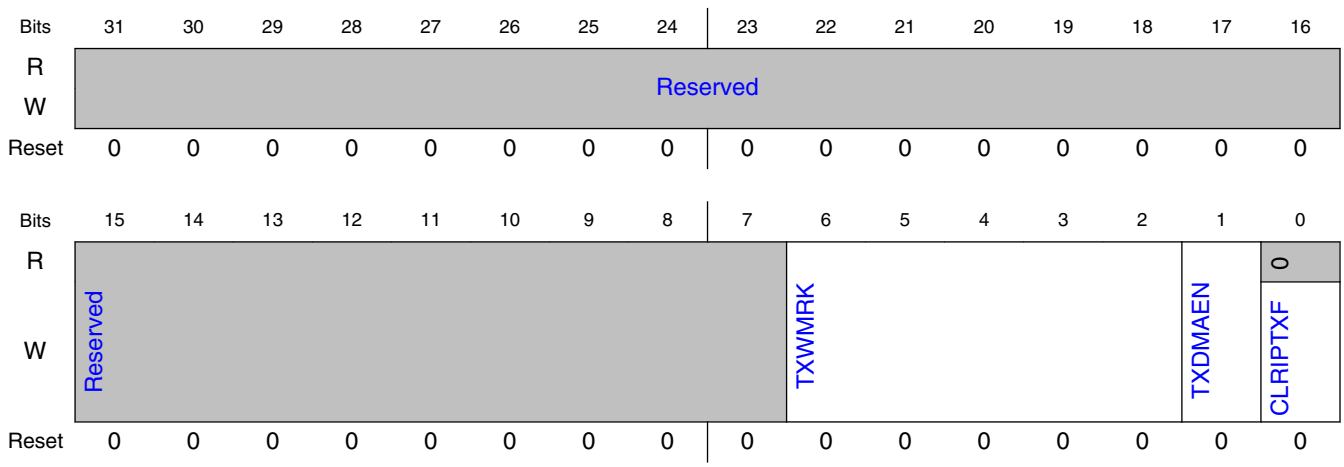
30.7.2.19.1 Offset

Register	Offset
IPTXFCR	BCh

30.7.2.19.2 Function

Provides the configuration fields for IP transmit FIFO management.

30.7.2.19.3 Diagram



30.7.2.19.4 Fields

Field	Function
31-7 —	Reserved
6-2 TXWMRK	Transmit Watermark Level Sets the transmit watermark level. The watermark level is (TXWMRK + 1) × 64 bits. INTR[IPTXWE] is set when FlexSPI empties the IP transmit FIFO ≥ the watermark level. When the empty level ≥ the watermark level and IPTXFCR[TXDMAEN] = 1, a DMA request occurs. When the empty level ≥ the watermark level and INTEN[IPTXWEEN] = 1, an INTR[IPTXWE] interrupt is generated. **NOTE:** • The watermark level should not be larger than the write window. • The watermark level should not be larger than the IP transmit FIFO size. • The write address to the IP receive FIFO should roll back to the start address of the write window. After pushing the IP transmit fifo, you should write 1 to INTR[IPTXWE] to clear it, which will perform the rollback.
1 TXDMAEN	Transmit FIFO DMA Enable Selects whether DMA or processor fills IP transmit FIFO. 0b - Processor 1b - DMA

Table continues on the next page...

Field	Function
0 CLRIPTXF	Clear IP Transmit FIFO Clears all valid data entries in IP transmit FIFO. The read and write pointers in IP transmit FIFO are reset. 0b - No function 1b - A clock cycle pulse clears all valid data entries in the IP transmit FIFO.

30.7.2.20 DLL Control 0 (DLLACR - DLLBCR)

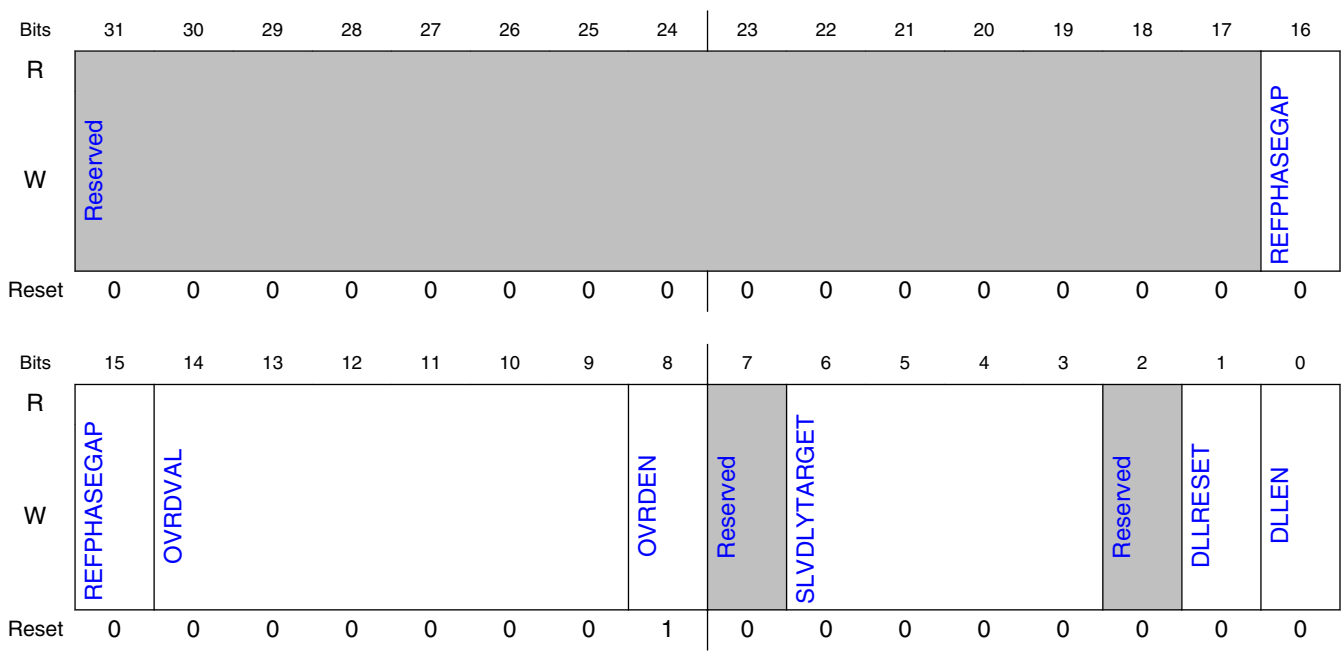
30.7.2.20.1 Offset

Register	Offset
DLLACR	C0h
DLLBCR	C4h

30.7.2.20.2 Function

Configures Flash A and B sample clock DLL.

30.7.2.20.3 Diagram



30.7.2.20.4 Fields

Field	Function
31-17 —	Reserved
16-15 REFPHASEGAP	Reference Clock Delay Line Phase Adjust Gap. REFPHASEGAP setting of 2h is recommended if DLLEN is set.
14-9 OVRDVAL	Target Clock Delay Line Override Value Configures the override value for the target clock line delay cell number. When OVRDEN = 1, the delay cell number in DLL is OVRDVAL + 1. See DLL configuration for sampling.
8 OVRDEN	Target Clock Delay Line Override Value Enable Enables the override value for the target clock line delay cell number. 0b - Disable 1b - Enable
7 —	Reserved
6-3 SLVDLYTARGET	Target Delay Line Configures the target delay line for the target. The delay target for target delay line is: ((SLVDLYTARGET +1) × 1/32 × clock cycle of reference clock (serial root clock). If serial root clock is ≥ 100 MHz, DLLEN is set to 1, OVRDEN is set to 0, then SLVDLYTARGET setting is up to flash parameters used.
2 —	Reserved
1 DLLRESET	DLL reset Forces a DLL reset. The forced reset causes the DLL to lose lock and recalibrate to detect a ref_clock half-period phase shift. The reset action is edge-triggered, so software must write 0 to this field after writing 1 to it (no delay limitation). 0b - No function 1b - Force DLL reset.
0 DLLEN	DLL Calibration Enable Enables DLL calibration. When DLL calibration is disabled, the delay cell number in the target delay line is always 1. When DLLxCR[OVRDEN] = 1, the target delay line is overridden and this field is ignored. 0b - Disable 1b - Enable

30.7.2.21 Misc Control 4 (MISCCR4)

30.7.2.21.1 Offset

Register	Offset
MISCCR4	D0h

30.7.2.21.2 Function

Contains information about ECC multibit error interrupt.

30.7.2.21.3 Diagram

30.7.2.22.4 Fields

Field	Function
31-0 ECCSINGLEERRORCORR	ECC Single-Bit Error Correction Indicator Stores single-bit ECC error correction information for first single ECC error after exiting single-bit ECC error interrupt.

30.7.2.23 Miscellaneous Control 6 (MISCCR6)

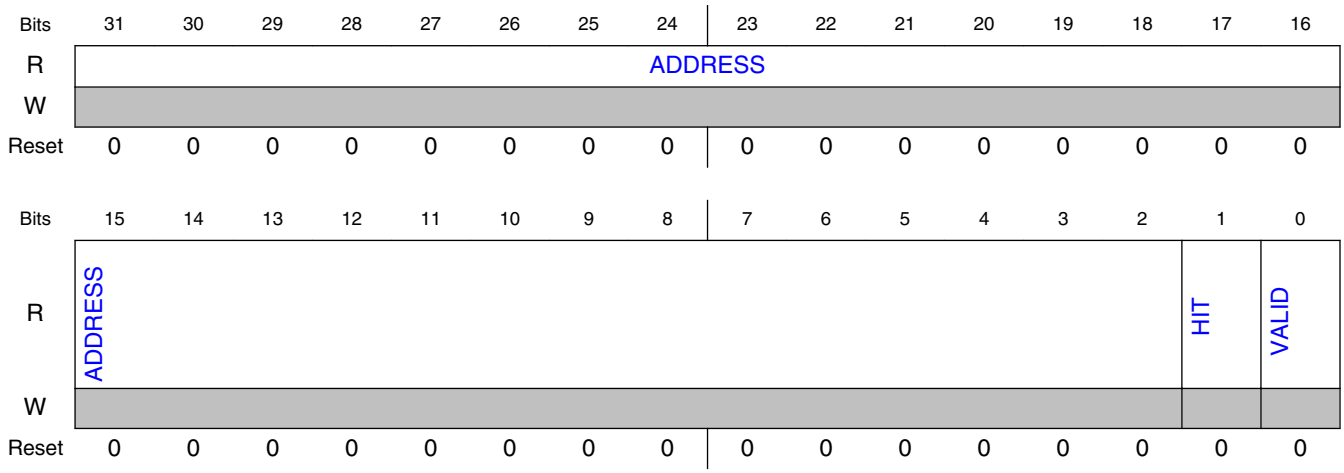
30.7.2.23.1 Offset

Register	Offset
MISCCR6	D8h

30.7.2.23.2 Function

Stores information about the first ECC single-bit error after exiting an ECC single-bit error interrupt.

30.7.2.23.3 Diagram



30.7.2.23.4 Fields

Field	Function
31-2 ADDRESS	ECC Single-Bit Error Address Contains the AHB bus address of the first ECC single-bit error encountered since the last ECC single-bit error interrupt.
1 HIT	ECC Single-Bit Error Information Hit Indicates whether the current read address on the AHB bus with the single-bit error has hit the information stored in MISCCR6[ADDRESS]. Only the address that caused the INTR[ECCSINGLEERR] interrupt is stored and compared; all subsequent single-bit errors are ignored. 0b - Address not hit 1b - Address hit
0 VALID	ECC Single-Bit Error Information Valid Indicates whether the information in MISCCR5 and MISCCR6 registers is valid. AHBCR[ECCSINGLEERRCLR] or reset can clear this field. When 0, do not use any other fields in MISCCR5 and MISCCR6 registers. 0b - Invalid 1b - Valid

30.7.2.24 Miscellaneous Control 7 (MISCCR7)

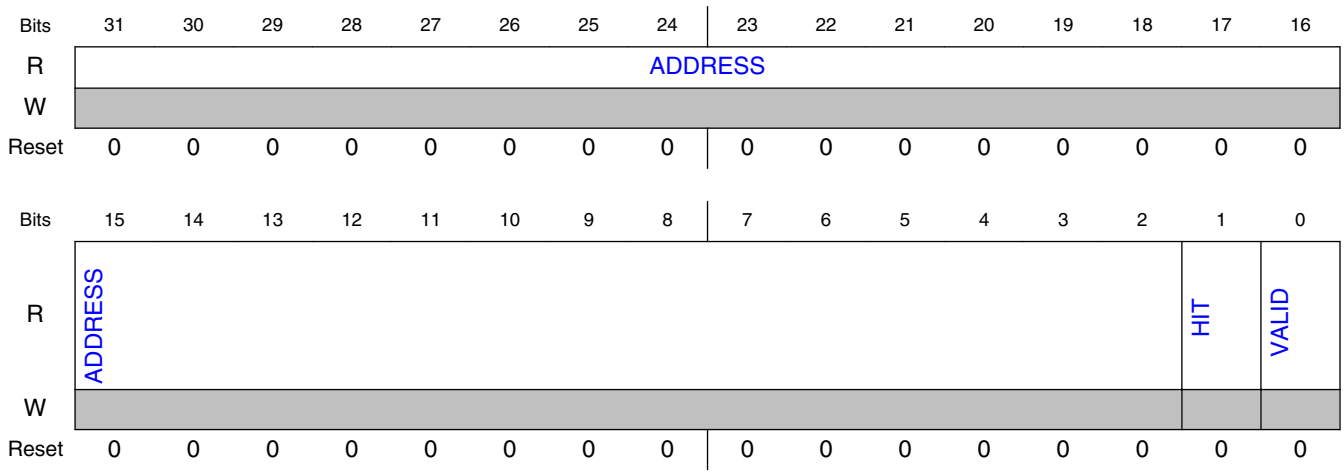
30.7.2.24.1 Offset

Register	Offset
MISCCR7	DCh

30.7.2.24.2 Function

Stores information about the first ECC multibit error after exiting ECC multibit error interrupt.

30.7.2.24.3 Diagram



30.7.2.24.4 Fields

Field	Function
31-2 ADDRESS	ECC multi error address Contains the AHB bus address of the first ECC multibit error encountered since the last ECC multibit error interrupt.
1 HIT	ECC Multibit Error Information Hit Indicates whether the current read address on the AHB bus with the multibit error has hit the information stored in MISCCR7[ADDRESS]. Only the address that caused the INTR[ECCMULTIERR] interrupt is stored and compared; all subsequent multibit errors are ignored. 0b - Address not hit 1b - Address hit
0 VALID	ECC Multibit Error Information Valid Indicates that the information in MISCCR7 register is valid. AHBCR[ECCMULTIERRCLR] or reset can clear this field. When 0, do not use any other fields in MISCCR7 register.

30.7.2.25 Status 0 (STS0)

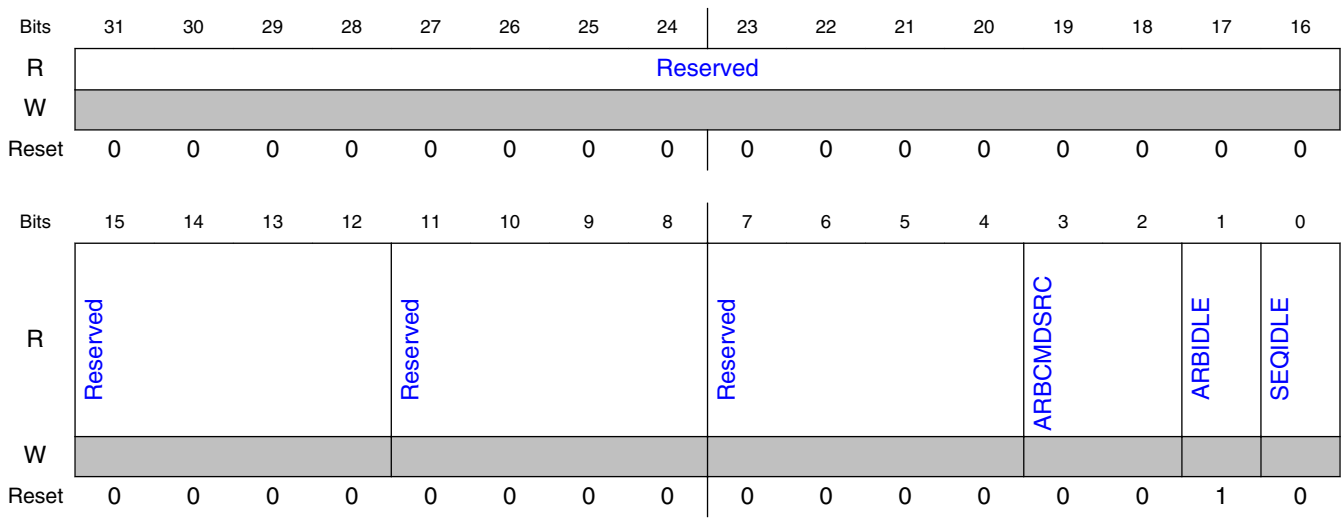
30.7.2.25.1 Offset

Register	Offset
STS0	E0h

30.7.2.25.2 Function

Indicates the status of the internal state machine.

30.7.2.25.3 Diagram



30.7.2.25.4 Fields

Field	Function
31-12 —	Reserved
11-8 —	Reserved
7-4 —	Reserved
3-2 ARBCMDSRC	ARB Command Source Indicates the trigger source of current command sequence that the arbitrator has granted. When ARB_CTL is not busy (STS0[ARBIDLE] = 1), the value of this field does not matter. 00b - Trigger source is AHB read command. 01b - Trigger source is AHB write command. 10b - Trigger source is IP command (by writing 1 to IPCMD[TRG]). 11b - Trigger source is a suspended command that has resumed.

Table continues on the next page...

Field	Function
1 ARBIDLE	ARB_CTL State Machine Idle Indicates whether the state machine in ARB_CTL is idle, or a command sequence that the arbitrator granted has not finished on the FlexSPI interface. When idle, no transaction is occurring on the FlexSPI interface (STS0[SEQIDLE] = 1). When waiting for the FlexSPI controller to become idle, poll this field instead of STS0[SEQIDLE]. 0b - Not idle 1b - Idle
0 SEQIDLE	SEQ_CTL State Machine Idle Indicates whether the state machine in SEQ_CTL is idle, or a command sequence is executing on the FlexSPI interface. 0b - Not idle 1b - Idle

30.7.2.26 Status 1 (STS1)

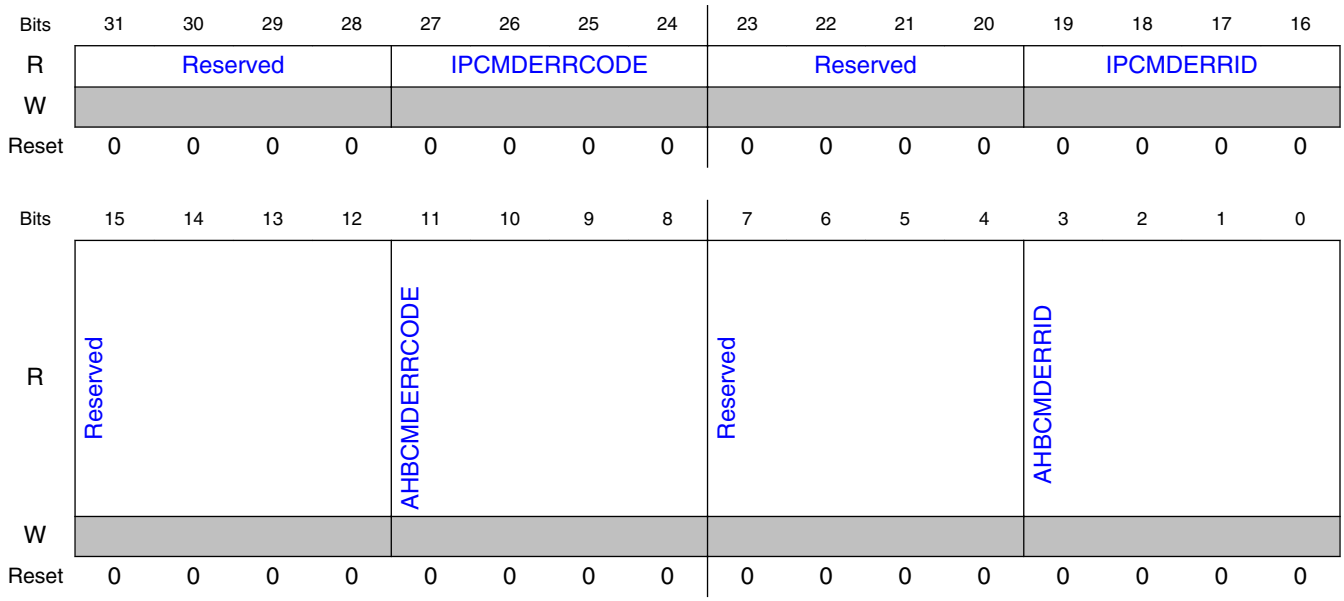
30.7.2.26.1 Offset

Register	Offset
STS1	E4h

30.7.2.26.2 Function

Indicates the error code of the AHB or IPS interface error response.

30.7.2.26.3 Diagram



30.7.2.26.4 Fields

Field	Function
31-28 —	Reserved
27-24 IPCMDERRCODE	IP Command Error Code When an IP command Error is detected, indicates the error code. This field returns to zero when INTR[IPCMDERR] is cleared. 0000b - No error 0010b - IP command with JMP_ON_CS instruction used in the sequence 0011b - Unknown instruction opcode in the sequence 0100b - DUMMY_SDR or DUMMY_RWDS_SDR instruction used in DDR sequence 0101b - DUMMY_DDR or DUMMY_RWDS_DDR instruction used in SDR sequence 0110b - Flash memory access start address exceeds entire flash address range (A1, A2, B1, and B2) 1110b - Sequence execution timeout 1111b - Flash boundary crossed
23-20 —	Reserved
19-16 IPCMDERRID	IP Command Error ID When an IP command error is detected, indicates the sequence index. This field returns to zero when INTR[IPCMDERR] is cleared.
15-12 —	Reserved
11-8	AHB Command Error Code

Table continues on the next page...

Field	Function
AHBCMDERRCODE	Contains the error code when an AHB command error is detected. This field returns to zero when INTR[AHBCMDERR] is cleared. 0000b - No error 0010b - AHB Write command with JMP_ON_CS instruction used in the sequence 0011b - Unknown instruction opcode in the sequence 0100b - DUMMY_SDR or DUMMY_RWDS_SDR instruction used in DDR sequence 0101b - DUMMY_DDR or DUMMY_RWDS_DDR instruction used in SDR sequence 1110b - Sequence execution timeout
7-4 —	Reserved
3-0 AHBCMDERRID	AHB Command Error ID When an AHB command error is detected, indicates the sequence index. This field returns to zero when INTR[AHBCMDERR] is cleared.

30.7.2.27 Status 2 (STS2)

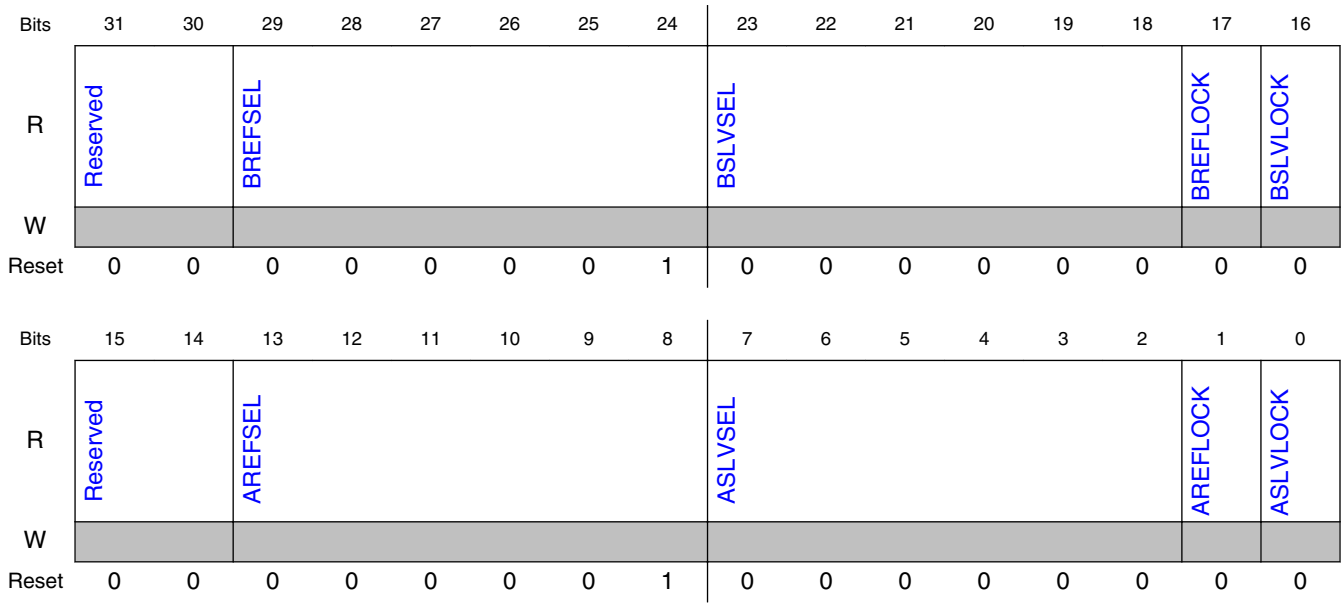
30.7.2.27.1 Offset

Register	Offset
STS2	E8h

30.7.2.27.2 Function

Indicates the status of Flash A and B sample clock DLLs.

30.7.2.27.3 Diagram



30.7.2.27.4 Fields

Field	Function
31-30 —	Reserved
29-24 BREFSEL	Flash B Sample Clock Reference Delay Line Delay Cell Number Indicates the sample clock reference delay line delay cell number for Flash B. There are 0-63 phases. • 000001b - Indicates lock phase 0. • 100000b - Indicates lock phase 63.
23-18 BSLVSEL	Flash B Sample Clock Target Delay Line Delay Cell Number Indicates the sample clock target delay line delay cell number for Flash B. There are 0-63 phases. • 000001b - Indicates lock phase 0. • 100000b - Indicates lock phase 63.
17 BREFLOCK	Flash B Sample Clock Reference Delay Line Locked 0b - Not locked 1b - Locked
16 BSLVLOCK	Flash B Sample Target Reference Delay Line Locked 0b - Not locked 1b - Locked
15-14 —	Reserved
13-8 AREFSEL	Flash A Sample Clock Reference Delay Line Delay Cell Number Indicates the sample clock reference delay line delay cell number for Flash A. There are 0-63 phases. • 000001b - Indicates lock phase 0. • 100000b - Indicates lock phase 63.

Table continues on the next page...

Field	Function
7-2 ASLVSEL	Flash A Sample Clock Target Delay Line Delay Cell Number Indicates the sample clock target delay line delay cell number for Flash A. There are 0-63 phases. • 000001b - Indicates lock phase 0. • 100000b - Indicates lock phase 63.
1 AREFLOCK	Flash A Sample Clock Reference Delay Line Locked 0b - Not locked 1b - Locked
0 ASLVLOCK	Flash A Sample Target Delay Line Locked 0b - Not locked 1b - Locked

30.7.2.28 AHB Suspend Status (AHBSPNDSTS)

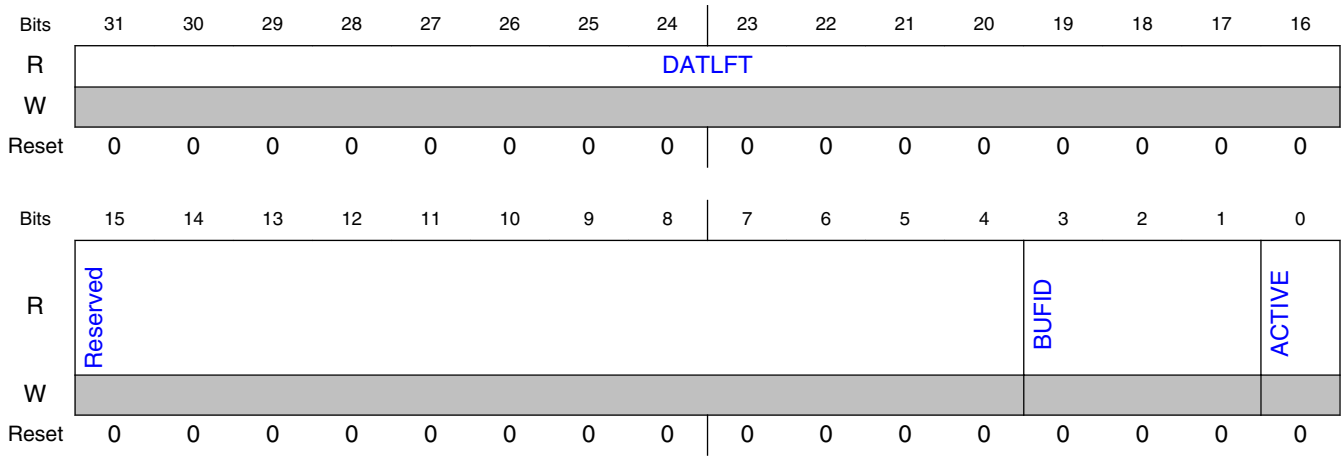
30.7.2.28.1 Offset

Register	Offset
AHBSPNDSTS	ECh

30.7.2.28.2 Function

Indicates the status of suspended AHB read prefetch command sequence. When an IP or AHB command is triggered while the arbitrator processes an AHB read sequence (prefetching additional data not for current AHB burst), the prefetch sequence is suspended. When there are no longer transactions on FlexSPI, the prefetch sequence may be resumed. FlexSPI saves only one AHB prefetch sequence. When a new prefetch sequence is suspended with an active sequence already suspended, the previous suspended sequence is removed and never resumed. See Command abort and suspend.

30.7.2.28.3 Diagram



30.7.2.28.4 Fields

Field	Function
31-16 DATLFT	Data Left Contains the data size remaining (in bytes) for a suspended command sequence.
15-4 —	Reserved
3-1 BUFID	AHB Receive Buffer ID for Suspended Command Sequence
0 ACTIVE	Active AHB Read Prefetch Suspended Indicates whether an AHB read prefetch command sequence has been suspended. 0b - No suspended AHB read prefetch command. 1b - An AHB read prefetch command sequence has been suspended.

30.7.2.29 IP Receive FIFO Status (IPRXFSTS)

30.7.2.29.1 Offset

Register	Offset
IPRXFSTS	F0h

30.7.2.29.2 Function

Indicates the status of IP receive FIFO.

30.7.2.29.3 Diagram

30.7.2.30.4 Fields

Field	Function
31-16 WRCNTR	Write Data Counter Contains counter for total data written. The data written is the value of this field × 64 bits.
15-8 —	Reserved
7-0 FILL	Fill Level of IP Transmit FIFO Indicates how full the IP transmit FIFO is. The fill level is the value of this field × 64 bits.

30.7.2.31 IP Receive FIFO Data a (RFDR0 - RFDR31)

30.7.2.31.1 Offset

For a = 0 to 31:

Register	Offset
RFDRa	100h + (a × 4h)

30.7.2.31.2 Function

Provides read access to IP receive FIFO via IPS bus. The read value is unknown for read access to invalid entries in the IP receive FIFO.

30.7.2.31.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

30.7.2.32.4 Fields

Field	Function
31-0 TXDATA	Transmit Data Contains transmit data. See Writing data to IP transmit FIFO.

30.7.2.33 Lookup Table a (LUT0 - LUT63)

30.7.2.33.1 Offset

For a = 0 to 63:

Register	Offset
LUTa	200h + (a × 4h)

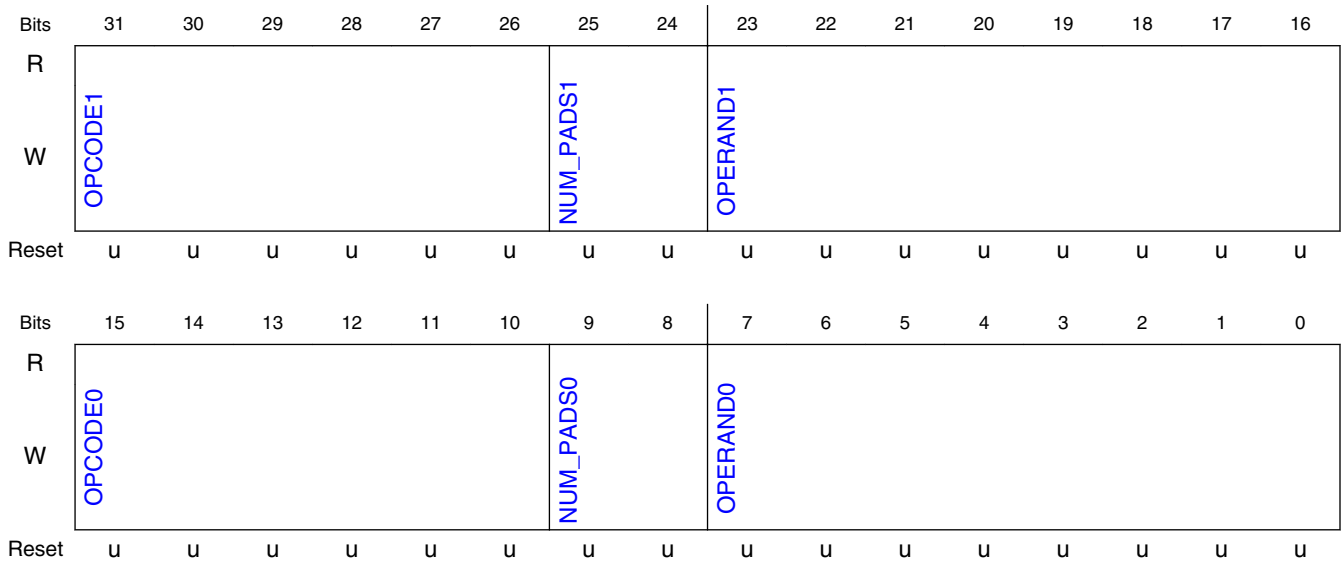
30.7.2.33.2 Function

Contains a lookup table for command sequences. Software should set the sequence index before triggering an IP command or AHB command. FlexSPI fetches the command sequence from LUT when an IP or AHB command is triggered. There are 16 command sequences in LUT. See Lookup table (LUT) and Programmable sequence engine.

NOTE

LUT is implemented as memory, so the reset value is unknown.

30.7.2.33.3 Diagram



30.7.2.33.4 Fields

Field	Function
31-26 OPCODE1	OPCODE1
25-24 NUM_PADS1	NUM_PADS1
23-16 OPERAND1	OPERAND1
15-10 OPCODE0	OPCODE
9-8 NUM_PADS0	NUM_PADS0
7-0 OPERAND0	OPERAND0

30.7.2.34 AHB Controller ID 0 Control (HMSTR0CR)

30.7.2.34.1 Offset

Register	Offset
HMSTR0CR	400h

30.7.2.34.2 Function

Contains the expected controller ID and the ID mask.

30.7.2.34.3 Diagram

30.8 AHB memory map definition

This section describes FlexSPI module AHB memory map in detail.

30.8.1 AHB memory map for serial flash memory and RAM access

AHB read and write access for serial flash and RAM memory are mapped to a specific address range. See the system memory map for specific address ranges supported.

AHB bus features supported for serial flash and RAM memory reading:

- Cacheable and non-cacheable access
- Prefetch enable and disable
- Burst size: 8, 16, 32, 64 bits
- All burst types: types: SINGLE, INCR, WRAP4, INCR4, WRAP8, INCR8, WRAP16, INCR16

AHB bus features for Serial RAM writing:

- Bufferable and Non-Bufferable access
- Burst size: 8, 16, 32, 64 bits
- All burst types: SINGLE, INCR, WRAP4, INCR4, WRAP8, INCR8, WRAP16, INCR16

See Flash memory access via AHB command for details about AHB access to serial flash memory and RAM.

30.8.2 AHB Memory Map for IP RX FIFO read access

See chip-specific section for the address range mapped for AHB read access.

AHB Bus feature supported for IP RX FIFO reading:

- Burst size: 8/16/32/64 bits
- All burst type: SINGLE/INCR/WRAP4/INCR4/WRAP8/INCR8/WRAP16/INCR16

Refer Reading data from IP receive FIFO for more details about IP RX FIFO reading.

30.8.3 AHB Memory Map for IP TX FIFO write access

See chip-specific section for the address range mapped for AHB write access.

AHB Bus feature supported for IP TX FIFO writing:

- Burst size: 8/16/32/64 bits
- All burst type: SINGLE/INCR/WRAP4/INCR4/WRAP8/INCR8/WRAP16/INCR16

Refer Writing data to IP transmit FIFO for more details about IP TX FIFO filling.

Chapter 31
External ECC Controller (XECC)

31.1 Chip-specific XECC information

Table 31-1. Reference links to related information

Topic	Related module(s)	Reference
System memory map	-	System Memory Map
Clocking	CCM	Clock Management Clock Control Module (CCM)
Power management	PMU	Power Management Power Management Unit
Signal multiplexing	IOMUX	External Signals and Pin Multiplexing IOMUX
Interrupts, DMA Events and XBAR Assignments	-	Interrupts, DMA Events and XBAR Assignments

31.2 Overview

The External ECC Controller (XECC) can be used as a gasket to provide ECC function for external memories. External memory address space can be divided into ECC regions and non-ECC regions, where there can be up to four ECC regions. XECC supports Single Error Correction and Double Error Detection (SEC-DED) ECC functions to provide reliability for external memory ECC region accesses. The XECC generates a 4-bit ECC code by Hsiao Hamming algorithm for every 4 bits in 32 bits data. 32 bits data is extended to 64 bits (32 bits data followed by 32 bits ECC code) before be written into external memory.

31.2.1 Block diagram

The following diagram shows 3 kinds of possible data flows for AXI access:

- When ECC is disabled, NIC301 and RECC/WECC modules are bypassed. AXI accesses directly pass through XECC.
- When ECC is enabled and AXI access address is out of all the ECC regions, AXI accesses pass through NIC301 between m_0 port and s_0 port and RECC/WECC is bypassed.
- When ECC is enabled and AXI access address hits one of the defined ECC regions, AXI accesses enter the WECC/RECC channel for ECC encode and decode.

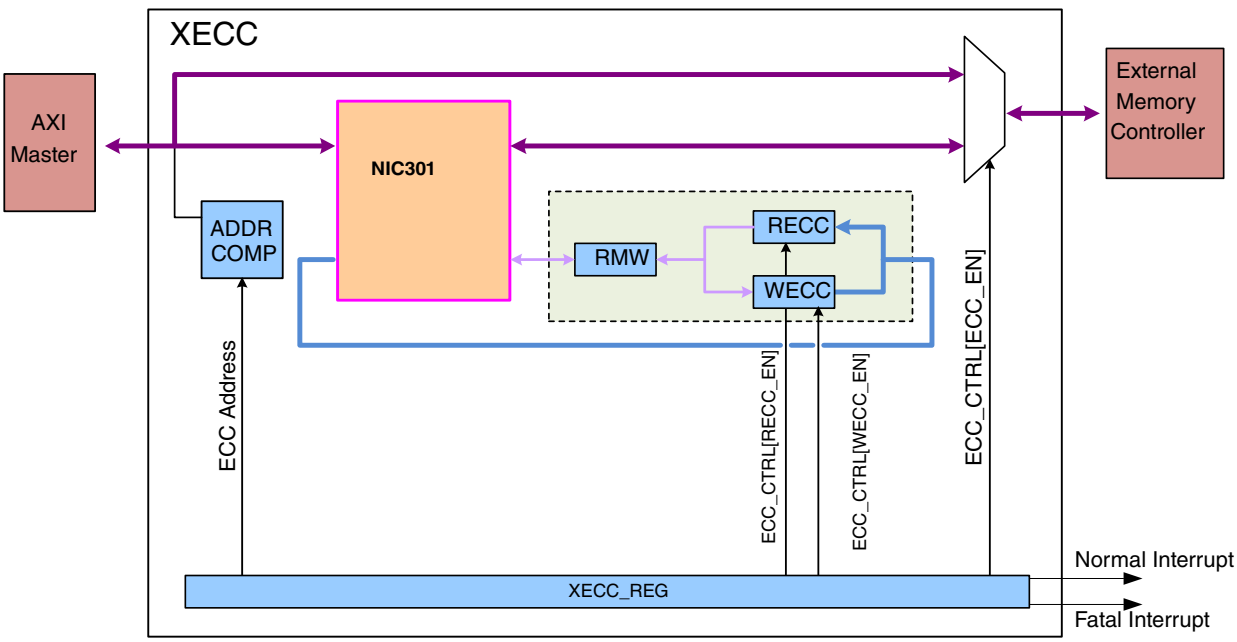

Figure 31-1. XECC block diagram

31.2.2 Features

The XECC includes the following features:

- Supports four configurable ECC regions for external memory space
- Supports SEC-DED ECC on every 4 bits in 32 bits data
- Supports error injection on data and ECC code
- ECC encode and decode functions can be disabled separately
- Separated interrupts for single bit error and multiple bits error

31.3 Functional description

The XECC can provide ECC function for the external memory ECC region. When ECC is off, XECC is totally transparent. When ECC is on, the number of total clock periods needed to pass the XECC module varies. Different AXI bursts have different conditions and pass times. For one AXI burst, the XECC waits for all transfers of this burst, then estimates if this burst is aligned or not. If it is not aligned, then the XECC reads memory data back, and combines them together to do the ECC calculation. The ECC calculation time is transparent.

31.3.1 ECC region

The XECC can provide four ECC region allocation for external memory space. The ECC regions address ranges are assigned by ECC_BASE_ADDRn and ECC_END_ADDRn registers (n=0,1,2,3). When ECC is enabled, the XECC checks if the AXI access address hits one of 4 ECC regions first. If the AXI access address is outside of ECC region, the AXI access directly passes through NIC301 and no ECC operation is executed. Otherwise, the AXI access enters the WECC and RECC channel for ECC encode and decode.

31.3.2 ECC encode

When ECC_CTRL[WECC_EN] and ECC_CTRL[ECC_EN] are set and AXI write address hits ECC regions, write data is encoded. The XECC generates 4 bits ECC code by Hsiao Hamming algorithm for every 4 bits in 32 bits data. After encode, 32 bits data is extended to 64 bits (32 bits data following by 32 bits ECC code) before a write into external memory. Therefore, there is address mapping from AXI master port to AXI slave port when write ECC is enabled. Address space should be doubled for ECC region in external memory.

If the write data is less than 32 bits, the XECC first executes a read-modify-write operation to extend the write data to 32 bits. The XECC then generates 32 bits ECC code. The resulting data written to external memory is 64 bits (32 bits data and 32 bits ECC code).

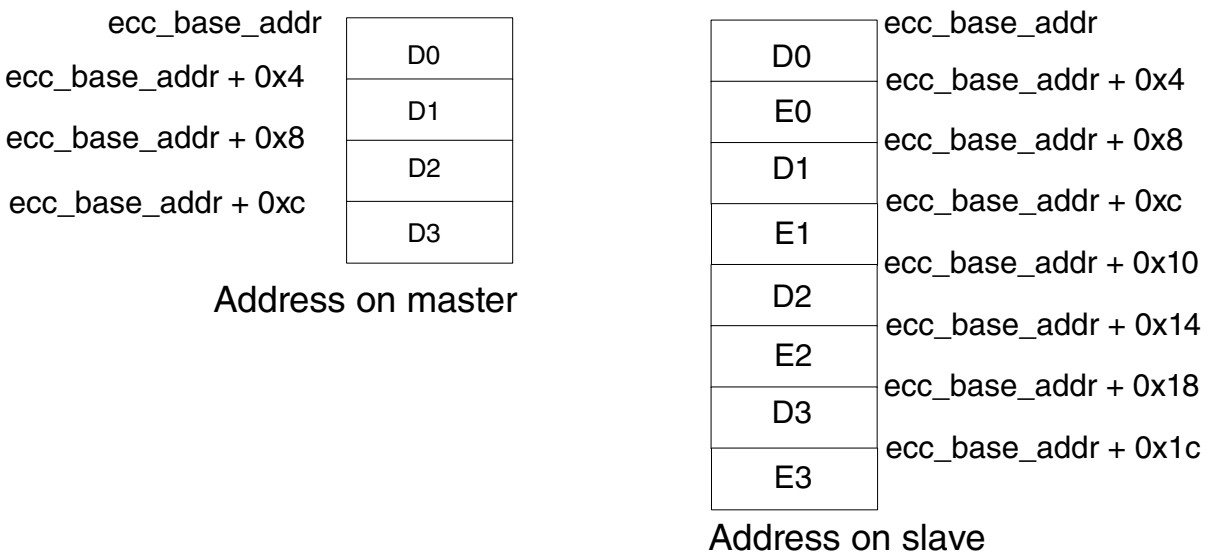

Figure 31-2. Address mapping after ECC encode

31.3.3 Error injection

XECC can inject error in write data and ECC code by configuring ERR_DATA_INJ and ERR_ECC_INJ registers. The 32 bits write data and 32 bits ECC code can be inverted if corresponding bits in ERR_DATA_INJ and ERR_ECC_INJ registers are set.

ERR_ECC_INJ registers are used for verification to test the ECC function. ERR_ECC_INJ registers keep injecting errors in write data, so bus error and interrupt continue to be received. For real cases (cases where ERR_ECC_INJ registers are not used for testing), bus error and interrupt only occur on real error data.

31.3.4 ECC decode

When ECC_CTRL[RECC_EN] and ECC_CTRL[ECC_EN] are set and AXI read address hits ECC regions, 32 bit read access must be extended to 64 bit read access to read data and ECC code back together. Therefore, there is also address mapping from AXI master port to AXI slave port when read ECC is enabled. After read address mapping, 64 bits read data from external memory enters into the RECC module and is decoded. The higher 32 bits in 64 bits read data are used as ECC code to decode low 32 bits in 64 bits read data. It can correct one bit error or detect 2 or more bits error for every 4 bits in low 32 bits read data. At the same time, error information is stored into XECC error registers for debug. Since 32 bits data have eight 4-bits fields, it is possible to report single bit error

and multiple bits error for different 4-bits field in one 32 bits data at same time. SINGLE_ERR_BIT_FIELD and MULTI_ERR_BIT_FIELD registers indicate which 4-bits fields are corrected or have multiple bits error.

NOTE

The XECC returns an error on the internal bus if an uncorrectable multi-bit error is detected.

31.3.5 ECC encode and decode bypass

To bypass all the ECC functions, SW should clear ECC_CTRL[ECC_EN]. To bypass either the ECC encode or decode, SW can clear ECC_CTRL[WECC_EN] or ECC_CTRL[RECC_EN]. If either the ECC encode or decode is bypassed, the same function should be implemented in external memory controller.

31.3.6 Data swap

The XECC can provide one bit correction for every 4 bits in 32 bits data. Though the sum of correctable bits can be up to 8 in 32 bits data, it cannot correct if 8 bits error are all in a single byte of 32 bits data. After the ECC_CTRL[SWAP_EN] bit is set, every bit in one byte of 32 bits data can be dispersed to different 4-bit fields before ECC encoding. That way, even if 8 bits in a single byte are all wrong, the XECC can still correct them.

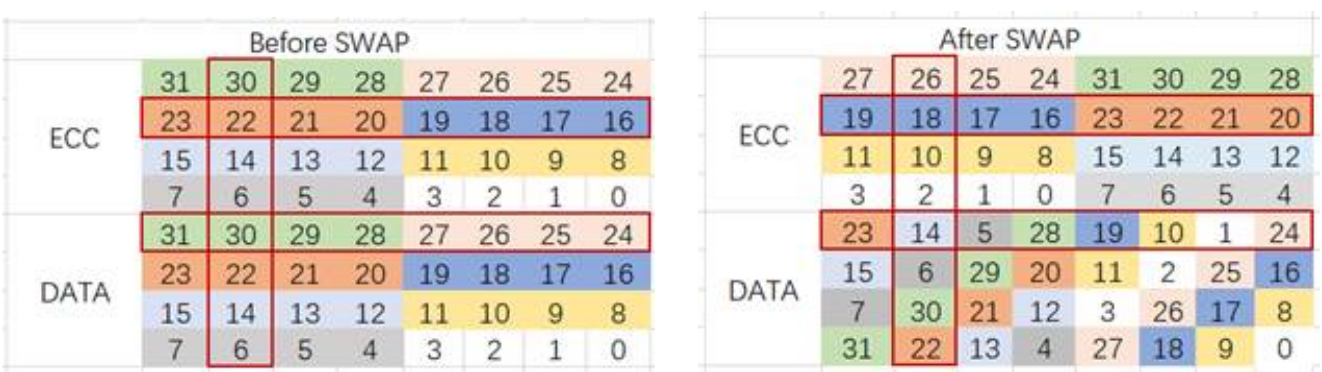

Figure 31-3. XECC Data Swap

In the figure above, the image on the left is ECC and data before swap, and the right image is ECC and data after swap. Every 4 bits of data has 4 bits ECC data. For example, write data [31:28] has its corresponding ECC data [31:28], indicated as green in the before-swap image. Corresponding post-swap data and ECC are marked as the same color in the after-swap image. The XECC can detect and correct the error if only one bit

error occurs in 8 bits (4 bits data + 4 bits ECC), no matter if the error occurs in data or ECC. The XECC can detect the error but cannot correct it if two bits of error or more occur in 8 bits.

In most situations, error bits in memory are more likely to be all in one row or one column like the marked red boxes indicated above.

If error bits happen in one column before swap, there are 2 bits error in 8 bits. But after swap, these errors could be dispersed to different 4-bit fields.

If error bits happen in one row and in the data area before swap, there are 4 bits error in 8 bits. But after swap, they could also be dispersed to different fields.

If error bits happen at one row and at ECC area, the situation is the same. Data is correct and only ECC is wrong in this case. Data is not changed. A fatal interrupt (fatal_int) is asserted for this error.

31.3.7 Clocks

There are two clocks in the XECC module:

Clock	Description
clk	Main XECC clock
ipg_clk	Used to read/write registers

See clocking chapter for this device for more information.

31.3.8 Interrupts

XECC can generate 2 kinds of interrupts:

- Normal interrupts - A normal interrupt can be generated when a single bit error is corrected for read.
- Fatal interrupts - A fatal interrupt can be generated when multiple bits error is detected for read. If fatal error interrupts are not needed, they can be disabled by changing ERR_SIG_EN[MULT_ERR_SIG_EN]=0. When this is disabled, only bus error is sent.

31.4 External Signals

The XECC does not have external signals.

31.5 Initialization

The following registers need to be configured to provide ECC function for external memories:

1. Configure ECC Control register (ECC_CTRL[ECC_EN]) to enable ECC
2. Configure ECC Region registers (ECC_BASE_ADDR*x*, ECC_END_ADDR*x*)

After steps 1 and 2 above are complete, ECC is enabled and AXI bursts can be sent to XECC

31.6 Memory Map and register definition

This section includes the XECC module memory map and detailed descriptions of all registers.

31.6.1 XECC register descriptions

31.6.1.1 XECC memory map

31.6.1.10.4 Fields

Field	Function
31-0 SINGLE_ERR_ECC	Single Error ECC code When a single bit error is corrected in an AXI read access, this stores the read ECC code.

31.6.1.11 Single Error Bit Position (SINGLE_ERR_POS)

31.6.1.11.1 Offset

Register	Offset
SINGLE_ERR_POS	24h

31.6.1.11.2 Function

When a single bit error is corrected in an AXI read access, this indicates which bit is corrected in an AXI read data. This register stores the error bit position for the first error that happens. The register does not update again if additional errors occur until the ERR_STATUS[SINGLE_ERR] flag is cleared and then another error occurs.

31.6.1.11.3 Diagram

Chapter 32
Ultra Secured Digital Host Controller (uSDHC)

32.1 Chip-specific uSDHC information

Table 32-1. Reference links to related information

Topic	Related module(s)	Reference
System memory map	-	System Memory Map
Clocking	CCM	Clock Management Clock Control Module (CCM)
Power management	PMU	Power Management Power Management Unit
Signal multiplexing	IOMUX	External Signals and Pin Multiplexing IOMUX
Interrupts, DMA Events and XBAR Assignments	-	Interrupts, DMA Events and XBAR Assignments

- The 32 KHz clock used for card detection is sourced from OSC_32K
- Only uSDHC2 supports HS400, uSDHC1 does not support HS400.

32.2 Overview

The Ultra Secured Digital Host Controller (uSDHC) provides the interface between the host system and the SD/SDIO/MMC cards, as shown in Figure 32-2. The module acts as a bridge, passing host bus transactions to the SD/SDIO/MMC cards by sending commands and performing data accesses to/from the cards. It handles the SD/SDIO/MMC protocols at the transmission level.

32.2.1 Block Diagram

The following figure illustrates the block diagram for uSDHC.

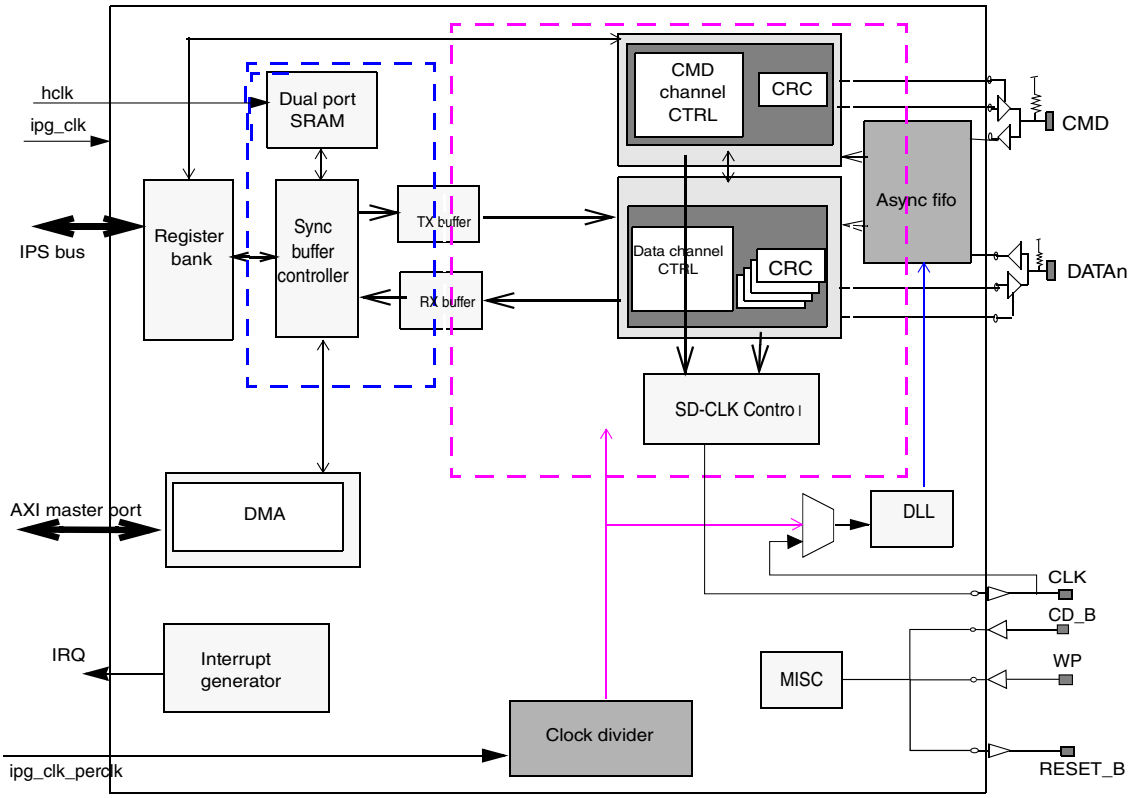

Figure 32-1. uSDHC block diagram

The figure below shows the System connection of uSDHC:

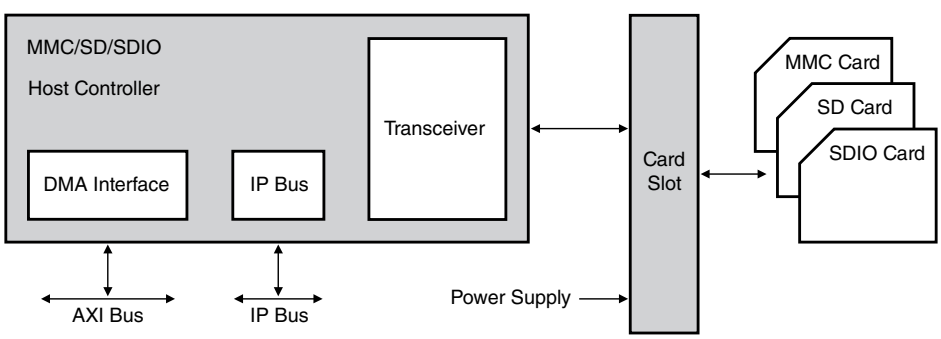

Figure 32-2. System connection of uSDHC

The following are brief descriptions of the cards supported by uSDHC:

- The Multi Media Card (MMC) is a universal low-cost data storage and communication media designed to cover a wide array of applications including mobile video and gaming. Previous MMC cards were based on a 7-pin serial bus with a single data pin, while the new high speed MMC communication is based on an advanced 11-pin serial bus designed to operate in the low-voltage range.

- The Secure Digital Card (SD) is an evolution of the old MMC technology. It is specifically designed to meet the security, capacity, performance, and environmental requirements inherent in newly emerging audio and video consumer electronic devices. The physical form factor, pin assignment, and data transfer protocol are backward compatible with the old MMC (with some additions).
- Under the SD protocol, system connection can be categorized into memory card, I/O card, and combo card, which have both memory and I/O functions. The memory card invokes a copyright protection mechanism that complies with the security of the SDMI standard. The I/O card, which is also known as SDIO card, provides high-speed data I/O with low-power consumption for mobile electronic devices. For the sake of simplicity, the next figure does not show cards with reduced size or mini cards.

32.2.2 Features

The list given below shows the features of the uSDHC module:

- Conforms to the SD Host Controller Standard Specification version 2.0/3.0
- Compatible with the MMC System Specification version 4.2/4.3/4.4/4.41/4.5/5.0
- Compatible with the SD Memory Card Specification version 3.0 and supports the Extended Capacity SD Memory Card
- Compatible with the SDIO Card Specification version 2.0/3.0
- Designed to work with SD Memory, miniSD Memory, SDIO, miniSDIO, SD Combo, MMC, MMC plus, and MMC RS cards
- Card bus clock frequency up to 208 MHz
- Supports 1-bit/4-bit SD and SDIO modes, and 1-bit/4-bit/8-bit MMC modes
  - Up to 832 Mbps of data transfer for SDIO cards using four parallel data lines in the Single Data Rate (SDR) mode
  - Up to 400 Mbps of data transfer for SDIO card using four parallel data lines in the Dual Data Rate (DDR) mode
  - Up to 832 Mbps of data transfer for SDXC cards using four parallel data lines in the Single Data Rate (SDR) mode
  - Up to 400 Mbps of data transfer for SDXC card using four parallel data lines in the Dual Data Rate (DDR) mode
  - Up to 1600 Mbps of data transfer for MMC cards using eight parallel data lines in the Single Data Rate (SDR) mode
  - Up to 3200 Mbps of data transfer for MMC cards using eight parallel data lines in the Dual Data Rate (DDR) mode
- Supports single block/multi-block read and write
- Supports block sizes of 1 ~ 4096 bytes
- Supports the write protection switch for write operations

- Supports both synchronous and asynchronous abort
- Supports pause during the data transfer at block gap
- Supports SDIO Read Wait and Suspend Resume operations
- Supports Auto CMD12 for multi-block transfer
- Host can initiate non-data transfer command while data transfer is in progress
- Allows cards to interrupt the host in 1-bit and 4-bit SDIO modes; also supports interrupt period
- Embodies a fully configurable 128x32-bit FIFO for read/write data
- Supports internal DMA capabilities
- Support voltage selection by configuring vendor-specific register bit
- Supports Advanced DMA to perform linked memory access

NOTE

This block can support all the above-listed speed mode and maximum data throughput. However, these may be specific to the device. See the corresponding chip-specific information or the device data sheet for accurate details.

32.3 Functional description

The following sections provide a brief functional description of the major system blocks, including the data buffer, DMA AXI interface, register bank as well as IP Bus interface, dual-port memory wrapper, data/command controller, clock and reset manager, and clock generator.

32.3.1 Modes and operations

32.3.1.1 Data transfer modes

The uSDHC module can select the following modes for data transfer:

- SD 1-bit
- SD 4-bit
- MMC 1-bit
- MMC 4-bit
- MMC 8-bit
- Identification mode (up to 400 kHz)
- MMC full-speed mode (up to 26 MHz)
- MMC high-speed mode (up to 52 MHz)

- MMC HS200 mode(up to 200 MHz)
- MMC HS400 mode (200 MHz both edges)
- MMC DDR mode (52 MHz both edges)
- SD/SDIO full-speed mode (up to 25 MHz)
- SD/SDIO high-speed mode (up to 50 MHz)
- SD/SDIO UHS-I mode(up to 208 MHz in SDR mode, up to 50 MHz in the DDR mode)

NOTE

This block can support all the above listed speed mode and maximum clock frequency. However, these may be specific to the device. See the corresponding chip-specific information or the device data sheet for accurate details.

32.3.2 Data buffer

The uSDHC module uses one configurable data buffer to transfer data between the system bus (IP bus or advanced extensible interface (AXI) bus) and the SD card in an optimized manner, maximizing throughput between the two clock domains (IP peripheral clock and the master clock).

The buffer is used as a temporary storage for transferring data between the host system and the card. The watermark levels for read and write are both configurable and can range between 1 to 128 words. When using internal DMA mode, The watermark level for read should be configured to 16 and watermark level for write should be configured to integral multiple of 16 to get max AXI bus throughput. The next figure provides the uSDHC buffer scheme.

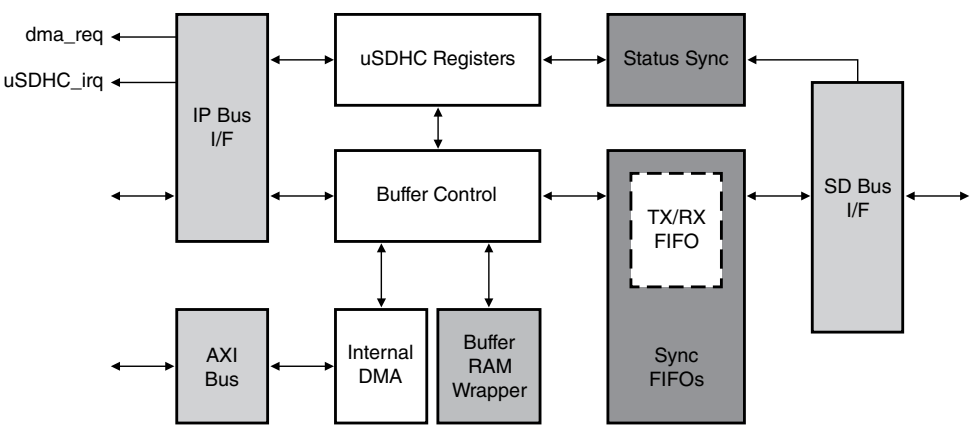

Figure 32-3. uSDHC buffer scheme

Here are 2 transfer modes to access the data buffer:

- CPU polling mode:
  - For a host-read operation, when the number of words received in the buffer meets or exceeds the RD_WML watermark value, by polling the BRR bit, the host driver can read the Buffer Data Port register to fetch the amount of words set in the RD_WML register from the buffer. The write operation is similar. For more information on the process of writing operation, see Write operation sequence.
- Internal DMA mode (includes simple and advanced DMA accesses):
  - The internal DMA access, either by simple or advanced DMA, is over the AXI bus.

For a read operation, when there are more words in the buffer than the amount set in the RD_WML register, the internal DMA starts fetching data over the AXI bus.

The Write operation functions in a similar manner—sequential and contiguous access is necessary to ensure that the pointer address value is correct. Random or skipped access is not possible. The byte order, by reset, is little endian mode. The actual byte order is swapped inside the buffer, according to the endian mode configured by software (see the following figures). For a host write operation, the byte order is swapped after the data is fetched from the buffer and ready to send to the SD Bus. For a host read operation, the byte order is swapped before the data is stored in the buffer.

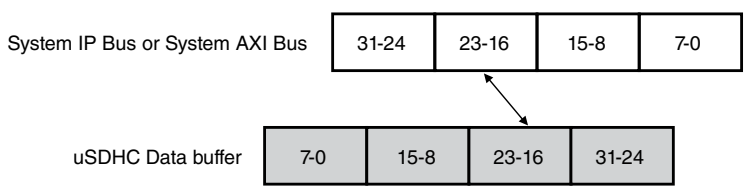

Figure 32-4. Data swap between system bus and uSDHC data buffer in the byte little endian mode

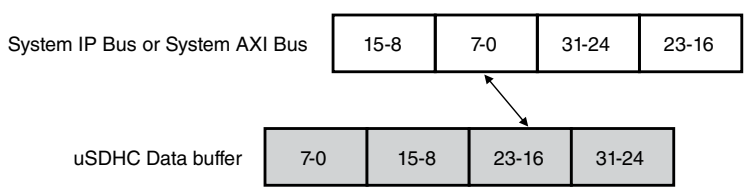

Figure 32-5. Data swap between system bus and uSDHC data buffer in half word big endian mode

32.3.2.1 Write operation sequence

There are 2 ways to write data into the buffer when the user transfers data to the card:

- Processor core polling through the BWR bit in the Interrupt Status register (interrupt or polling)
- Internal DMA

When the internal DMA is not used, the DMAEN bit in the Transfer Type register is not set when the command is sent, uSDHC asserts a DMA request when the amount of buffer space exceeds the value set in the WR_WML register and is ready for receiving new data. At the same time, uSDHC sets the BWR bit. The buffer write ready interrupt is generated if it is enabled by software.

When internal DMA is used, uSDHC does not inform the system before all the required number of bytes are transferred (if no error is encountered). When an error occurs during the data transfer, uSDHC aborts the data transfer and abandons the current block. The host driver should read the contents of the DMA System Address register to obtain the starting address of the abandoned data block. If the current data transfer is in multi-block mode, uSDHC does not automatically send CMD12, even though the AC12EN bit in the Transfer Type register is set. The host driver sends CMD12 in this scenario and restarts the write operation from that address. It is recommended that a software reset for Data be applied before the transfer is restarted.

The uSDHC module does not start data transmission until the buffer has been filled with the number of words set in the WR_WML register. If the buffer is empty and the host system does not write data in time, uSDHC stops the CLK to avoid the data buffer underrun situation.

32.3.2.2 Read operation sequence

There are 2 ways to read data from the buffer when the data is received from the card:

- Processor core polling through the BRR bit in the Interrupt Status register (interrupt or polling)
- Internal DMA

When internal DMA is not used (DMAEN bit in Transfer Type register is not set when the command is sent), uSDHC asserts a DMA request when the amount of data exceeds the value set in the RD_WML register, which is available and ready for system fetching data. At the same time, uSDHC sets the BRR bit. The buffer read ready interrupt is generated if it is enabled by the software.

When internal DMA is used, uSDHC does not inform the system before all the required number of bytes are transferred (if no error is encountered). When an error occurs during the data transfer, uSDHC aborts the data transfer and abandons the current block. The host driver should read the content of the DMA System Address register to get the

starting address of the abandoned data block. If the current data transfer is in multi-block mode, uSDHC does not automatically send CMD12, even though the AC12EN bit in the Transfer Type register is set. The host driver sends CMD12 in this scenario and restarts the read operation from that address. It is recommended that a software reset (in register RSTD) for data be applied before the transfer is restarted.

For any write transfer mode, uSDHC does not start data transmission until the number of words set in the RD_WML register are in buffer. If the buffer is full and the host system does not read data in time, uSDHC stops the CLK to avoid the data buffer overrun situation.

32.3.2.3 Data buffer and block size

In the uSDHC module, the data buffer can hold up to 256 words (32-bit) and the watermark levels for write and read can be configured accordingly. The user needs to know the buffer size for the buffer operation during a data transfer to utilize it in the most optimized way.

The host driver may configure the value according to the system and requirement.

During a multi-block data transfer, the block length can be set to any value between 1 and 4096 bytes, satisfying the requirements of the external card. The only restriction is from the external card, which can be limited in size or support of a partial block access (which is not the integer times of 512 bytes).

As uSDHC treats each block individually, for block sizes which are not multiples of four (not word-aligned), stuffed bytes are required at the end of each block. For example, if the block size is 7 bytes and there are 12 blocks to write, the software side must write twice for each block. For each block, the ending byte is abandoned by uSDHC because it only sends 7 bytes to the card and picks data from the following system write, resulting in 24 beats of write access in total.

32.3.2.4 Dividing large data transfer

This SDIO command CMD53 definition limits the maximum data size of data transfers according to the following formula:

Max data size = Block size x Block count

The length of a multiple block transfer needs to be in multiples of block size. If the total data length cannot be divided evenly into a multiple of the block size, then there are two options to transfer the data. These two options depend on the function and the card design. Option 1 is for the host driver to split the transaction. The remainder of the block

size data is then transferred by using a single block command at the end. Option 2 is to add dummy data in the last block to fill the block size. For option 2, the card must manage the removal of the dummy data.

See the figure below for an example showing the division of large data transfers, assuming a kind of WLAN SDIO card that only supports a block size of up to 64 bytes. Although uSDHC supports a block size of up to 4096 bytes, the SDIO can only accept a block size of less than 64 bytes, so the data must be divided (see the example below).

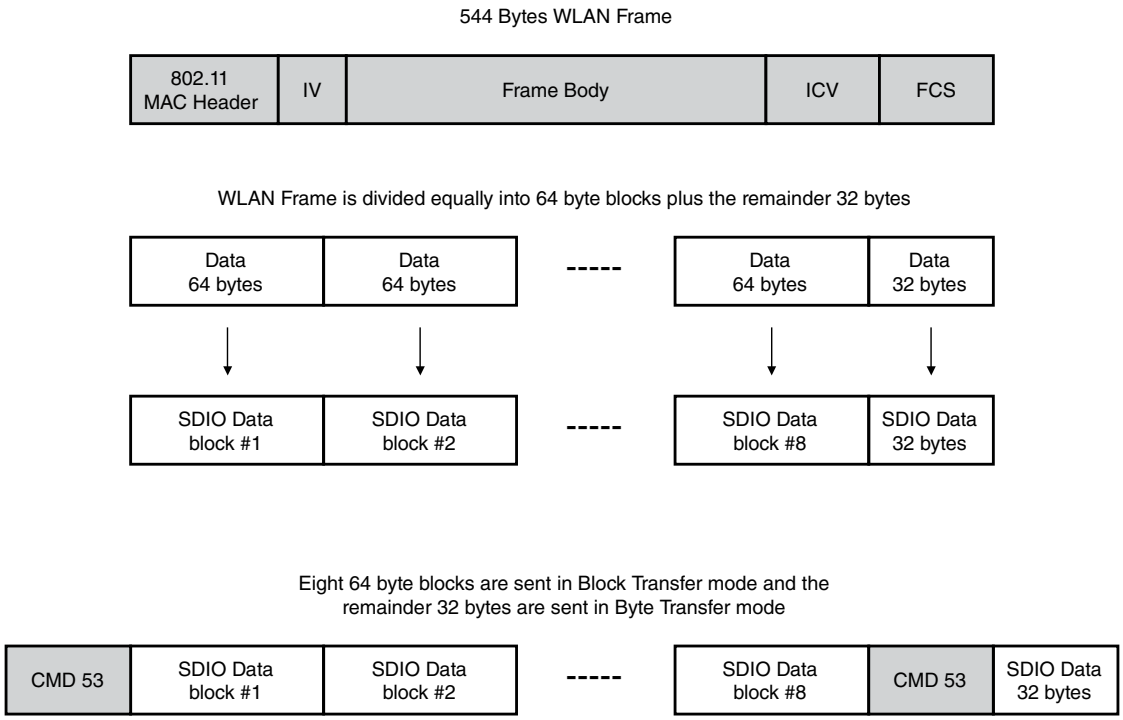

Figure 32-6. Example for dividing large data transfers

32.3.3 DMA AXI interface

The internal DMA implements a DMA engine and the AXI master. When the internal DMA is enabled, but the BWR and BRR bits are set if the BWRSEN and BRRSEN bits have been set in the Interrupt Status Enable register.

See the figure below for an illustration of the DMA AXI interface block.

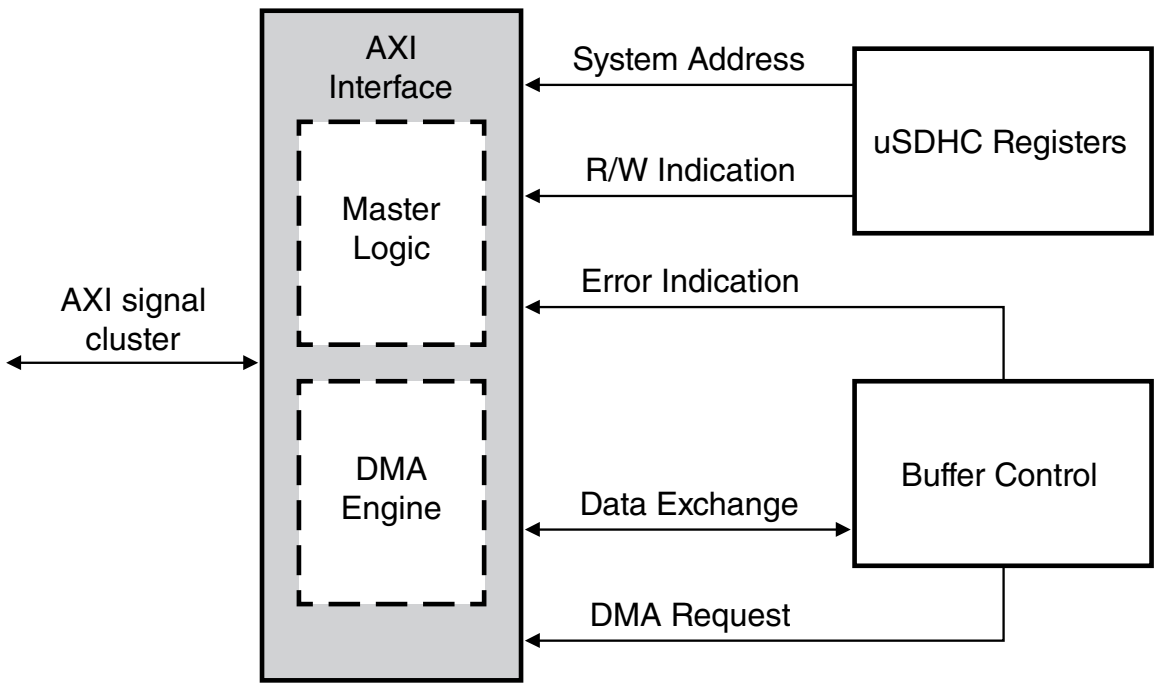

Figure 32-7. DMA AXI interface block

32.3.3.1 Internal DMA request

If the watermark level requirement is met in data transfer or if the last data of current block is ready in the data buffer, and the Internal DMA is enabled, the data buffer block sends a DMA request to AXI interface.

The delay in response from the internal DMA engine depends on the system AXI bus loading and the priority assigned to uSDHC. The DMA engine does not respond to the request during its burst transfer, but is ready to serve as soon as the burst is over. The data buffer de-asserts the request if the data buffer space (for write) or bytes in data buffer is smaller than the watermark level. Upon access to the buffer by internal DMA, the data buffer updates its internal buffer pointer, and when the watermark level is satisfied or the last data of the current block is ready in the data buffer, another DMA request is sent.

The data transfer is in the block unit, and the subsequent watermark level is always automatically set as the remaining number of words. For instance, for a multi block data read with each block size of 31 bytes, and the watermark level set to six words (24 bytes). After the first burst transfer, if there are greater than or equal to two words in the buffer, which might contain some data of the next block), another DMA request is sent. This is because the remaining number of words to transfer for the current block is ceiling((31 - 6 * 4) / 4) = 2. The uSDHC module reads two words out of the buffer, with seven valid bytes and one stuffed byte.

32.3.3.2 AXI master interface

It is possible that the internal AXI DMA engine could fail during the data transfer. Upon detection of an AXI bus error during DMA transfer, the DMA engine stops the transfer and goes to the idle state. At that point, the internal data buffer stops receiving incoming data and sending out data. The DMAE bit in the Interrupt Status register is generated to host CPU to report a bus error condition.

After the DMAE interrupt is received, the software sends a CMD12 to abort the current transfer and read the DS_ADDR bits of the DMA System Address register to get the starting address of the corrupted block. After the DMA error is fixed, the software should apply a data reset and restart the transfer from this address to recover the corrupted block.

32.3.3.3 ADMA engine

In the SD host controller standard, a new DMA transfer algorithm called the Advanced DMA (ADMA) is defined. For simple DMA, after the page boundary is reached, a DMA interrupt is generated and the new system address is programmed by the host driver.

The ADMA defines the programmable descriptor table in the system memory. The host driver can calculate the system address at the page boundary and program the descriptor table before executing ADMA. It reduces the frequency of interrupts to the host system. Therefore, higher speed DMA transfers could be realized because the host MCU intervention is not be needed during long DMA-based data transfers.

There are two types of ADMA in host controller: ADMA1 and ADMA2. ADMA1 can support data transfer of 4KB aligned data in system memory, and ADMA2 eliminates the restriction so that the data of any location and any size can be transferred in system memory. Their formats of Descriptor Table are different.

ADMA can recognize all kinds of descriptors defined in SD host controller Standard, and if the "End" flag is detected in the descriptor, ADMA stops after this descriptor is processed.

32.3.3.3.1 ADMA concept and descriptor format

ADMA1 includes the following descriptors:

- Valid/invalid descriptor
- Nop descriptor
- Set data length descriptor
- Set data address descriptor
- Link descriptor
- Interrupt flag and end flag in descriptor

ADMA2 includes the following descriptors:

- Valid/invalid descriptor
- Nop descriptor
- Rsv descriptor (new in ADMA2)
- Set data length and address descriptor
- Link descriptor
- Interrupt flag and end flag in descriptor

ADMA starts read/write operation after it reaches the tran state, using the data length and data address analyzed from most recent descriptor(s).

For ADMA1, the valid data length descriptor is the last set type descriptor before the tran type descriptor. Every tran type descriptor triggers a transfer, and the transfer data length is extracted from the most recent set type descriptor. If there is no set type descriptor after the previous Trans descriptor, the data length is the value for previous transfer, or 0 if no set descriptor is ever met.

For ADMA2, the tran type descriptor contains both data length and transfer data address, so the tran type descriptor itself can start a data transfer.

See the figure below for the format of the descriptor table for ADMA1.

Address/ Page Field		Address/ Page Field		Attribute Field					
31	12	11	6	5	4	3	2	1	0
Address or Data Length		000000		Act 2	Act 1	0	Int	End	Valid

Act 2	Act1	Symbol	Comment	31- 28	27- 12
0	0	Nop	No Operation	Don't Care	
0	1	Set	Set Data Length	0000	Data Length
1	0	Tran	Transfer Data	Data Address	
1	1	Link	Link Descriptor	Descriptor Address	

Valid	Valid = 1 indicates this line of descriptor is effective. If Valid = 0 generate ADMA Error Interrupt and stop ADMA.
End	End = 1 indicates current descriptor is the ending one.
Int	Int = 1 generates DMA Interrupt when this descriptor is processed.

Figure 32-8. Format of the ADMA1 descriptor table

See the figure below for the concept and access method of the descriptor table for ADMA1.

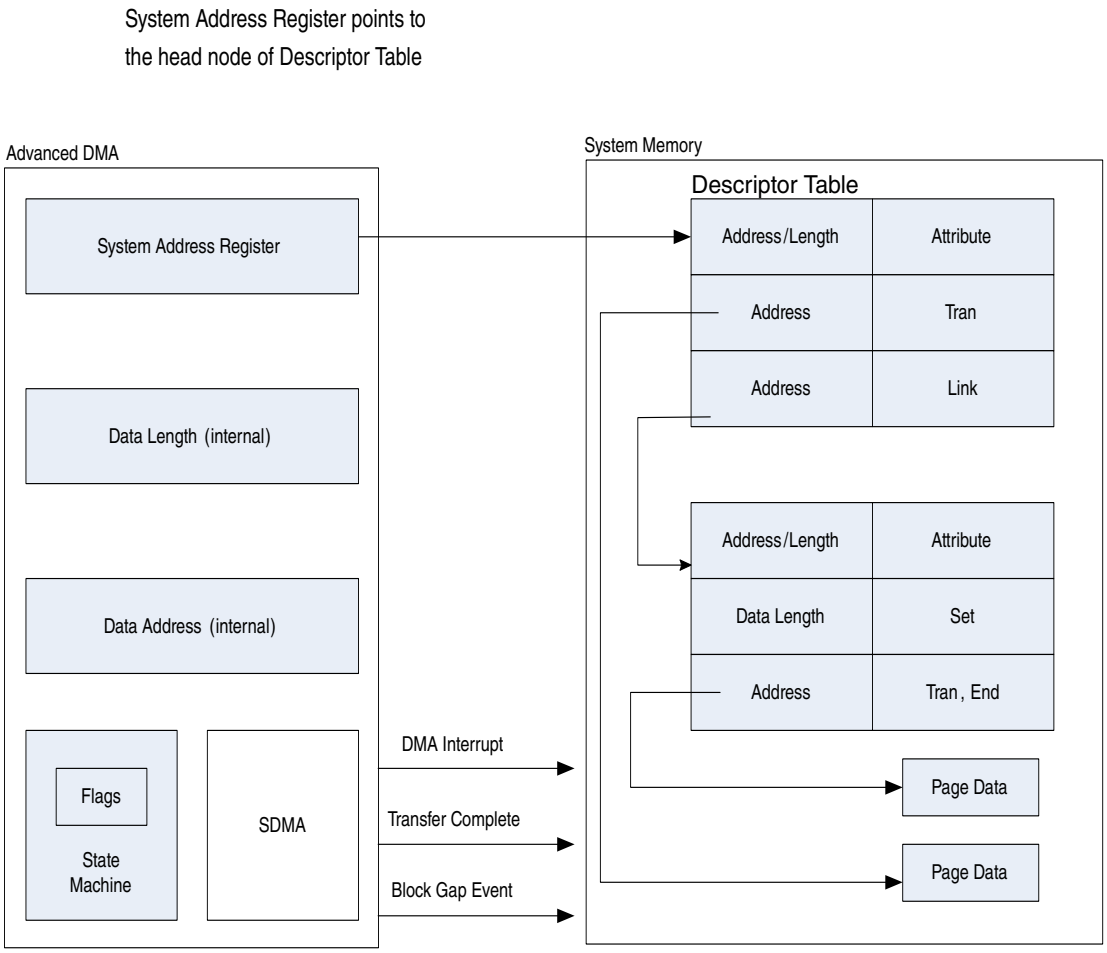

Figure 32-9. Concept and access method of the ADMA1 descriptor table

The figure below explains the ADMA2 format. ADMA2 deals with the lower 32-bit first, and then the higher 32-bit. If the 'Valid' flag of descriptor is 0, it ignores the higher 32-bit. The Address field should be set to word aligned (lower 2-bit is always set to 0). Data length is in byte unit.

Address Field		Length		Reserved		Attribute Field					
63	32	31	16	15	06	05	04	03	02	01	00
32-bit Address		16-bit length		0000000000		Act 2	Act 1	0	Int	End	Valid

Act 2	Act1	Symbol	Comment	Operation
0	0	Nop	No Operation	Don't Care
0	1	Rsv	Reserved	Same as Nop. Read this line and go to next one
1	0	Tran	Transfer Data	Transfer data with address and length set in this descriptor line
1	1	Link	Link Descriptor	Link to another descriptor

Valid	Valid = 1 indicates this line of descriptor is effective. If Valid = 0 generate ADMA Error Interrupt and stop ADMA.
End	End = 1 indicates current descriptor is the ending one.
Int	Int = 1 generates DMA Interrupt when this descriptor is processed.

Figure 32-10. Format of the ADMA2 descriptor table

See the figure below for the concept and access method of the descriptor table for ADMA2.

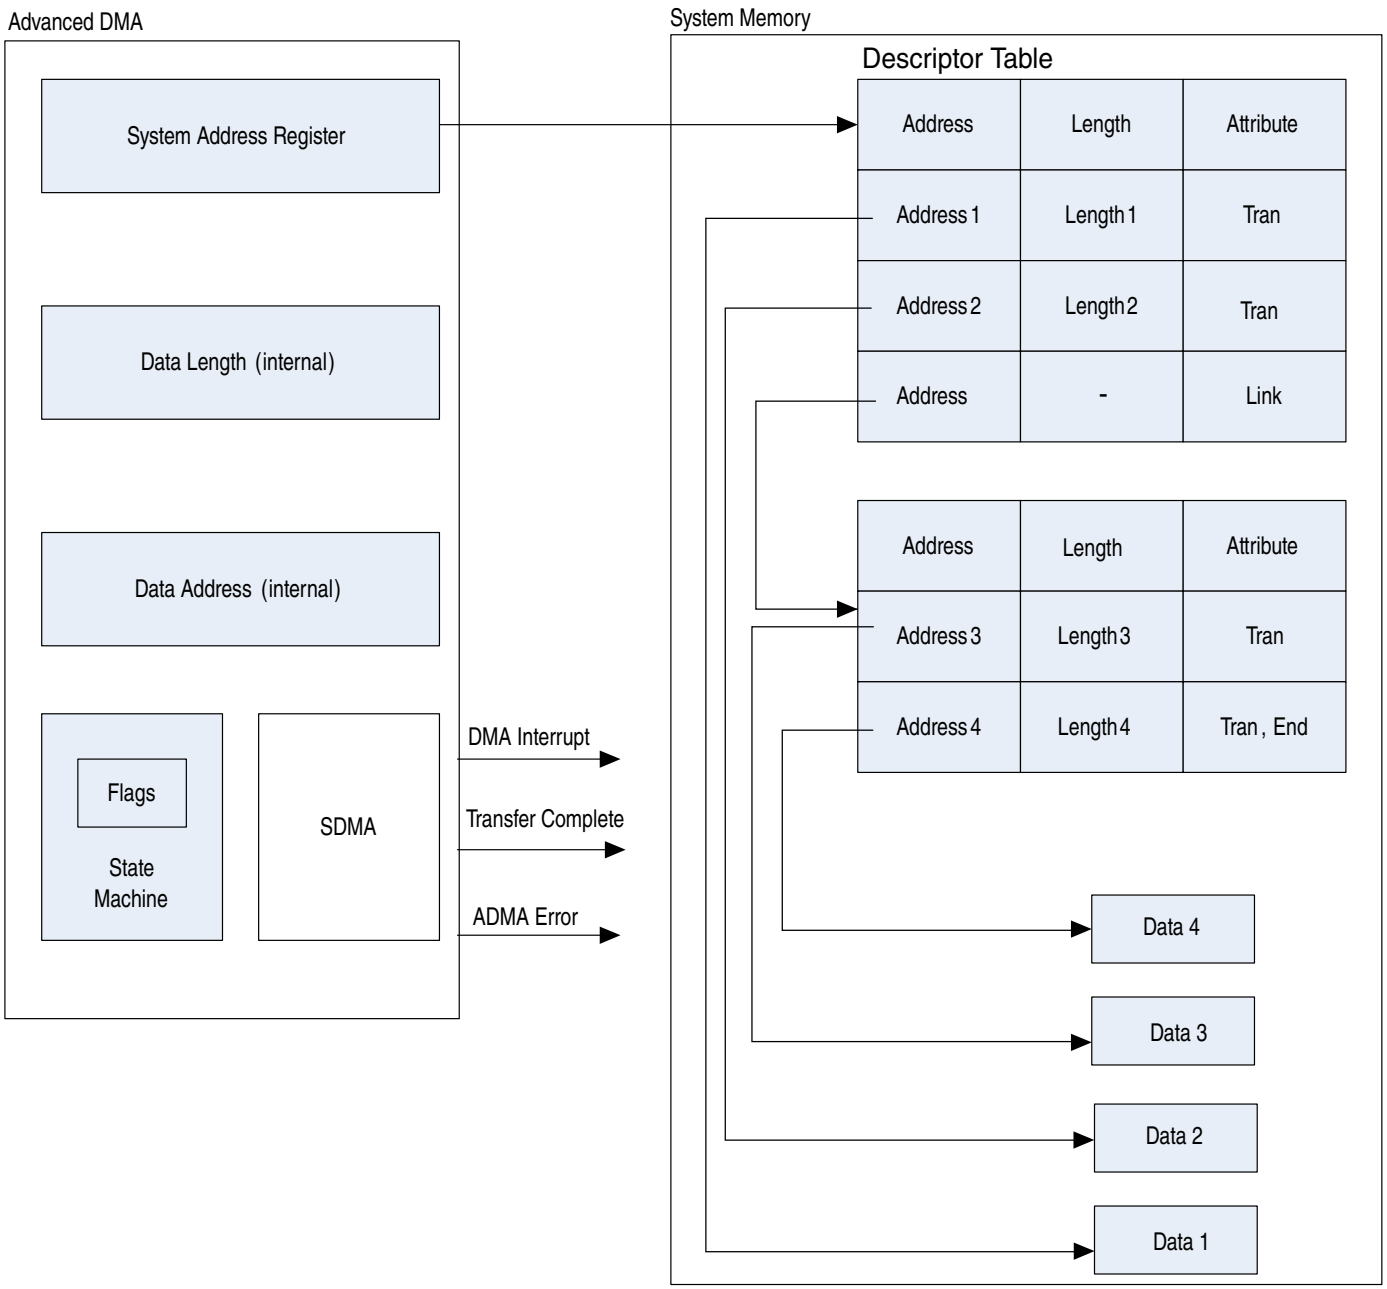

Figure 32-11. Concept and access method of the ADMA2 descriptor table

32.3.3.3.2 ADMA interrupt

If the interrupt flag descriptor is set, ADMA generates an interrupt according to various types of descriptors.

For ADMA1:

- Set type of descriptor: interrupt is generated when data length is set.
- Tran type descriptor: interrupt is generated when this transfer is complete.
- Link type of descriptor: interrupt is generated when new descriptor address is set.
- Nop type of descriptor: interrupt is generated just after this descriptor is fetched.

For ADMA2:

- Tran type of descriptor: interrupt is generated when this transfer is complete.
- Link type of descriptor: interrupt is generated when new descriptor address is set.
- Nop/Rsv type of descriptor: interrupt is generated just after this descriptor is fetched.

32.3.3.3.3 ADMA error

The ADMA stops whenever an error is encountered. These errors include:

- Fetching descriptor error
- AXI response error
- Data length mismatch error

An ADMA descriptor error is generated when it fails to detect a "valid" flag in the descriptor. If an ADMA descriptor error occurs, the interrupt is not generated even if the "Interrupt" flag of this descriptor is set.

When BLKCNTEN bit is set, data length set in register BLK_ATT must be equal to the whole data length set in descriptor, otherwise data length mismatch error is generated.

When BLKCNTEN bit is not set, then the whole data length set in descriptor is a multiple of block lengths; otherwise, when data set in the descriptor nodes are not performed at block boundaries, then data mismatch errors occur.

32.3.4 Register bank with IP bus interface

Register accesses through the IP bus interface are on the register bank.

See the figure below for the block diagram.

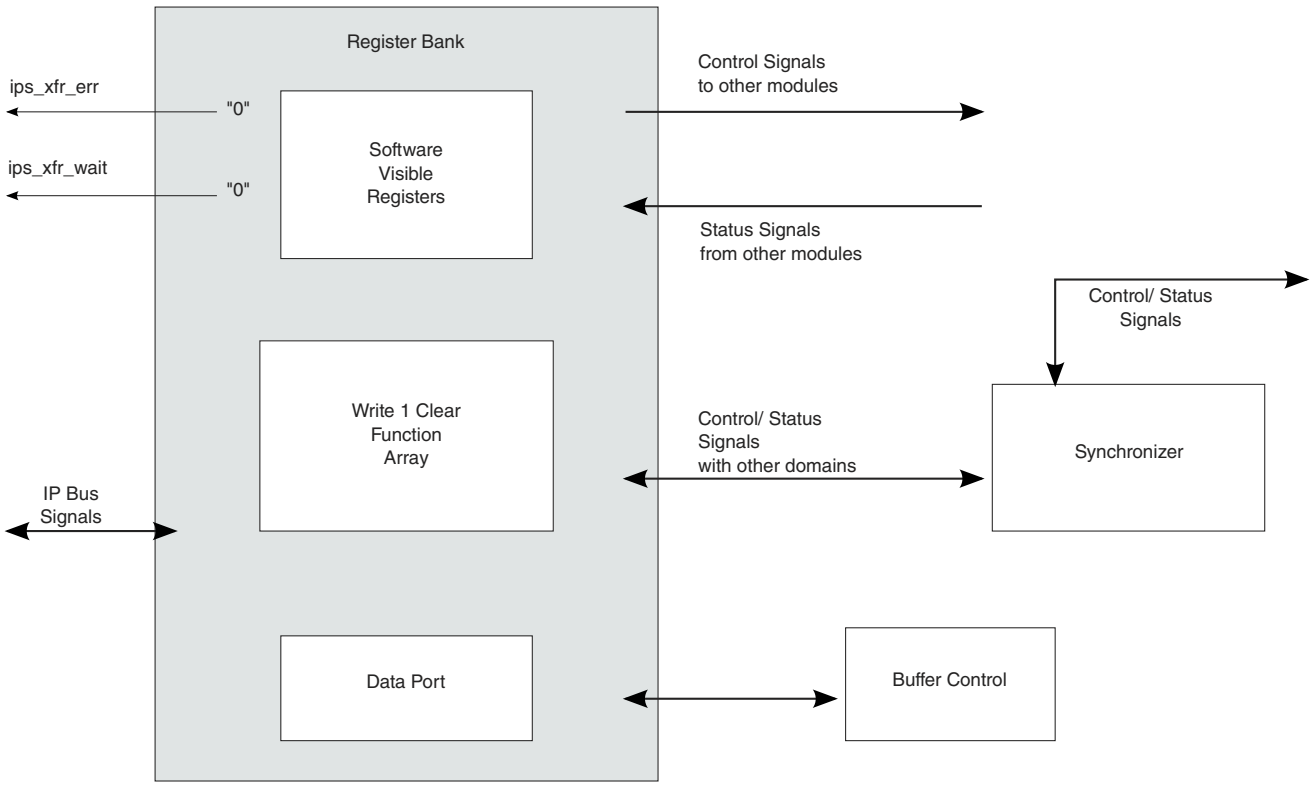

Figure 32-12. Register bank diagram

Only a 32-bit access is allowed, and no partial read/write is supported; therefore, all accesses are word aligned.

Access to an unimplemented address within the register memory map space does not generate a transfer error.

32.3.4.1 SD protocol unit

The SD protocol unit deals with all SD protocol affairs.

The SD protocol unit performs the following functions:

- Acts as the bridge between the internal buffer and the SD bus
- Sends the command data as well as its argument serially
- Stores the serial response bit stream into corresponding registers
- Detects the bus state on the CMD/DAT lines
- Monitors the interrupt from the SDIO card
- Asserts the read wait signal
- Gates off the SD clock when buffer is announcing danger status
- Detects the write protect state

The SD protocol unit consists of four submodules:

- SD control misc
- Command control
- Data control
- Clock control

32.3.4.2 SD control misc

In the SD control misc unit:

- The card detection (including CD_B and DATA3 for card detection) and card interrupt are implemented.
- The module monitors the signal level on all the eight data lines and the command lines. It directly routes the level values into the register bank.
- The module also detects the Write Protect (WP) line. If WP is active, writes to the register bank are ignored.

32.3.4.3 SD clock control

If the internal data buffer is near full (for read) or near empty (for write), the SD clock must be gated off to avoid buffer over/under-run. This module asserts the gate of the output SD clock to shut the clock off. After the buffer has space (for read) or has data (for write), the clock gate of this module opens, and the SD clock is active again.

32.3.4.4 Command control

The Command Control module deals with the transactions on the CMD line.

See the figure below for an illustration of the structure for the Command CRC shift register.

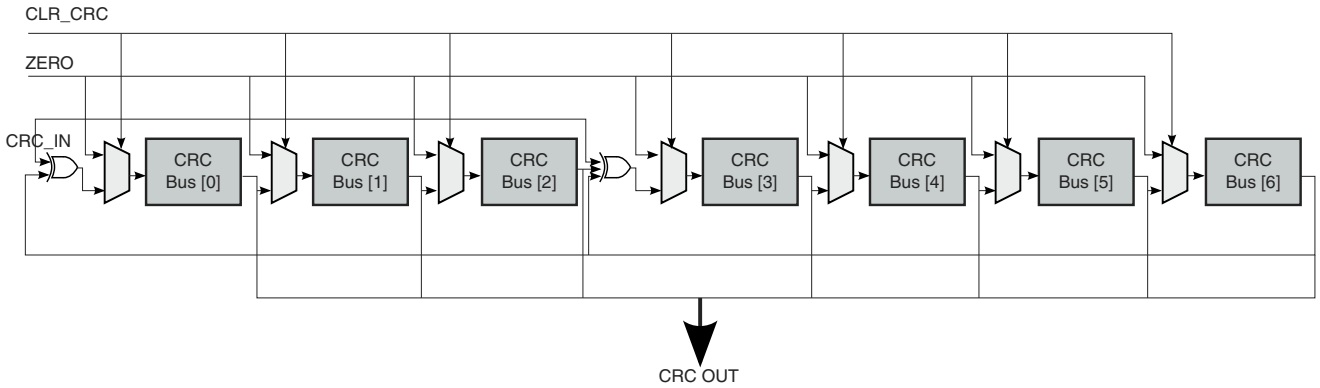

Figure 32-13. Command CRC shift register

The CRC polynomials for the CMD are as follows:

Generator polynomial: $G(x) = x^7 + x^3 + 1$
$M(x) = (\text{first bit}) * x^n + (\text{second bit}) * x^{n-1} + ... + (\text{last bit}) * x^0$
$CRC[6:0] = \text{Remainder } [(M(x) * x^7) / G(x)]$

32.3.4.5 Data control

The data agent deals with the transactions on the eight data lines. Moreover, this module also detects the busy state on the DATA0 line and generates the read wait state by the request from the transceiver.

The CRC polynomials for the data are as follows:

Generator polynomial: $G(x) = x^{16} + x^{12} + x^5 + 1$

$M(x) = (\text{first bit}) * x^n + (\text{second bit}) * x^{n-1} + ... + (\text{last bit}) * x^0$

$CRC[15:0] = \text{Remainder } [(M(x) * x^{16}) / G(x)]$

32.3.5 Card insertion and removal detection

The uSDHC module uses either the DATA3 pin or the CD_B pin to detect card insertion or removal. When there is no card on the MMC/SD bus, the DATA3 is pulled to a low voltage level by default.

When any card is inserted to or removed from the socket, uSDHC detects the logic value changes on the DATA3 pin and generates an interrupt. When the DATA3 pin is not used for card detection (for example, it is implemented in GPIO), the CD_B pin must be connected for card detection. Whether DATA3 is configured for card detection or not, the

CD_B pin is always a reference for card detection. Whether the DATA3 pin or the CD_B pin is used to detect card insertion, uSDHC sends an interrupt (if enabled) to inform the Host system that a card is inserted.

32.3.6 Power management and wakeup events

When there is no operation between uSDHC and the card through the SD bus, the user can completely disable the peripheral clock and base clock in the chip-level clock control module to save power. When the user needs to use uSDHC to communicate with the card, it can enable the clock and start the operation.

In some circumstances, when the clocks to uSDHC are disabled, for instance, when the system is in low-power mode, there are some events for which the user needs to enable the clock and handle the event. These events are called wakeup interrupts. The uSDHC module can generate these interrupts even when there are no clocks enabled. The three interrupts that can be used as wakeup events are these:

- Card removal interrupt
- Card insertion interrupt
- Interrupt from SDIO card (not available in multiple block data transfers)

These three wakeup events (or wakeup interrupts) can also be used to wakeup the system from low-power modes.

NOTE

To make the interrupt a wakeup event, when all the clocks to uSDHC are disabled or when the entire system is in low power mode, the corresponding wakeup enabled bit needs to be set. Refer to Protocol Control (PROT_CTRL) for more information on the uSDHC Protocol Control register.

32.3.6.1 Setting wakeup events

For uSDHC to respond to a wakeup event, the software must set the respective wakeup enable bit before the CPU enters the sleep mode.

Before the software disables the host clock, it should ensure that all the following conditions have been met:

- No read or write transfer is active
- Data and command lines are not active
- No interrupts are pending
- Internal data buffer is empty

32.3.7 MMC fast boot

The Embedded MultiMediaCard (eMMC4.3) specification adds a fast boot feature that requires hardware support. There are two types of fast boot modes in the eMMC4.3 specification: boot operation and alternative boot operation. Each type also has with-acknowledge and without-acknowledge modes.

In the boot operation mode, the master (MultiMediaCard host) can read boot data from the slave (MMC device) by keeping CMD line low after power-on, or sending CMD0 with argument + 0xFFFFFFFA (optional for slave), before issuing CMD1.

NOTE

For the eMMC4.3 card setting, please see the eMMC4.3 specification.

32.3.7.1 Boot operation

If the CMD line is held low for 74 clock cycles and more after power-up before the first command is issued, the slave recognizes that boot mode is being initiated and starts preparing boot data internally.

Within one second after the CMD line goes low, the slave starts to send the first boot data to the master on the DATA line(s). The master must keep the CMD line low to read all of the boot data.

NOTE

For the purposes of this documentation, fast boot is called "normal fast boot mode".

If boot acknowledge is enabled, the slave has to send acknowledge pattern '010' to the master within 50ms after the CMD line goes low. If boot acknowledge is disabled, the slave does not send out acknowledge pattern '010'.

The master can terminate the boot mode with the CMD line high.

The boot operation is terminated when all the contents of the enabled boot data are sent to the master. After the boot operation is executed, the slave gets ready for the CMD1 operation and the master needs to start a normal MMC initialization sequence by sending CMD1.

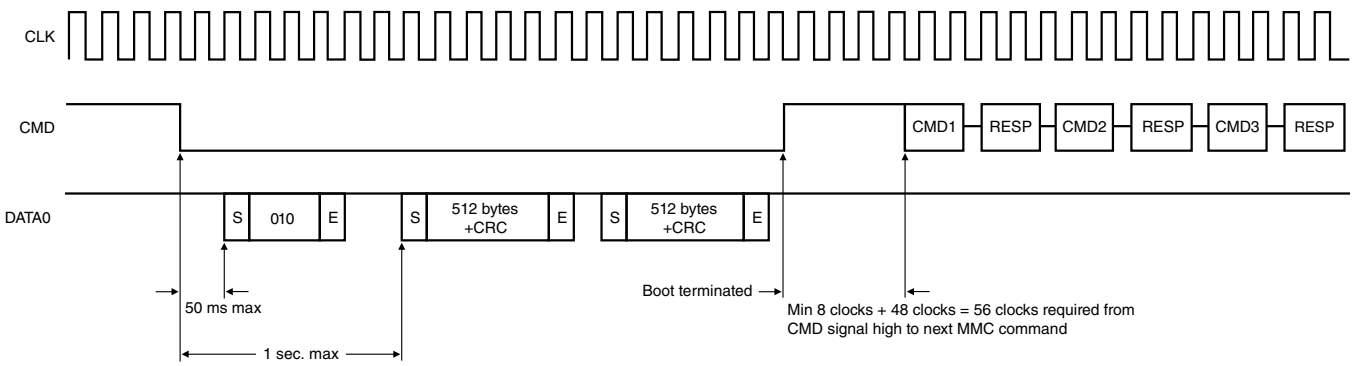

Figure 32-14. MultiMediaCard state diagram (normal boot mode)

32.3.7.2 Alternative boot operation

This boot function is optional for the device. If bit 0 in the extended CSD byte[228] is set to '1', the device supports the alternative boot operation.

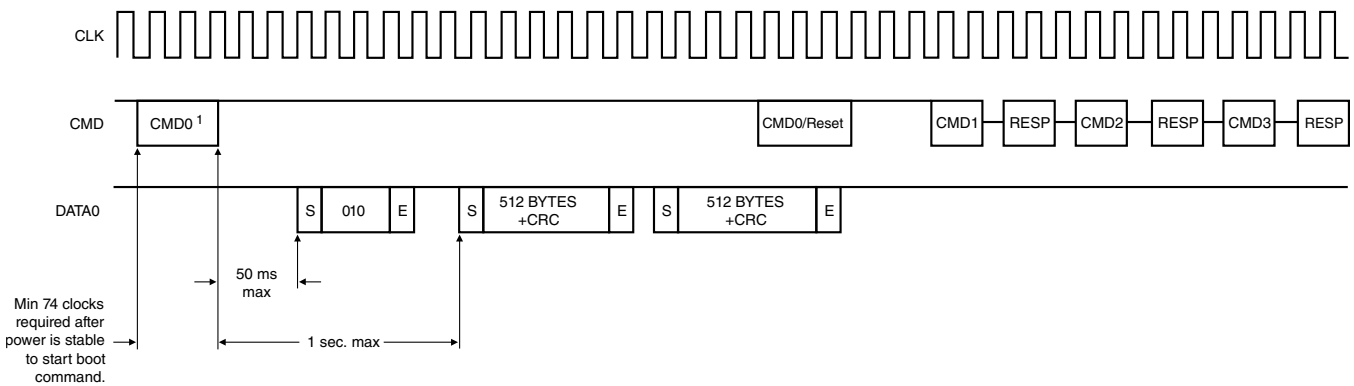
After power-up, if the host issues CMD0 with the argument of 0xFFFFFFFA after 74 clock cycles, before CMD1 is issued or the CMD line goes low, the slave recognizes that boot mode is being initiated and starts preparing boot data internally.

Within one second after CMD0 with the argument of 0xFFFFFFFA is issued, the slave starts to send the first boot data to the master on the DATA line(s).

If boot acknowledge is enabled, the slave must send the acknowledge pattern '010' to the master within 50ms after the CMD0 with the argument of 0xFFFFFFFA is received. If boot acknowledge is disabled, the slave does not send out acknowledge pattern '010'.

The master can terminate the boot mode by issuing CMD0 (Reset).

Boot operation is terminated when all the contents of the enabled boot data are sent to the master. After the boot operation is executed, the slave gets ready for the CMD1 operation and the master needs to start a normal MMC initialization sequence by sending CMD1.



NOTE 1: CMD0 with argument 0xFFFFFFFA

Figure 32-15. MultiMediaCard state diagram (alternative boot mode)

32.3.8 Commands for MMC/SD/SDIO

A table containing the list of commands for the MMC/SD/SDIO cards is provided here.

Refer to the corresponding specifications for more details about the command information.

There are four kinds of commands defined to control the MultiMediaCard:

- Broadcast commands (bc), no response
- Broadcast commands with response (bcr), response from all cards simultaneously
- Addressed (point-to-point) commands (ac), no data transfer on the DATA
- Addressed (point-to-point) data transfer commands (adtc)

Response: A response is a token that is sent from the card to the host as an answer to a previously received command. A response is transferred serially on the CMD line.

Table 32-2. Commands for MMC/SD/SDIO cards

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD0	bc	[31:0] stuff bits	-	GO_IDLE_STATE	Resets all MMC and SD memory cards to idle state.
CMD1	bcr	[31:0] OCR without busy	R3	SEND_OP_COND	Asks all MMC and SD Memory cards in idle state to send their operation conditions register contents in the response on the CMD line.
CMD2	bcr	[31:0] stuff bits	R2	ALL_SEND_CID	Asks all cards to send their CID numbers on the CMD line.
CMD3[1]	ac	[31:6] RCA [15:0] stuff bits	R1 R6 (SDIO)	SET/ SEND_RELATIVE_ADDR	Assigns relative address to the card.

Table continues on the next page...

Table 32-2. Commands for MMC/SD/SDIO cards (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD4	bc	[31:0] DSR [15:0] stuff bits	-	SET_DSR	Programs the DSR of all cards.
CMD5	bc	[31:0] OCR without busy	R4	IO_SEND_OP_COND	Asks all SDIO cards in idle state to send them operation conditions register contents in the response on the CMD line.
CMD6[2]	adtc	[31] Mode 0: Check function 1: Switch function [30:8] Reserved for function groups 6 ~ 3 (All 0 or 0xFFFF) [7:4] Function group1 for command system [3:0] Function group2 for access mode	R1	SWITCH_FUNC	Checks switch ability (mode 0) and switch card function (mode 1). Refer to "SD Physical Specification V1.1" for more details.
CMD6[3]	ac	[31:26] Set to 0 [25:24] Access [23:16] Index [15:8] Value [7:3] Set to 0 [2:0] Cmd Set	R1b	SWITCH	Switches the mode of operation of the selected card or modifies the EXT_CSD registers. Refer to "The MultiMediaCard System Specification Version 4.0 Final draft 2" for more details.
CMD7	ac	[31:6] RCA [15:0] stuff bits	R1b	SELECT/ DESELECT_CARD	Toggles a card between the stand-by and transfer states or between the programming and disconnect states. In both cases, the card is selected by its own relative address and gets deselected by any other address. Address 0 deselects all.
CMD8	adtc	[31:0] stuff bits	R1	SEND_EXT_CSD	The card sends its EXT_CSD register as a block of data, with a block size of 512 bytes.
CMD9	ac	[31:6] RCA [15:0] stuff bits	R2	SEND_CSD	Addressed card sends its card-specific data (CSD) on the CMD line.
CMD10	ac	[31:6] RCA [15:0] stuff bits	R2	SEND_CID	Addressed card sends its card-identification (CID) on the CMD line.
CMD11	adtc	[31:0] data address	R1	READ_DAT_UNTIL_STOP	Reads data stream from the card, starting at the given address, until a STOP_TRANSMISSION follows.
CMD12	ac	[31:0] stuff bits	R1b	STOP_TRANSMISSION	Forces the card to stop transmission.
CMD13	ac	[31:6] RCA [15:0] stuff bits	R1	SEND_STATUS	Addressed card sends its status register.

Table continues on the next page...

Table 32-2. Commands for MMC/SD/SDIO cards (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD14	Reserved				
CMD15	ac	[31:6] RCA [15:0] stuff bits	-	GO_INACTIVE_STATE	Sets the card to inactive state in order to protect the card stack against communication breakdowns.
CMD16	ac	[31:0] block length	R1	SET_BLOCKLEN	Sets the block length (in bytes) for all following block commands (read and write). Default block length is specified in the CSD.
CMD17	adtc	[31:0] data address	R1	READ_SINGLE_BLOCK	Reads a block of the size selected by the SET_BLOCKLEN command.
CMD18	adtc	[31:0] data address	R1	READ_MULTIPLE_BLOCK	Continuously transfers data blocks from card to host until interrupted by a stop command.
CMD19	adtc	[31:0] reserved bits(all 0)	R1	SEND_TUNING_BLOCK	64 bytes tuning pattern is sent for SDR50 and SDR104.
CMD20	adtc	[31:0] data address	R1	WRITE_DAT_UNTIL_STOP	Writes data stream from the host, starting at the given address, until a STOP_TRANSMISION follows.
CMD21	adtc	[31:0] stuff bits	R1	SEND_TUNING_BLOCK	128 clocks of tuning pattern (64 byte in 4 bit mode or 128 byte in 8 bit mode) is sent for HS200 optimal sampling point detection.
CMD22-23	Reserved				
CMD24	adtc	[31:0] data address	R1	WRITE_BLOCK	Writes a block of the size selected by the SET_BLOCKLEN command.
CMD25	adtc	[31:0] data address	R1	WRITE_MULTIPLE_BLOCK	Continuously writes blocks of data until a STOP_TRANSMISSION follows.
CMD26	adtc	[31:0] stuff bits	R1	PROGRAM_CID	Programming of the card identification register. This command is issued only once per card. The card contains hardware to prevent this operation after the first programming. Normally this command is reserved for the manufacturer.
CMD27	adtc	[31:0] stuff bits	R1	PROGRAM_CSD	Programming of the programmable bits of the CSD.
CMD28	ac	[31:0] data address	R1b	SET_WRITE_PROT	If the card has write protection features, this command sets the write protection bit of the addressed group. The properties of write protection are coded in the card specific data (WP_GRP_SIZE).

Table continues on the next page...

Table 32-2. Commands for MMC/SD/SDIO cards (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD29	ac	[31:0] data address	R1b	CLR_WRITE_PROT	If the card provides write protection features, this command clears the write protection bit of the addressed group.
CMD30	adtc	[31:0] write protect data address	R1	SEND_WRITE_PROT	If the card provides write protection features, this command asks the card to send the status of the write protection bits.
CMD31	Reserved				
CMD32	ac	[31:0] data address	R1	TAG_SECTOR_START	Sets the address of the first sector of the erase group.
CMD33	ac	[31:0] data address	R1	TAG_SECTOR_END	Sets the address of the last sector in a continuous range within the selection of a single sector to be selected for erase.
CMD34	ac	[31:0] data address	R1	UNTAG_SECTOR	Removes one previously selected sector from the erase selection.
CMD35	ac	[31:0] data address	R1	TAG_ERASE_GROUP_START	Sets the address of the first erase group within a range to be selected for erase.
CMD36	ac	[31:0] data address	R1	TAG_ERASE_GROUP_END	Sets the address of the last erase group within a continuous range to be selected for erase.
CMD37	ac	[31:0] data address	R1	UNTAG_ERASE_GROUP	Removes one previously selected erase group from the erase selection.
CMD38	ac	[31:0] stuff bits	R1b	ERASE	Erase all previously selected sectors.
CMD39	ac	[31:0] RCA [15] register write flag [14:8] register address [7:0] register data	R4	FAST_IO	Used to write and read 8-bit (register) data fields. The command addresses a card, and a register, and provides the data for writing if the write flag is set. The R4 response contains data read from the address register. This command accesses application dependent registers which are not defined in the MMC standard.
CMD40	bcr	[31:0] stuff bits	R5	GO_IRQ_STATE	Sets the system into interrupt mode.
CMD41	Reserved				
CDM42	adtc	[31:0] stuff bits	R1b	LOCK_UNLOCK	Used to set/reset the password or lock/unlock the card. The size of the data block is set by the SET_BLOCK_LEN command.
CMD43~51	Reserved				

Table continues on the next page...

Table 32-2. Commands for MMC/SD/SDIO cards (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD52	ac	[31:0] stuff bits	R5	IO_RW_DIRECT	Access a single register within the total 128k of register space in any I/O function.
CMD53	ac	[31:0] stuff bits	R5	IO_RW_EXTENDED	Accesses a multiple I/O register with a single command. Allows the reading or writing of a large number of I/O registers.
CMD54	Reserved				
CMD55	ac	[31:16] RCA [15:0] stuff bits	R1	APP_CMD	Indicates to the card that the next command is an application specific command rather than a standard command.
CMD56	adtc	[31:1] stuff bits [0]: RD/WR	R1b	GEN_CMD	Used either to transfer a data block to the card or to get a data block from the card for general purpose / application specific commands. The size of the data block is set by the SET_BLOCK_LEN command.
CMD57-59	Reserved				
CMD60	adtc	[31] WR [30:24] stuff bits [23:16] address [15:8] stuff bits [7:0] byte count	R1b	RW_MULTIPLE_REGISTER	These registers are used to control the behavior of the device and to retrieve status information regarding the operation of the device. All Status and Control registers are WORD (32-bit) in size and are WORD aligned. CMD60 is used to read and write these registers.
CMD61	adtc	[31] WR [30:16] stuff bits [15:0] data unit count	R1b	RW_MULTIPLE_BLOCK	The host issues a RW_MULTIPLE_BLOCK (CMD61) to begin the data transfer.
CMD62-63	Reserved				
ACMD6[4]	ac	[31:2] stuff bits [1:0] bus width	R1	SET_BUS_WIDTH	Defines the data bus width ('00'=1bit or '10'=4bit bus) to be used for data transfer. The allowed data bus widths are given in SCR register.
ACMD13[4]	adtc	[31:0] stuff bits	R1	SD_STATUS	Send the SD Memory Card status.
ACMD22[4]	adtc	[31:0] stuff bits	R1	SEND_NUM_WR_SECTORS	Send the number of the written sectors (without errors). Responds with 32-bit plus the CRC data block.
ACMD23[4]	ac	[31:23] stuff bits [22:0] Number of blocks	R1	SET_WR_BLK_ERASE_COUNT	Set the number of write blocks to be pre-erased before writing (to be used for fast Multiple Block WR command). "1"=default(one write block).

Table continues on the next page...

Table 32-2. Commands for MMC/SD/SDIO cards (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
ACMD41[4]	bcr	[31:0] OCR	R3	SD_APP_OP_COND	Asks the accessed card to send its operating condition register (OCR) contents in the response on the CMD line.
ACMD42[4]	ac	[31:1] stuff bits [0] set_cd	R1	SET_CLR_CARD_DETECT	Connect(1)/Disconnect(0) the 50KOhm pull-up resistor on CD_B/DATA3 of the card.
ACMD51[4]	adtc	[31:0] stuff bits	R1	SEND_SCR	Reads the SD Configuration Register (SCR).

1. CMD3 differs for MMC and SD cards. For MMC cards, it is referred to as SET_RELATIVE_ADDR, with a response type of R1. For SD cards, it is referred to as SEND_RELATIVE_ADDR, with a response type of R6 (with RCA inside).
2. CMD6 differs completely between high speed MMC cards and high-speed SD cards. Command SWITCH_FUNC is for high-speed SD cards.
3. Command SWITCH is for high speed MMC cards. The Index field can contain any value from 0-255, but only values 0-191 are valid. If the Index value is in the 192-255 range the card does not perform any modification and the SWITCH_ERROR status bit in the EXT_CSD register is set. The Access Bits are shown in Table 2.
4. ACMDs is preceded with the APP_CMD command. Commands listed are used for SD only, other SD commands not listed are not supported on this module.

The access bits for the EXT_CSD access modes are listed in the following table.

Table 32-3. EXT_CSD access modes

Bits	Access name	Operation
00	Command set	The command set is changed according to the Cmd Set field of the argument.
01	Set bits	The bits in the pointed byte are set, according to the bits set to 1 in the Value field.
10	Clear bits	The bits in the pointed byte are cleared, according to the bits set to 1 in the Value field.
11	Write byte	The Value field is written into the pointed byte.

32.3.9 Clocks

The table found here describes the clock sources for uSDHC. For more information on clocking, see the Clocking chapter.

Table 32-4. Clocks

Clock name	Description
hclk	Bus clock
ipg_clk	Peripheral clock
ipg_clk_s	Peripheral access clock for register access
ipg_clk_perclk	Base clock

32.3.10 Clock and reset manager

This module controls all four kinds reset signals within uSDHC:

- Hardware reset
- Software reset for all logic
- Software reset for the data logic
- Software reset for the command logic

All these signals are fed into this module and stable signals are generated inside the module to reset all other modules. The module also gates off all the inside signals.

32.3.11 Clock generator

The clock generator generates the card CLK by peripheral source clock in two stages. The clock divisor can be configured through register SYS_CTRL [SDCLKFS] for prescaler configuration while the [DVS] for divisor configuration. Details can be found in the register function description. See the following figure for the structure of the divider. The term "Base" represents the frequency of peripheral source clock.

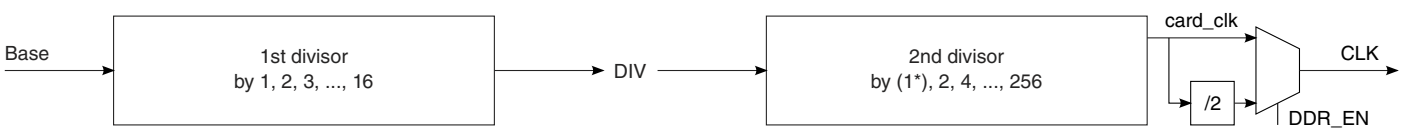


Figure 32-16. Two stages of the clock divider

The first stage outputs an intermediate clock (DIV) that can be Base, Base/2, Base/3, ..., or Base/16.

The second stage is a prescaler and outputs the actual internal working clock (card_clk). This clock is the driving clock for all the sub modules of the SD protocol unit, and helps in syncing FIFOs (see Figure 32-3) to synchronize with the data rate from the internal data buffer. The frequency of the clock output from this stage can be DIV, DIV/2, DIV/4,..., or DIV/256. Therefore, the highest frequency of the card_clk is base, and the next highest is Base/2, while the lowest frequency is Base/4096. If the duty cycle of the base clock is 50%, the duty cycle of card_clk is also 50%, even when the compound divisor is an odd value.

NOTE

CLK is different for the SDR and DDR modes.

- In the SDR mode, CLK is equal to the internal working clock (card_clk).

- In the DDR mode, CLK is equal to card_clk/2.

32.3.12 SDIO card interrupt

Information on interrupts in 1-bit mode, interrupts in 4-bit mode, and card interrupt handling are detailed in the sections below.

32.3.12.1 Interrupts in 1-bit mode

In this case, the DATA1 pin provides the interrupt function. An interrupt is asserted by pulling the DATA1 low from the SDIO card, until the interrupt service is finished to clear the interrupt.

32.3.12.2 Interrupt in 4-bit mode

As the interrupt and data line 1 share pin 8 in a 4-bit mode, an interrupt is only sent by the card and recognized by the host during a specific time. This is known as the interrupt period. The uSDHC module only provides samples the level on pin 8 during the interrupt period. At all other times, the host treats it as the data signal. The definition of the interrupt period is different for operations with single block and multiple block data transfers.

In the case of normal single data block transmissions, the interrupt period becomes active two clock cycles after the completion of a data packet. This interrupt period lasts until after the card receives the end bit of the next command that has a data block transfer associated with it.

For multiple block data transfers in a 4-bit mode, there is only a limited period of time that the interrupt period can be active because of the limited period of data line availability between the multiple blocks of data. This requires stricter definition of the interrupt period. For this case, the interrupt period is limited to two clock cycles. This begins two clocks after the end bit of the previous data block. During this 2-clock cycle interrupt period, if an interrupt is pending, the DATA1 line holds low for one clock cycle, then pulls high for the next clock cycle . On completion of the interrupt period, the card releases the DATA1 line into the high Z state. The uSDHC module provides sample of the DATA1 during the interrupt period when the IABG bit in the Protocol Control register is set.

Refer to SDIO Card Specification v1.10 for further information about the SDIO card interrupt.

32.3.12.3 Card interrupt handling

When the CINTIEN bit in the Interrupt Signal Enable Register is set to 0, uSDHC clears the interrupt request to the host system. The host driver should clear this bit before servicing the SDIO interrupt, and should set this bit again after all interrupt requests from the card are cleared to prevent inadvertent interrupts.

The SDIO Card Interrupt Status can be cleared by writing 1 to this bit. But as the interrupt source from the SDIO card does not clear, this bit is set again. To clear this bit, it is required to reset the interrupt source from the external card followed by writing 1 to this bit. In a 1-bit mode, uSDHC detects the SDIO interrupt with or without the SD clock (to support wakeup). In a 4-bit mode, the interrupt signal is sampled during the interrupt period, so there are some sample delays between the interrupt signal from the SDIO card and the interrupt to the Host System Interrupt Controller. When the SDIO status is set and the host driver needs to service this interrupt, the SDIO bit in the Interrupt Control Register of SDIO card is cleared. This is required to clear the SDIO interrupt status latched in uSDHC and to stop driving the interrupt signal to the System Interrupt Controller. The host driver must issue a CMD52 to clear the card interrupt. After completion of the card interrupt service, the SDIO Interrupt Status Enable bit is set to 1 and uSDHC starts sampling the interrupt signal again.

See the figure below for an illustration of the SDIO card interrupt scheme and for the sequences of software and hardware events that take place during a card interrupt handling procedure.

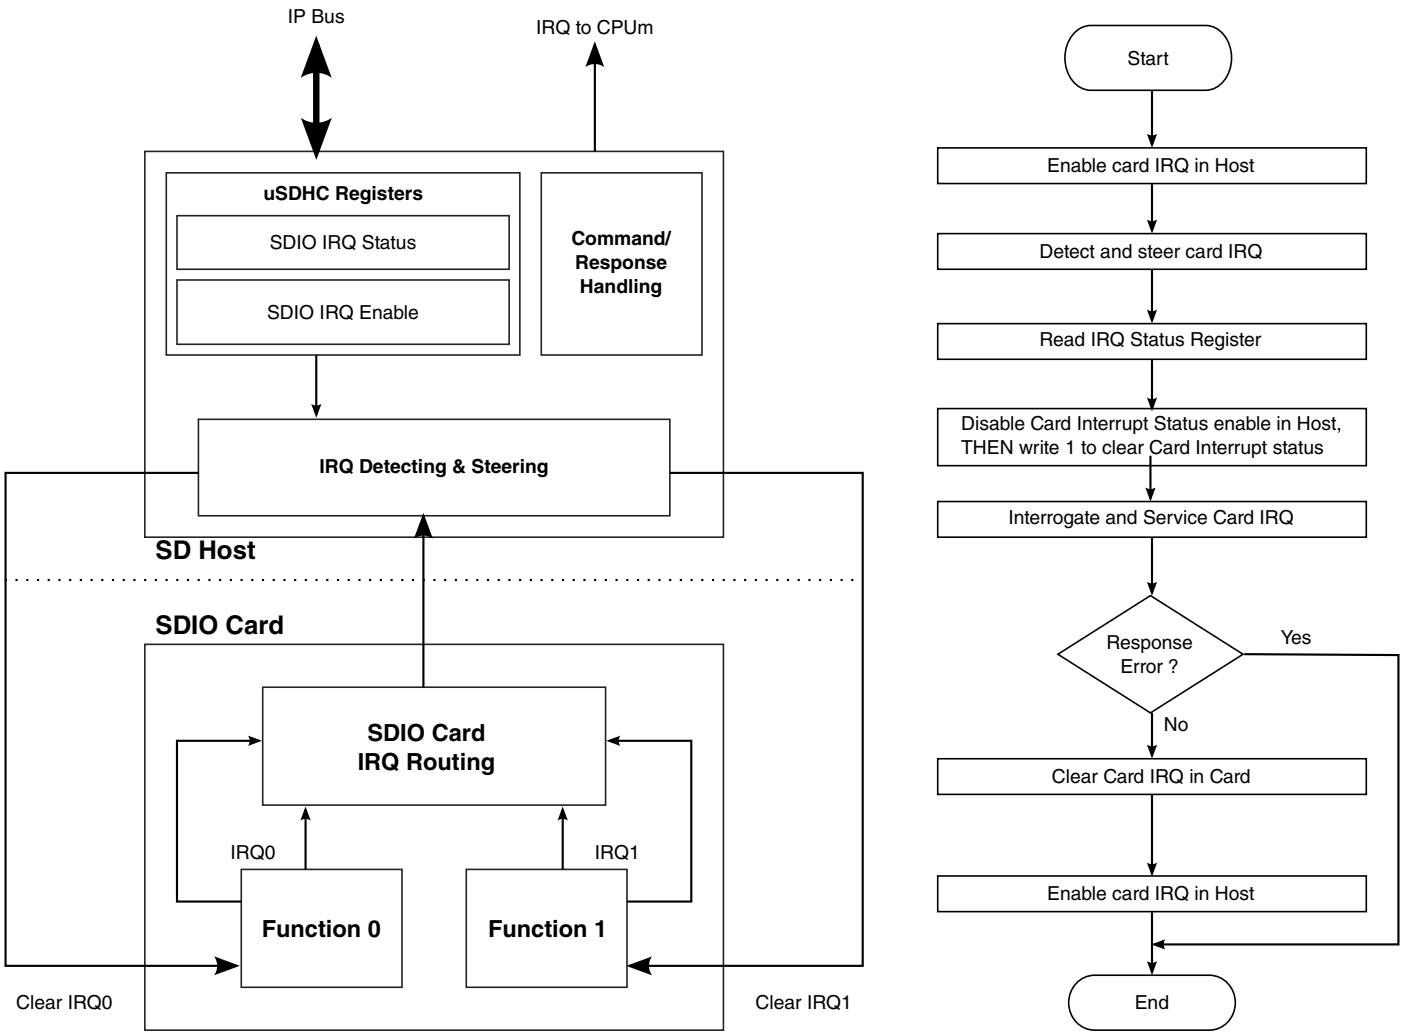

Figure 32-17. Card interrupt scheme, card interrupt detection, and handling procedure

32.3.13 Speed mode selection

To access card with card clock above 52 MHz, you must switch the timing mode to one of supported higher speed timing modes: “High Speed” for frequencies between 26 MHz and 52 MHz. HS200 mode or HS400 mode for frequencies above 52 MHz up to 200 MHz. Note that while the actual timing change is done, the behavior of any command given (such as CMD13) cannot be guaranteed due to the asynchronous operation. Therefore, you must not use CMD13 to check the busy completion of the timing change indication. In case, CMD13 is used, the host must ignore CRC errors, if appear. And, the max frequency for HS200 mode and HS400 mode could be slower than 200 MHz based on the chip implementation, you must confirm with SoC before setting the target frequency for these two speed modes. Following sections describe the mode selections for HS200 mode and HS400 mode in detail.

32.3.13.1 HS200 mode selection

To switch to HS200, the Driver must perform the following steps:

1. Select the chip (through sending CMD7) and make sure it is unlocked (through CMD42).
2. Read the DEVICE_TYPE [196] field of the Extended CSD register to validate if the chip supports HS200 at the IO voltage appropriate for both host and chip (through CMD8).
3. Read the DRIVER_STRENGTH [197] field of the Extended CSD register to find the supported chip Driver Strengths (through CMD8). The default setting is 50 Ohm. The Host Designer might simulate its specific system, using a device driver models. Host can select the optimal Driver Type that might drive the host system load at the required operating frequency with the minimal noise generated.

NOTE

This step can be skipped if changes of Driver strength is not needed.

4. Check the setting of PROT_CTRL[DTW], make sure the data transfer width is set as expected.

   Make sure the I/O pad voltage is 1.8V and corresponding drive strength is set to proper value.

   Set HS200 bit and Driver Strength value in the HS_TIMING [185] field of the Extended CSD register by issuing CMD6. If the host attempts to write an invalid value, the HS_TIMING byte is not changed, the HS200 interface timing is not enabled, the Driver Strength is not changed, and the SWITCH_ERROR field is set. After the chip responds with R1, it might assert Busy signal. Once the busy signal gets de-asserted, the host may send a SEND_STATUS Command (CMD13) using the HS200 timing and after it receives a Trans State indication and No Error it means that the chip is set to HS200 timing and the Driver Strength is set to the selected settings.

5. At this point, the host can set the frequency to ≤ 200 MHz.
6. The host might invoke the HS200 standard tuning procedure, by sending CMD21 to the chip.

NOTE

The host must switch to the required bus width before starting the tuning operation to allow the tuning sequence to be done using the proper bus operating conditions.

32.3.13.2 Standard Tuning Procedure

By default, lower frequency operation, a fixed sampling clock is used to receive signals on CMD and DAT[3:0]. Before using the HS200, HS400, SDR104, or SDR50 modes, the Host Driver executes the tuning procedure at the mode switch sequence.

1. Issue uSDHC SW reset, set SYS_CTRL[RSTT] to 1.
2. Set VEND_SPEC[FRC_SDCLK_ON] to 1.
3. Set TUNING_CTRL[DIS_CMD_CHK_FOR_STD_TUNING] to 1.
4. Start the tuning procedure by setting TUNING_CTRL[STD_TUNING_EN] and MIX_CTRL[EXE_TUNE] to 1.
5. Issue CMD19(SD)/ CMD21(eMMC) with the proper Command Transfer Type (CMD_XFR_TYP) and Mixer Control (MIX_CTRL) settings.
6. Wait for uSDHC BRR (Buffer Read Ready) interrupt signal is 1.
7. Check MIX_CTRL[EXE_TUNE]. If MIX_CTRL[EXE_TUNE] = 1, repeat 5~6. If MIX_CTRL[EXE_TUNE] = 0, standard tuning has completed, or the tuning has not completed within 40 attempts. The Host Driver might abort this loop if the number of loops exceeds 40 or 150ms timeout occurs. In this case, a fixed sampling clock should be used, (AUTOCMD12_ERR_STATUS[SMP_CLK_SEL] = 0).
8. Sampling Clock Select, AUTOCMD12_ERR_STATUS[SMP_CLK_SEL] , is valid after MIX_CTRL[EXE_TUNE] has changed from 1 to 0. AUTOCMD12_ERR_STATUS[SMP_CLK_SEL] = 1, indicates tuning procedure passed. AUTOCMD12_ERR_STATUS[SMP_CLK_SEL] = 0, indicates tuning procedure failed. The tuning result is applied to the delay chain, CLK Tuning Control and Status (CLK_TUNE_CTRL_STATUS) [30:16], upon successful tuning procedure completion.
9. Clear VEND_SPEC[FRC_SDCLK_ON].
10. Set MIX_CTRL[AUTO_TUNE_EN] to 1.

While the tuning sequence is being performed, the Host Controller does not generate interrupts (including Command Complete), except Buffer Read Ready. CMD19 response errors are not indicated.

Writing AUTOCMD12_ERR_STATUS[SMP_CLK_SEL] to 0 forces the Host Controller to use a fixed sampling clock and resets the tuning circuit of the Host Controller.

NOTE

- There could be slight difference on delay cell delay in each project, and this difference can lead to different loop

number needed. TUNING_CTRL[TUNING_STEP] can be used to control how may taps are to be added for each step.
- Manual tuning might be required in cases where standard tuning is not able to close passing window with CMD19/21 transfer fail.

32.3.13.3 Manual tuning procedure

Manual tuning controls more detail in the tuning procedure, and some corner cases. Manual tuning provides control to tuning start point, tuning steps, and delay chains. To start manual tuning:

1. Set TUNING_CTRL[STD_TUNING_EN] to 0.
2. Set SYS_CTRL[RSTA] to reset all.
3. Set MIX_CTRL[SMP_CLK_SEL] and MIX_CTRL[EXE_TUNE] to start tuning.
4. Set VEND_SPEC[FRC_SDCLK_ON] to 1.
5. Config delay chain, CLK_TUNE_CTRL_STATUS[DLY_CELL_SET_PRE] with the valueA. The valueA must start from 0.
6. Send CMD19/21 to card.
7. Poll for CC,CIE,CEBE,CCE,CTOE of Interrupt Status (INT_STATUS) assertion, then go to the step 5.
8. Poll for TC, DEBE, DCE and DTOE of Interrupt Status (INT_STATUS) assertion.
9. Check TP of Interrupt Status (INT_STATUS); TP = 1 & no dat/cmd error indicates current CMD19/21 transfer is passed; otherwise, indicates failed.
10. If TP = 0 or command/data error is observed, increase the valueA with the required tuning step(1~127) and repeat step 5~9.
11. If TP = 1 & no dat/cmd error was met after a loop with TP=0 (or cmd/data error), save the current valueA as value_start. Increase valueA with the required tuning step, and repeat step 5~9 until TP = 0 (or cmd/data error) again. Save the current valueA as value_end.
12. Set MIX_CTRL[EXE_TUNE] to 0.
13. Set VEND_SPEC[FRC_SDCLK_ON] to 0.
14. Set SYS_CTRL[RSTA] to reset all.
15. Set MIX_CTRL[SMP_CLK_SEL] to 1.
16. Set bit[14:0] of CLK Tuning Control and Status (CLK_TUNE_CTRL_STATUS) with the output of expression {(((value_start+value_end)/2)< < 8)& 0xffffff00 -0x300 } | 0x33.
17. Poll bit[30:16] of CLK Tuning Control and Status (CLK_TUNE_CTRL_STATUS) until the value written in the step 16 is read.
18. Set MIX_CTRL[AUTO_TUNE_EN] to 1.

The manual tuning procedure defines a passing window, inside which the tuned clock can capture the correct data, and delay chain is to be configured as centered within the passing window.

It is not a fixed flow as the standard tuning. Any step can be changed based on the real case. In cases where passing window is not closed with a tuning fail, the center of the passing region must be applied for the delay chain setting. In cases where two passing windows separated by tuning fail(s) is observed, the center of the first passing window must be applied for the delay chain setting.

NOTE

Both the standard tuning and manual tuning are only for tuning of SD_CLK, cannot be used to tune STROBE clock of HS400 and HS400 enhanced mode.

32.4 External signals

The following table describes the uSDHC external signals:

Table 32-5. uSDHC external signals

Signal	Description	Direction
CLK	Clock for MMC/SD/SDIO card	O
CMD	CMD line connect to card	I/O
DATA7	DAT7 line in the 8-bit mode — Not used in other modes	I/O
DATA6	DAT6 line in the 8-bit mode — Not used in other modes	I/O
DATA5	DAT5 line in the 8-bit mode — Not used in other modes	I/O
DATA4	DAT4 line in the 8-bit mode — Not used in other modes	I/O
DATA3	DAT3 line in the 4/8-bit mode or configured as card detection pin. The bit may be configured as card detection pin in the 1-bit mode.	I/O
DATA2	DAT2 line or Read Wait in the 4-bit mode Read Wait in 1-bit mode	I/O
DATA1	DAT1 line in the 4/8-bit mode Also, used to detect interrupt in 1/4-bit mode	I/O
DATA0	DAT0 line in all the modes Also, used to detect busy state	I/O

Table continues on the next page...

Table 32-5. uSDHC external signals (continued)

Signal	Description	Direction
CD_B	Card detection pin If not used (for the embedded memory), tie low to indicate that there is a card attached.	I
WP	Card write protect detect If not used (for the embedded memory), tie low to indicate that it is not write protected.	I
RESET_B	Card hardware reset signal, active low	O
VSELECT	IO power voltage selection signal	O

32.4.1 Signals overview

uSDHC has 15 associated I/O signals.

- The CLK is an internally generated clock used to drive the MMC, SD, and SDIO cards.
- The CMD I/O is used to send commands and receive responses to and from the card. Eight data lines (DAT7~DAT0) are used to perform data transfers between the uSDHC module and the card.
- The CD is card detection signal directly routed from the socket. This signal is active low (0). A low on CD# means that a card is inserted. It is optional for system implementation.
- The WP is write protection signals directly routed from the socket. This signal is active low (0). A high on WP means that the write protect switch is active. It is optional for system implementation.
- RST is an output signal used to reset the MMC card.
- VSELECT is an output signal used to change the voltage of the external power supplier. It is optional for system implementation.

If uSDHC needs to support a 4-bit data transfer, DAT7~DAT4 can also be optional and tied to high.

32.5 Application of uSDHC

All communication between the system and cards are controlled by the host. The host sends commands of two types: broadcast and addressed (point-to-point).

Broadcast commands are intended for all cards, such as GO_IDLE_STATE, SEND_OP_COND, and ALL_SEND_CID. In the Broadcast mode, all cards are in the open-drain mode to avoid bus contention. Refer to Commands for MMC/SD/SDIO for the commands of bc and bcr categories.

After the broadcast command CMD3 is issued, the cards enter the standby mode. Addressed type commands are used from this point. In this mode, the CMD/DATA I/O pads turns to the push-pull mode to have the driving capability for maximum frequency operation. Refer to Commands for MMC/SD/SDIO for the commands of ac and adtc categories.

A uSDHC FIFO control problem exists with a software reset for a single block read. See MIX_CTRL[DTDSEL] for more information.

32.5.1 Command send & response receive basic operation

Assuming that the data type WORD is an unsigned 32-bit integer, the flow indicated below presents a guideline for sending a command to the card(s):

```
send_command(cmd_index, cmd_arg, other requirements)
{
WORD wCmd; // 32-bit integer to make up the data to write into Transfer Type register, it is
recommended to implement in a bit-field manner
wCmd = (<cmd_index> & 0x3f) << 24; // set the first 8 bits as '00'+<cmd_index>
set CMDTYP, DPSEL, CICEN, CCCEN, RSTTYP, DTDSEL accorind to the command index;
if (internal DMA is used) wCmd |= 0x1;
if (multi-block transfer) {
          set MSBSEL bit;
          if (finite block number) {
                    set BCEN bit;
                    if (auto12 command is to use) set AC12EN bit;
          }
}
write_reg(CMDARG, <cmd_arg>); // configure the command argument
write_reg(XFERTYP, wCmd); // set Transfer Type register as wCmd value to issue the command
}
wait_for_response(cmd_index)
{
```

```
while (CC bit in IRQ Status register is not set); // wait until Command Complete bit is set
read IRQ Status register and check if any error bits about Command are set
if (any error bits are set) report error;
write 1 to clear CC bit and all Command Error bits;
}
```

For the sake of simplicity, the function wait_for_response is implemented here by means of polling. For an effective and formal way, the response is usually checked after the Command Complete Interrupt is received. When doing this, make sure that the corresponding interrupt status bits are enabled.

For some scenarios, the response time-out is expected. For instance, after all cards respond to CMD3 and move to the Standby state no response to the Host when CMD2 is sent. The host driver deals with "fake" errors like this with caution.

32.5.2 Card identification mode

When a card is inserted to the socket or the card is reset by the host, the host needs to validate the operation voltage range, identify the cards, request the cards to publish the Relative Card Address (RCA) or to set the RCA for MMC cards.

32.5.2.1 Card detect

See the figure below for a flow diagram showing the detection of MMC, SD, and SDIO cards using uSDHC.

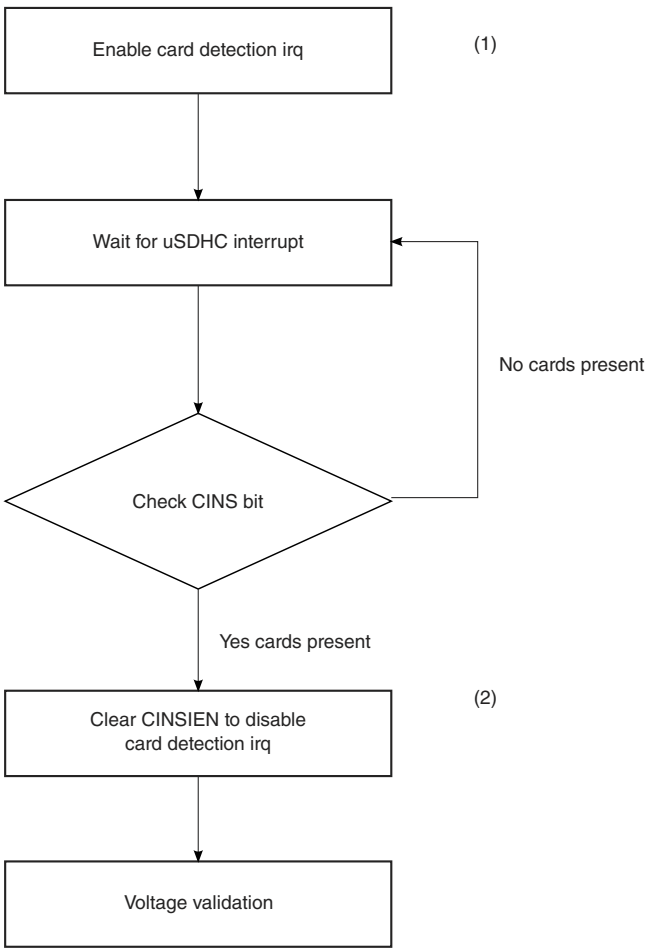

Figure 32-18. Flow diagram for card detection

Here is the card detect sequence:

- Set the CINSIEN bit to enable card detection interrupt.
- When an interrupt from uSDHC is received, check the CINS bit in the Interrupt Status register to see if it was caused by card insertion.
- Clear the CINSIEN bit to disable the card detection interrupt and ignore all card insertion interrupts afterwards.

32.5.2.2 Reset

The host consists of three types of resets:

- Hardware reset (Card and Host) that is driven by Power On Reset (POR).

- Software reset (Host only) is initiated by the write operation on the RSTD, RSTC, or RSTA bits of the System Control register to reset the data part, command part, or all parts of the host controller, respectively.
- Card reset (Card only): The command, "Go_Idle_State" (CMD0), is the software reset command for all types of MMC cards and SD memory cards. This command sets each card into the idle state regardless of the current card state. For an SDIO card, CMD52 is used to write an I/O reset in CCCR. The cards are initialized with a default relative card address (RCA=0x0000) and with a default driver stage register setting (lowest speed, highest driving current capability).

After the card is reset, the host needs to validate the voltage range of the card. See the figure below for the software flow to reset both uSDHC and the card.

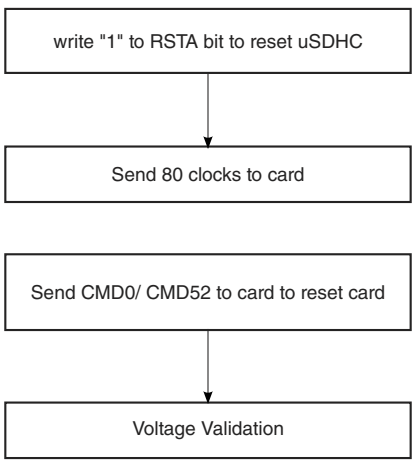

Figure 32-19. Flow chart for resetting uSDHC and SD I/O card

```
software_reset() { set_bit(SYSCTRL, RSTA); // software reset the Host set DTOCV and
      SDCLKFS bit fields to get the CLK of frequency around 400kHz configure IO pad to set
the power
      voltage of external card to around 3.0V poll bits CIHB and CDIHB bits of PRSSTAT to
wait both
      bits are cleared set_bit(SYSCTRL, INTIA); // send 80 clock ticks for card to power up
      send_command(CMD_GO_IDLE_STATE, <other parameters>); // reset the card with CMD0 or
      send_command(CMD_IO_RW_DIRECT, <other parameters>); }
```

32.5.2.3 Voltage validation

All cards should be able to establish communication with the host using any operation voltage in the maximum allowed voltage range specified in the card specification. However, the supported minimum and maximum values for VDD are defined in the Operation Conditions Register (OCR) and may not cover the whole range.

Cards that store the CID and CSD data in the preload memory are only able to communicate this information under data transfer VDD conditions. This means that if the host and card have non-common VDD ranges, the card is neither able to complete the identification cycle nor able to send CSD data.

Therefore, special commands Send_Op_Cont (CMD1 for MMC), SD_Send_Op_Cont (ACMD41 for SD Memory), and IO_Send_Op_Cont (CMD5 for SD I/O) are used. The voltage validation procedure is designed to provide a mechanism to identify and reject cards that do not match the VDD range(s) desired by the host. This is accomplished when the host sends the desired VDD voltage window as the operand of this command. Cards that cannot perform the data transfer in the specified range must discard themselves from further bus operations and go into the Inactive state. By omitting the voltage range in the command, the host can query each card and determine the common voltage range before sending out-of-range cards into the Inactive state. This query should be used if the host is able to select a common voltage range or if a notification is sent to the system when a non-usable card in the stack is detected.

The following steps show how to perform voltage validation when a card is inserted:

```
voltage_validation(voltage_range_arguement) { label the card as UNKNOWN;
      send_command(IO_SEND_OP_COND, 0x0, <other parameters are omitted>); // CMD5, check SDIO
      operation voltage, command argument is zero if (RESP_TIMEOUT !=
      wait_for_response(IO_SEND_OP_COND)) { // SDIO command is accepted if (0 < number of IO
      functions) { label the card as SDIO; IORDY = 0; while (!(IORDY in IO OCR response))
{ // set
      voltage range for each IO function send_command(IO_SEND_OP_COND, <voltage range>,
      <other parameter>); wait_for_response(IO_SEND_OP_COND); } // end of while ... } // end
      of if (0 < ... if (memory part is present inside SDIO card) Label the card as
SDCombo; //
      this is an SD-Combo card } // end of if (RESP_TIMEOUT ... if (the card is labelled as
SDIO
      card) return; // card type is identified and voltage range is set, so exit the
function;
      send_command(APP_CMD, 0x0, <other parameters are omitted>); // CMD55, Application
      specific CMD prefix if (no error calling wait_for_response(APP_CMD, <...>) { // CMD55
is
      accepted send_command(SD_APP_OP_COND, <voltage range>, <...>); // ACMD41, to set
      voltage range for memory part or SD card wait_for_response(SD_APP_OP_COND); // voltage
range
      is set if (card type is UNKNOWN) label the card as SD; return; // } // end of if (no
error ...
      else if (errors other than time-out occur) { // command/response pair is corrupted
deal with
      it by program specific manner; } // of else if (response time-out else { // CMD55 is
refuse,
      it must be MMC card if (card is already labelled as SDCombo) { // change label re-
label the
      card as SDIO; ignore the error or report it; return; // card is identified as SDIO
card } //
      of if (card is ... send_command(SEND_OP_COND, <voltage range>, <...>); if
      (RESP_TIMEOUT == wait_for_response(SEND_OP_COND)) { // CMD1 is not accepted, either
label the
      card as UNKNOWN; return; } // of if (RESP_TIMEOUT ... } // of else }
```

32.5.2.4 Card registry

This section briefly describes the registry flow. For details, please refer to the card specifications. Card registry for the MMC and SD/SDIO/SD combo cards are different. For the SD card, the identification process starts at a clock rate lower than 400 kHz and the power voltage higher than 2.7 V (as defined by the card spec). Currently, the CMD line output drives are push-pull drivers instead of open-drain. After the bus is activated, the host requests the card to send their valid operation conditions.

The response to ACMD41 is the operation condition register of the card. The same command is sent to all the new cards in the system. Incompatible cards are put into the Inactive state. The host then issues the command, All_Send_CID (CMD2), to each card to get its unique card identification (CID) number. Cards that are currently unidentified (in the Ready state), send their CID number as the response. After the CID is sent by the card, the card goes into the Identification state.

The host then issues Send_Relative_Addr (CMD3), requesting the card to publish a new relative card address (RCA) that is shorter than the CID. This RCA is used to address the card for future data transfer operations. After the RCA is received, the card changes its state to the Standby state. At this point, if the host wants the card to have an alternative RCA number, it may ask the card to publish a new number by sending another Send_Relative_Addr command to the card. The last published RCA is the actual RCA of the card.

The host repeats the identification process with CMD2 and CMD3 for each card in the system until the last CMD2 gets no response from any of the cards in the system.

For MMC operation, the host starts the card identification process in the open-drain mode with the identification clock rate lower than 400 kHz and the power voltage higher than 2.7 V. The open drain driver stages on the CMD line to allow parallel card operation during card identification. After the bus is activated, the host requests the cards to send their valid operation conditions (CMD1). The response to CMD1 is the "wired AND " operation on the condition restrictions of all cards in the system. Incompatible cards are sent into the Inactive state. The host then issues the broadcast command All_Send_CID (CMD2), asking all cards for their unique card identification (CID) number. All unidentified cards (the cards in the Ready state) simultaneously start sending their CID numbers serially, while bit-wise monitoring their outgoing bit stream. Those cards, whose outgoing CID bits do not match the corresponding bits on the command line in any one of the bit periods, stop sending their CID immediately and must wait for the next identification cycle. As the CID is unique for each card, only one card can be successfully sent its full CID to the host. This card then goes into the Identification state. Thereafter, the host issues Set_Relative_Addr (CMD3) to assign a relative card address (RCA) to the card. After the RCA is received, the state of the card changes to standby, and the card does not react in further identification cycles. Also, its output driver switches

from open-drain to push-pull. The host repeats the process, mainly CMD2 and CMD3, until the host receives a time-out condition to recognize the completion of the identification process.

The following steps show how to perform an operation using MMC cards:

```
card_registry() { do { // decide RCA for each card until response time-out
            if(card is labelled as SDCombo or SDIO) { // for SDIO card like device
            send_command(SET_RELATIVE_ADDR, 0x00, <...>); // ask SDIO card to publish its RCA
            retrieve RCA from response; } // end if (card is labelled as SDCombo ... else if
(card
            is labelled as SD) { // for SD card send_command(ALL_SEND_CID, <...>); if
            (RESP_TIMEOUT == wait_for_response(ALL_SEND_CID)) break;
send_command(SET_RELATIVE_ADDR,
            <...>); retrieve RCA from response; } // else if (card is labelled as SD ... else
            if (card is labelled as MMC) { send_command(ALL_SEND_CID, <...>); rca = 0x1; //
            arbitrarily set RCA, 1 here for example send_command(SET_RELATIVE_ADDR, 0x1 <<
16,
            <...>); // send RCA at upper 16 bits } // end of else if (card is labelled as MMC
            ... } while (response is not time-out); }
```

32.5.3 Card access

Information about Block Write, Block Read, Suspense Resume, ADMA Usage, Transfer Error, and Card Interrupt are detailed in the sections below.

32.5.3.1 Block write

Information on Normal Write, DDR Write, and Write with Pause are detailed in the sections below.

32.5.3.1.1 Normal Write

During a block write (CMD24 - 27, CMD60, CMD61), one or more blocks of data are transferred from the host to the card with a CRC appended to the end of each block by the host. If the CRC fails, the card indicates that the failure on the DATA line. The transferred data is discarded and not written, and all further transmitted blocks (in multiple block write mode) are ignored.

If the host uses partial blocks whose accumulated length is not block aligned and block misalignment is not allowed (CSD parameter WRITE_BLK_MISALIGN is not set), the card detects the block misalignment error and aborts the programming before the beginning of the first misaligned block. The card sets the ADDRESS_ERROR error bit in the status register, and while ignoring all further data transfer, waits in the Receive-data-State for a stop command. The write operation is also aborted if the host tries to write over a write-protected area.

For MMC and SD cards, programming of the CID and CSD registers does not require a previous block length setting. The transferred data is also CRC protected. If a part of the CSD or CID register is stored in ROM, then this unchangeable part must match the corresponding part of the receive buffer. If this match fails, then the card reports an error and does not change any register contents.

For all types of cards, some may require long and unpredictable periods of time to write a block of data. After receiving a block of data and completing the CRC check, the card begins writing and holds the DATA line low if its write buffer is full and unable to accept new data from a new WRITE_BLOCK command. The host may poll the status of the card with a SEND_STATUS command (CMD13) or other means for SDIO cards at any time, and the card responds with its status. The responded status indicates whether the card can accept new data or whether the write process is still in progress. The host may deselect the card by issuing a CMD7 (to select a different card) to place the card into the Standby state and release the DATA line without interrupting the write operation. When re-selecting the card, it reactivates the busy indication by pulling data to low if the programming is still in progress and the write buffer is unavailable.

The software flow to write to a card that incorporates the internal DMA and the write operation is a multi-block write with the Auto CMD12 enabled. For the other methods ((CPU polling status) with different transfer methods, the internal DMA parts should be removed and the alternative steps should be straightforward.

The software flow to write to a card is described below:

1. Check the card status, wait until the card is ready for data.
2. Set the card block length/size:
   - For SD/MMC cards, use SET_BLOCKLEN (CMD16).
   - For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT (CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7).
3. Set the uSDHC block length register to be the same as the block length set for the card in step 2.
4. Set the uSDHC number block register (NOB), where nob is 5, for instance.
5. Disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
6. Wait for the Transfer Complete interrupt.
7. Check the status bit to see if a write CRC error occurred, or another error that occurred during the auto12 command sending and response receiving.

32.5.3.1.2 DDR write

uSDHC supports the dual data rate mode.

The software flow to write to a card in the DDR mode is described as below:

1. Check the card status and wait until the card is ready for data.

NOTE

For eMMC card, block length only can be set to 512byte.

2. Set the uSDHC number block register (NOB), where nob is 5, for instance.
3. Set the eMMC card to high-speed mode and use SWITCH(CMD6).
4. Set the eMMC card bus with 4-bit/8-bit DDR mode and use SWITCH(CMD6).
5. Disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer. The DDR_EN and AC12EN bits should be set.
6. Wait for the Transfer Complete interrupt.
7. Check the status bit to see if a write CRC error occurred or another error that occurred during the auto12 command sending and response receiving.

32.5.3.1.3 Write with Pause

The write operation can be paused during the transfer. Instead of stopping the CLK at any time to pause all the operations, which is also inaccessible to the host driver, the driver can set the Stop At Block Gap Request (SABGREQ) bit in the Protocol Control register to pause the transfer between the data blocks. As there is no time-out condition in a write operation during the data blocks, a write to all types of cards can be paused in this way, and if the DATA0 line is not required to de-assert to release the busy state, no suspend command is needed.

Similar to the flow described in Normal Write, the write with pause is shown with the same kind of write operation:

1. Check the card status and wait until the card is ready for data.
2. Set the card block length/size:
   - For SD/MMC, use SET_BLOCKLEN (CMD16).
   - For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7).
3. Set the uSDHC block length register to be the same as the block length set for the card in step 2.
4. Set the uSDHC number block register (NOB), where nob is 5, for instance.

5. Disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
6. Set the SABGREQ bit.
7. Wait for the Transfer Complete interrupt.
8. Clear the SABGREQ bit.
9. Check the status bit to see if a write CRC error occurred.
10. Set the CREQ bit to continue the write operation.
11. Wait for the Transfer Complete interrupt.
12. Check the status bit to see if a write CRC error occurred or some another error that occurred during the auto12 command sending and response receiving.

The number of blocks left during the data transfer is accessible by reading the contents of the BLKCNT field in the Block Attribute register. As the data transfer and the setting of the SABGREQ bit are concurrent, and the delay of register read and the register setting, the actual number of blocks left may not be exactly the value read earlier. The host driver reads the value of BLKCNT after the transfer is paused and the Transfer Complete interrupt is received.

It is also possible that the last block has begun when the Stop At Block Gap Request is sent to the buffer. In this case, the next block gap is the end of the transfer. These types of requests are ignored, the driver should treat these as a non-pause transfer, and deal with it as a common write operation.

When the write operation is paused, the data transfer inside the host system is not stopped, and the transfer is active until the data buffer is full. Because of this, it is recommended to avoid using the Suspend command for the SDIO card. This is because when such a command is sent, uSDHC interprets the system that switches to another function on the SDIO card and flush the data buffer. uSDHC takes the Resume command as a normal command with data transfer, and it is left for the host driver to set all the relevant registers before the transfer is resumed. If there is only one block to send when the transfer is resumed, the MSBSEL and BCEN bits of the Transfer Type register are set as well as the AC12EN bit. However, the uSDHC module automatically sends a CMD12 to mark the end of the multi-block transfer.

32.5.3.2 Block read

Information about Normal read, DDR read, Read with Pause, and Delay Line (DLL) in Read Path are detailed in the sections below.

32.5.3.2.1 Normal read

For block reads, the basic unit of data transfer is a block whose maximum size is stored in areas defined by the corresponding card specification. A CRC is appended to the end of each block, ensuring data transfer integrity. The CMD17, CMD18, CMD53, CMD60, CMD61, and so on, can initiate a block read. After completing the transfer, the card returns to the Transfer state. For multi blocks read, data blocks are continuously transferred until a stop command is issued.

The software flow to read from a card that incorporates the internal DMA and the read operation is a multi-block read with the Auto CMD12 enabled. For the other methods ((CPU polling status) with different transfer methods, the internal DMA parts should be removed and the alternative steps should be straightforward.

The software flow to read from a card is described below:

1. Check the card status and wait until card is ready for data.
2. Set the card block length/size:
   - For SD/MMC, use SET_BLOCKLEN (CMD16).
   - For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7).
3. Set the uSDHC block length register to be the same as the block length set for the card in step 2.
4. Set the uSDHC number block register (NOB), where nob is 5, for instance.
5. Disable the buffer read ready interrupt, configure the DMA settings, and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
6. Wait for the Transfer Complete interrupt.
7. Check the status bit to see if a read CRC error occurred, or another error occurred during the auto12 command sending and response receiving.

32.5.3.2.2 DDR read

The uSDHC module supports dual data rate mode.

The software flow to write to a card in the DDR mode is described below:

1. Check the card status and wait until the card is ready for data.

NOTE

For eMMC card, block length can be set to only 512 bytes.

2. Set the uSDHC number block register (NOB) where nob is 5, for instance.
3. Set the eMMC card to high-speed mode and use SWITCH (CMD6).

4. Set the eMMC card bus with 4-bit /8-bit DDR mode and use SWITCH(CMD6).
5. Disable the buffer write ready interrupt, configure the DMA settings, and enable the uSDHC DMA when sending the command with data transfer. The DDR_EN and AC12EN bits should be set.
6. Wait for the Transfer Complete interrupt.
7. Check the status bit to see if a write CRC error occurred, or another error that occurred during the auto12 command sending and response receiving.

32.5.3.2.3 Read with Pause

The read operation is not generally able to pause. Only the SDIO card (and SDCombo card working under I/O mode) supporting the Read Wait feature can pause during the read operation. If the SDIO card supports Read Wait (SRW bit in CCCR register is 1), the host driver can set the SABGREQ bit in the Protocol Control register to pause the transfer between the data blocks.

Before setting the SABGREQ bit, ensure that the RWCTL bit in the Protocol Control register is set, otherwise uSDHC does not assert the Read Wait signal during the block gap and data corruption occurs. It is recommended to set the RWCTL bit after the Read Wait capability of the SDIO card is recognized.

Similar to the flow described in Normal read, the read with pause is shown with the same kind of read operation:

1. Check the SRW bit in the CCR register on the SDIO card to confirm that the card supports the Read Wait mode.
2. Set the RWCTL bit.
3. Check the card status and wait until the card is ready for data.
4. Set the card block length/size:
   - For SD/MMC, use SET_BLOCKLEN (CMD16).
   - For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7).
5. Set the uSDHC block length register to be the same as the block length set for the card in step 2.
6. Set the uSDHC number block register (NOB), where nob is 5, for instance.
7. Disable the buffer read ready interrupt, configure the DMA setting, and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
8. Set the SABGREQ bit.
9. Wait for the Transfer Complete interrupt.
10. Clear the SABGREQ bit.
11. Check the status bit to see if read CRC error occurred.

12. Set the CREQ bit to continue the read operation.
13. Wait for the Transfer Complete interrupt.
14. Check the status bit to see if a read CRC error occurred, or another error occurred during the auto12 command sending and response receiving.

Similar to the Write operation, it is possible to meet the ending block of the transfer when paused. In this case, uSDHC ignores the Stop At Block Gap Request and treats it as a command read operation.

Unlike the write operation, there is no remaining data inside the buffer when the transfer is paused. All data received before the pause is transferred to the host system. No matter if the Suspend command is sent or not, the internal data buffer is not flushed.

If the Suspend command is sent and the transfer is later resumed by means of a Resume command, uSDHC takes the command as a normal one accompanied with data transfer. It is left for the host driver to set all the relevant registers before the transfer is resumed. If there is only one block to send when the transfer is resumed, the MSBSEL and BCEN bits of the Transfer Type register are set, as well as the AC12EN bit. However, the uSDHC automatically sends CMD12 to mark the end of multi-block transfer.

32.5.3.2.4 Delay Line (DLL) in read path

The DLL is newly added to assist in sampling read data. The DLL provides the ability to programmatically select a quantized delay (in fractions of the clock period) regardless of on-chip variations such as process, voltage, and temperature (PVT).

The reasons why DLL is needed for uSDHC are these:

- The path of read data traveling from card to host varies.
- In the SD/MMC DDR mode, the minimum input setup and hold time are both at 2.5 ns.

The data sampling window is so small that the delay of loopback clock needs to be accurate and consistent regardless of PVT. The DLL takes the divided card_clk as the reference clock and loopback clock as the input clock. It then generates a delayed version of the input clock according to the programmed target delay.

The DLL can be disabled or bypassed, and it can also be manually set for a fixed delay in the override mode. The override value set is the number of delay cells. In the override mode, there is no need to set the DLL_enable. Another DLL mode is target value mode. In this mode, the DLL automatically adjusts the number of delay cells according to the target value set by the user and PVT changes. Be aware that the target value is in units of 1/32 of the clock reference period. If the card_clk is 100Mhz, then the reference clock period is 10ns; setting target value of 16 means 5ns =(16/32)*10ns. The software can disable automatic update by the setting dll_gate_update bit.

As you might change the frequency of card_clk from time to time by changing SDCLKFS[7:0]/DVS[3:0], the software must adjust the delay value to ensure it works correctly when the reference clock (card_clk) is changed. If DLL is to be used, make sure SDCLKFS is used (at least be set to divided by 2) so that the REF_CLK generated are the same frequency as card_clk. There are two DLLs, PARTS DLL and STROBE DLL. PARTS DLL controls the SD_CLK loop back delay for which DLL (Delay Line) Control (DLL_CTRL) and DLL Status (DLL_STATUS) are used. STROBE DLL controls the STROBE loop back delay for which Strobe DLL control (STROBE_DLL_CTRL) and Strobe DLL status (STROBE_DLL_STATUS) are used. For PARTS DLL, below flow can be taken as reference. For STROBE DLL, similar register field with prefix STROBE in Strobe DLL control (STROBE_DLL_CTRL) and Strobe DLL status (STROBE_DLL_STATUS) must be used.

Step 1: Set the DLL_CTRL_RESET and DLL_CTRL_ENABLE fields

Step 2: Configure the SDCLKFS[7:0] and DVS[3:0]

Step 3: Wait until SDSTB is asserted

Step 4: Clear the DLL_CTRL_RESET field

Step 5: Wait until both the DLL_STS_SLV_LOCK and DLL_STS_REF_LOCK are asserted

Step 6: Set the DLL_CTRL_SLV_FORCE_UPD

Step 7: Clear the DLL_CTRL_SLV_FORCE_UPD

NOTE

The software should make sure that the DLL_CTRL_SLV_FORCE_UPD lasts for at least one card_clk. So, the software may need to add some delay between step 6 and step 7.

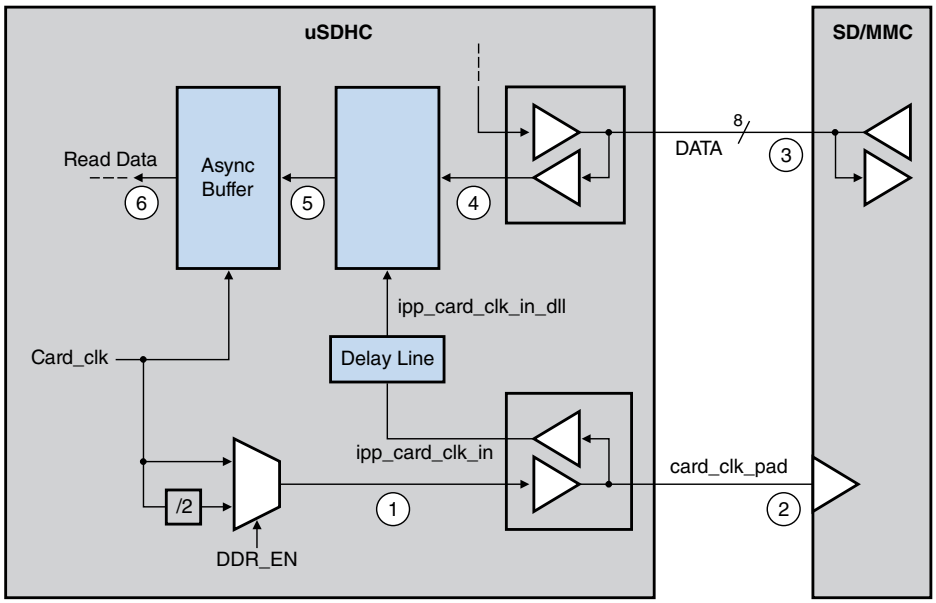

Figure 32-20. DLL in read path

32.5.3.3 Suspend Resume

The uSDHC module supports the Suspend Resume operations of SDIO cards, although slightly different than the suggested implementation of Suspend in the SDIO card specification.

32.5.3.3.1 Suspend

After setting the SABGREQ bit, the host driver may send a Suspend command to switch to another function of the SDIO card. The uSDHC module does not monitor the content of the response, so it does not know if the Suspend command succeeded or not. Accordingly, it does not de-assert Read Wait for read pause. To solve this problem, the host driver does not mark the Suspend command as "Suspend", (that is, setting the CMDTYP bits to 01). Instead, the driver sends this command as if it were a normal command, and only when the command succeeds, and the BS bit is set in the response, can the Driver send another command marked as "Suspend" to inform uSDHC that the current transfer is suspended. Here is the sequence for the Suspend operation:

1. Set the SABREQ bit to pause the current data transfer at block gap.
2. After the BGE bit is set, send the Suspend command to suspend the active function. The CMDTYP bit field must be 2'b00.
3. Check the BS bit of the CCCR in the response. If it is 1, repeat this step until the BS bit is cleared or abandon the suspend operation according to the Driver strategy.

4. Send another normal I/O command to the suspended function. The CMDTYP of this command must be 2'b01, so uSDHC can detect this special setting and be informed that the paused operation has successfully suspended. If the paused transfer is a read operation, uSDHC stops driving DATA2 and goes to the idle state.
5. Save the context registers in the system memory for later use, including the DMA System Address Register (for internal DMA operation), and the Block Attribute Register.
6. Begin operation for another function on the SDIO card.

32.5.3.3.2 Resume

To resume the data transfer, a Resume command is issued:

1. To resume the suspended function, restore the context register with the saved value in step #5 of the Suspend operation.
2. Send the Resume command: In the Transfer Type register, all the bit fields are set to the value as if this were another ordinary data transfer instead of a transfer resume (except the CMDTYP is set to 2'b10).
3. If the Resume command has responded, the data transfer is resumed.

32.5.3.4 ADMA usage

To use the ADMA in a data transfer, the host driver must prepare the correct descriptor chain prior to sending the read/write command.

The steps to prepare the correct descriptor chain are these:

1. Create a descriptor to set the data length that the current descriptor group is about to transfer. The data length should be even numbers of the block size.
2. Create another descriptor to transfer the data from the address setting in this descriptor. The data address must be at a page boundary (4KB address aligned).
3. If necessary, create a Link descriptor containing the address of the next descriptor. The descriptor group is created in steps 1 ~ 3.
4. Repeat steps 1 ~ 3 until all descriptors are created.
5. In the last descriptor, set the End flag to 1 and make sure the total length of all descriptors matches the product of the block size and block number configured in the Block Attribute Register.
6. Set the ADMA System Address Register to the address of the first descriptor and set the DMAS field in the Protocol Control Register to 01 to select the ADMA.
7. Issue a write or read command with the DMAEN bit set to 1 in the Transfer Type Register.

Steps 1 ~ 5 are independent of step 6, so step 6 can finish before steps 1 ~ 5. Regarding the descriptor configuration, it is recommended not to use the Link descriptor as it requires extra system memory access.

32.5.3.5 Transfer error

Information about CRC, Internal DMA, Transfer ADMA, and Auto CMD12 errors are detailed in the sections below.

32.5.3.5.1 CRC error

It is possible at the end of a block transfer that a write CRC status error or read CRC error occurs. For this type of error, the latest block received is discarded. This is because the integrity of the data block is not guaranteed. It is recommended to discard the following data blocks and re-transfer the block from the corrupted one.

For a multi-block transfer, the host driver issues a CMD12 to abort the current process and start the transfer by a new data command. In this scenario, even when the AC12EN and BCEND bits are set, uSDHC does not automatically send a CMD12 because the last block is not transferred. On the other hand, if it is within the last block that the CRC error occurs, an Auto CMD12 is sent by uSDHC. In this case, the host driver re-sends or re-obtains the last block with a single block transfer.

32.5.3.5.2 Internal DMA error

During the data transfer with internal Simple DMA, if the DMA engine encounters an error on the AXI bus, the DMA operation is aborted, and the DMA error interrupt is sent to the host system. When acknowledged by such an interrupt, the host driver calculates the start address of data block in which the error occurs.

The start address can be calculated by either:

- Reading the DMA System Address register: The error occurs during the previous burst. Considering the block size, and the start address of the next burst transfer, it is straight forward to obtain the start address of the corrupted block.
- Reading the BLKCNT field of the Block Attribute register: Considering the number of blocks left, the total number to transfer, the start address of transfer, and the size of each block, the start address of corrupted block can be determined.To use this method, MIX_CTRL[BCEN] bit has to be set to enable Block Attribute register update.

When a DMA error occurs, it is recommended to abort the current transfer by means of a CMD12 (for multi block transfer), apply a reset for data, and restart the transfer from the corrupted block to recover from the error.

32.5.3.5.3 Transfer ADMA error

There are three kinds of possible ADMA errors: The AXI transfer, invalid descriptor, and data-length mismatch. Whenever these errors occur, the DMA transfer stops and the corresponding error status bit is set.

For acknowledging the status, the host driver should recover the error as shown below and re-transfer from the place of interruption.

- AXI transfer error: Such errors may occur during data transfer or descriptor fetch. For either scenario, it is recommended to retrieve the transfer context, reset for the data part and re-transfer the block that was corrupted, or to the next block if no block is corrupted.
- Invalid descriptor error: For such errors, it is recommended to retrieve the transfer context, reset for the data part and recreate the descriptor chain from the invalid descriptor and issue a new transfer. As the data to transfer now may be less than the previous setting, the data length configured in the new descriptor chain should match the new value.
- Data-length mismatch error: It is similar to recover from this error. The Host Driver polls relating registers to retrieve the transfer context, apply a reset for the data part, configure a new descriptor chain and make another transfer if there is data left. Like the previous scenario of the invalid descriptor error, the data length must match the new transfer.

32.5.3.5.4 Auto CMD12 error

After the last block of the multi-block transfer is sent or received, and the AC12EN bit is set when the data transfer is initiated by the data command, uSDHC automatically sends a CMD12 to the card to stop the transfer.

When errors with this command occur, it is recommended to the host driver to deal with the situations in the following manner:

- Auto CMD12 response time-out: It is not certain whether the command is accepted by the card or not. The host driver clears the auto CMD12 error status bits and re-send CMD12 until it is accepted by the card.

- Auto CMD12 response CRC error: As the card responds to CMD12, it aborts the transfer. The host driver may ignore the error and clear the error status bit.
- Auto CMD12 conflict error or not sent: The command is not sent; therefore, the host driver sends a CMD12 manually.

32.5.3.6 Card interrupt

The external cards can inform the host controller by means of some special signals. For the SDIO card, it can be the low-level on the DATA1 line during some special period. The uSDHC module only monitors the DATA1 line and supports the SDIO interrupt.

When the SDIO interrupt is captured by uSDHC, and the host system is informed by uSDHC asserting the uSDHC interrupt line, the interrupt service from the host driver is called.

As the interrupt source is controlled by the external card, the interrupt from the SDIO card must be serviced before the CINT bit is cleared. Refer to Card interrupt handling for the card interrupt handling flow.

32.5.4 Switch function

A switch command is issued by the host driver to enable new features added to the SD/MMC spec. The SD/MMC cards can transfer data at bus widths other than 1-bit. Different speed modes are also defined. To enable these features, a switch command is issued by the host driver.

For SDIO cards, the high-speed mode/DDR50/SDR50/SDR104 are enabled by writing the EHS bit in the CCCR register after the SHS bit is confirmed as high. For SD cards, the high-speed mode/DDR50/SDR50/SDR104 are queried and enabled by a CMD6 (with the mnemonic symbol as SWITCH_FUNC). For MMC cards, the high-speed mode/ HS200/HS400 are queried by a CMD8 and enabled by a CMD6 (with the mnemonic symbol as SWITCH).

The SDR4-bit, SDR8-bit, DDR4-bit, and DDR8-bit width of MMC is also enabled by the SWITCH command, but with a different argument.

These new functions can also be disabled by a software reset. For SDIO cards, it can be done by setting the RES bit in the CCCR register. For other cards, it can be accomplished by issuing a CMD0. This method of restoring to the normal mode is not recommended because a complete identification process is needed before the card is ready for data transfer.

For the sake of simplicity, the following pseudocode examples do not show current capability check, which is recommended in the function switch process.

32.5.4.1 Query, enable, and disable SDIO high-speed mode

```
enable_sdio_high_speed_mode(void)
{
send CMD52 to query bit SHS at address 0x13;
if (SHS bit is '0') report the SDIO card does not support high speed mode and return;
send CMD52 to set bit EHS at address 0x13 and read after write to confirm EHS bit is set;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of around 50MHz;
(data transactions like normal peers)
}
disable_sdio_high_speed_mode(void)
{
send CMD52 to clear bit EHS at address 0x13 and read after write to confirm EHS bit is
cleared;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of the desired value below 25MHz;
(data transactions like normal peers)
}
```

32.5.4.2 Query, enable, and disable SD high-speed mode/DDR50/ SDR50/SDR104

```
enable_sd_speed_mode(void)
{
set BLKCNT field to 1 (block), set BLKSIZE field to 64 (bytes);
send CMD6, with argument 0xFFFFFx and read 64 bytes of data accompanying the R1 response;
(high speed mode,x=1; SDR50,x=2; SDR104,x=3; DDR50,x=4;)
wait data transfer done bit is set;
check if the bit x of received 512 bits is set;
if (bit 401 is '0') report the SD card does not support high speed mode and return;
if (bit 402 is '0') report the SD card does not support SDR50 mode and return;
if (bit 403 is '0') report the SD card does not support SDR104 mode and return;
if (bit 404 is '0') report the SD card does not support DDR50 mode and return;
send CMD6, with argument 0x80FFFFFx and read 64 bytes of data accompanying the R1 response;
(high speed mode,x=1; SDR50,x=2; SDR104 x=3; DDR50 x=4;)
check if the bit field 379~376 is 0xF;
if (the bit field is 0xF) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of around 50MHz for high speed mode, 100MHz for SDR50, 200MHz for SDR104, 50MHz for
DDR50;
(data transactions like normal peers)
}
disable_sd_speed_mode(void)
{
set BLKCNT field to 1 (block), set BLKSIZE field to 64 (bytes);
send CMD6, with argument 0x80FFFFF0 and read 64 bytes of data accompanying the R1 response;
check if the bit field 379~376 is 0xF;
if (the bit field is 0xF) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of the desired value below 25MHz;
(data transactions like normal peers)
}
```

32.5.4.3 Query, enable, and disable MMC high-speed mode

```
enable_mmc_high_speed_mode(void)
{
send CMD9 to get CSD value of MMC;
check if the value of SPEC_VER field is 4 or above;
if (SPEC_VER value is less than 4) report the MMC does not support high speed mode and
return;
set BLKCNT field to 1 (block), set BLKSIZE field to 512 (bytes);
send CMD8 to get EXT_CSD value of MMC;
extract the value of CARD_TYPE field to check the 'high speed mode' in this MMC is 26MHz or
52MHz;
send CMD6 with argument 0x1B90100;
send CMD13 to wait card ready (busy line released);
send CMD8 to get EXT_CSD value of MMC;
check if HS_TIMING byte (byte number 185) is 1;
if (HS_TIMING is not 1) report MMC switching to high speed mode failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of around 26MHz or 52MHz according to the CARD_TYPE;
(data transactions like normal peers)
}
disable_mmc_high_speed_mode(void)
{
send CMD6 with argument 0x2B90100;
set BLKCNT field to 1 (block), set BLKSIZE field to 512 (bytes);
send CMD8 to get EXT_CSD value of MMC;
check if HS_TIMING byte (byte number 185) is 0;
if (HS_TIMING is not 0) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of the desired value below 20MHz;
(data transactions like normal peers)
}
```

32.5.4.4 Set MMC bus width

```
change_mmc_bus_width(void)
{
send CMD9 to get CSD value of MMC;
check if the value of SPEC_VER field is 4 or above;
if (SPEC_VER value is less than 4) report the MMC does not support multiple bit width and
return;
send CMD6 with argument 0x3B70x00; (8-bit(dual data rate), x=6; 4-bit(dual data rate), x=5;8-
bit, x=2; 4-bit, x=1; 1-bit, x=0)
send CMD13 to wait card ready (busy line released);
(data transactions like normal peers)
}
```

32.5.5 ADMA operation

Here are the codes for the ADMA1 and ADMA2 operations.

32.5.5.1 ADMA1 operation

```
Set_adma1_descriptor
{
if (to start data transfer) {
// Make sure the address is 4KB align.
Set 'Set' type descriptor;
```

```
{
Set Act bits to 01;
Set [31:12] bits data length (byte unit);
}
Set 'Tran' type descriptor;
{
Set Act bits to 10;
Set [31:12] bits address (4KB align);
}
}
else if (to fetch descriptor at non-continuous address) {
Set Act bits to 11;
Set [31:12] bits the next descriptor address (4KB aligned);
}
else { // other types of descriptor
Set Act bits accordingly
}
if (this descriptor is the last one) {
Set End bit to 1;
}
if (to generate interrupt for this descriptor) {
Set Int bit to 1;
}
Set Valid bit to 1;
}
```

32.5.5.2 ADMA2 operation

```
Set_adma2_descriptor
{
if (to start data transfer) {
// Make sure the address is a 32-bit boundary (lower 2-bit are always '00').
Set higher 32-bit of descriptor for this data transfer initial address;
Set [31:16] bits data length (byte unit);
Set Act bits to '10';
}
else if (to fetch descriptor at non-continuous address) {
Set Act bits to '11';
// Make sure the address is 32-bit boundary (lower 2-bit are always set to '00').
Set higher 32-bit of descriptor for the next descriptor address;
}
else { // other types of descriptor
Set Act bits accordingly
}
if (this descriptor is the last one) {
Set 'End' bit '1';
}
if (to generate interrupt for this descriptor) {
Set 'Int' bit '1';
}
Set the 'Valid' bit to '1';
}
```

32.5.6 Fast boot operation

32.5.6.1 Normal fast boot flow

Here are the steps for normal fast boot flow:

1. Software must configure the SYS_CTRL[INITA] bit to make sure that 74 card clocks are finished.
2. Software must configure the MMC Boot Register (offset 0xc4) bit 6 to 1 (enable boot), and bit 5 to 0 (normal fast boot), and bit 4 to select the ack mode. If the data is sent through the DMA mode, the software should configure bit 7 to enable the automatic stop at block gap feature, and configure bit 3-bit 0 to select the ack timeout value according to the SD CLK frequency.
3. Software then needs to configure the Block Attributes Register to set the block size and count. If in DDR fast boot mode, the block size only can be configured to 512 bytes.
4. Software must configure the Protocol control register to set Data Transfer Width (DTW). If in the DDR fast boot mode, DTW only can be configured to 4-bit/8-bit dataline mode.
5. Software needs to configure the Command Argument Register to set argument if needed (no need in normal fast boot).
6. Software must configure the Transfer Type Register to start the boot process. In normal boot mode, CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN and DMAEN retain the default value, where DPSEL bit is set to 1, DTDSEL is set to 1 and MSBSEL is set to 1.
7. DMAEN should be configured as 0 in the polling mode and if BCEN is configured as 1, it is recommended to configure the number of blocks in the Block Attributes Register to the maximum value. If in DDR fast boot mode, DDR_EN needs to be set to 1.
8. When step 6 is configured, the boot process begins. The software needs to poll the data buffer ready status to read the data from the buffer in time. If a boot timeout happens (ack times out or the first data read times out), an interrupt is triggered, and the software must configure MMC Boot Register to bit 6 to 0 to disable boot. This makes CMD high, then after at least 56 clocks, it is ready to begin a normal initialization process.
9. If there is no timeout, software needs to determine when the data read is finished and then configure MMC Boot Register bit 6 to 0 to disable boot. This render CMD line high and command completed asserted. After at least 56 clocks, it is ready to begin the normal initialization process.
10. You must reset the host and begin the normal process.

32.5.6.2 Alternative fast boot flow

Here are the steps for alternative fast boot flow:

1. Software needs to configure SYS_CTRL[INITA] to make sure 74 card clocks are finished.

2. Software needs to configure MMC Boot Register (offset 0xc4) bit 6 to 1 (enable boot), and bit 5 to 1 (alternative boot), and bit 4 to select the ack mode or not. If data needs to be sent through the DMA mode, then configure bit 7 to enable the automatic stop at block gap feature. Software should also configure bit 3-bit 0 to select the ack timeout value according to the SD clock frequency.
3. Software then needs to configure the Block Attributes Register to set the block size and count. If in the DDR fast boot mode, the block size only can be configured to 512 bytes.
4. Software needs to configure the Protocol control register to set the data transfer width (DTW). If in the DDR fast boot mode, DTW only can be configured to 4-bit/8-bit dataline mode.
5. Software needs to configure Command Argument Register to set argument to 0xFFFFFFFA.
6. Software needs to configure the Transfer Type Register to start the boot process by CMD0 with the 0xFFFFFFFA argument. In alternative boot, CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN, and DMAEN retain the default value. DPSEL bit is set to 1, DTDSEL is set to 1, and MSBSEL is set to 1. Note DMAEN should be configured as 0 in the polling mode, and if BCEN is configured as 1 in polling mode, it is recommended to configure the block count in the Block Attributes Register to the maximum value. If in the DDR fast boot mode, DDR_EN needs to be set to 1.
7. When step 6 is configured, the boot process begins. Software needs to poll the data buffer ready status to read the data from the buffer in time. If there is a boot timeout (ack data timeout in 50ms or data timeout in 1s), the host sends out the interrupt and the software needs to send CMD0 with reset and then configure the boot enable bit to 0 to stop this process.
8. If there is no time out, the software needs to decide when to stop the boot process, and send out the CMD0 with reset and then after the command is completed, configure the MMC Boot Register bit 6 to stop the process. After 8 clocks from the command completion, the slave (card) is ready for the identification step.
9. You must reset the host and begin the normal process.

32.5.6.3 Fast boot application case (in DMA mode)

In the boot application case, because the image destination and the image size are contained in the beginning of the image, it is necessary to switch DMA parameters on the fly during MMC fast boot.

In fast boot, the host can use Advanced DMA2 (ADMA2) with two destinations.

The detailed flow is described below:

1. The software needs to configure INIT_ACTIVE bit (system control register bit 27) to make sure that 74 card clocks are finished.
2. The software needs to configure the MMC Boot Register (offset 0xc4) bit 6 to 1 (enable boot); and bit 5 to 0 (normal fast boot) or 1 (alternative boot); and bit 4 to select the ack mode. In DMA mode, configure bit 7 to 1 to enable the automatic stop at block gap feature. Also configure bits[31-16] to set the (BLK_CNT - VALUE1). Here VALUE1 is the value of the block count that needs to transfer the first time, so that the host stops at the block gap when the uSDHC controller gets VAULE1 blocks from the device. Also, configure bits[3-0] to select the ack timeout value according to the SD clock frequency.
3. The software then needs to configure the Block Attributes Register to set block size and count. If in DDR fast boot mode, the block size only can be configured to 512 bytes. In DMA mode, it is recommended to set the block count (BLK_CNT) to the max value (16'hffff).
4. The software needs to configure Protocol Control Register to set DTW (data transfer width). If in DDR fast boot mode, the DTW only can be configured to 4-bit/8-bit dataline mode.
5. Software enable ADMA2 by configuring Protocol Control Register bits [9-8].
6. The software needs to set at least three pairs of ADMA2 descriptor in boot memory (that is, in IRAM, at least six words). The first pair descriptor defines the start address (that is, IRAM) and data length (that is,512byte*VALUE1) of the first part boot code. The software also needs to set the second pair descriptor, the second start address (any value that is writable), and data length is suggested to set 1~2word (record as VALUE2). Note that the second couple desc also transfers useful data even at lease 1 word, because our ADMA2 cannot support 0 data_length data transfer descriptor.
7. The software needs to configure Command Argument Register to set argument to 0xFFFFFFFA in alternative fast boot and do not need to be set in normal fast boot.
8. The software needs to configure Transfer Type Register to start the boot process. CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN, and DMAEN retain the default value. DPSEL bit is set to 1, DTDSEL is set to 1, and MSBSEL is set to 1. DMAEN is configured as 1 in the DMA mode. And, if BCEN is configured as 1, then configure blk no in Bock Attributes Register to the max value. And, if in the DDR fast boot mode, DDR_EN needs to be set to 1.
9. When step 8 is configured, boot process begins, the first VALUE1 block number data gets transferred. The software needs to poll the TC bit (bit1 in Interrupt Status Register) to determine first transfer is ended. Also, the software needs to polling the BGE bit (bit2 in Interrupt Status Register) to determine if the first transfer stops at the block gap.
10. When TC and BGE bits are set to 1, the software can analyze the first code of VALUE1 block, initializes the new memory device, if required, and sets the third

pair of descriptors to define the start address and length of the remaining part of the boot code (VALUE3, the remain boot code block). Remember to set the last descriptor with END.

11. The software needs to configure the MMC Boot Register (offset 0xc4) again. Set bit 6 to 1 (enable boot); and bit 5 to 0 (normal fast boot), to 1 (alternative boot); and bit 4 to select the ack mode or not. In the DMA mode, configure bit 7 to 1 for enabling the automatically stop at block gap feature. Also, configure bit31-bit16 to set the (BLK_CNT - (VALUE1+1+VALUE3)), that host stops at block gap when the uSDHC controller gets (VALUE1+1+VALUE3)) blocks from device totally include the blocks received in step 9. And need to configure bit 3-bit0 to select the ack timeout value according to the sd clk frequency. Note that the software does not need to configure the BLK_CNT again, because it is counted down automatically by the uSDHC controller.
12. The software needs to clear the TC and BGE bits and the software needs to clear SABGREQ (bit 16 in the Protocol control register) and set CREQ (bit17 in the Protocol control register) to 1 to resume the data transfer. Host transfers the VALUE2 and VALUE3 data to the destination that is set by descriptor.
13. The software needs to do poll BGE bit to determine if the fast boot is over.

Note:

- When ADMA boot flow starts, for uSDHC, it is like a normal ADMA read operation. So, set ADMA2 descriptor as the normal ADMA2 transfer.
- Need a few words length memory to keep descriptor.
- For the 1~2-word data in second descriptor setting, it is a useful data, so the software needs to deal the data because of the application case.

32.6 Software restrictions

32.6.1 Initialization active

The driver cannot set INITA bit in System Control register when any of the command line or data lines are active, so the driver must ensure both CDIHB and CIHB bits are cleared.

32.6.2 Software polling procedure

For polling read or write, after the software begins a buffer read or write, it must access exactly the number of times as the values set in the Watermark Level Register; moreover, if the block size is not a multiple of the value in the Watermark Level Register (read and write respectively), the software must access exactly the remaining number of words at the end of each block.

For example, for a read operation, if the RD_WML is 4, indicating the watermark level is 16 bytes, block size is 40 bytes, and the block number is 2, then the access times for the burst sequence in the whole transfer process must be 4, 4, 2, 4, 4, 2.

32.6.3 Suspend operation

To suspend the data transfer, the software must inform uSDHC that the suspend command is successfully accepted. To achieve this, after the Suspend command is accepted by the SDIO card, software must send another normal command marked as suspend command (CMDTYP bits set as '01') to inform uSDHC that the transfer is suspended.

If software needs to resume the suspended transfer, it should read the value in BLKCNT register to save the remaining number of blocks before sending the normal command marked as suspend, otherwise on sending such a 'suspend' command, uSDHC treats the current transfer is aborted and change the BLKCNT register to its original value, instead of retaining the remaining number of blocks.

32.6.4 Data length setting

For either ADMA (ADMA1 or ADMA2) transfer, the data in the data buffer must be word aligned, so the data length set in the descriptor must be a multiple of 4.

ADMA1 is 4KB aligned.

32.6.5 (A)DMA address setting

To configure the ADMA1/ADMA2/DMA address register, when TC bit is set, the register always updates itself with the internal address value to support dynamic address synchronization, so the software must ensure that the TC bit is cleared prior to configuring the ADMA1/ADMA2/DMA address register.

32.6.6 Data port access

Data port does not support parallel access. For example, during an internal DMA access, it is not allowed to write any data to the data port by CPU; or during a CPU read operation, it is also prohibited to write any data to the data port, by either CPU or internal DMA. Otherwise the data is corrupted inside the uSDHC buffer.

32.6.7 Change clock frequency

The uSDHC module does not automatically gate off the card clock when the host driver changes the clock frequency. To prevent possible glitch on the card clock, clear the FRC_SDCLK_ON bit when changing the clock divisor value (SDCLKFS or DVS in System Control Register) or setting the RSTA bit.

Also, before changing the clock divisor value, the host driver should make sure that the SDSTB bit is high.

32.6.8 Multi-block read

For pre-defined multi-block read operation, that is, the number of blocks to read has been defined by previous CMD23 for MMC, or pre-defined number of blocks in CMD53 for SDIO/SDCombo, or whatever multi-block read without abort command at card side, an abort command, either automatic or manual CMD12/CMD52, is still required by uSDHC after the pre-defined number of blocks are done, to drive the internal state machine to idle mode.

In this case, the card may not respond to this extra abort command and uSDHC gets response timeout. It is recommended to manually send an abort command with RSPTYP[1:0] both bits cleared.

32.7 uSDHC memory map/register definition

32.7.1 uSDHC register descriptions

This section includes the module memory map and detailed descriptions of all registers.

See the table below for the register memory map of uSDHC. All these registers only support 32-bit accesses.

NOTE

The uSDHC registers are 32-bit wide and only support 32-bit access.

32.7.1.1 uSDHC memory map

USDHC1 base address: 4041_8000h

USDHC2 base address: 4041_C000h

32.7.1.2.3 Fields

Field	Description
31-0 DS_ADDR	System address **DMA system address / argument 2** When ACMD23_ARGU2_EN is set to 0, SDMA uses this register as system address and supports only 32-bit addressing mode. Auto CMD23 cannot be used with SDMA. When ACMD23_ARGU2_EN is set to 1, SDMA uses ADMA System Address register (05Fh – 058h) instead of this register to support both 32-bit and 64-bit addressing. This register is used only for Argument2 and SDMA may use Auto CMD23.

Field	Description
	1. **SDMA system address** Because the address must be word (4 bytes) aligned, the least two bits are reserved and always set to 0. When uSDHC stops a DMA transfer, this register points out the system address of the next contiguous data position. It can be accessed only when no transaction is executing (that is, after a transaction has stopped). Read operation during transfers may return an invalid value. The host driver initializes this register before starting a DMA transaction. After DMA has stopped, the system address of the next contiguous data position can be read from this register. This register is protected during a data transfer. When data lines are active, write to this register is ignored. The host driver waits until the DLA field in the Present State register is cleared, before writing to this register. The uSDHC internal DMA does not support a virtual memory system. It only supports continuous physical memory access. Because this register supports dynamic address reflecting, when TC field is set, it automatically alters the value of internal address counter, so the software cannot change this register when TC field is set. Such restriction is also listed in Software restrictions. 2. **Argument 2** This register is used with the Auto CMD23 to set a 32-bit block count value to the argument of the CMD23 while executing Auto CMD23. If Auto CMD23 is used with ADMA, the full 32-bit block count value can be used. If Auto CMD23 is used without ADMA, the available block count value is limited by the Block Count register. 65535 blocks is the maximum value in this case.

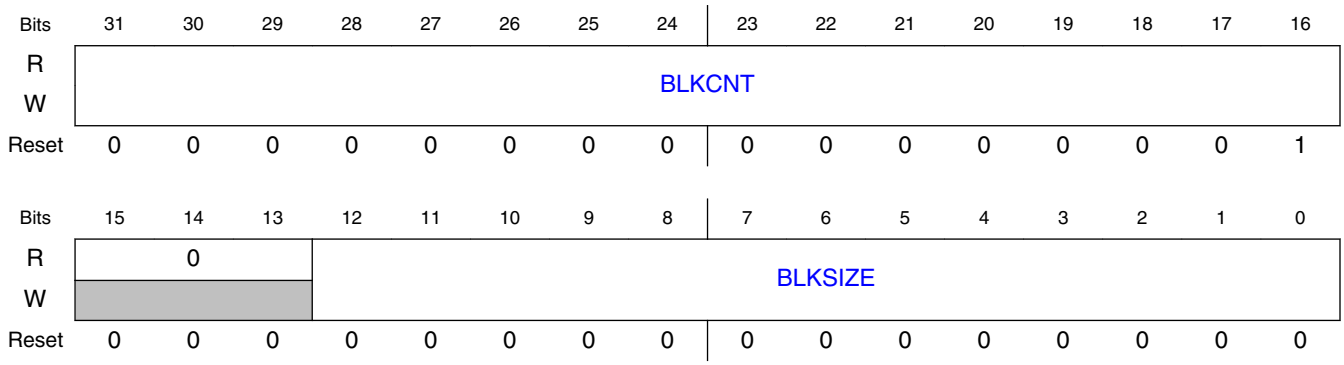
32.7.1.3 Block Attributes (BLK_ATT)

This register is used to configure the number of data blocks and the number of bytes in each block.

32.7.1.3.1 Offset

Register	Offset
BLK_ATT	4h

32.7.1.3.2 Diagram



32.7.1.3.3 Fields

Field	Description
31-16 BLKCNT	Blocks count for current transfer This field is enabled when the Block Count Enable field in the Transfer Mode register is set to 1 and is valid only for multiple block transfers. For single block transfer, this field always reads as 1. The host driver sets this field to a value between 1 and the maximum block count. The uSDHC module decrements the block count after each block transfer and stops when the count reaches zero. Setting the block count to zero results in no data blocks being transferred. This field should be accessed only when no transaction is executing (that is, after transactions are stopped). During data transfer, read operations on this field may return an invalid value and write operations are ignored. When saving transfer content because of a Suspend command, the number of blocks yet to be transferred can be determined by reading this field. The reading of this field should be applied after transfer is paused by stop at block gap operation and before sending the command marked as suspend. This is because when the Suspend command is sent out, uSDHC treats the current transfer as aborted and change the BLKCNT field back to its original value instead of keeping the dynamical indicator of the remaining block count. When restoring transfer content prior to issuing a Resume command, the host driver restores the previously saved block count. **NOTE:** Although the BLKCNT field is 0 after reset, the read of reset value is 0x1. This is because when MSBSEL field is indicating a single block transfer, the read value of BLKCNT is always 1. 0000000000000000 - Stop count 0000000000000001 - 1 block 0000000000000010 - 2 blocks 1111111111111111 - 65535 blocks
15-13 —	Reserved
12-0 BLKSIZE	Transfer block size This field specifies the block size for block data transfers. Values ranging from 1 byte up to the maximum buffer size can be set. It can be accessed only when no transaction is executing (that is, after a transaction has stopped). Read operations during transfers may return an invalid value, and write operations are ignored.

Field	Description
	0000000000000 - No data transfer 0000000000001 - 1 byte 0000000000010 - 2 bytes 0000000000011 - 3 bytes 0000000000100 - 4 bytes 0000111111111 - 511 bytes 0001000000000 - 512 bytes 0100000000000 - 2048 bytes 1000000000000 - 4096 bytes

32.7.1.4 Command Argument (CMD_ARG)

This register contains the SD/MMC command argument.

32.7.1.4.3 Fields

Field	Description
31-0	Command argument

Field	Description
CMDARG	The SD/MMC command argument is specified as bits 39-8 of the command format in the SD or MMC specification. This field is write protected when the Command Inhibit (CMD) field in the Present State register is set.

32.7.1.5 Command Transfer Type (CMD_XFR_TYP)

This register is used to control the operation of data transfers. The host driver sets this register before issuing a command followed by a data transfer or before issuing a Resume command. To prevent data loss, uSDHC prevents writing to the bits, which are involved in the data transfer of this register, when data transfer is active. These fields are DPSEL, MBSEL, DTDSEL, AC12EN, BCEN, and DMAEN.

The host driver checks the Command Inhibit DAT field (PRES_STATE[CDIHB]) and the Command Inhibit CMD field (PRES_STATE[CIHB]) in the Present State register before writing to this register. When the CDIHB field in the Present State register is set, any attempt to send a command with data by writing to this register is ignored; when the CIHB field is set, any write to this register is ignored.

On sending commands with data transfer involved, it is mandatory that the block size is non-zero. Block count must also be non-zero, or indicated as a single block transfer (bit 5 of this register is '0' when written), or block count is disabled (bit 1 of this register is '0' when written), otherwise uSDHC ignores the sending of this command and do nothing. For write command, with all above restrictions, it is also mandatory that the write protect switch is not active (PRES_STATE[WPSPL] field of Present State register is '1'); otherwise, uSDHC also ignores the command.

If the commands with data transfer do not receive the response in 64 clock cycles, that is, if response time-out happens, uSDHC treats the external device, does not accept the command, and aborts the data transfer. In this scenario, the driver should issue the command again to retry the transfer. It is also possible that for some reason the card responds to the command but uSDHC does not receive the response, and if it is internal DMA (either simple DMA or ADMA) read operation, the external system memory is over-written by the internal DMA with data sent back from the card.

The table below shows the summary of how register settings determine the type of data transfer.

Table 32-6. Transfer type register setting for various transfer types

Multi/single block select	Block count enable	Block count	Function
0	Do not care	Do not care	Single transfer
1	0	Do not care	Infinite transfer
1	1	Positive number	Multiple transfer
1	1	Zero	No data transfer

The table below shows the relationship between the Command Index Check Enable and the Command CRC Check Enable, regarding the Response Type bits as well as the name of the response type.

Table 32-7. Relationship between parameters and the name of the response type

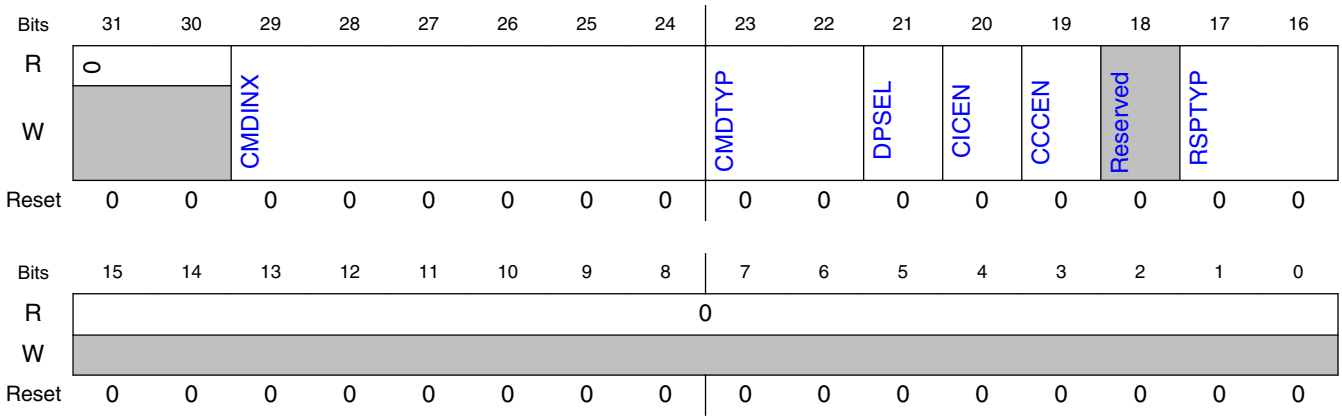
Response type	Index check enable	CRC check enable	Name of response type
00	0	0	No response
01	0	1	R2
10	0	0	R3, R4
10	1	1	R1, R5, R6
11	1	1	R1b,R5b

- In the SDIO specification, response type notation for R5b is not defined. R5 includes R5b in the SDIO specification, but R5b is defined in this specification to specify that uSDHC checks the busy status after receiving a response. For example, usually CMD52 is used with R5, but the I/O abort command is used with R5b.
- The CRC fields for R3 and R4 are expected to be all 1 bits. The CRC check is disabled for these response types.

32.7.1.5.1 Offset

Register	Offset
CMD_XFR_TYP	Ch

32.7.1.5.2 Diagram



32.7.1.5.3 Fields

Field	Description
31-30 —	Reserved
29-24 CMDINX	Command index These fields are set to the command number that is specified in bits 45-40 of the command-format in the SD Memory Card Physical Layer Specification and SDIO Card Specification.
23-22 CMDTYP	Command type There are three types of special commands: Suspend, Resume, and Abort. These fields are set to 00b for all other commands. • Suspend command: If the Suspend command succeeds, uSDHC assumes that the card bus has been released and that it is possible to issue the next command that uses the DATA line. Because uSDHC does not monitor the content of command response, it does not know if the Suspend command succeeded or not. It is the host driver's responsibility to check the status of the Suspend command and send another command marked as Suspend to inform uSDHC that a Suspend command was successfully issued. See Suspend Resume for more details. After the end bit of command is sent, uSDHC deasserts Read Wait for read transactions and stops checking busy for write transactions. In a 4-bit mode, the interrupt cycle starts. If the Suspend command fails, uSDHC maintains its current state, and the host driver restarts the transfer by setting the Continue Request field in the Protocol Control register. • Resume command: The host driver re-starts the data transfer by restoring the registers saved before sending the Suspend command and then sends the Resume command. The uSDHC module checks for a pending busy state before starting write transfers. • Abort command: If this command is set when executing a read transfer, uSDHC stops reads to the buffer. If this command is set when executing a write transfer, uSDHC stops driving the DATA line. After issuing the Abort command, the host driver should issue a software reset (Abort Transaction). 00 - Normal other commands 01 - Suspend CMD52 for writing bus suspend in CCCR 10 - Resume CMD52 for writing function select in CCCR 11 - Abort CMD12, CMD52 for writing I/O Abort in CCCR
21	Data present select

Table continues on the next page...

Field	Description
DPSEL	This field is set to 1 to indicate that data is present and is transferred using the DATA line. It is set to 0 for the following: • Commands using only the CMD line (for example, CMD52) • Commands with no data transfer, but using the busy signal on DATA0 line (R1b or R5b (for example, CMD38)) **NOTE:** In resume command, this field is set, and other bits in this register is set the same as when the transfer was initially launched. When the write protect switch is on, (that is, the WPSPL field is active as '0'), any command with a write operation ignored. When this field is set, while the DTDSEL field is 0, writes to the register Transfer Type are ignored. 0 - No data present 1 - Data present
20 CICEN	Command index check enable If this field is set to 1, uSDHC checks the Index field in the response to see if it has the same value as the command index. If it is not, it is reported as a Command Index Error. If this field is set to 0, the Index field is not checked. 0 - Disable command index check 1 - Enables command index check
19 CCCEN	Command CRC check enable If this field is set to 1, uSDHC checks the CRC field in the response. If an error is detected, it is reported as a Command CRC Error. If this field is set to 0, the CRC field is not checked. The number of bits checked by the CRC field value changes according to the length of the response. See RSPTYP[1:0] and Command Transfer Type (CMD_XFR_TYP). 0 - Disables command CRC check 1 - Enables command CRC check
18 —	Reserved
17-16 RSPTYP	Response type select 00 - No response 01 - Response length 136 10 - Response length 48 11 - Response length 48, check busy after response
15-0 —	Reserved

32.7.1.6 Command Response0 (CMD_RSP0)

32.7.1.8.3 Fields

Field	Description
31-0 CMDRSP2	Command response 2 See Command Response3 (CMD_RSP3) for the mapping of command responses from the SD bus to this field for each response type.

32.7.1.9 Command Response3 (CMD_RSP3)

This register is used to store part 3 of the response bits from the card.

The table below describes the mapping of command responses from the SD bus to Command Response registers for each response type. In this table, R[ ] refers to a bit range within the response data as transmitted on the SD bus.

Table 32-8. Response bit definition for each response type

Response type	Meaning of response	Response field	Response register
R1,R1b (normal response)	Card status	R[39:8]	CMDRSP0
R1b (auto CMD12 response)	Card status for auto CMD12	R[39:8]	CMDRSP3
R2 (CID, CSD register)	CID/CSD register [127:8]	R[127:8]	{CMDRSP3[23:0], CMDRSP2, CMDRSP1, CMDRSP0}
R3 (OCR register)	OCR register for memory	R[39:8]	CMDRSP0
R4 (OCR register)	OCR register for I/O etc.	R[39:8]	CMDRSP0
R5, R5b	SDIO response	R[39:8]	CMDRSP0

Table continues on the next page...

Table 32-8. Response bit definition for each response type (continued)

Response type	Meaning of response	Response field	Response register
R6 (publish RCA)	New published RCA[31:16] and card status[15:0]	R[39:9]	CMDRSP0

This table shows that most responses with a length of 48 (R[47:0]) have 32-bits of the response data (R[39:8]) stored in the CMDRSP0 register. Responses of type R1b (Auto CMD12 responses) have response data bits (R[39:8]) stored in the CMDRSP3 register. Responses with length 136 (R[135:0]) have 120-bits of the response data (R[127:8]) stored in the CMDRSP0, 1, 2, and 3 registers.

To be able to read the response status efficiently, uSDHC only stores part of the response data in the Command Response registers. This enables the host driver to efficiently read 32-bits of response data in one read cycle on a 32-bit bus system. Parts of the response, the Index field and the CRC, are checked by uSDHC (as specified by the Command Index Check Enable and the Command CRC Check Enable bits in the Transfer Type register) and generate an error interrupt if any error is detected. The bit range for the CRC check depends on the response length. If the response length is 48, uSDHC checks R[47:1], and if the response length is 136 the uSDHC checks R[119:1].

Because uSDHC may have a multiple block data transfer executing concurrently with a CMD_wo_DAT command, uSDHC stores the Auto CMD12 response in the CMDRSP3 register. The CMD_wo_DAT response is stored in CMDRSP0. This allows uSDHC to avoid overwriting the Auto CMD12 response with the CMD_wo_DAT and vice versa. When uSDHC modifies part of the Command Response registers, as shown in the table above, it preserves the unmodified bits.

32.7.1.10.3 Fields

Field	Description
31-0 DATCONT	Data content This field is used to access the internal buffer.

32.7.1.11 Present State (PRES_STATE)

The host driver can get status of uSDHC from this 32-bit read only register.

The host driver can issue CMD0, CMD12, CMD13 (for memory) and CMD52 (for SDIO) when the DATA lines are busy during a data transfer. These commands can be issued when Command Inhibit (CMD) is set to zero. Other commands are issued when Command Inhibit (DATA) is set to zero. Possible changes to the SD Physical Specification may add other commands to this list in the future.

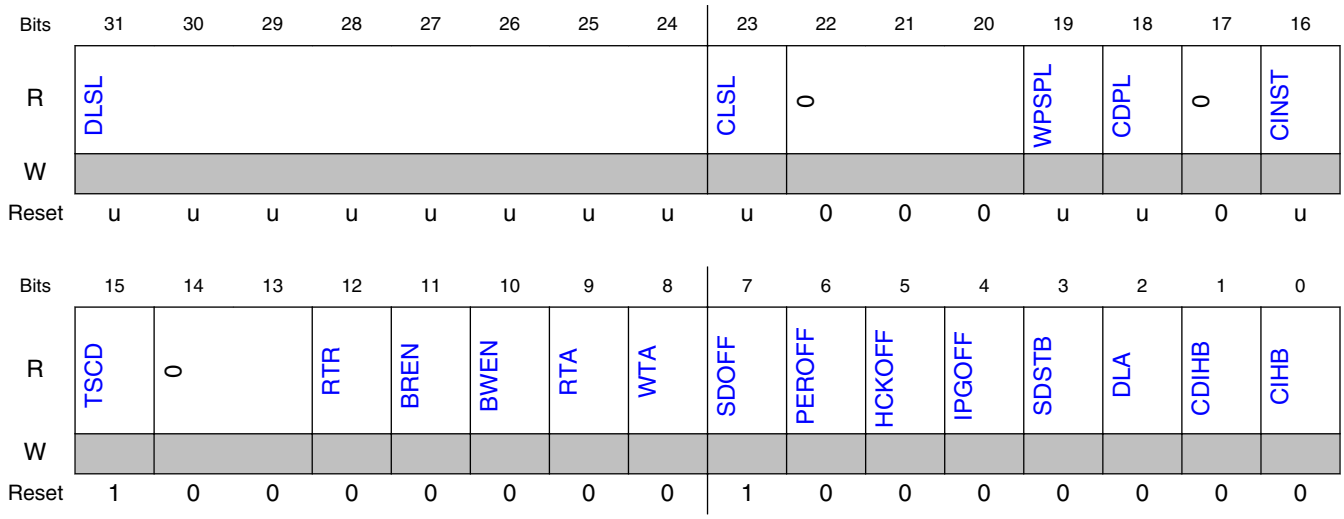
NOTE

The reset value of Present State register depends on board connectivity.

32.7.1.11.1 Offset

Register	Offset
PRES_STATE	24h

32.7.1.11.2 Diagram



32.7.1.11.3 Fields

Field	Description
31-24 DLSL	DATA[7:0] line signal level This field is used to check the DATA line level to recover from errors, and for debugging. This is especially useful in detecting the busy signal level from DATA0. The reset value is affected by the external pull-up / pull-down resistors. By default, the read value of this field after reset is 8'b11110111, when DATA3 is pulled down and the other lines are pulled up. 00000000 - Data 0 line signal level 00000001 - Data 1 line signal level 00000010 - Data 2 line signal level 00000011 - Data 3 line signal level 00000100 - Data 4 line signal level 00000101 - Data 5 line signal level 00000110 - Data 6 line signal level 00000111 - Data 7 line signal level
23 CLSL	CMD line signal level This field is used to check the CMD line level to recover from errors, and for debugging. The reset value is affected by the external pull-up / pull-down resistor, by default, the read value of this field after reset is 1'b1, when the command line is pulled up.
22-20 —	Reserved
19 WPSPL	Write protect switch pin level The Write Protect switch is supported for memory and combo cards. This field reflects the inverted value of the WP pin of the card socket. A software reset does not affect this field. The reset value is affected by the external write protect switch. If the WP pin is not used, it should be tied low, so that the reset value of this field is high and write is enabled.

Table continues on the next page...

Field	Description
	0 - Write protected (WP = 1) 1 - Write enabled (WP = 0)
18 CDPL	Card detect pin level This field reflects the inverse value of the CD_B pin for the card socket. Debouncing is not performed on this field. This field may be valid, but is not guaranteed, because of propagation delay. Use of this field is limited to testing because it must be debounced by software. A software reset does not affect this field. A write to the Force Event Register does not affect this field. The reset value is affected by the external card detection pin. This field shows the value on the CD_B pin (that is, when a card is inserted in the socket, it is 0 on the CD_B input, and consequently, the CDPL reads 1. 0 - No card present (CD_B = 1) 1 - Card present (CD_B = 0)
17 —	Reserved
16 CINST	Card inserted This field indicates whether a card has been inserted. The uSDHC module debounces this signal so that the host driver does not need to wait for it to stabilize. Changing from a 0 to 1 generates a Card Insertion interrupt in the Interrupt Status register. Changing from a 1 to 0 generates a Card Removal interrupt in the Interrupt Status register. A write to the Force Event Register does not affect this field. The Software Reset For All in the System Control register does not affect this field. A software reset does not affect this field. 0 - Power on reset or no card 1 - Card inserted
15 TSCD	Tap select change done This field indicates the delay setting is effective after write CLK_TUNE_CTRL_STATUS register. 0 - Delay cell select change is not finished. 1 - Delay cell select change is finished.
14-13 —	Reserved
12 RTR	Re-Tuning Request (only for SD3.0 SDR104 mode,and EMMC HS200 mode) Host controller may request host driver to execute re-tuning sequence by setting this field when the data window is shifted by temperature drift and a tuned sampling point does not have a good margin to receive correct data. This field is cleared when a command is issued with setting Execute Tuning field in MIX_CTRL register. Changing of this field from 0 to 1 generates Re-Tuning Event. See Interrupt status registers for more detail. This field isn't set to 1 if Sampling Clock Select in the MIX_CTRL register is set to 0 (using fixed sampling clock). 0 - Fixed or well tuned sampling clock 1 - Sampling clock needs re-tuning
11 BREN	Buffer read enable This status field is used for non-DMA read transfers. The uSDHC module implements an internal buffer to transfer data efficiently. This read only flag indicates that valid data exists in the host side buffer. If this field is high, valid data greater than the watermark level exist in the buffer. A change of this field from 1 to 0 occurs when some reads from the buffer (read DATPORT (Base + 0x20)) are made and the buffer

Table continues on the next page...

Field	Description
	hasn't valid data greater than the watermark level. A change of this field from 0 to1 occurs when there is enough valid data ready in the buffer and the Buffer Read Ready interrupt has been generated and enabled. 0 - Read disable 1 - Read enable
10 BWEN	Buffer write enable This status field is used for non-DMA write transfers. The uSDHC module implements an internal buffer to transfer data efficiently. This read only flag indicates if space is available for write data. If this field is 1, valid data greater than the watermark level can be written to the buffer. A change of this field from 1 to 0 occurs when some writes to the buffer (write DATPORT (Base + 0x20)) are made and the buffer hasn't valid space greater than the watermark level. A change of this field from 0 to 1 occurs when the buffer can hold valid data greater than the write watermark level and the Buffer Write Ready interrupt is generated and enabled. 0 - Write disable 1 - Write enable
9 RTA	Read transfer active This status field is used for detecting completion of a read transfer. This field is set for either of the following conditions: • After the end field of the read command • When writing a 1 to the Continue Request field in the Protocol Control register to restart a read transfer A transfer complete interrupt is generated when this field changes to 0. This field is cleared for either of the following conditions: • When the last data block as specified by block length is transferred to the System, that is, all data are read away from uSDHC internal buffer. • When all valid data blocks have been transferred from uSDHC internal buffer to the System and no current block transfers are being sent because of the Stop At Block Gap Request being set to 1. 0 - No valid data 1 - Transferring data
8 WTA	Write transfer active This status field indicates a write transfer is active. If this field is 0, it means no valid write data exists in uSDHC. This field is set in either of the following cases: • After the end field of the write command • When writing 1 to the Continue Request field in the Protocol Control register to restart a write transfer This field is cleared in either of the following cases: • After getting the CRC status of the last data block as specified by the transfer count (Single and Multiple) • After getting the CRC status of any block where data transmission is about to be stopped by a Stop At Block Gap Request During a write transaction, a Block Gap Event interrupt is generated when this field is changed to 0, as result of the Stop At Block Gap Request being set. This status is useful for the host driver in determining when to issue commands during Write Busy state. 0 - No valid data

Table continues on the next page...

Field	Description
	1 - Transferring data
7 SDOFF	SD clock gated off internally This status field indicates that the SD clock is internally gated off, because of buffer over / under-run or read pause without read wait assertion, or the driver set FRC_SDCLK_ON field is 0 to stop the SD clock in idle status. This field is for the host driver to debug data transaction on the SD bus. 0 - SD clock is active. 1 - SD clock is gated off.
6 PEROFF	IPG_PERCLK gated off internally This status field indicates that the IPG_PERCLK is internally gated off. This field is for the host driver to debug transaction on the SD bus. When IPG_CLK_SOFT_EN is cleared, IPG_PERCLK is gated off, otherwise IPG_PERCLK is always active. 0 - IPG_PERCLK is active. 1 - IPG_PERCLK is gated off.
5 HCKOFF	HCLK gated off internally This status field indicates that the HCLK is internally gated off. This field is for the host driver to debug during a data transfer. 0 - HCLK is active. 1 - HCLK is gated off.
4 IPGOFF	Peripheral clock gated off internally This status field indicates that the peripheral clock is internally gated off. This field is for the host driver to debug. 0 - Peripheral clock is active. 1 - Peripheral clock is gated off.
3 SDSTB	SD clock stable This status field indicates that the internal card clock is stable. This field is for the host driver to poll clock status when changing the clock frequency. It is recommended to clear FRC_SDCLK_ON field in System Control register to remove glitches on the card clock when the frequency is changing. Before changing clock divisor value (SDCLKFS or DVS), host driver should make sure the SDSTB field is high. 0 - Clock is changing frequency and not stable. 1 - Clock is stable.
2 DLA	Data line active This status field indicates whether one of the DATA lines on the SD bus is in use. In the case of read transactions: This status indicates if a read transfer is executing on the SD bus. Changes in this value from 1 to 0, between data blocks, generates a Block Gap Event interrupt in the Interrupt Status register. This field is set in either of the following cases: • After the end field of the read command • When writing a 1 to the Continue Request field in the Protocol Control register to restart a read transfer This field is cleared in either of the following cases: • When the end field of the last data block is sent from the SD bus to uSDHC. • When the Read Wait state is stopped by a Suspend command and the DATA2 line is released.

Table continues on the next page...

Field	Description
	The uSDHC module waits at the next block gap by driving Read Wait at the start of the interrupt cycle. If the Read Wait signal is already driven (data buffer cannot receive data), uSDHC can wait for a current block gap by continuing to drive the Read Wait signal. It is necessary to support Read Wait to use the suspend / resume function. This field remains 1 during Read Wait. In the case of write transactions: This status indicates that a write transfer is executing on the SD bus. Changes in this value from 1 to 0 generate a Transfer Complete interrupt in the Interrupt Status register. This field is set in either of the following cases: • After the end field of the write command • When writing to 1 to the Continue Request field in the Protocol Control register to continue a write transfer This field is cleared in either of the following cases: • When the SD card releases Write Busy of the last data block, uSDHC also detects if the output is not busy. If the SD card does not drive the busy signal after the CRC status is received, uSDHC assumes the card drive "Not Busy". • When the SD card releases write busy, prior to waiting for write transfer, and because of a Stop At Block Gap Request. In the case of command with busy pending: This status indicates that a busy state follows the command and the data line is in use. This field is cleared when the DATA0 line is released. 0 - DATA line inactive 1 - DATA line active
1 CDIHB	Command Inhibit Data (DATA) This status field is generated if either the DAT Line Active or the Read Transfer Active is set to 1. If this field is 0, it indicates that uSDHC can issue the next SD / MMC Command. Commands with a busy signal belong to Command Inhibit (DATA) (for example. R1b, R5b type). Changing from 1 to 0 generates a Transfer Complete interrupt in the Interrupt Status register. **NOTE:** The SD host driver can save registers for a suspend transaction after this field has changed from 1 to 0. 0 - Can issue command that uses the DATA line 1 - Cannot issue command that uses the DATA line
0 CIHB	Command inhibit (CMD) If this status bit is 0, it indicates that the CMD line is not in use and uSDHC can issue a SD / MMC command using the CMD line. This field is set also immediately after the Transfer Type register is written. This field is cleared when the command response is received. Even if the Command Inhibit (DATA) is set to 1, commands using only the CMD line can be issued if this field is 0. Changing from 1 to 0 generates a Command Complete interrupt in the Interrupt Status register. If uSDHC cannot issue the command because of a command conflict error (see Command CRC Error) or because of a Command Not Issued By Auto CMD12 Error, this field remains 1 and the Command Complete is not set. The Status of issuing an auto CMD12 does not show on this field. 0 - Can issue command using only CMD line 1 - Cannot issue command

32.7.1.12 Protocol Control (PROT_CTRL)

This register controls three cases to restart the transfer after stop at the block gap. Which case is appropriate depends on whether uSDHC issues a Suspend command or the SD card accepts the Suspend command.

- If the host driver does not issue a Suspend command, the Continue request is used to restart the transfer.
- If the host driver issues a Suspend command and the SD card accepts it, a Resume command is used to restart the transfer.
- If the host driver issues a Suspend command and the SD card does not accept it, the Continue request is used to restart the transfer.

Any time stop at block gap request stops the data transfer, the host driver waits for a Transfer Complete (in the Interrupt Status register), before attempting to restart the transfer. When restarting the data transfer by Continue Request, the host driver clears the Stop At Block Gap Request before or simultaneously.

32.7.1.12.1 Offset

Register	Offset
PROT_CTRL	28h

32.7.1.12.3 Fields

Field	Description
31 —	Reserved Always write as 0
30 NON_EXACT_BLK_RD	Non-exact block read Current block read is non-exact block read. It is only used for SDIO. 0 - The block read is exact block read. Host driver does not need to issue abort command to terminate this multi-block read. 1 - The block read is non-exact block read. Host driver needs to issue abort command to terminate this multi-block read.
29-27 —	Reserved
26 WECRM	Wakeup event enable on SD card removal This field enables a wakeup event, via a card removal, in the Interrupt Status register. FN_WUS (Wakeup Support) in CIS does not affect this field. When this field is set, the Card Removal Status and uSDHC interrupt can be asserted without CLK toggling. When the wakeup feature is not enabled, the CLK must be active to assert the Card Removal Status and uSDHC interrupt. 0 - Disables wakeup event enable on SD card removal 1 - Enables wakeup event enable on SD card removal
25 WECINS	Wakeup event enable on SD card insertion This field enables a wakeup event, via a card insertion, in the Interrupt Status register. FN_WUS (Wakeup Support) in CIS does not affect this field. When this field is set, the Card Insertion Status and uSDHC interrupt can be asserted without CLK toggling. When the wakeup feature is not enabled, the CLK must be active to assert the Card Insertion Status and uSDHC interrupt. 0 - Disable wakeup event enable on SD card insertion 1 - Enable wakeup event enable on SD card insertion
24 WECINT	Wakeup event enable on card interrupt This field enables a wakeup event, via a card interrupt, in the Interrupt Status register. This field can be set to 1 if FN_WUS (Wakeup Support) in CIS is set to 1. When this field is set, the Card Interrupt Status and uSDHC interrupt can be asserted without CLK toggling. When the wakeup feature is not enabled, the CLK must be active to assert the Card Interrupt Status and uSDHC interrupt. 0 - Disables wakeup event enable on card interrupt 1 - Enables wakeup event enable on card interrupt
23-21 —	Reserved Always write as 3'b100
20 RD_DONE_NO_8CLK	Read performed number 8 clock According to the SD/MMC spec, for read data transaction, 8 clocks are needed after the end field of the last data block. So, by default(RD_DONE_NO_8CLK=0), eight clocks are active after the end field of the last read data transaction. However, these 8 clocks should not be active if user wants to use stop at block gap (include the auto stop at block gap in boot mode) feature for read and the RWCTL field (bit18) is not enabled. In this case, software should set RD_DONE_NO_8CLK to avoid these 8 clocks. Otherwise, the device might send extra data to uSDHC while uSDHC ignores these data.

Table continues on the next page...

Field	Description
	In a summary, this field should be set only if the use case needs to use stop at block gap feature while the device can't support the read wait feature.
19 IABG	Interrupt at block gap This field is valid only in 4-bit mode, of the SDIO card, and selects a sample point in the interrupt cycle. Setting to 1 enables interrupt detection at the block gap for a multiple block transfer. Setting to 0 disables interrupt detection during a multiple block transfer. If the SDIO card cannot signal an interrupt during a multiple block transfer, this field should be set to 0 to avoid an inadvertent interrupt. When the host driver detects an SDIO card insertion, it sets this field according to the CCCR of the card. 0 - Disables interrupt at block gap 1 - Enables interrupt at block gap
18 RWCTL	Read wait control The read wait function provided by this field is optional for SDIO cards. If the card supports read wait, set this field to enable use of the read wait protocol to stop read data using the DATA2 line. Otherwise, uSDHC has to stop the SD clock to hold read data, which restricts commands generation. When the host driver detects an SDIO card insertion, it sets this field according to the CCCR of the card. If the card does not support read wait, this field should never be set to 1; otherwise, DATA line conflicts might occur. If this field is set to 0, stop at block gap during read operation is also supported, but uSDHC stops the SD clock to pause reading operation. 0 - Disables read wait control and stop SD clock at block gap when SABGREQ field is set 1 - Enables read wait control and assert read wait without stopping SD clock at block gap when SABGREQ field is set
17 CREQ	Continue request This field is used to restart a transaction which was stopped using the stop at block gap request. When a suspend operation is not accepted by the card, it is also by setting this field to restart the paused transfer. To cancel stop at the block gap, set stop at block gap request to 0 and set this field to 1 to restart the transfer. The uSDHC module automatically clears this field, therefore it is not necessary for the host driver to set this field to 0. If both stop at block gap request and this field are 1, the continue request is ignored. 0 - No effect 1 - Restart
16 SABGREQ	Stop at block gap request This field is used to stop executing a transaction at the next block gap for both DMA and non-DMA transfers. Until the transfer complete is set to 1, indicating a transfer completion, the host driver leaves this field set to 1. Clearing both the stop at block gap request and continue request does not cause the transaction to restart. Read Wait is used to stop the read transaction at the block gap. The uSDHC module supports the stop at block gap request for write transfers, but for read transfers it requires that the SDIO card support read wait. Therefore, the host driver does not set this field during read transfers unless the SDIO card supports Read Wait and has set the read wait control to 1; otherwise, uSDHC stops the SD bus clock to pause the read operation during block gap. In the case of write transfers in which the host driver writes data to the Data Port register, the host driver sets this field after all block data is written. If this field is set to 1, the host driver does not write data to the Data Port register after a block is sent. Once this field is set, the host driver does not clear this field before the Transfer Complete field in Interrupt Status register is set, otherwise uSDHC's behavior is undefined. This field effects read transfer active, write transfer active, DATA Line Active and Command Inhibit (DATA) in the Present State register. 0 - Transfer 1 - Stop
15-10	Reserved

Table continues on the next page...

Field	Description
—	
9-8 DMASEL	DMA select This field is valid while DMA (SDMA or ADMA) is enabled and selects the DMA operation. 00 - No DMA or simple DMA is selected. 01 - ADMA1 is selected. 10 - ADMA2 is selected. 11 - Reserved
7 CDSS	Card detect signal selection This field selects the source for the card detection. 0 - Card detection level is selected (for normal purpose). 1 - Card detection test level is selected (for test purpose).
6 CDTL	Card detect test level This field is enabled while the card detection signal selection is set to 1 and it indicates card insertion. 0 - Card detect test level is 0, no card inserted 1 - Card detect test level is 1, card inserted
5-4 EMODE	Endian mode This field supports all three endian modes in data transfer. See Data buffer for more details. 00 - Big endian mode 01 - Half word big endian mode 10 - Little endian mode 11 - Reserved
3 D3CD	DATA3 as card detection pin If this field is set, DATA3 should be pulled down to act as a card detection pin. Be cautious when using this feature, because DATA3 is also a chip-select for the SPI mode. A pull-down on this pin and CMD0 might set the card into the SPI mode, which uSDHC does not support. 0 - DATA3 does not monitor card insertion 1 - DATA3 as card detection pin
2-1 DTW	Data transfer width This field selects the data width of the SD bus for a data transfer. The host driver sets it to match the data width of the card. Possible data transfer width is 1-bit, 4-bits or 8-bits. 00 - 1-bit mode 01 - 4-bit mode 10 - 8-bit mode 11 - Reserved
0 —	Reserved

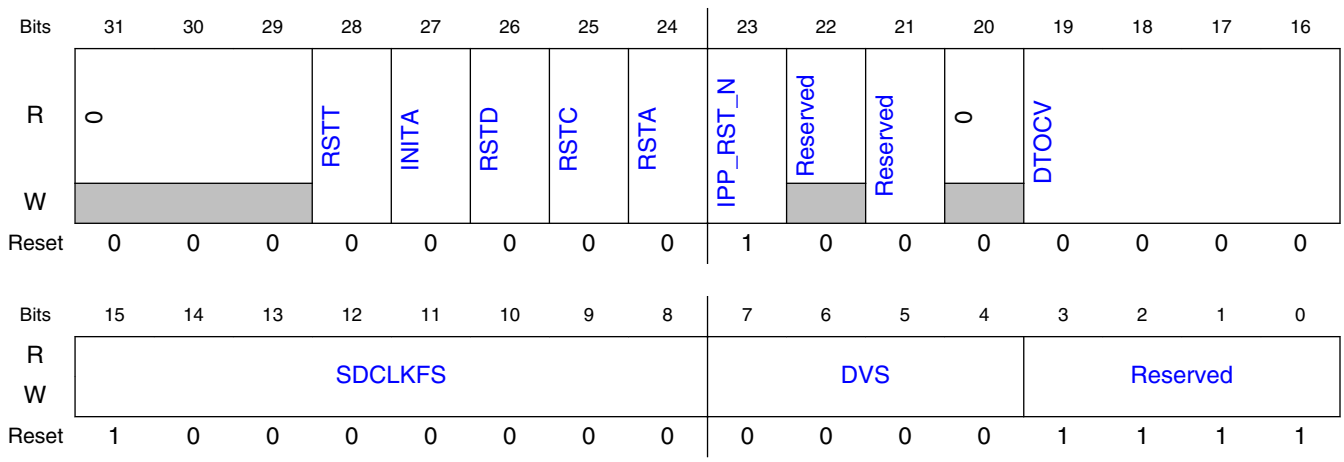
32.7.1.13 System Control (SYS_CTRL)

This register provides control of the system. See detail in the field description.

32.7.1.13.1 Offset

Register	Offset
SYS_CTRL	2Ch

32.7.1.13.2 Diagram



32.7.1.13.3 Fields

Field	Description
31-29 —	Reserved
28 RSTT	Reset tuning When set this field to 1, it resets tuning circuit. After tuning circuits are reset, bit value is 0. Clearing execute_tuning field in AUTOCMD12_ERR_STATUS also sets this field to 1 to reset tuning circuit
27 INITA	Initialization active When this field is set, 80 SD-clocks are sent to the card. After the 80 clocks are sent, this field is self cleared. This field is very useful during the card power-up period when 74 SD-clocks are needed and the clock auto gating feature is enabled. Writing 1 to this bit when this field is already 1 has no effect. Writing 0 to this field at any time has no effect. When either of the CIHB and CDIHB fields in the Present State register are set, writing 1 to this field is ignored (that is, when command line or data lines are active, write to this field is not allowed). On the other-hand, when this field is set, that is, during initialization active period, it is allowed to issue command, and the command bit stream appears on the CMD pad after all 80 clock cycles are done. So, when this command ends, the driver can make sure the 80 clock cycles are sent out. This is very useful when the driver needs to send 80 cycles to the card and does not want to wait till this field is self cleared.

Table continues on the next page...

Field	Description

26
RSTD
	Software reset for data line
	Only part of the data circuit is reset. DMA circuit is also reset. After this field is set, the software waits for self-clear.
	The following registers and bits are cleared by this field:
	• Data Port register
	  • Buffer is cleared and initialized
	• Present State register
	  • Buffer read enable
	  • Buffer write enable
	  • Read transfer active
	  • Write transfer active
	  • DATA line active
	  • Command Inhibit (DATA)
	• Protocol Control register
	  • Continue request
	• Interrupt Status register
	  • Buffer read ready
	  • Buffer write ready
	  • DMA interrupt
	  • Block gap event
	  • Transfer complete
	NOTE: When reset, the software must make sure there is no incomplete data transferring. If there is data transfer going on, the software needs to wait TC or DC INT_STATUS register is set.
	0 - No reset
	1 - Reset

25
RSTC
	Software reset for CMD line
	Only part of the command circuit is reset. After this field is set, the software waits for self-clear.
	The following registers and bits are cleared by this field:
	• Present State Register
	  • Command Inhibit (CMD)
	• Interrupt Status Register
	  • Command Complete
	0 - No reset
	1 - Reset

24 RSTA	Software reset for all This reset affects the entire host controller except for the card detection circuit. RSTA resets all the registers that can be reset by RSTC/RSTD. During its initialization, the host driver is set this field to 1 to reset uSDHC. The uSDHC module resets this field to 0 when the capabilities registers are valid and the host driver can read them. Additional use of Software Reset For All does not affect the value of the capabilities registers. After this field is set, it is recommended that the host driver reset the external card and re-initialize it. After this field is set, the software should wait for self-clear. In tuning process, after every CMD19 is finished, this field is set to retest uSDHC. **NOTE:** When reset, the software must make sure there is no incomplete data transferring. If there is data transfer going on, the software needs to wait TC or DC INT_STATUS register is set. 0 - No reset 1 - Reset
23	Hardware reset

Table continues on the next page...

Field	Description
IPP_RST_N	This field's value is output to card through pad directly to hardware reset pin of the card if the card supports this feature.
22 —	Reserved
21 —	Reserved
20 —	Reserved
19-16 DTOCV	Data timeout counter value This value determines the interval by which DAT line timeouts are detected. See the Data Timeout Error field in the Interrupt Status register for information on factors that dictate time-out generation. Time-out clock frequency is generated by dividing the base clock SDCLK value by this value. The host driver can clear the Data Timeout Error Status Enable (in the Interrupt Status Enable register) to prevent inadvertent time-out events. 0000 - SDCLK x 2^{14} 0001 - SDCLK x 2^{15} 0010 - SDCLK x 2^{16} 0011 - SDCLK x 2^{17} 0100 - SDCLK x 2^{18} 0101 - SDCLK x 2^{19} 0110 - SDCLK x 2^{20} 0111 - SDCLK x 2^{21} 1000 - SDCLK x 2^{22} 1001 - SDCLK x 2^{23} 1010 - SDCLK x 2^{24} 1011 - SDCLK x 2^{25} 1100 - SDCLK x 2^{26} 1101 - SDCLK x 2^{27} 1110 - SDCLK x 2^{28} 1111 - SDCLK x 2^{29}
15-8 SDCLKFS	SDCLK frequency select This field is used to select the frequency of the SDCLK pin. The frequency is not programmed directly, rather this field holds the prescaler (of this register) and divisor (next register) of the Base Clock Frequency register. In Single Data Rate mode (DDR_EN field of MIXERCTRL is '0') Only the following settings are allowed: 80h) Base clock divided by 256 40h) Base clock divided by 128 20h) Base clock divided by 64 10h) Base clock divided by 32 08h) Base clock divided by 16

Table continues on the next page...

Field	Description
	04h) Base clock divided by 8 02h) Base clock divided by 4 01h) Base clock divided by 2 00h) Base clock divided by 1 While in Dual Data Rate mode (DDR_EN field of MIXERCTRL is '1') Only the following settings are allowed: 80h) Base clock divided by 512 40h) Base clock divided by 256 20h) Base clock divided by 128 10h) Base clock divided by 64 08h) Base clock divided by 32 04h) Base clock divided by 16 02h) Base clock divided by 8 01h) Base clock divided by 4 00h) Base clock divided by 2 When the software changes the DDR_EN field, SDCLKFS might need to be changed also. In Single Data Rate mode, setting 00h bypasses the frequency prescaler of the SD clock. Multiple bits must not be set, or the behavior of this prescaler is undefined. The two default divider values can be calculated by the frequency of ipg_perclk and the following Divisor bits. The frequency of SDCLK is set by the following formula: Clock Frequency = (Base Clock) / (prescaler x divisor) For example, in Single Data Rate mode, if the Base Clock Frequency is 96 MHz, and the target frequency is 25 MHz, then choosing the prescaler value of 01h and divisor value of 1h yields 24 MHz, which is the nearest frequency less than or equal to the target. Similarly, to approach a clock value of 400 kHz, the prescaler value of 08h and divisor value of eh yields the exact clock value of 400 kHz. The reset value of this field is 80h, so if the input Base Clock (ipg_perclk) is about 96 MHz, the default SD clock after reset is 375 kHz. Before changing clock divisor value (SDCLKFS or DVS), host driver should make sure the SDSTB field is high. If setting SDCLKFS and DVS can generate the same clock frequency,(for example, in SDR mode, SDCLKFS = 01h is same as DVS = 01h.), SDCLKFS is highly recommended. For HS400 mode, SDCLKFS must be used so that REF_CLK, generated for STROBE DLL, is at the same frequency as STROBE clock. For HS200 and SDR104 mode, if DLL is to be used, make sure SDCLKFS is used so that REF_CLK, generated for PARTS DLL, is at the same frequency as SD_CLK.
7-4 DVS	Divisor This field is used to provide a more exact divisor to generate the desired SD clock frequency. Note the divider can even support odd divisors without deterioration of duty cycle. Before changing clock divisor value (SDCLKFS or DVS), Host driver should make sure the SDSTB field is high. The settings are as follows: 0000 - Divide-by-1

Table continues on the next page...

Field	Description
	0001 - Divide-by-2 1110 - Divide-by-15 1111 - Divide-by-16
3-0 —	Reserved Always write as 1.

32.7.1.14 Interrupt Status (INT_STATUS)

An interrupt is generated when the normal interrupt signal enable is enabled and at least one of the status fields is set to 1. For all fields, writing 1 to a bit clears it; writing to 0 keeps the bit unchanged. More than one status can be cleared with a single register write. For card interrupt, before writing 1 to clear, it is required that the card stops asserting the interrupt, meaning that when the card driver services the interrupt condition; otherwise, the CINT field is asserted again.

The table below shows the relationship between the command timeout error and the command complete.

Table 32-9. uSDHC status for command timeout error/command complete bit combinations

Command CRC Error	Command timeout error	Meaning of the status
0	0	X
X	1	Response not received within 64 SDCLK cycles
1	0	Response received

The table below shows the relationship between the transfer complete and the data timeout error.

Table 32-10. uSDHC status for data timeout error/transfer complete bit combinations

Transfer complete	Data timeout error	Meaning of the status
0	0	X
0	1	Timeout occurred during transfer
1	X	Data transfer complete

The table below shows the relationship between the command CRC error and command timeout error.

Table 32-11. uSDHC status for command CRC error/command timeout error bit combinations

Command complete	Command timeout error	Meaning of the status
0	0	No error
0	1	Response timeout error
1	0	Response CRC error
1	1	CMD line conflict

32.7.1.14.3 Fields

Field	Description
31-29 —	Reserved
28 DMAE	DMA error Occurs when an Internal DMA transfer has failed. This field is set to 1, when some error occurs in the data transfer. This error can be caused by either simple DMA or ADMA, depending on which DMA is in use. The value in DMA System Address register is the next fetch address where the error occurs.

Table continues on the next page...

Field	Description
	Because any error corrupts the whole data block, the host driver restarts the transfer from the corrupted block boundary. The address of the block boundary can be calculated either from the current DS_ADDR value or from the remaining number of blocks and the block size. 0 - No error 1 - Error
27 —	Reserved
26 TNE	Tuning error: (only for SD3.0 SDR104 mode and EMMC HS200 mode) This field is set when an unrecoverable error is detected in a tuning circuit. By detecting Tuning Error, host driver needs to abort a command executing and perform tuning.
25 —	Reserved
24 AC12E	Auto CMD12 error Occurs when detecting that one of the fields in the Auto CMD12 Error Status register has changed from 0 to 1. This field is set to 1, not only when the errors in Auto CMD12 occur, but also, when the Auto CMD12 is not executed due to the previous command error. 0 - No error 1 - Error
23 —	Reserved
22 DEBE	Data end bit error Occurs either when detecting 0 at the end field position of read data that uses the DATA line, or at the end field position of the CRC. This field is not asserted in tuning process. 0 - No error 1 - Error
21 DCE	Data CRC error Occurs when detecting a CRC error when transferring read data that uses the DATA line, or when detecting the Write CRC status having a value other than 010. This field is not asserted in tuning process. 0 - No error 1 - Error
20 DTOE	Data timeout error Occurs when detecting one of following time-out conditions. • Busy time-out for R1b, R5b type • Busy time-out after Write CRC status • Read Data time-out. This field is not asserted in tuning process. 0 - No error 1 - Time out
19 CIE	Command index error Occurs if a command index error occurs in the command response.

Table continues on the next page...

Field	Description
	This field is not asserted in tuning process. 0 - No error 1 - Error
18 CEBE	Command end bit error Occurs when detecting that the end field of a command response is 0. This field is not asserted in tuning process. 0 - No error 1 - End bit error generated
17 CCE	Command CRC error Command CRC Error is generated in two cases. • If a response is returned and the Command Timeout Error is set to 0 (indicating no time-out), this field is set when detecting a CRC error in the command response. • The uSDHC module detects a CMD line conflict by monitoring the CMD line when a command is issued. If uSDHC drives the CMD line to 1, but detects 0 on the CMD line at the next SDCLK edge, then uSDHC aborts the command (Stop driving CMD line) and set this bit to 1. The Command Timeout Error should also be set to 1 to distinguish CMD line conflict. This field is not asserted in tuning process. 0 - No error 1 - CRC error generated
16 CTOE	Command timeout error Occurs only if no response is returned within 64 SDCLK cycles from the end field of the command. If uSDHC detects a CMD line conflict, in which case a Command CRC Error is also be set (as shown in Interrupt Status (INT_STATUS)), this field is set without waiting for 64 SDCLK cycles. This is because the command is aborted by uSDHC. This field is not asserted in tuning process. 0 - No error 1 - Time out
15 —	Reserved
14 TP	Tuning pass:(only for SD3.0 SDR104 mode and EMMC HS200 mode) Current CMD19 transfer is done successfully. That is, current sampling point is correct.
13 —	Reserved
12 RTE	Re-tuning event: (only for SD3.0 SDR104 mode and EMMC HS200 mode) This status is set if Re-Tuning Request in the Present State register changes from 0 to 1. host controller requests host driver to perform re-tuning for next data transfer. Current data transfer (not large block count) can be completed without re-tuning. 0 - Re-tuning is not required. 1 - Re-tuning should be performed.
11-9 —	Reserved
8	Card interrupt

Table continues on the next page...

Field	Description
CINT	This status field is set when an interrupt signal is detected from the external card. In 1-bit mode, uSDHC detects the Card Interrupt without the SD clock to support wakeup. In 4-bit mode, the card interrupt signal is sampled during the interrupt cycle, so the interrupt from card can only be sampled during interrupt cycle, introducing some delay between the interrupt signal from the SDIO card and the interrupt to the host system. Writing this field to 1 can clear this field, but as the interrupt source from the SDIO card does not clear, this field is set again. to clear this field, it is required to reset the interrupt source from the external card followed by a writing 1 to this field. When this status has been set, and the host driver needs to service this interrupt, the Card Interrupt Signal Enable in the Interrupt Signal Enable register should be 0 to stop driving the interrupt signal to the host system. After completion of the card interrupt service (It should reset the interrupt sources in the SDIO card and the interrupt signal might not be asserted), write 1 to clear this field, set the Card Interrupt Signal Enable to 1, and start sampling the interrupt signal again. 0 - No card interrupt 1 - Generate card interrupt
7 CRM	Card removal This status field is set if the Card Inserted field in the Present State register changes from 1 to 0. When the host driver writes this field to 1 to clear this status, the status of the Card Inserted in the Present State register should be confirmed. Because the card state might possibly be changed when the host driver clears this field and the interrupt event might not be generated. When this field is cleared, it is set again if no card is inserted. to leave it cleared, clear the Card Removal Status Enable field in Interrupt Status Enable register. 0 - Card state unstable or inserted 1 - Card removed
6 CINS	Card insertion This status field is set if the Card Inserted field in the Present State register changes from 0 to 1. When the host driver writes this field to 1 to clear this status, the status of the Card Inserted in the Present State register should be confirmed. Because the card state might possibly be changed when the host driver clears this field and the interrupt event might not be generated. When this field is cleared, it is set again if a card is inserted. to leave it cleared, clear the Card Inserted Status Enable field in Interrupt Status Enable register. 0 - Card state unstable or removed 1 - Card inserted
5 BRR	Buffer read ready This status field is set if the Buffer Read Enable field, in the Present State register, changes from 0 to 1. See the Buffer Read Enable field in the Present State register for additional information. This field indicates that cmd19 is finished in tuning process. 0 - Not ready to read buffer 1 - Ready to read buffer
4 BWR	Buffer write ready This status field is set if the Buffer Write Enable field, in the Present State register, changes from 0 to 1. See the Buffer Write Enable field in the Present State register for additional information. 0 - Not ready to write buffer 1 - Ready to write buffer
3 DINT	DMA interrupt Occurs only when the internal DMA finishes the data transfer successfully. Whenever errors occur during data transfer, this field does not be set. Instead, the DMAE field is set. Either Simple DMA or ADMA finishes data transferring, this field is set.

Table continues on the next page...

Field	Description
	0 - No DMA interrupt 1 - DMA interrupt is generated.
2 BGE	Block gap event If the Stop At Block Gap Request field in the Protocol Control register is set, this field is set when a read or write transaction is stopped at a block gap. If Stop At Block Gap Request is not set to 1, this field is not set to 1. In the case of a Read Transaction: This field is set at the falling edge of the DATA Line Active Status (When the transaction is stopped at SD bus timing). The Read Wait must be supported to use this function. In the case of Write Transaction: This field is set at the falling edge of Write Transfer Active Status (After getting CRC status at SD Bus timing). 0 - No block gap event 1 - Transaction stopped at block gap
1 TC	Transfer complete This field is set when a read or write transfer is completed. In the case of a Read Transaction: This field is set at the falling edge of the Read Transfer Active Status. There are two cases in which this interrupt is generated. The first is when a data transfer is completed as specified by the data length (after the last data has been read to the host system). The second is when data has stopped at the block gap and completed the data transfer by setting the Stop At Block Gap Request field in the Protocol Control register (after valid data has been read to the host system). In the case of a Write Transaction: This field is set at the falling edge of the DATA Line Active Status. There are two cases in which this interrupt is generated. The first is when the last data is written to the SD card as specified by the data length and the busy signal is released. The second is when data transfers are stopped at the block gap, by setting the Stop At Block Gap Request field in the Protocol Control register, and the data transfers are completed. (after valid data is written to the SD card and the busy signal released). In the case of a command with busy, this field is set when busy is deasserted. This field is not asserted in tuning process. 0 - Transfer does not complete 1 - Transfer complete
0 CC	Command complete This field is set when you receive the end field of the command response (except auto CMD12). See the Command Inhibit (CMD) in the Present State register. This field is not asserted in tuning process. 0 - Command not complete 1 - Command complete

32.7.1.15 Interrupt Status Enable (INT_STATUS_EN)

Setting any bit in this register to 1 enables the corresponding interrupt status be requested to the system. If any bit is set to 0, the corresponding interrupt request gets blocked.

- Depending on IABG field setting, uSDHC might be programmed to sample the card interrupt signal during the interrupt period and hold its value in the flip-flop. There are some delays on the Card Interrupt, asserted from the card, to the time the host system is informed.
- To detect a CMD line conflict, the host driver must set both Command Timeout Error Status Enable and Command CRC Error Status Enable to 1.

32.7.1.16 Interrupt Signal Enable (INT_SIGNAL_EN)

This register is used to select which interrupt status is indicated to the host system as the interrupt. These status fields all share the same interrupt lines. Setting any of these fields to 1 enables interrupt generation. The corresponding Status register field generates an interrupt when the corresponding interrupt signal enable field is set.

32.7.1.17 Auto CMD12 Error Status (AUTOCMD12_ERR_STATUS)

When the Auto CMD12 Error Status field in the Status register is set, the host driver checks this register to identify what kind of error the Auto CMD12 / CMD 23 indicated. Auto CMD23 errors are indicated in field 04-01. This register is valid only when the Auto CMD12 Error status field is set.

The table below shows the relationship between the Auto CMGD12 CRC Error and the Auto CMD12 Command Timeout Error.

Table 32-12. Relationship between command CRC error and command timeout error for auto CMD12

Auto CMD12 CRC error	Auto CMD12 timeout error	Type of error
0	0	No error
0	1	Response timeout error
1	0	Response CRC error
1	1	CMD line conflict

Changes in Auto CMD12 Error Status register can be classified in three scenarios:

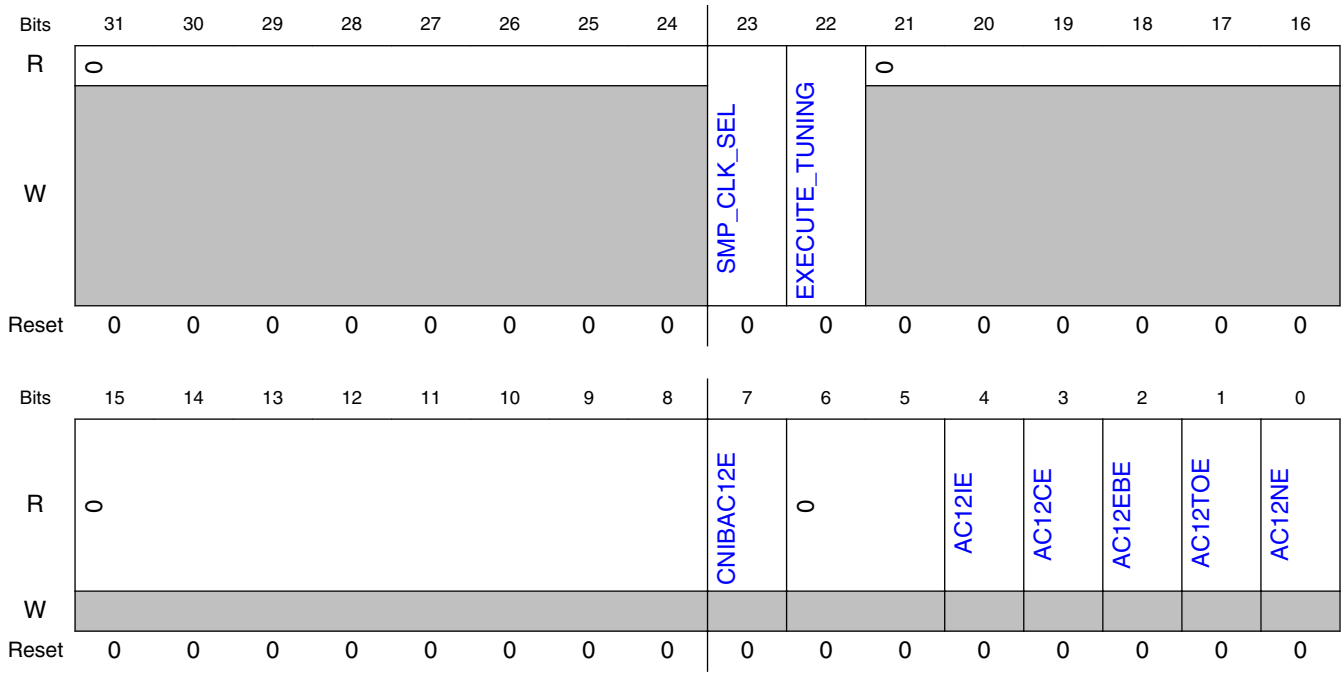
- When uSDHC is going to issue an Auto CMD12
  - Set field 0 to 1 if the Auto CMD12 cannot be issued due to an error in the previous command
  - Set field 0 to 0 if the Auto CMD12 is issued
- At the end field of an Auto CMD12 response
  - Check errors correspond to fields 1-4
  - Set fields 1-4 corresponding to detected errors
  - Clear fields 1-4 corresponding to detected errors
- Before reading the Auto CMD12 Error Status field 7
  - Set field 7 to 1 if there is a command that can't be issued
  - Clear field 7 if there is no command to issue

The timing for generating the Auto CMD12 Error and writing to the Command register are asynchronous. After that, field 7 is sampled when the driver is not writing to the Command register. So, it is suggested to read this register only when the AC12E field in Interrupt Status register is set. An Auto CMD12 Error Interrupt is generated when one of the error fields (0-4) is set to 1. The Command Not Issued By Auto CMD12 Error does not generate an interrupt.

32.7.1.17.1 Offset

Register	Offset
AUTOCMD12_ERR_STATUS	3Ch

32.7.1.17.2 Diagram



32.7.1.17.3 Fields

Field	Description
31-24 —	Reserved
23 SMP_CLK_SEL	Sample clock select This field is used to select sampling clock to receive CMD and DATA. This field is functional only when TUNING_CTRL[STD_TUNING_EN] is set. Otherwise, this field is reserved. This field is controlled by re-tuning procedure and is valid after the tuning procedure is complete (AUTOCMD12_ERR_STATUS[EXECUTE_TUNING]=0). A value of '1' means that tuning has been completed successfully and a value of '0' implies the tuning has failed. Writing '1' to this field is meaningless and ignored when the tuning has failed. The tuning circuit is reset by writing '0' to this field. This field can be cleared by setting AUTOCMD12_ERR_STATUS[EXECUTE_TUNING]=1. Once the tuning circuit is reset, it takes time to complete tuning sequence. Therefore, host driver should keep this field as 1 to perform the re-tuning sequence in a short time. This field cannot be changed while the Host controller is receiving response or a read data block. 0 - Fixed clock is used to sample data 1 - Tuned clock is used to sample data
22 EXECUTE_TUNING	Execute tuning This field is used to start the tuning procedure. This field is functional only when TUNING_CTRL[STD_TUNING_EN] is set. Otherwise, this field is reserved. This field is set to start tuning procedure and automatically cleared when tuning procedure is completed. The result of tuning is indicated to AUTOCMD12_ERR_STATUS[SMP_CLK_SEL]. 0 - Tuning procedure is aborted 1 - Start tuning procedure

Table continues on the next page...

Field	Description
21-8 —	Reserved
7 CNIBAC12E	Command not issued by Auto CMD12 error Setting this field to 1 means CMD_wo_DAT is not executed due to an Auto CMD12 error (D04-D01) in this register. 0 - No error 1 - Not issued
6-5 —	Reserved
4 AC12IE	Auto CMD12 / 23 index error Occurs if the command index error occurs in response to a command. 0 - No error 1 - Error, the CMD index in response is not CMD12/23
3 AC12CE	Auto CMD12 / 23 CRC error Occurs when detecting a CRC error in the command response. 0 - No CRC error 1 - CRC error met in Auto CMD12/23 response
2 AC12EBE	Auto CMD12 / 23 end bit error Occurs when detecting that the end field of command response is 0 which should be 1. 0 - No error 1 - End bit error generated
1 AC12TOE	Auto CMD12 / 23 timeout error Occurs if no response is returned within 64 SDCLK cycles from the end field of the command. If this field is set to1, the other error status fields (2-4) have no meaning. 0 - No error 1 - Time out
0 AC12NE	Auto CMD12 not executed If memory multiple block data transfer is not started, due to a command error, this field is not set because it is not necessary to issue an Auto CMD12. Setting this field to 1 means uSDHC cannot issue the Auto CMD12 to stop a memory multiple block data transfer due to some error. If this field is set to 1, other error status fields (1-4) have no meaning. 0 - Executed 1 - Not executed

32.7.1.18 Host Controller Capabilities (HOST_CTRL_CAP)

This register provides the host driver with information specific to uSDHC implementation. The value in this register is the power-on-reset value and does not change with a software reset.

32.7.1.18.1 Offset

Register	Offset
HOST_CTRL_CAP	40h

32.7.1.19.3 Fields

Field	Description
31-29 —	Reserved
28-24 —	Reserved
23-16 WR_WML	Write watermark level This field indicates the number of words used as the watermark level (FIFO threshold) in a DMA write operation. Also, the number of words as a sequence of write bursts in back-to-back mode. The maximum legal value for the write watermark level is 128.When using internal DMA, WR_WML can be set any value between 1 and 128. To get max AXI throughput, we recommend to use integer multiple of 16.
15-13 —	Reserved
12-8 —	Reserved
7-0 RD_WML	Read watermark level This field indicates the number of words used as the watermark level (FIFO threshold) in a DMA read operation. Also, the number of words as a sequence of read bursts in back-to-back mode. The maximum legal value for the read water mark level is 128.When using internal DMA mode, RD_WML must be set to the value less than 16. To get max AXI throughput, recommend to use 16.

32.7.1.20 Mixer Control (MIX_CTRL)

This register is used to DMA and data transfer. To prevent data loss, the software should check if data transfer is active before writing this register. These fields are DPSEL, MBSEL, DTDSEL, AC12EN, BCEN, and DMAEN.

Table 32-13. Transfer type register setting for various transfer types

Multi/single block select	Block count enable	Block count	Function
0	Do not care	Do not care	Single transfer
1	0	Do not care	Infinite transfer
1	1	Positive number	Multiple transfer
1	1	Zero	No data transfer

Table continues on the next page...

Field	Description
29 —	Reserved Always write as 0.
28 —	Reserved
27 —	Reserved
26 HS400_MODE	Enable HS400 mode HS400 Enable
25 FBCLK_SEL	Feedback clock source selection (Only used for SD3.0, SDR104 mode and EMMC HS200 mode) 0 - Feedback clock comes from the loopback CLK 1 - Feedback clock comes from the ipp_card_clk_out
24 AUTO_TUNE_EN	Auto tuning enable (Only used for SD3.0, SDR104 mode and and EMMC HS200 mode) 0 - Disable auto tuning 1 - Enable auto tuning
23 SMP_CLK_SEL	Clock selection When TUNING_CTRL[STD_TUNING_EN] is 0, this field is used to select Tuned clock or Fixed clock to sample data / cmd (Only used for SD3.0, SDR104 mode and EMMC HS200 mode) 0 - Fixed clock is used to sample data / cmd 1 - Tuned clock is used to sample data / cmd
22 EXE_TUNE	Execute tuning: (Only used for SD3.0, SDR104 mode and EMMC HS200 mode) When TUNING_CTRL[STD_TUNING_EN] is 0, this field is set to 1 to indicate the host driver is starting tuning procedure. Tuning procedure is aborted by writing 0. 0 - Not tuned or tuning completed 1 - Execute tuning
21-8 —	Reserved
7 AC23EN	Auto CMD23 enable When this field is set to 1, the host controller issues a CMD23 automatically before issuing a command specified in the Command Register.
6 NIBBLE_POS	Nibble position indication This field indicates the nibble position in the DDR 4-bit mode. 0- the sequence is 'odd high nibble -> even high nibble -> odd low nibble -> even low nibble'; 1- the sequence is 'odd high nibble -> odd low nibble -> even high nibble -> even low nibble'.
5 MSBSEL	Multi / Single block select This field enables multiple block DATA line data transfers. For any other commands, this field can be set to 0. If this field is 0, it is not necessary to set the Block Count register. See Command Transfer Type (CMD_XFR_TYP). 0 - Single block 1 - Multiple blocks
4 DTDSEL	Data transfer direction select This field defines the direction of DATA line data transfers. The field is set to 1 by the host driver to transfer data from the SD card to uSDHC and is set to 0 for all other commands.

Table continues on the next page...

Field	Description
	If a CMD with the response data size cannot be divided by 64 bytes, is given without a STOP CMD, and is followed by a software reset, then you must write a 0 to DTDSEL before inserting a software reset. This is necessary to avoid any issue during the SD card reinitialization. Read multiple blocks will not be affected as it is required to have a STOP CMD. 0 - Write (Host to card) 1 - Read (Card to host)
3 DDR_EN	Dual data rate mode selection
2 AC12EN	Auto CMD12 enable Multiple block transfers for memory require a CMD12 to stop the transaction. When this field is set to 1, uSDHC issues a CMD12 automatically when the last block transfer has completed. The host driver is not set this field to issue commands that do not require CMD12 to stop a multiple block data transfer. In particular, secure commands defined in File Security Specification (see reference list) do not require CMD12. In single block transfer, uSDHC ignores this field no matter it is set or not. 0 - Disable 1 - Enable
1 BCEN	Block count enable This field is used to enable the Block Count register, which is only relevant for multiple block transfers. When this field is 0, the internal counter for block is disabled, which is useful in executing an infinite transfer. 0 - Disable 1 - Enable
0 DMAEN	DMA enable This field enables DMA functionality. If this field is set to 1, a DMA operation begins when the host driver sets the DPSEL field of this register. Whether the simple DMA or the advanced DMA is active depends on the DMA Select field of the Protocol Control register. 0 - Disable 1 - Enable

32.7.1.21 Force Event (FORCE_EVENT)

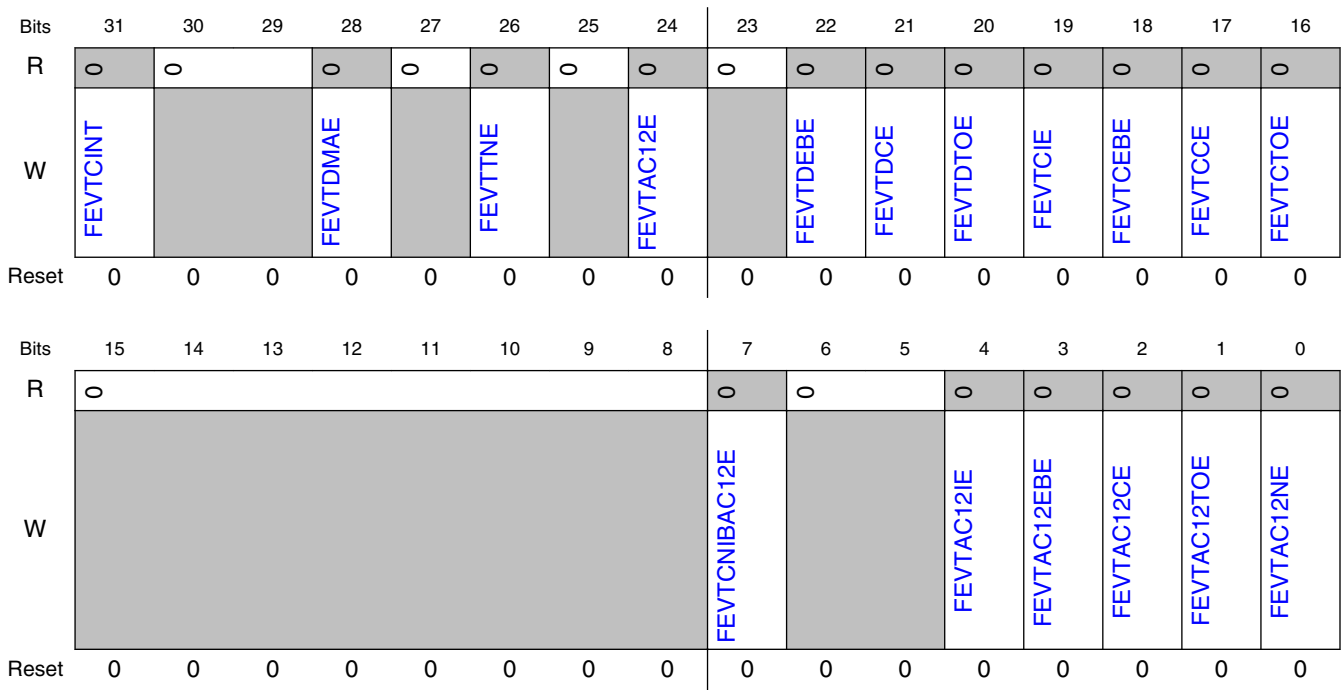
This register is not a physically implemented register. Rather, it is an address at which the Interrupt Status register can be written if the corresponding field of the Interrupt Status Enable Register is set. This register is a write only register and writing 0 to it has no effect. Writing 1 to this register sets the corresponding field of Interrupt Status register. A read from this register always results in 0's. to change the corresponding status fields in the Interrupt Status register, make sure to set IPGEN field in System Control Register so that peripheral clock is always active.

Forcing a card interrupt generates a short pulse on the DATA1 line, and the driver might treat this interrupt as a normal interrupt. The interrupt service routine might skip polling the card interrupt factor as the interrupt is self cleared.

32.7.1.21.1 Offset

Register	Offset
FORCE_EVENT	50h

32.7.1.21.2 Diagram



32.7.1.21.3 Fields

Field	Description
31 FEVTCINT	Force event card interrupt Writing 1 to this field generates a short low-level pulse on the internal DATA1 line, as if a self-clearing interrupt was received from the external card. If enabled, the CINT field is set and the interrupt service routine might treat this interrupt as a normal interrupt from the external card.
30-29 —	Reserved

0 FEVTAC12NE	Force event auto command 12 not executed Forces the AC12NE field in the Auto Command12 Error Status register to be set

32.7.1.22 ADMA Error Status (ADMA_ERR_STATUS)

When an ADMA Error Interrupt has occurred, the ADMA error sates field in this register holds the ADMA state and the ADMA System Address register holds the address around the error descriptor.

For recovering from this error, the host driver requires the ADMA state to identify the error descriptor address as follows:

- ST_STOP: Previous location set in the ADMA System Address register is the error descriptor address.
- ST_FDS: Current location set in the ADMA System Address register is the error descriptor address.
- ST_CADR: This state is never set because it only increments the descriptor pointer and does not generate an ADMA error.
- ST_TFR: Previous location set in the ADMA System Address register is the error descriptor address.

In case of a write operation, the host driver should use the ACMD22 to get the number of the written block, rather than using this information, because unwritten data might exist in the host controller.

The host controller generates the ADMA Error Interrupt when it detects invalid descriptor data (Valid=0) in the ST_FDS state. The host driver can distinguish this error by reading the Valid field of the error descriptor.

Table 32-14. ADMA error state coding

D01-D00	ADMA error state (when error has occurred)	Contents of ADMA System Address register
00	ST_STOP (Stop DMA)	Holds the address of the next executable descriptor command
01	ST_FDS (Fetch descriptor)	Holds the valid descriptor address
10	ST_CADR (Change address)	No ADMA error is generated
11	ST_TFR (Transfer data)	Holds the address of the next executable descriptor command

32.7.1.22.1 Offset

Register	Offset
ADMA_ERR_STATUS	54h

32.7.1.22.3 Fields

Field	Description
31-4 —	Reserved
3 ADMADCE	ADMA descriptor error This error occurs when invalid descriptor fetched by ADMA. 0 - No error 1 - Error
2 ADMALME	ADMA length mismatch error This error occurs in the following two cases: • While the block count enable is being set, the total data length specified by the descriptor table is different from that specified by the block count and block length. • Total data length cannot be divided by the block length. 0 - No error 1 - Error
1-0 ADMAES	ADMA error state (when ADMA error is occurred) This field indicates the state of the ADMA when an error has occurred during an ADMA data transfer. See ADMA Error Status (ADMA_ERR_STATUS) for more details.

32.7.1.23 ADMA System Address (ADMA_SYS_ADDR)

This register holds the word address of the executing command in the Descriptor table. At the start of ADMA, the host driver sets the start address of the Descriptor table. The ADMA engine increments this register address whenever fetching a Descriptor command. When the ADMA is stopped at the Block Gap, this register indicates the address of the next executable Descriptor command. When the ADMA Error Interrupt is generated, this register holds the valid Descriptor address depending on the ADMA state. The lower 2 bits of this register is tied to '0' so the ADMA address is always word aligned.

Because this register supports dynamic address reflecting, when TC field is set, it automatically alters the value of internal address counter, so the software cannot change this register when TC field is set. Such restriction is also listed in Software restrictions.

32.7.1.23.3 Fields

Field	Description
31-2	ADMA system address

Table continues on the next page...

Field	Description
ADS_ADDR	This field contains the physical system memory address used for ADMA transfers.
1-0 —	Reserved

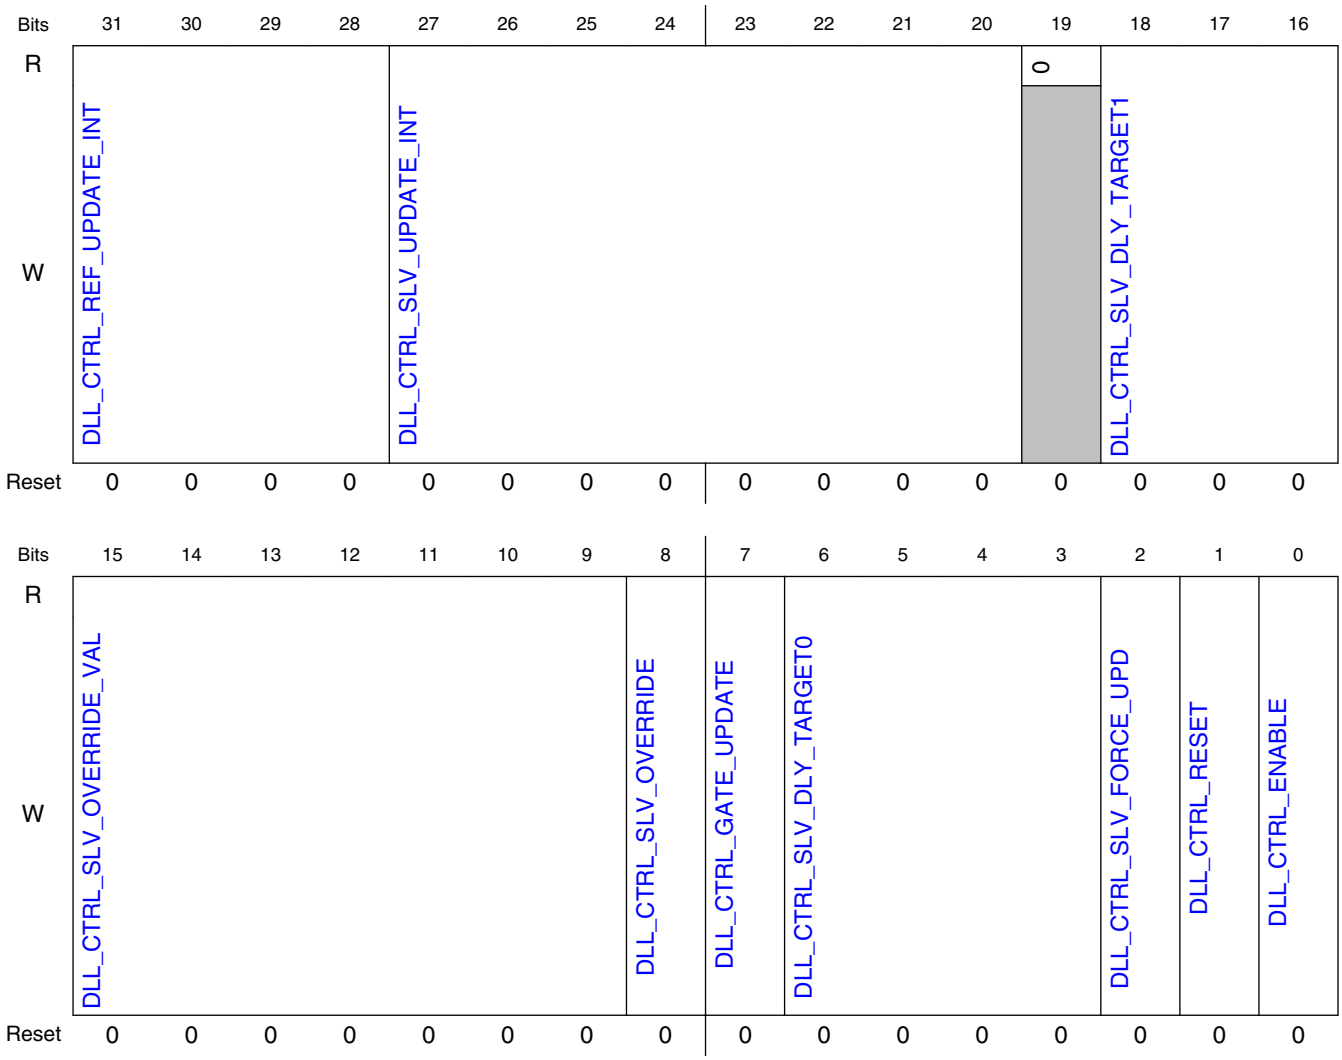
32.7.1.24 DLL (Delay Line) Control (DLL_CTRL)

This register contains control fields for DLL.

32.7.1.24.1 Offset

Register	Offset
DLL_CTRL	60h

32.7.1.24.2 Diagram



32.7.1.24.3 Fields

Field	Description
31-28 DLL_CTRL_REF_UPDATE_INT	DLL control loop update interval The interval cycle is (2 + REF_UPDATE_INT) * REF_CLOCK. By default, the DLL control loop updates every two REF_CLOCK cycles. It should be noted that increasing the reference delay-line update interval reduces the ability of the DLL to adjust to fast changes in conditions that might effect the delay (such as voltage and temperature)
27-20 DLL_CTRL_SLV_UPDATE_INT	Slave delay line update interval If default 0 is used, it means 256 cycles of REF_CLOCK. A value of 0x0f results in 15 cycles and so on. Note that software can always cause an update of the slave-delay line using the SLV_FORCE_UPDATE register. Note that the slave delay line also updates automatically when the reference DLL transitions to a locked state (from an un-locked state).
19	Reserved

Table continues on the next page...

Field	Description
—	
18-16 DLL_CTRL_SLV_DLY_TARGET1	DLL slave delay target1 See DLL_CTRL_SLV_DLY_TARGET0 below.
15-9 DLL_CTRL_SLV_OVERRIDE_VAL	DLL slave override val When SLV_OVERRIDE = 1, this field is used to select 1 of 128 physical taps manually. A value of 0 selects tap 1, and a value of 0x7f selects tap 128.
8 DLL_CTRL_SLV_OVERRIDE	DLL slave override Set this field to 1 to Enable manual override for slave delay chain using SLV_OVERRIDE_VAL; to set 0 to disable manual override. This feature does not require the DLL to be enabled using the ENABLE field. In fact to reduce power, if SLV_OVERRIDE is used, it is recommended to disable the DLL with ENABLE = 0
7 DLL_CTRL_GATE_UPDATE	DLL gate update Set this field to 1 to prevent the DLL from updating (because when clock_in exists, glitches might appear during DLL updates). This field might be used by software if such a condition occurs. Clear the bit to 0 to allow the DLL to update automatically.
6-3 DLL_CTRL_SLV_DLY_TARGET0	DLL slave delay target0 The delay target for uSDHC loopback read clock can be programmed in 1/16th increments of an ref_clock half-period. The delay is (({DLL_CTRL_SLV_DLY_TARGET1,DLL_CTRL_SLV_DLY_TARGET0} +1)* REF_CLOCK / 2) / 16 So the input read-clock can be delayed relative input data from (REF_CLOCK / 2) / 16 to REF_CLOCK * 4. **NOTE:** For the restrictions of delay cell implementation, the delay target must be set between REF_CLOCK/16 and REF_CLOCK*2 when REF_CLOCK is running at 200 MHz. When REF_CLOCK frequency is slower than 100 MHz, the maximum delay target might not reach REF_CLOCK*2.
2 DLL_CTRL_SLV_FORCE_UPD	DLL slave delay line Setting this field to 1, forces the slave delay line to update to the DLL calibrated value immediately. The slave delay line updates automatically based on the SLV_UPDATE_INT interval or when a DLL lock condition is sensed. Subsequent forcing of the slave-line update can only occur if SLV_FORCE_UP is set back to 0 and then asserted again (edge triggered). Be sure to use it when uSDHC is idle. This function might not work when uSDHC is working on data / cmd / response.
1 DLL_CTRL_RESET	DLL reset Setting this field to 1 force a reset on DLL. This causes the DLL to lose lock and re-calibrate to detect an REF_CLOCK half period phase shift. This signal is used by the DLL as edge-sensitive, so to create a subsequent reset, RESET must be taken low and then asserted again.
0 DLL_CTRL_ENABLE	DLL and delay chain Set this field to 1 to enable the DLL and delay chain; otherwise; set to 0 to bypasses DLL. Note that using the slave delay line override feature with SLV_OVERRIDE and SLV_OVERRIDE VAL, the DLL does not need to be enabled.

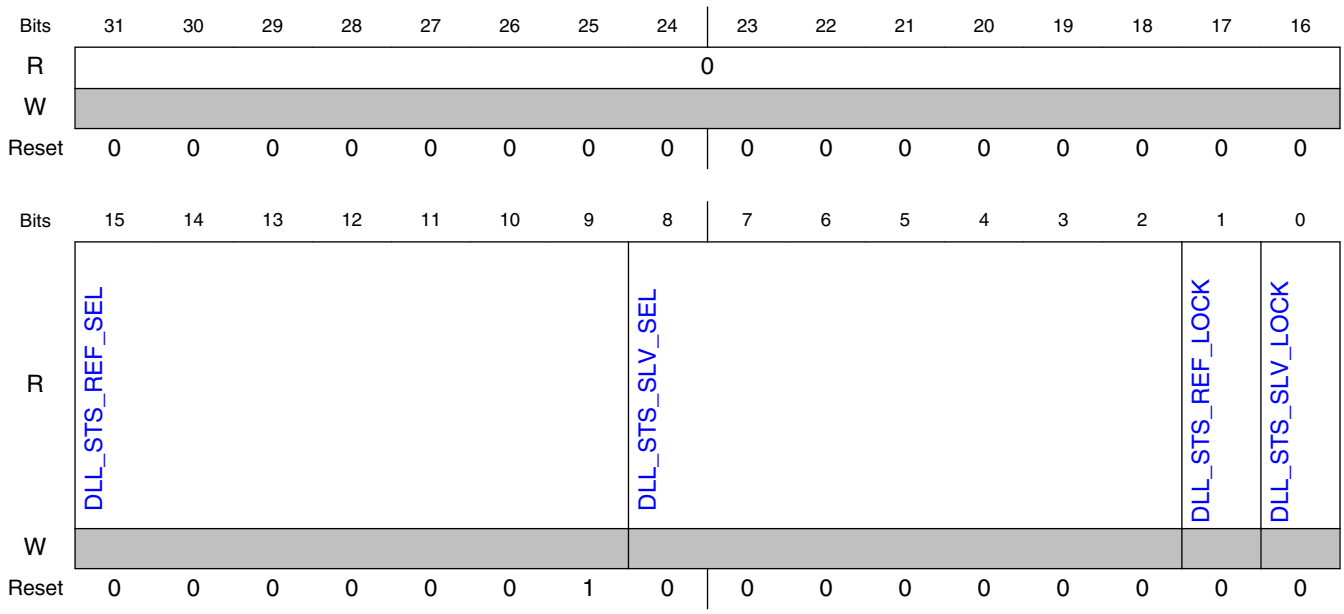
32.7.1.25 DLL Status (DLL_STATUS)

This register contains the DLL status information. All fields are read only and reads the same as the power-reset value.

32.7.1.25.1 Offset

Register	Offset
DLL_STATUS	64h

32.7.1.25.2 Diagram



32.7.1.25.3 Fields

Field	Description
31-16 —	Reserved
15-9 DLL_STS_REF_SEL	Reference delay line select taps This is encoded by 7 fields for 127 taps.
8-2 DLL_STS_SLV_SEL	Slave delay line select status This is the instant value generated from reference chain. Because the reference chain can only be updated when REF_CLOCK is detected, this value should be the right value to be updated when the reference is locked.
1	Reference DLL lock status

Table continues on the next page...

Field	Description
DLL_STS_REF_LOCK	This signifies that the DLL has detected and locked to a half-phase ref_clock shift, allowing the slave delay-line to perform programmed clock delays
0	Slave delay-line lock status
DLL_STS_SLV_LOCK	This signifies that a valid calibration has been set to the slave-delay line and that the slave-delay line is implementing the programmed delay value

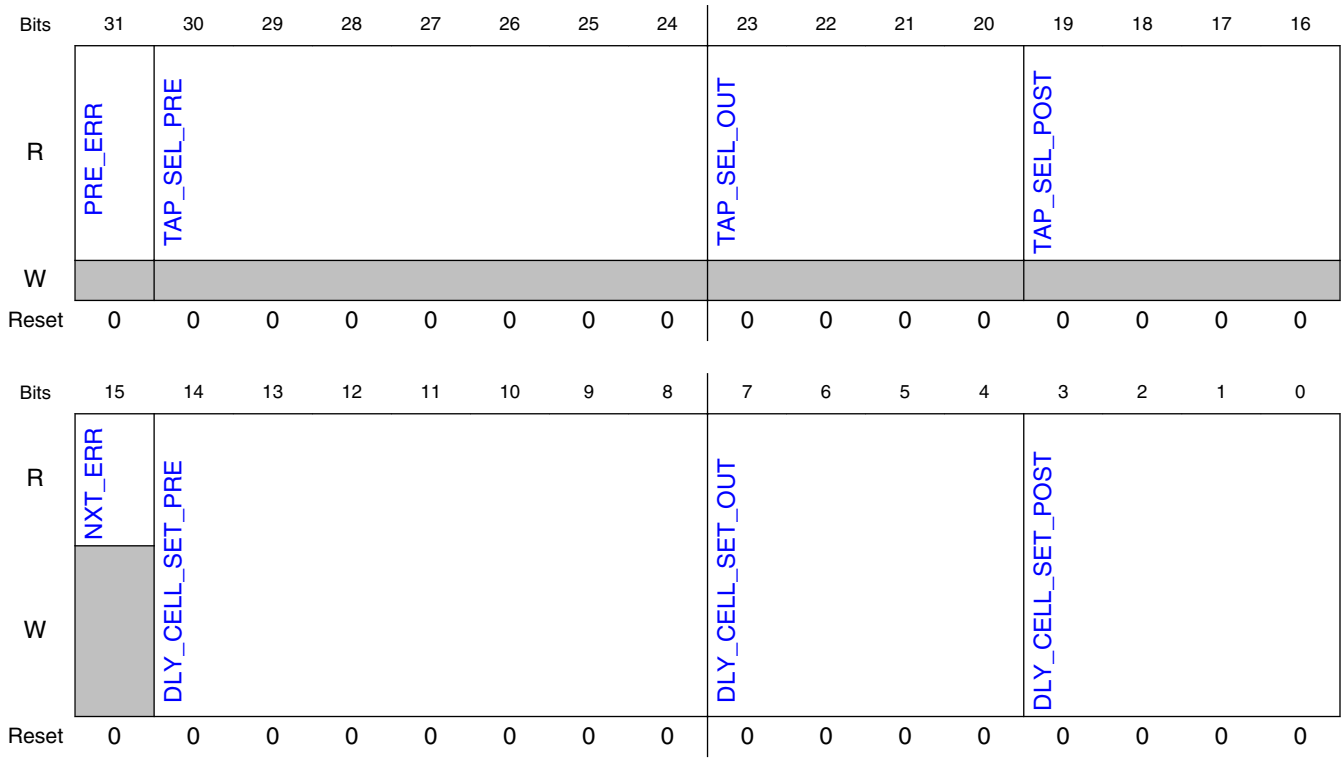
32.7.1.26 CLK Tuning Control and Status (CLK_TUNE_CTRL_STATUS)

This register contains the Clock Tuning Control status information. All fields are read only and reads the same as the power-reset value. This register is added to support SD3.0 UHS-I SDR104 mode and EMMC HS200 mode.

32.7.1.26.1 Offset

Register	Offset
CLK_TUNE_CTRL_STATUS	68h

32.7.1.26.2 Diagram



32.7.1.26.3 Fields

Field	Description
31 PRE_ERR	PRE error PRE error which means the number of delay cells added on the feedback clock is too small. It is valid only when SMP_CLK_SEL of Mix control register (bit23 of 0x48) is enabled.
30-24 TAP_SEL_PRE	TAP_SEL_PRE Reflects the number of delay cells added on the feedback clock between the feedback clock and CLK_PRE. When AUTO_TUNE_EN (bit24 of 0x48) is disabled, TAP_SEL_PRE is always equal to DLY_CELL_SET_PRE. When AUTO_TUNE_EN (bit24 of 0x48) is enabled, TAP_SEL_PRE is updated automatically according to the status of the auto tuning circuit to adjust the sample clock phase.
23-20 TAP_SEL_OUT	Delay cells added on the feedback clock between CLK_PRE and CLK_OUT Reflects the number of delay cells added on the feedback clock between CLK_PRE and CLK_OUT.
19-16 TAP_SEL_POST	Delay cells added on the feedback clock between CLK_OUT and CLK_POST Reflects the number of delay cells added on the feedback clock between CLK_OUT and CLK_POST.
15 NXT_ERR	NXT error NXT error which means the number of delay cells added on the feedback clock is too large. It's valid only when SMP_CLK_SEL of Mix control register (bit23 of 0x48) is enabled.

Table continues on the next page...

Field	Description
14-8 DLY_CELL_SET_PRE	delay cells on the feedback clock between the feedback clock and CLK_PRE Set the number of delay cells on the feedback clock between the feedback clock and CLK_PRE.
7-4 DLY_CELL_SET_OUT	Delay cells on the feedback clock between CLK_PRE and CLK_OUT Set the number of delay cells on the feedback clock between CLK_PRE and CLK_OUT.
3-0 DLY_CELL_SET_POST	Delay cells on the feedback clock between CLK_OUT and CLK_POST Set the number of delay cells on the feedback clock between CLK_OUT and CLK_POST.

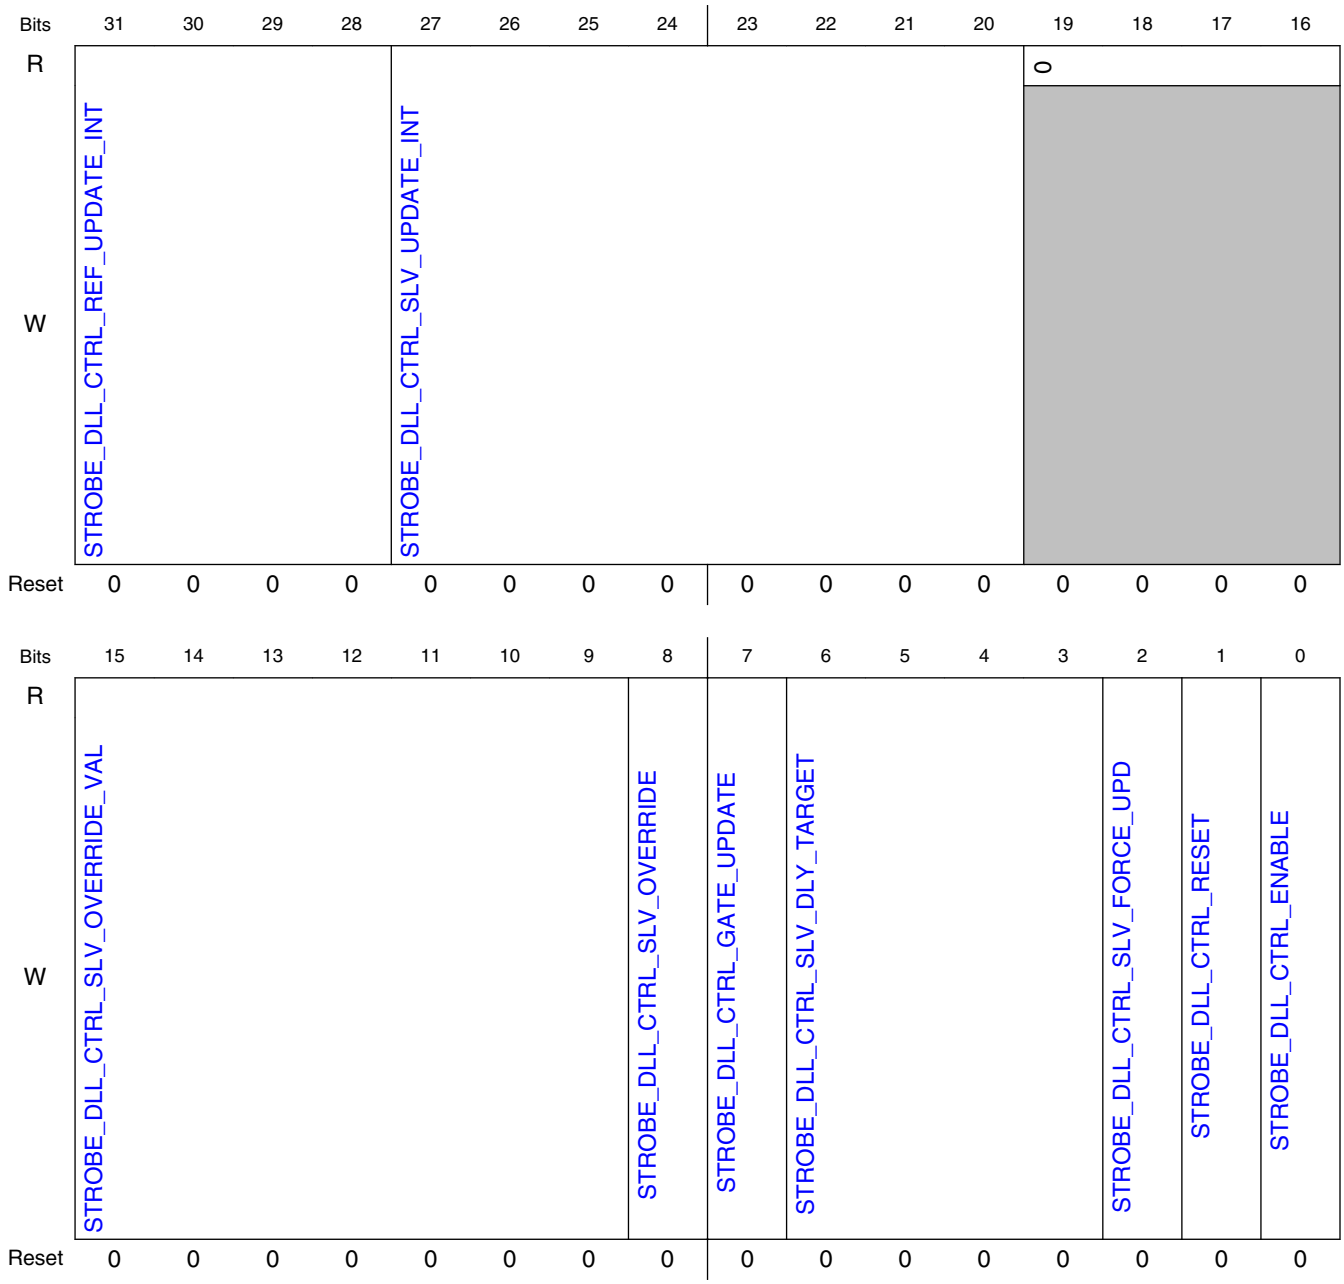
32.7.1.27 Strobe DLL control (STROBE_DLL_CTRL)

This register contains the strobe DLL control information.

32.7.1.27.1 Offset

Register	Offset
STROBE_DLL_CTRL	70h

32.7.1.27.2 Diagram



32.7.1.27.3 Fields

Field	Description
31-28 STROBE_DLL_CTRL_REF_UPDATE_INT	Strobe DLL control reference update interval The interval cycle is (2 + STROBE_REF_UPDATE_INT) * STROBE_REF_CLOCK. By default, the DLL control loop updates every two STROBE_REF_CLOCK cycles.

Table continues on the next page...

Field	Description
	NOTE: Increasing the reference delay-line update interval reduces the ability of the DLL to adjust to fast changes in conditions that might effect the delay (such as voltage and temperature)
27-20 STROBE_DLL_CTRL_SLV_UPDATE_INT	Strobe DLL control slave update interval Slave delay line update interval. If default 0 is used, it means 256 cycles of STROBE_REF_CLOCK. A value of 0x0F results in 15 cycles and so on. **NOTE:** software can always cause an update of the slave-delay line using the STROBE_SLV_FORCE_UPDATE register. The slave delay line also updates automatically when the reference DLL transitions to a locked state (from an un-locked state).
19-16 —	This field is reserved. This read-only field is reserved and always has the value 0.
15-9 STROBE_DLL_CTRL_SLV_OVERRIDE_VAL	Strobe DLL control slave Override value When STROBE_SLV_OVERRIDE = 1, this field is used to manually select one of 128 physical taps. A value of 0 selects tap 1, and a value of 0x7F selects tap 128.
8 STROBE_DLL_CTRL_SLV_OVERRIDE	Strobe DLL control slave override Set this field to 1 to Enable manual override for slave delay chain using STROBE_SLV_OVERRIDE_VAL; set this field to 0 to disable manual override. This feature does not require the DLL to be enabled using the ENABLE field. In fact to reduce power, if STROBE_SLV_OVERRIDE is used, it is recommended to disable the DLL with ENABLE = 0.
7 STROBE_DLL_CTRL_GATE_UPDATE	Strobe DLL control gate update Set this field to 1 to prevent the DLL from updating (because when STROBE_CLOCK_IN exists, glitches might appear during DLL updates). This field can be used by software if such a condition occurs. Clear the field to 0 to allow the DLL to update automatically.
6-3 STROBE_DLL_CTRL_SLV_DLY_TARGET	Strobe DLL Control Slave Delay Target The delay target for uSDHC loopback read clock can be programmed in 1/16th increments of an STROBE_REF_CLOCK half-period. The delay is ((STROBE_DLL_CTRL_SLV_DLY_TARGET + 1) * STROBE_REF_CLOCK / 2) / 16, So the input read-clock can be delayed relative input data from (STROBE_REF_CLOCK / 2) / 16 to (STROBE_REF_CLOCK *4)/16. **NOTE:** For the restrictions of delay cell implementation, the minimum delay target that can be set is REF_CLOCK/16.
2 STROBE_DLL_CTRL_SLV_FORCE_UPD	Strobe DLL control slave force updated Setting this field to 1, forces the slave delay line to update to the DLL calibrated value immediately. The slave delay line should automatically update the STROBE_SLV_UPDATE_INT interval or when a DLL lock condition is sensed. Subsequent forcing of the slave-line update can only occur if STROBE_SLV_FORCE_UP is set back to 0 and then asserted again (edge triggered). Be sure to use it when uSDHC is idle. This function might not work when uSDHC is working on data / cmd / response.
1 STROBE_DLL_CTRL_RESET	Strobe DLL control reset Setting this field to 1 to force a reset on DLL. This causes the DLL to lose lock and re-calibrate to detect an REF_CLOCK half period phase shift. This signal is used by the DLL as edge-sensitive, to create a subsequent reset, RESET must be taken low and then asserted again.
0 STROBE_DLL_CTRL_ENABLE	Strobe DLL control enable Set this field to 1 to enable the DLL and delay chain; otherwise, set to 0 to bypasses DLL. **NOTE:** Using the slave delay line override feature with STROBE_SLV_OVERRIDE and STROBE_SLV_OVERRIDE VAL, the DLL does not need to be enabled.

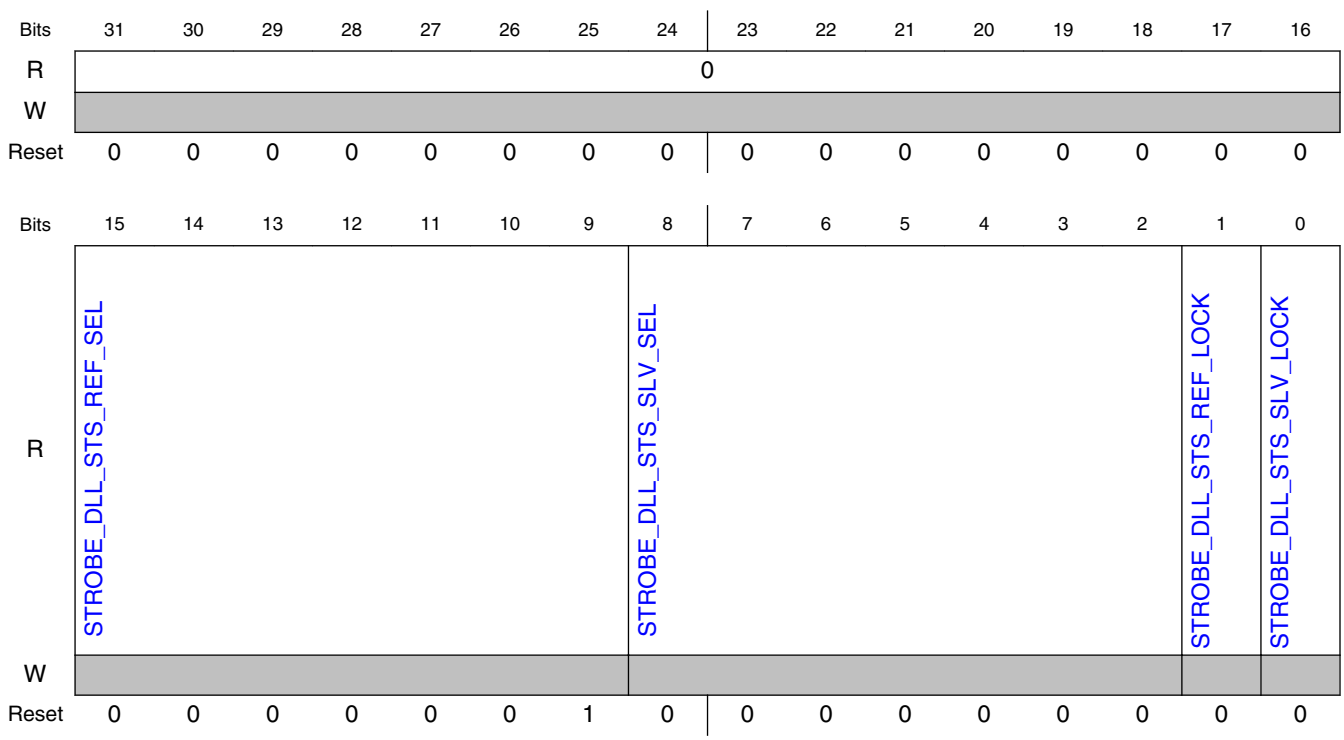
32.7.1.28 Strobe DLL status (STROBE_DLL_STATUS)

This register contains the strobe DLL status information. All fields are read only and read the same as the power-reset value.

32.7.1.28.1 Offset

Register	Offset
STROBE_DLL_STATUS	74h

32.7.1.28.2 Diagram



32.7.1.28.3 Fields

Field	Description
31-16	This field is reserved.
—	This read-only field is reserved and always has the value 0.

Table continues on the next page...

Field	Description
15-9 STROBE_DLL_STS_REF_SEL	Strobe DLL status reference select Reference delay line select taps. This is encoded by 7 fields for 127 taps.
8-2 STROBE_DLL_STS_SLV_SEL	Strobe DLL status slave select Slave delay line select status. This is the instant value generated from reference chain. Because the reference chain can only be updated when STROBE_REF_CLOCK is detected, this value can be updated with the right value when the reference is locked.
1 STROBE_DLL_STS_REF_LOCK	Strobe DLL status reference lock This signifies that the DLL has detected and locked to a half-phase REF_CLOCK shift, it allows the slave delay-line to perform programmed clock delays.
0 STROBE_DLL_STS_SLV_LOCK	Strobe DLL status slave lock Slave delay-line lock status. This signifies that a valid calibration has been set to the slave-delay line, and the slave-delay line is implementing the programmed delay value.

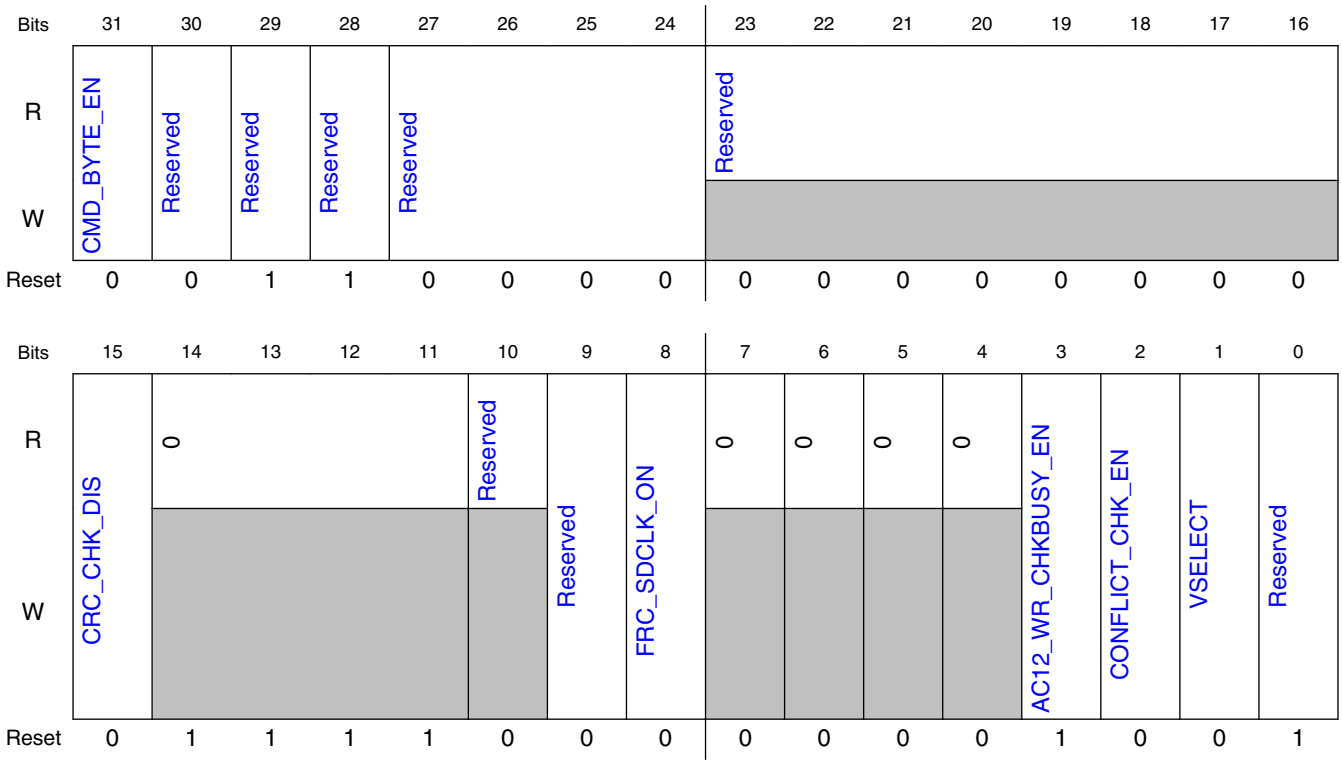
32.7.1.29 Vendor Specific Register (VEND_SPEC)

This register contains the vendor specific control/status register.

32.7.1.29.1 Offset

Register	Offset
VEND_SPEC	C0h

32.7.1.29.2 Diagram



32.7.1.29.3 Fields

Field	Description
31 CMD_BYTE_EN	Byte access This field controls the byte access. 0 - Disable 1 - Enable
30 —	Reserved Always write as 0.
29 —	Reserved Always write as 1
28 —	Reserved Always write as 0.
27-24 —	Reserved Always write as 4'b0000.
23-16 —	Reserved Always write as 8'h00.
15 CRC_CHK_DIS	CRC Check Disable 0 - Check CRC16 for every read data packet and check CRC fields for every write data packet

Table continues on the next page...

Field	Description
	1 - Ignore CRC16 check for every read data packet and ignore CRC fields check for every write data packet
14-11 —	Reserved Reserved
10 —	Reserved Always write as 0.
9 —	Reserved Always write as 0.
8 FRC_SDCLK_ON	Force CLK Force CLK output active Do not set this bit to 1 unless it is necessary. Also, make sure that this bit is cleared when uSDHC's clock is about to be changed (frequency change, clock source change, or delay chain tuning). 0 - CLK active or inactive is fully controlled by the hardware. 1 - Force CLK active
7 —	Reserved
6 —	Reserved
5 —	Reserved
4 —	Reserved
3 AC12_WR_CHKBUSY_EN	Check busy enable Check busy enable after auto CMD12 for write data packet 0 - Do not check busy after auto CMD12 for write data packet 1 - Check busy after auto CMD12 for write data packet
2 CONFLICT_CHK_EN	Conflict check enable It is not implemented in uSDHC IP. 0 - Conflict check disable 1 - Conflict check enable
1 VSELECT	Voltage selection Change the value of output signal VSELECT to control the voltage on pads for external card. There must be a control circuit out of uSDHC to change the voltage on pads. 0 - Change the voltage to high voltage range, around 3.0 V 1 - Change the voltage to low voltage range, around 1.8 V
0 —	Reserved Always write as 0.

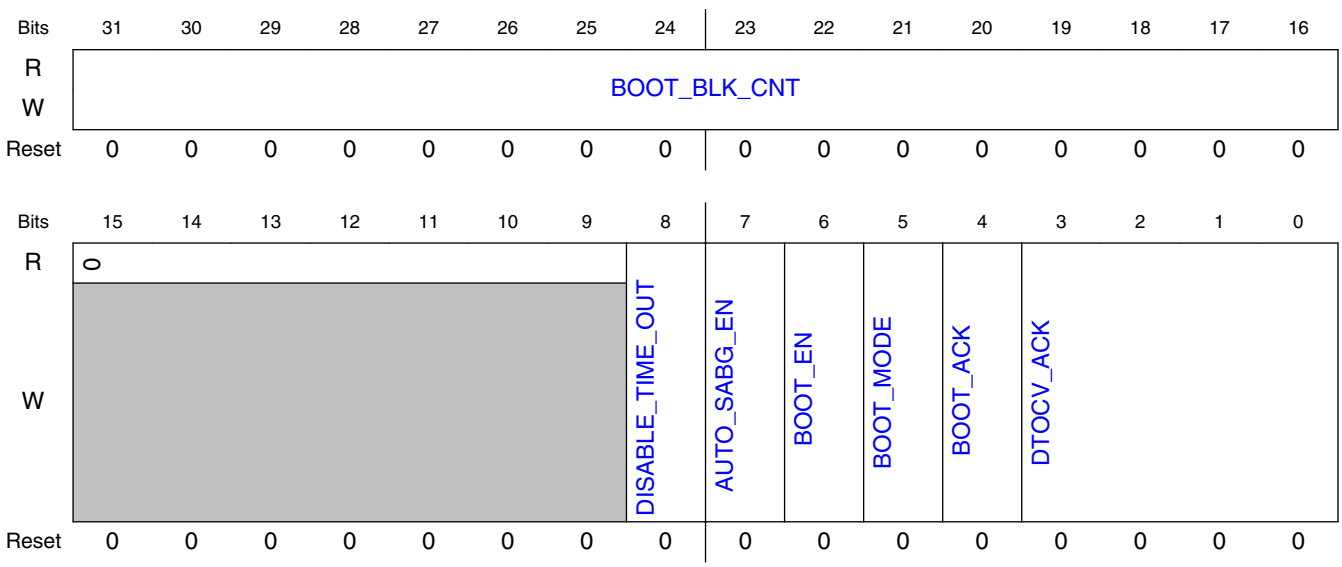
32.7.1.30 MMC Boot (MMC_BOOT)

This register contains the MMC Fast Boot control register.

32.7.1.30.1 Offset

Register	Offset
MMC_BOOT	C4h

32.7.1.30.2 Diagram



32.7.1.30.3 Fields

Field	Description
31-16 BOOT_BLK_CNT	Stop At Block Gap value of automatic mode The value defines the Stop At Block Gap value of automatic mode. When received, card block cnt is equal to (BLK_CNT - BOOT_BLK_CNT) and AUTO_SABG_EN is 1, then Stop At Block Gap. Here, BLK_CNT is defined in the Block Attributes Register, field 31 - 16 of 0x04.
15-9 —	Reserved
8 DISABLE_TIME_OUT	Time out **NOTE:** When this field is set, there is no timeout check no matter whether BOOT_EN is set or not. 0 - Enable time out

Table continues on the next page...

Field	Description
	1 - Disable time out
7 AUTO_SABG_EN	Auto stop at block gap During boot, enable auto stop at block gap function. This function is triggered, and host stops at block gap when received card block cnt is equal to (BLK_CNT - BOOT_BLK_CNT).
6 BOOT_EN	Boot enable Boot mode enable 0 - Fast boot disable 1 - Fast boot enable
5 BOOT_MODE	Boot mode Boot mode select 0 - Normal boot 1 - Alternative boot
4 BOOT_ACK	BOOT ACK Boot ACK mode select 0 - No ack 1 - Ack
3-0 DTOCV_ACK	Boot ACK time out Boot ACK time out counter value. 0000 - SDCLK x 2^14 0001 - SDCLK x 2^15 0010 - SDCLK x 2^16 0011 - SDCLK x 2^17 0100 - SDCLK x 2^18 0101 - SDCLK x 2^19 0110 - SDCLK x 2^20 0111 - SDCLK x 2^21 1110 - SDCLK x 2^28 1111 - SDCLK x 2^29

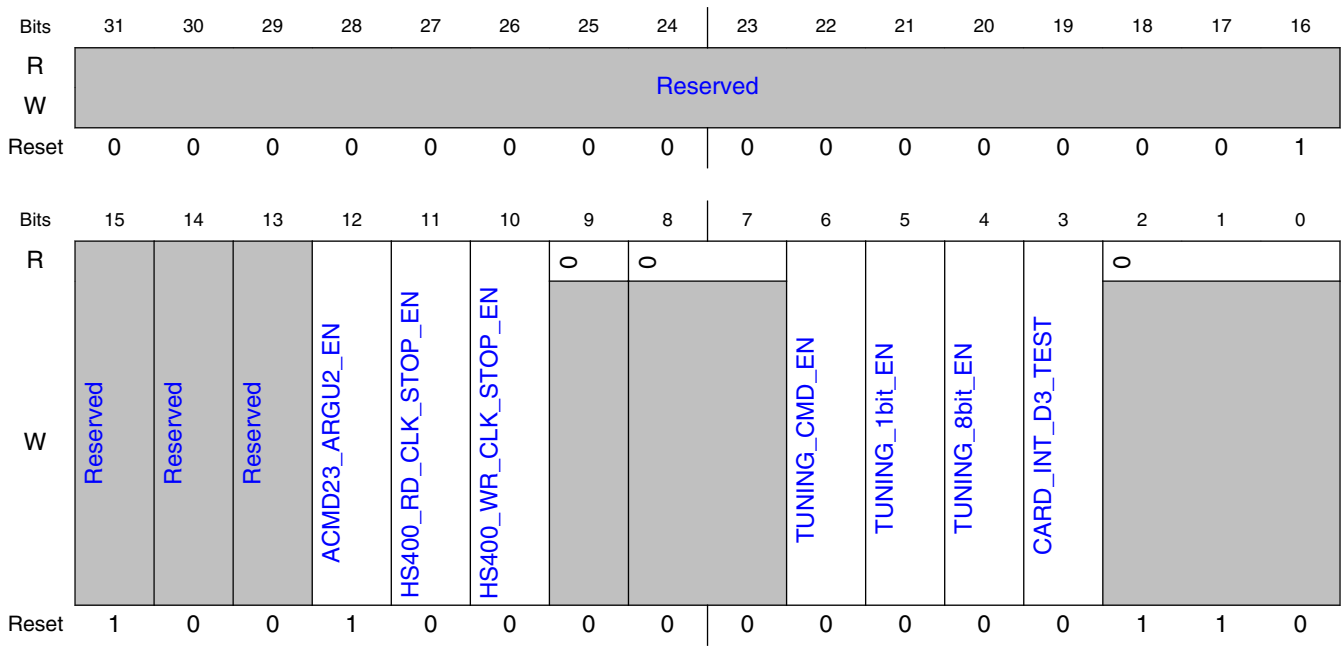
32.7.1.31 Vendor Specific 2 Register (VEND_SPEC2)

This register contains the vendor specific control 2 register.

32.7.1.31.1 Offset

Register	Offset
VEND_SPEC2	C8h

32.7.1.31.2 Diagram



32.7.1.31.3 Fields

Field	Description
31-15 —	Reserved
14 —	Reserved
13 —	Reserved
12 ACMD23_ARGU2_EN	Argument2 register enable for ACMD23 0 - Disable 1 - Argument2 register enable for ACMD23 sharing with SDMA system address register. Default is enabled.
11 HS400_RD_CLK_STOP_EN	HS400 read clock stop enable Only stop clock at read block gap.

Table continues on the next page...

Field	Description
10 HS400_WR_CLK_STOP_EN	HS400 write clock stop enable Only stop clock at write block gap.
9 —	Reserved
8-7 —	Reserved
6 TUNING_CMD_EN	Tuning command enable Enable the auto tuning circuit to check the CMD line. 0 - Auto tuning circuit does not check the CMD line. 1 - Auto tuning circuit checks the CMD line.
5 TUNING_1bit_EN	Tuning 1bit enable Enable the auto tuning circuit to check the DATA0 only. It is used with the TUNING_8bit_EN together.
4 TUNING_8bit_EN	Tuning 8bit enable Enable the auto tuning circuit to check the DATA[7:0]. It is used with the TUNING_1bit_EN together. 0b00 - Tuning circuit only checks the DATA[3:0] 0b01 - Tuning circuit only checks the DATA0 0b10 - Tuning circuit checks the whole DATA[7:0] 0b11 - Invalid **NOTE:** The format of these two fields are [TUNNING_8bit_EN:TUNNING_1bit_EN].
3 CARD_INT_D3_TEST	Card interrupt detection test This field is used only for debugging. 0 - Check the card interrupt only when DATA3 is high. 1 - Check the card interrupt by ignoring the status of DATA3.
2-0 —	Reserved

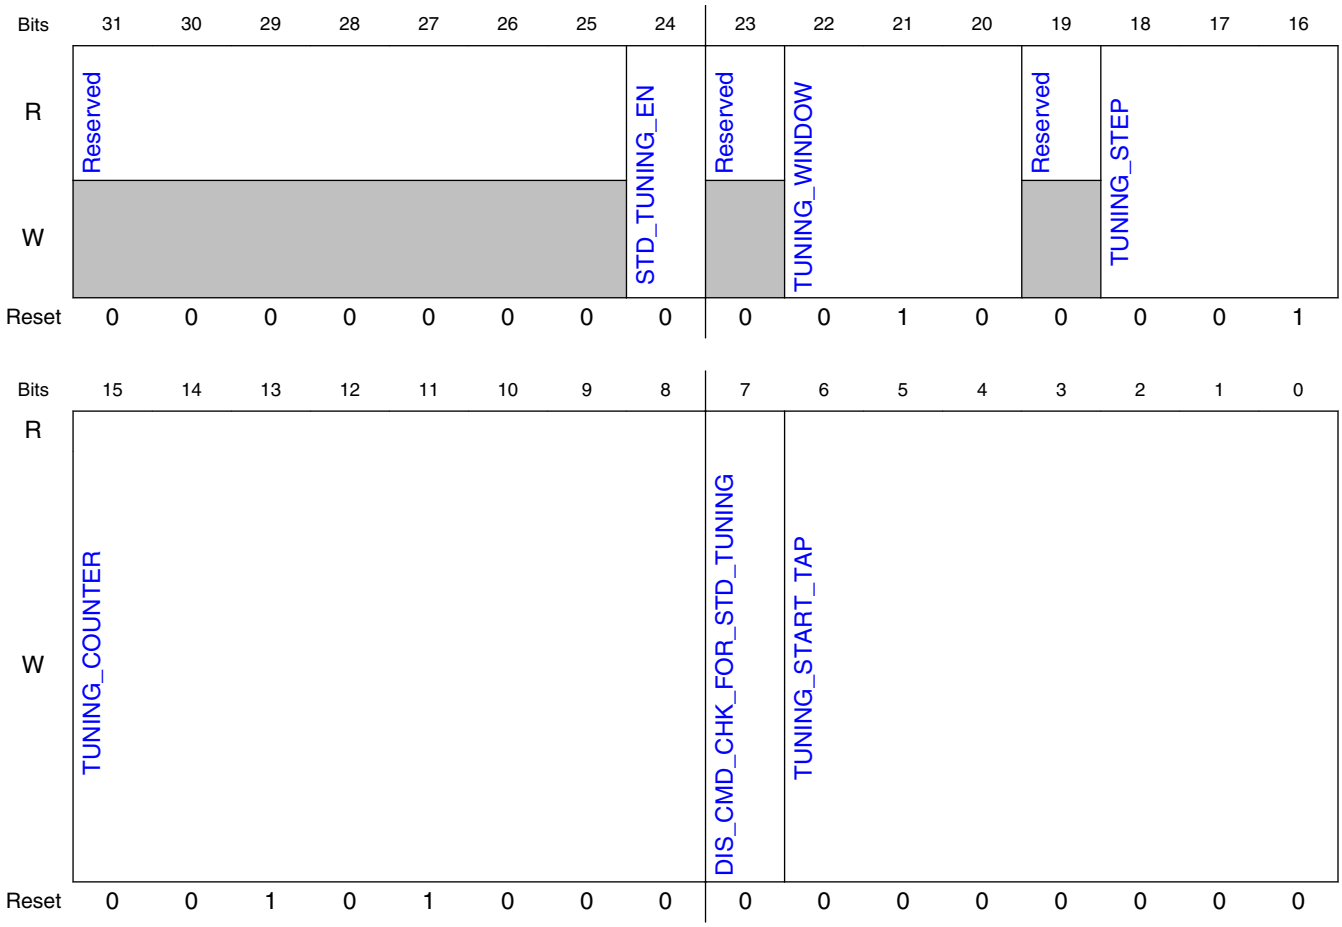
32.7.1.32 Tuning Control (TUNING_CTRL)

The register contains configuration of tuning circuit.

32.7.1.32.1 Offset

Register	Offset
TUNING_CTRL	CCh

32.7.1.32.2 Diagram



32.7.1.32.3 Fields

Field	Description
31-25 —	Reserved
24 STD_TUNING_EN	Standard tuning circuit and procedure enable This field is used to enable standard tuning circuit and procedure.
23 —	Reserved
22-20 TUNING_WINDOW	Data window Select data window value for auto tuning
19 —	Reserved
18-16	TUNING_STEP

Table continues on the next page...

Field	Description
TUNING_STEP	The increasing delay cell steps in tuning procedure.
15-8 TUNING_COUNTER	Tuning counter The MAX repeat CMD19 times in tuning procedure.
7 DIS_CMD_CHK_FOR_STD_TUNING	Disable command check for standard tuning Writing 1 to this field disables command check (command CRC, CMD end bit error, and CMD index error or CMD timeout error) for standard tuning flow after each tuning command is sent.
6-0 TUNING_START_TAP	Tuning start The start delay cell point when send first CMD19 in tuning procedure.

ICACHESIZE	I-cache Size (in k Bytes)	32
DCACHESIZE	D-cache Size (in k Bytes)	32

For the Cross Trigger Interface (CTI) integration in this chip, see the following diagram.

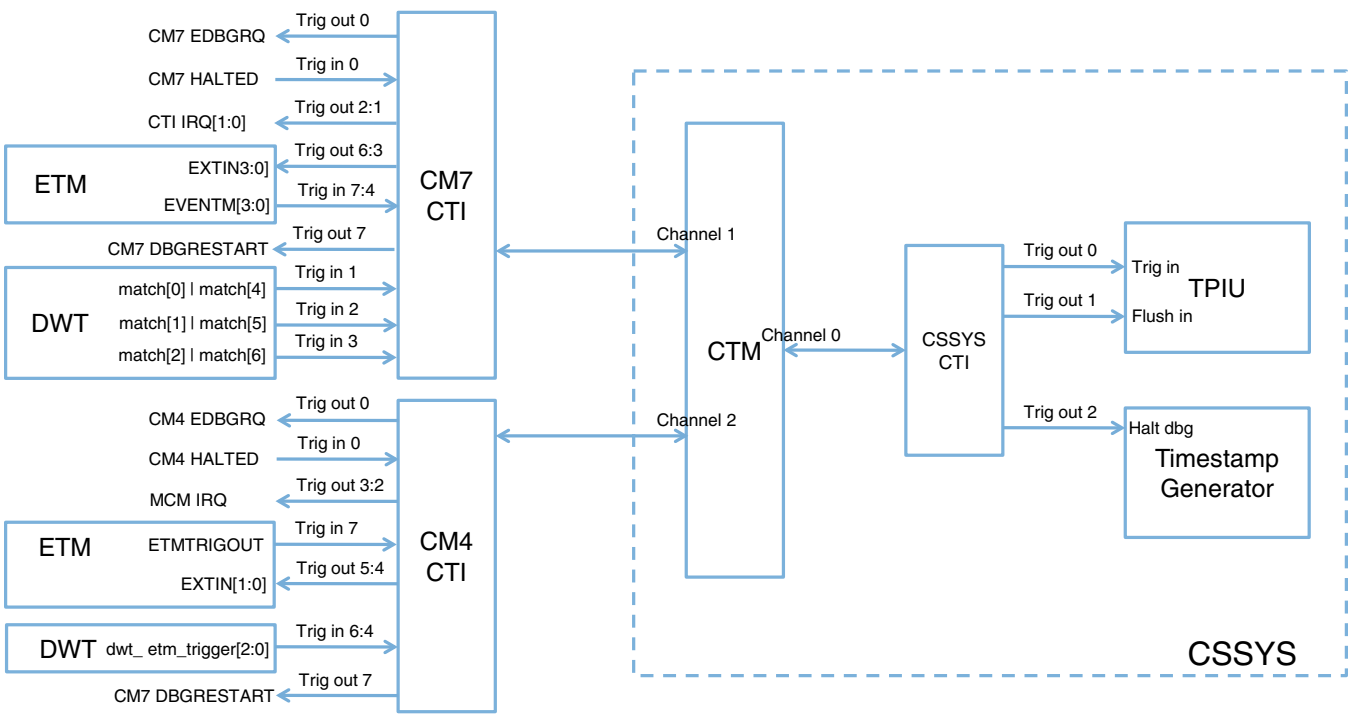

Figure 33-1. CTI inter-connections

33.2 Overview

The Cortex-M7 platform features a single Arm®Cortex®-M7 processor in this chip. The Arm®Cortex®-M7 processor is a highly efficient, high-performance, embedded processor that features low interrupt latency, low-cost debug, and has backwards compatibility with existing Cortex-M profile processors. The processor has an in-order super-scalar pipeline by which many instructions can be dual-issued, including load/load and load/store instruction pairs because of multiple memory interfaces.

33.2.1 Block Diagram

A block diagram for the Cortex-M7 is given below:

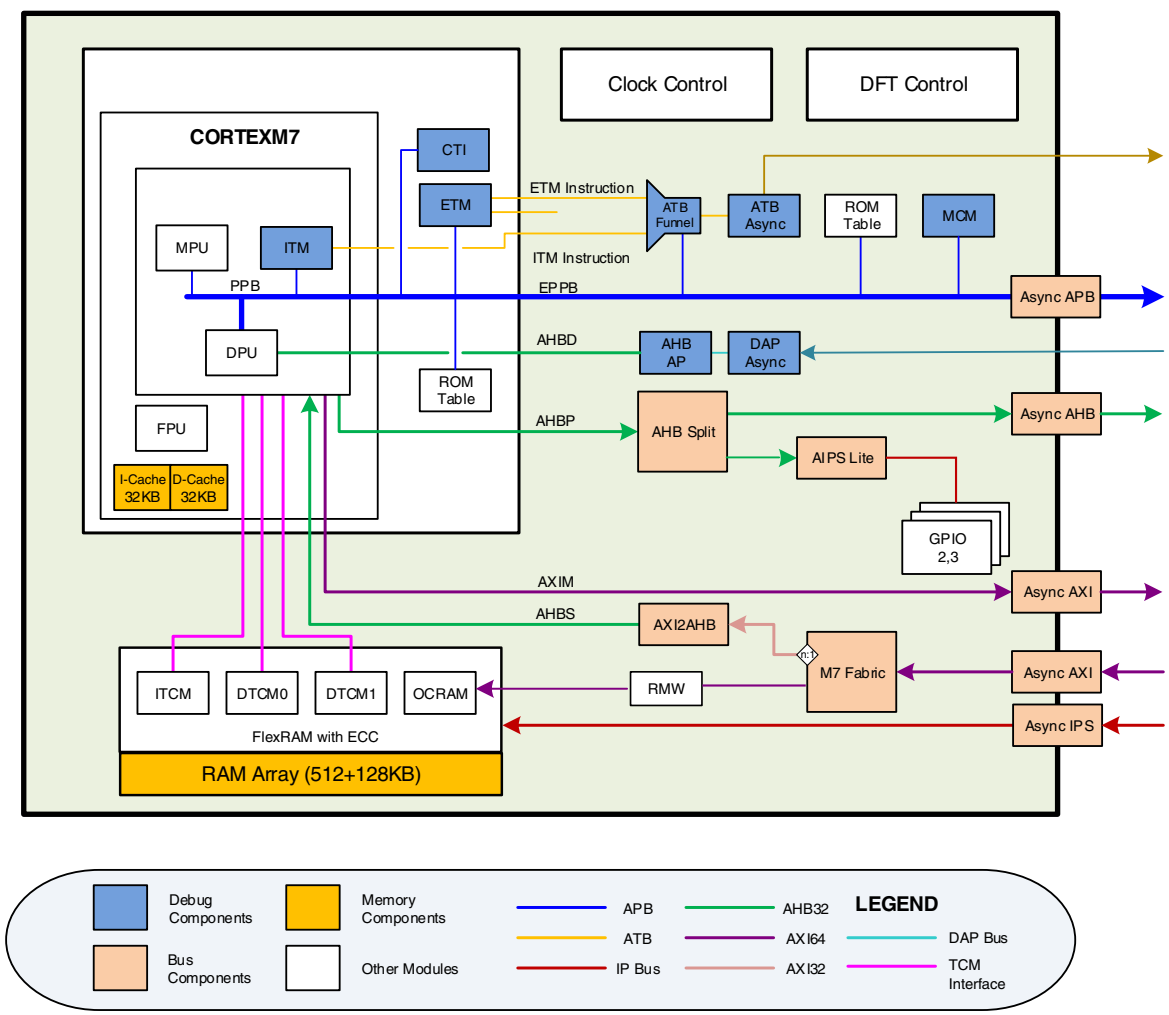

Figure 33-2. Cortex-M7 Platform Block Diagram

33.2.2 Features

The Cortex-M7 platform in this chip has the following features.

- 1× Cortex M7 processor: architecture Arm v7E-M
- floating point unit (FPU) FPv5 including single and double precision
- bus interface 64-bit AMBA4 AXI, 32-bit AHB peripheral port, 32-bit AMBA AHB slave port, AMBA APB interface for CoreSight debug components
- 32 KB instruction / 32 KB data L1 caches with ECC
- configurable size instruction and data TCM (default 256kB ITCM /256kB DTCM) with ECC interface
- 16 regions of MPU
- non-maskable (NMI) + 240 IRQs
- 16 interrupt priority levels (4-bits)
- sleep (WAIT) and deep sleep (STOP) power modes with integrated WFI, WFE, SLEEPONEXIT
- SWD and JTAG, with up to 8 breakpoints and 4 watchpoints
- dual core lock-step support DCLS

33.3 Functional Description

33.3.1 CM7_MCM sub-module

CM7_MCM is a miscellaneous control module for ARM Cortex-M7. It is connected onto the Cortex-M7 PPB bus. See the register descriptions for all its features.

33.3.2 Clocks

Table 33-3. Arm Cortex-M7 Clocks

Clock Name	Description
ipg_clk	Peripheral clock
axi_clk	Bus clock
main_clk	Arm core clock
trace_clk_in	Clock signal

33.3.3 Reset

The CM7_MCM module uses Cortex-M7's reset. Cold or soft resetting the CM7 core would also reset this module.

33.3.4 Interrupts

The CM7_MCM module has one interrupt request: mcm_irq.

The mcm_irq will be asserted when any of the interrupts in the register ISCR occurs.

33.4 External Signals

Table 33-4. External Signals

Signal	Description	Direction
TRACEn	Debug Trace Signal	O
SWO	Single Wire Output Signal	O

33.5 Memory Map and register definition

This section includes the CM7_MCM module memory map and detailed descriptions of all registers.

33.5.1 CM7_MCM register descriptions

33.5.1.1 CM7_MCM memory map

MCM base address: E008_0000h

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)
10	Interrupt Status and Control Register (ISCR)	32	RW	0000_0000

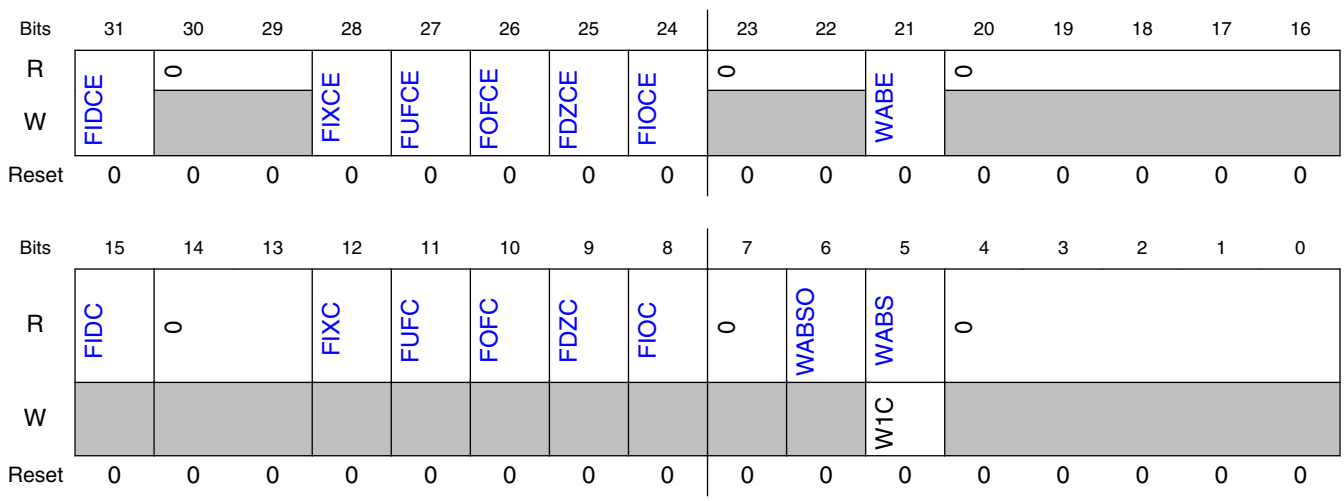
33.5.1.2 Interrupt Status and Control Register (ISCR)

The ISCR register defines the configuration and reports status for a number of core-related interrupt exception conditions. It includes the enable and status bits associated with the core's floating-point exceptions, and bus errors on TCM. The individual event indicators are first qualified with their exception enables and then logically summed to form an interrupt request sent to the core's NVIC. Bits 15-8 are read-only indicator flags based on the processor's FPSCR register. Attempted writes to these bits are ignored. Once set, the flags remain asserted until software clears the corresponding FPSCR bit.

33.5.1.2.1 Offset

Register	Offset
ISCR	10h

33.5.1.2.2 Diagram



33.5.1.2.3 Fields

Field	Description
31 FIDCE	FPU Input Denormal Interrupt Enable 0 - Disable interrupt 1 - Enable interrupt

Table continues on the next page...

Field	Description
30-29 —	Reserved
28 FIXCE	FPU Inexact Interrupt Enable 0 - Disable interrupt 1 - Enable interrupt
27 FUFCE	FPU Underflow Interrupt Enable 0 - Disable interrupt 1 - Enable interrupt
26 FOFCE	FPU Overflow Interrupt Enable 0 - Disable interrupt 1 - Enable interrupt
25 FDZCE	FPU Divide-by-Zero Interrupt Enable 0 - Disable interrupt 1 - Enable interrupt
24 FIOCE	FPU Invalid Operation Interrupt Enable 0 - Disable interrupt 1 - Enable interrupt
23-22 —	Reserved
21 WABE	TCM Write Abort Interrupt enable 0 - Disable interrupt 1 - Enable interrupt
20-16 —	Reserved
15 FIDC	FPU Input Denormal Interrupt Status This read-only bit is a copy of the core's FPSCR[IDC] bit and signals input denormalized number has been detected in the processor's FPU. Once set, this bit remains set until software clears the FPSCR[IDC] bit. 0 - No interrupt 1 - Interrupt occured
14-13 —	Reserved
12 FIXC	FPU Inexact Interrupt Status This read-only bit is a copy of the core's FPSCR[IXC] bit and signals an inexact number has been detected in the processor's FPU. Once set, this bit remains set until software clears the FPSCR[IXC] bit. 0 - No interrupt 1 - Interrupt occured
11 FUFC	FPU Underflow Interrupt Status This read-only bit is a copy of the core's FPSCR[UFC] bit and signals an underflow has been detected in the processor's FPU. Once set, this bit remains set until software clears the FPSCR[UFC] bit.

Table continues on the next page...

Field	Description
	0 - No interrupt 1 - Interrupt occured
10 FOFC	FPU Overflow interrupt status This read-only bit is a copy of the core's FPSCR[OFC] bit and signals an overflow has been detected in the processor's FPU. Once set, this bit remains set until software clears the FPSCR[OFC] bit. 0 - No interrupt 1 - Interrupt occured
9 FDZC	FPU Divide-by-Zero Interrupt Status This read-only bit is a copy of the core's FPSCR[DZC] bit and signals an divide-by-zero operation has been detected in the processor's FPU. Once set, this bit remains set until software clears FPSCR[DZC] bit. 0 - No interrupt 1 - Interrupt occured
8 FIOC	FPU Invalid Operation interrupt Status This read-only bit is a copy of the core's FPSCR[IOC] bit and signals an illegal operation has been detected in the processor's FPU. Once set, this bit remains set until software clears the FPSCR[IOC] bit. 0 - No interrupt 1 - Interrupt occured
7 —	Reserved
6 WABSO	Write Abort on Slave Overrun This read-only bit indicates if another write abort is detected before system software has retrieved all the information from the original event. When the WABS is cleared, this bit is also cleared. 0 - No write abort overrun 1 - Write abort overrun occurred
5 WABS	Write Abort on Slave This bit indicates when a write abort has occurred on AHBS interface. 0 - No abort 1 - Abort
4-0 —	Reserved

NOTE

In CM4 core, write error responses will be suppressed for buffered writes. To improve performance, the master can issue buffered writes to allow the master to move on to the next operations in its pipeline. When the buffered write finally reaches its destination slave, the master has no way to determine which of the earlier transfers requires an error response. If a write error response is essential for certain memory spaces, the target space needs to be configured to a strong ordered type in the MPU.

34.2 Overview

The Cortex-M4 implements the ARMv7- ME instruction set architecture (ISA) and adds significant capabilities with DSP and SIMD extensions. The ARM Cortex-M4 core provides additional general processing capability to the SoC with lower power and fast interrupt response time.

The Cortex-M4 also includes a single-precision floating-point unit (FPU) and two 32-bit system bus interfaces. The Cortex-M4 implementation includes two tightly coupled local memories, two cache memories connected to bus interfaces, 64-bit system bus interconnect, and supports a 32-byte cache line size.

34.2.1 Block Diagram

The block diagram details the ARM Cortex-M4 core and platform.

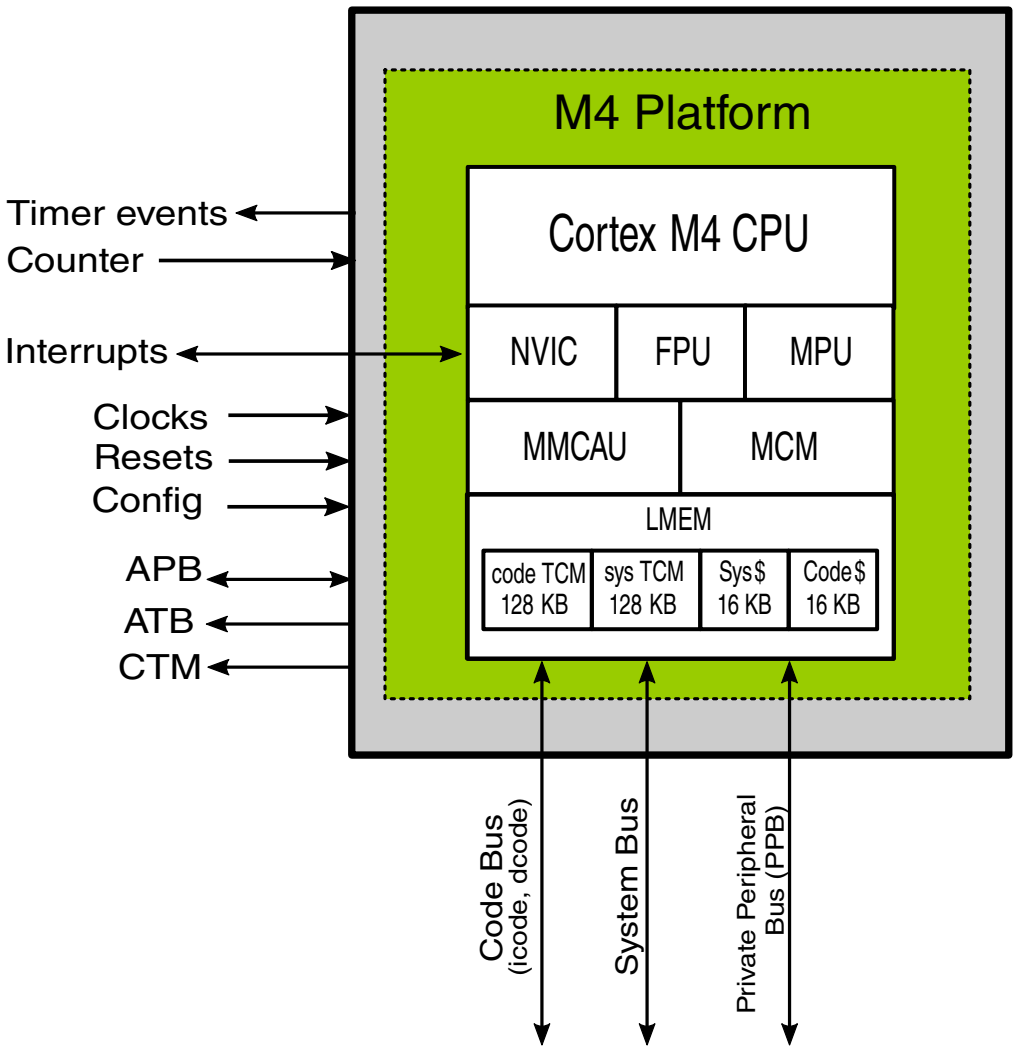

Figure 34-1. Cortex-M4 Platform Block Diagram

34.2.2 Features

The features of the Cortex-M4 platform are detailed below:

- 1x Cortex-M4 processor
- AHB LMEM (Local Memory Controller) including controllers for TCM and cache memories
- 256 KB TCM (128 KB TCMU, 128 KB TCML)
- 16 KB Code Bus Cache
- 16 KB System Bus Cache
- ECC for TCM memories and parity for code and system caches (see LMEM and MCM for more information)
- Integrated Nested Vector Interrupt Controller (NVIC)
- Wakeup Interrupt Controller (WIC)
- FPU (Floating Point Unit)

- Core MPU (Memory Protection Unit)
- Support for exclusive access on the system bus
- MMCAU (Crypto Acceleration Unit)
- MCM (Miscellaneous Control Module)

34.3 Configuration

The configuration of the bus, core, and memory are detailed in the features and sections below.

The Core revision number is Cortex-M4 r0p1.

Table 34-2. Cortex-M4 Configuration

Parameter	Description	Setting
NUM_IRQ	Number of Interrupts	218
LVL_WIDTH (translates to 2^n levels)	Number of interrupt priority bits	4
MPU_PRESENT	Exclude (0) or include (1) optional ARM MPU	1
DEBUG_LVL	Level of debug support	3
TRACE_LVL	Level of trace support 0 = No Trace 1 = ITM and DWT 2 = ITM, DWT, and ETM 3 = ITM, DWT, ETM, and HTM	2
RESET_ALL_REGS	Select whether all registers are reset (1)	1
JTAG_PRESENT	SWJ-DP (1) SW-DP (0)	0
CLKGATE_PRESENT	Disable (0) or enable (1) instantiation of architectural clock gates at all levels	1
WIC_PRESENT	Exclude (0) or include (1) optional ARM provided WIC	1
WIC_LINES	Select number of interrupts and/or events that WIC is sensitive to	NUM_IRQ+3
FPU_PRESENT	Exclude (0) or include (1) Floating Point Unit (FPU)	1
BB_PRESENT	Exclude (0) or include (1) Bit Banding logic	0
CONST_AHB_CTRL	Specifies whether the external AHB-Lite buses maintain control information during wait stated transfers	0

34.4 Performance

This section will discuss power and clocking performance of the Cortex-M4 Platform.

34.4.1 Power

There are several power states supported by the Cortex-M4. Supported primary core states are listed below:

- **Run** - Normal run state. CM4 Platform, TCM and cache memories on nominal voltage.
- **Sleep** – Wait power state. Depending on power state, CM4 Platform, TCM and cache memories can either be in nominal or low-voltage. State recovery through NVIC. NVIC clock is still running in this state.
- **Deep Sleep** – Stop power state. Depending on power state, CM4 Platform, TCM and cache memories can either be in nominal or low-voltage. State recovery through AWIC. Clocks can be completely stopped in this state.

34.4.2 Clocking

The M4 platform is provided a main processor clock that supplies the component clocks to the cluster components. The maximum frequency targets are specified in the chip datasheet. Please see the datasheet for more information. The clocks are described in the table below:

Table 34-3. CM4 Clocks

Clock Signal	Clock Name	Description
Core gated clock	cm4_hclk	Cortex-M4 core clock.
Core Free-Running Clock	cm4_fclk	CM4 NVIC and timer clock
TCM Controller Clock	cm4_tcmc_hclk	CM4 platform TCM controller clock
MMCAU Clock	cm4_mmcau_hclk	CM4 platform MMCAU module clock
Platform Clock	hclk	CM4 platform AXBS fabric and bus masters. Synchronous to the core clock.
Bus Clock	ipg_clk	Clock for bus slaves and peripherals. Synchronous to the system clock.

34.5 Platform sub-blocks

The sections below discuss the high-level overview of the ARM® Cortex®-M4 Platform components.

34.5.1 ARM Cortex-M4 Processor

The Cortex-M4 processor is a low-power processor that features low gate count, low interrupt latency, and low-cost debug. The Cortex-M4 includes floating point arithmetic functionality. The processor is intended for deeply embedded applications that require fast interrupt response features.

The Cortex-M4 implements the ARMv7-M architecture.

The ARM Cortex-M4 processor consists of:

- A processor core
- A Nested Vectored Interrupt Controller (NVIC) closely integrated with the processor core to achieve low-latency interrupt processing
- Multiple high-performance bus interfaces
- A low-cost debug solution with the optional ability to:
  - Implement breakpoints and code patches
  - Implement watchpoints, tracing, and system profiling
  - Support printf() style debugging
  - Bridge to a Trace Port Analyzer (TPA)
- Memory Protection Unit (MPU)
- Floating Point Unit (FPU)
- Crypto Acceleration Unit (MMCAU)
- Miscellaneous Control Module (MCM)

34.5.2 Nested Vectored Interrupt Controller (NVIC)

The M4 platform includes a Nested Vectored Interrupt Controller (NVIC) that is closely integrated with the processor core to achieve low-latency interrupt processing. The platform supports 16 priority levels for interrupts. The NVIC IPR registers will define 4 bits per IRQ.

34.5.3 Floating Point Unit (FPU)

The Cortex-M4 platform supports Floating Point Unit (FPU). The FPU implements the single precision variant of the ARMv7-M Floating-Point Extension (FPv4-SP), which supports single-precision add, subtract, multiply, divide, multiply and accumulate, and square root operations. FPU also provides conversions between fixed-point and floating-point data formats, and floating-point constant instructions.

The FPU provides floating-point computation functionality that is compliant with the ANSI/IEEE Std 754-2008, IEEE Standard for Binary Floating-Point Arithmetic, referred to as the IEEE 754 standard. The FPU contains 32 single-precision extension registers, which you can also access as 16 doubleword registers for load, store, and move operations.

34.5.4 Memory Protection Unit (MPU)

The Cortex-M4 platform supports Memory Protection Unit (MPU). The MPU enforces privilege rules, separates processes, and enforces access rules to memory, and supports the standard ARMv7 Protected Memory System Architecture model. The MPU provides full support for:

- Protection regions
- Overlapping protection regions, with ascending region priority:
  - 7 = highest priority
  - 0 = lowest priority
- Access permissions
- Exporting memory attributes to the system

MPU mismatches and permission violations invoke the programmable-priority MemManage fault handler. You can use the MPU to:

- Enforce privilege rules
- Separate processes
- Enforce access rules

34.6 Debug

This section gives a brief overview of the modules that are implemented within the Cortex-M4 Core Platform. The debug blocks are part of the overall CoreSight platform debug system, which include the ETR, CTM, CTI, ATB replicator, TPIU and DAP. The CoreSight™ compatible Embedded Trace Macrocell (ETM) enables traces of program flow to be collected, compressed, and fed into the trace infrastructure. The Cross Trigger Interface (CTI) is included to provide a common programming model for use by the debug tools, control the trigger sources, and interface to the Cross Trigger Matrix (CTM). The debug is controlled via an ARM Debug Access Port (DAP). For details of the full CoreSight debug subsystem, see the System Debug chapter.

34.6.1 Embedded Trace Router (ETR)

The Embedded Trace Router (ETR) is a CoreSight trace component which buffers trace data before dumping that data into DRAM through the AXI bus (via AXI master port). The output of the funnel is the ETR, and has the ability to buffer a certain amount before writing the data to DRAM.

34.6.2 Embedded Trace Macrocell (ETM)

The Embedded Trace Macrocell (ETM) is a CoreSight component. The ETM trace unit is a module that performs real-time instruction flow tracing based on the Embedded Trace Macrocell (ETM) architecture ETMv4.

34.6.3 Cross Trigger Matrix (CTM)

The CoreSight CTI channel signals from all the cores are combined using a Cross Trigger Matrix (CTM) block so that a single cross trigger channel interface is presented in the Cortex processor. This module can combine four internal channel interfaces corresponding to each core along with one external channel interface.

In the Cortex processor CTM, the external channel output is driven by the OR output of all internal channel outputs. Each internal channel input is driven by the OR output of internal channel outputs of all other CTIs in addition to the external channel input.

34.6.4 Cross Trigger Interface (CTI)

The Cortex processor has a single external cross trigger channel interface. This external interface is connected to the CoreSight Cross Trigger Interface (CTI) interface corresponding to each core through a Cross Trigger Matrix (CTM). A number of Embedded Cross Trigger (ECT) trigger inputs and trigger outputs are connected between debug components in the Cortex-A processor and CoreSight CTI blocks.

The CTI enables the debug logic, ETM trace unit, and performance monitoring, to interact with each other and with other CoreSight components. This is called cross triggering. For example, you configure the CTI to generate an interrupt when the ETM trace unit trigger event occurs.

34.6.5 Instrumentation Trace Macrocell (ITM)

The Instrumentation Trace Macrocell (ITM) is a application-driven trace source that supports printf style debugging to trace operating system and application events. The ITM generates diagnostic system information as packets. Multiple sources can generate packets. If multiple sources generate packets at the same time, the ITM arbitrates the order in which packets are output. These sources in decreasing order of priority are:

- **Software trace.** Software can write directly to ITM stimulus registers to generate packets.
- **Hardware trace.** The DWT generates these packets, and the ITM outputs them.
- **Time stamping.** Timestamps are generated relative to packets. The ITM contains a 21-bit counter to generate the timestamp. The Cortex-M processor clock or the bitclock rate of the Serial Wire Viewer (SWV) output clocks the counter.

34.6.6 Data Watchpoint and Trace (DWT)

The Data Watchpoint and Trace (DWT) debug unit provides watchpoints, data tracing, and system profiling for the processor.

34.6.7 Debug Access Port (DAP)

The Debug Access Port (DAP) is a physical port that connects to external debug tools. The DAP is part of the standardized ARM Debug Interface, and provides a bridge between a JTAG pin interface and on-chip memory mapped peripherals via the DAP bus. Transactions generated by the DAP are referred to as External Debugger Accesses.

34.7 Local Memory Controller (LMEM)

34.7.1 Overview

The Local Memory Controller (LMEM) provides the processor with tightly-coupled memory (TCM) and cache and bus paths to all slave memory spaces.

34.7.1.1 Block Diagram

The processor has a modified 32-bit Harvard bus architecture. Using a 32-bit address space, low-order addresses (0x0000_0000 through 0x1FFF_FFFF) use the Processor Code (PC) bus, and high-order addresses (0x2000_0000 through 0xFFFF_FFFF) use the Processor System (PS) bus. As the bus names imply, normal operation has code accesses on the PC bus and data accesses on the PS bus.

This device has been augmented with tightly-coupled RAM and cache for the PC and PS buses to provide zero wait state access to the RAM and cacheable address spaces.

The local memory controller includes the following memory controllers and their attached memories:

- TCM lower (code TCM) controller via the PC bus
- TCM upper (system TCM) controller via the PS bus
- Cache memory controller via the PC bus
- Cache memory controller via the PS bus

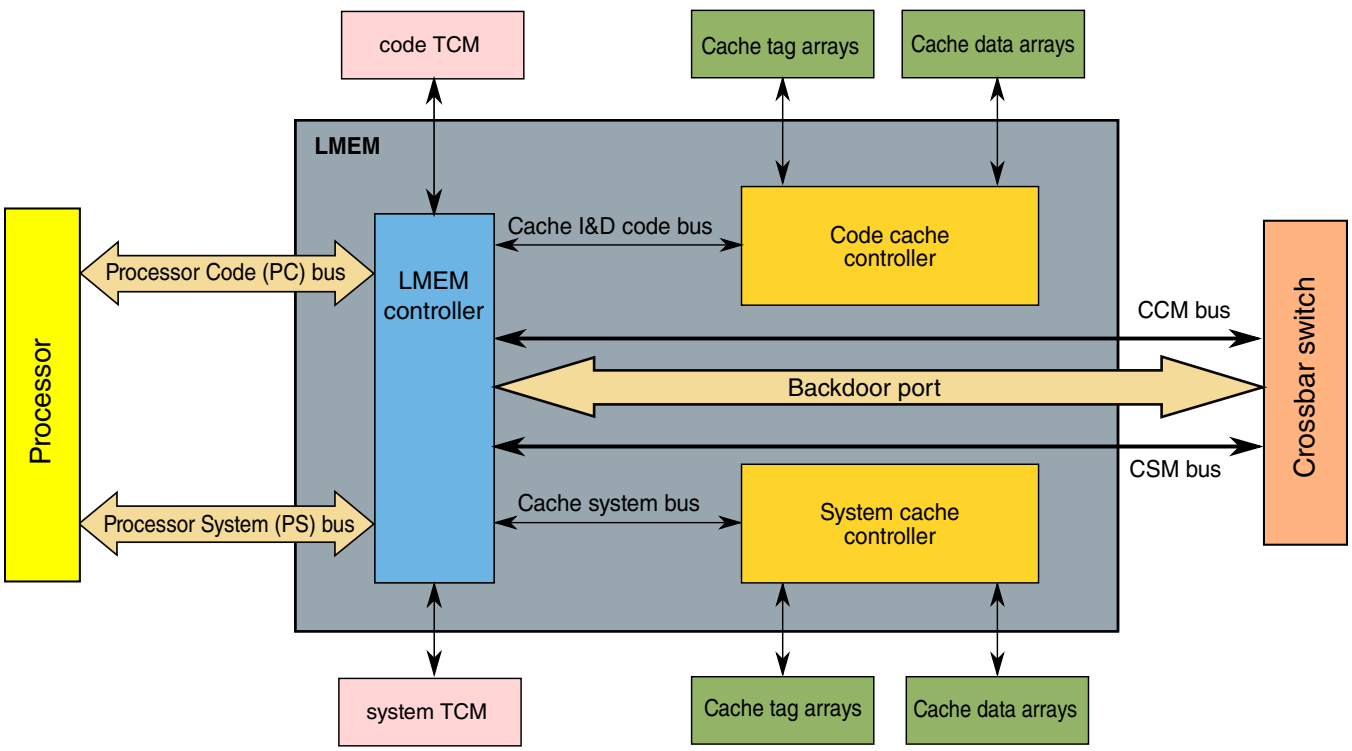

Figure 34-2. Local memory controller block diagram

NOTE

The TCM and cache controllers reside within the LMEM, but the single-port synchronous RAM arrays used by these controllers are external.

The LMEM contains address decode logic for the PC and PS buses. This logic routes the core's accesses to the various system resources. The address spaces are device-specific and are specified in the device's chip-specific information.

34.7.1.2 Cache Features

A cache is a block of high-speed memory locations containing address information (commonly known as a tag) and the associated data. The purpose is to decrease the average time of a memory access. Caches operate on two principles of locality:

- Spatial locality — An access to one location is likely to be followed by accesses from adjacent locations (for example, sequential instruction execution or usage of a data structure).
- Temporal locality — An access to an area of memory is likely to be repeated within a short time period (for example, execution of a code loop).

To minimize the quantity of control information stored, the spatial locality property is used to group several locations together under the same tag. This logical block is commonly known as a cache line.

Temporal locality is achieved by keeping recently accessed lines in the cache.

When data is loaded into a cache, access times for subsequent loads and stores are reduced, resulting in overall performance benefits. An access to information already in a cache is known as a cache hit, and other accesses are called cache misses.

Normally, caches are self-managing, with the updates occurring automatically. Whenever the processor wants to access a cacheable location, the cache is checked. If the access is a cache hit, the access occurs immediately. Otherwise, a location is allocated and the cache line is loaded from memory. Different cache topologies and access policies are possible. However, they must comply with the memory coherency model of the underlying architecture.

Caches introduce a number of potential problems, mainly because of:

- memory accesses occurring at times other than when the programmer would normally expect them,
- the existence of multiple physical locations where a data item can be held.

The local memory controller supports the following modes of operation:

1. Write-through — access to address spaces with this cache mode are cacheable.
   - If all cacheable spaces are read-only spaces, the cache will contain read-only data and all write to the cache will fault. See the chip-specific cacheable space information.

- A write-through read miss on the input bus causes a line read on the output bus of a 32-byte-aligned memory address containing the desired address. This miss data is loaded into the cache and is marked as valid and not modified.
- A write-through read hit to a valid cache location returns data from the cache with no output bus access.
- A write-through write miss bypasses the cache and writes to the output bus (no allocate on write miss policy for write-through mode spaces).
- A write-through write hit updates the cache hit line with the write data and writes to the output bus.
- The caches are processor-local and do not support hardware cache coherency. If the processor has accessed write-through regions and an external bus master (such as DMA) then needs update these regions, software must first perform explicit cache clears to any needed cache memory range to ensure all modified cache lines update their associated memories before being modified by external masters and subsequent processor accesses will get the updated memory.

2. Write-back — access to address spaces with this cache mode are cacheable.
   - Code Cache (PC Side Cache) does not support this mode of operation
   - A write-back read miss on the input bus will cause a line read on the output bus of a 32-byte-aligned memory address containing the desired address. This miss data is loaded into the cache and marked as valid and not modified.
   - A write-back read hit to a valid cache location will return data from the cache with no output bus access.
   - A write-back write miss will do a "read-to-write" (allocate on write miss policy for write-back mode spaces). A line read on the output bus of a 32 byte aligned memory address containing the desired write address is performed. This miss data is loaded into the cache and marked as valid and modified; and the write data will then update the appropriate cache data locations.
   - A write-back write hit updates the cache hit line with the write data plus marks the line as modified.
   - The caches are processor-local and do not support hardware cache coherency. If the processor has written to write-back regions and an external bus master (such as DMA) then needs to see these updates, software must perform explicit cache pushes to any needed cache memory range to ensure all modified cache lines update their associated memories before being read by external masters. Likewise, if the processor has accessed write-back or write-through regions and an external bus master (such as DMA) then needs update these regions, software must first perform explicit cache clears to any needed cache memory range to ensure all modified cache lines update their associated memories before being modified by external masters and subsequent processor accesses will get the updated memory.

3. Non-cacheable — access to address spaces with this cache mode are not cacheable. These accesses bypass the cache and access the output bus.

34.7.2 Functional Description

34.7.2.1 LMEM Function

The Local Memory Controller receives the following requests:

- Core master bus requests on the Processor Code (PC) bus
- Core master bus requests on the Processor Space (PS) bus
- TCM controller requests from all other bus masters on the backdoor port.

The Local Memory Controller address decode logic routes these accesses and also provides any crossbar switch slave target logic. Finally, the Local Memory controller provides the needed MPU connections for checking all TCM Controller and cacheable accesses.

The programming model for the Code and System Caches is accessed via the core's Private Peripheral Bus (PPB).

34.7.2.1.1 Processor Code accesses

Processor Code accesses are routed to the code TCM if they are mapped to that space. All other PC accesses are routed to the Code Cache Memory Controller. This controller then processes the cacheable accesses as needed, while bypassing the non-cacheable, cache write-through, cache miss, and cache maintenance accesses to the CCM bus and the crossbar switch using the Master0 port.

34.7.2.1.2 Processor System accesses

Processor Space accesses are routed to the system TCM if they are mapped to that space. All other PS accesses are routed to the PS Cache Memory Controller. This controller then processes the cacheable accesses as needed, while bypassing the non-cacheable, cache write-through, cache miss, and cache maintenance accesses to the CSM bus and the crossbar switch using the Master1 port.

34.7.2.1.3 Backdoor port accesses

All LMEM backdoor port accesses are only for the TCM controller, no access to cache controllers. These accesses go to the code TCM or the system TCM depending on their specific address.

34.7.2.2 TCM Function

34.7.2.2.1 TCM Configuration

The figure below shows how the TCM controller is configured.

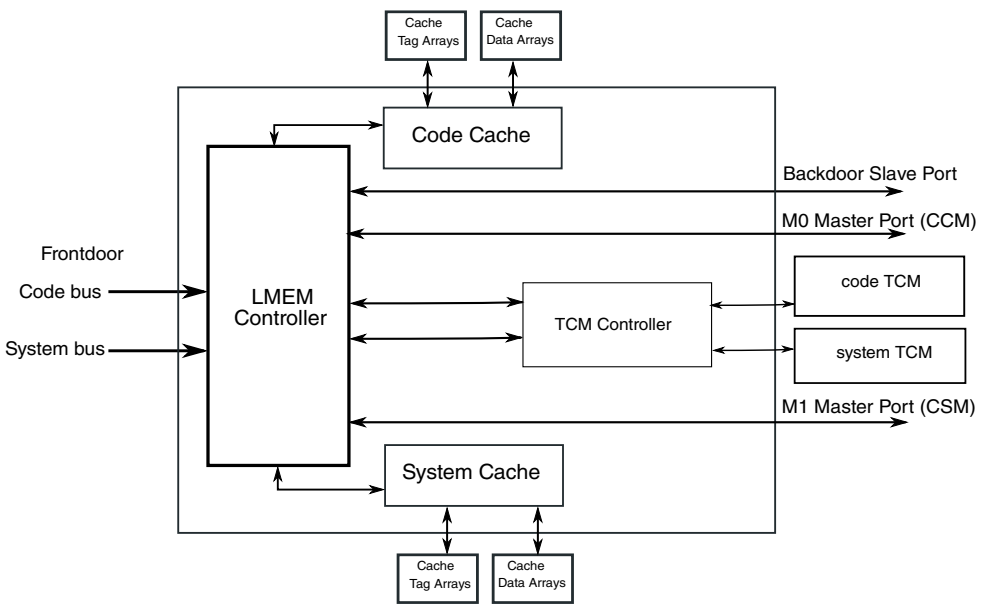

Figure 34-3. LMEM Interface to TCM

34.7.2.2.2 TCM Arrays

The on-chip TCM is split into two logical arrays, code TCM and system TCM.

code TCM size is 128 KBytes.

system TCM size is 128 KBytes.

Valid address ranges for code TCM and system TCM are then defined as:

- code TCM = 0x1FFFE0000 - 0x1FFFFFFF
- system TCM = 0x20000000 - 0x2001FFFF

code TCM and system TCM sizes do not have to be equal.

See the LMEM chip-specific information to confirm the TCM sizes on this device.

34.7.2.2.3 TCM Accesses

The TCM is split into two logical arrays that are 64-bits wide:

- code TCM — Accessible by the 32-bit datapath code bus of the core and by the 64-bit datapath backdoor port.
- system TCM — Accessible by the 32-bit datapath system bus of the core and by the 64-bit datapath backdoor port.

The backdoor port makes the TCM accessible to the non-core bus masters (such as DMA).

The following figure illustrates the TCM accesses within the device.

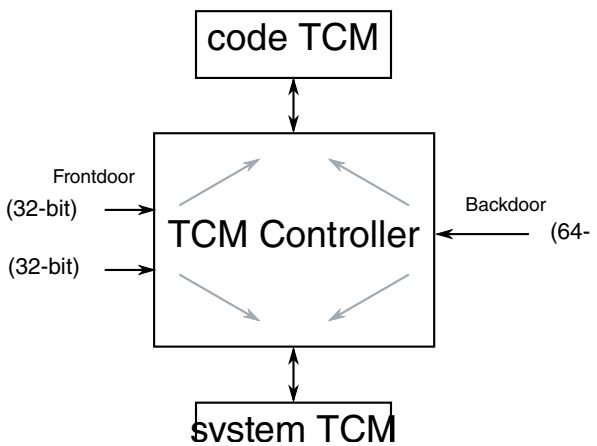

Figure 34-4. TCM access diagram

The following simultaneous accesses can be made to different logical halves of the TCM:

- Core code and core system
- Core code to code TCM and non-core master to system TCM
- Core system to system TCM and non-core master to code TCM

NOTE

Two non-core masters cannot access TCM simultaneously. The required arbitration and serialization is provided by the crossbar switch. The code TCM and system TCM arbitration is controlled by the TCM controller based on the configuration bits in the MCM module.

NOTE

Burst-access cannot occur across the 0x2000_0000 boundary that separates the two TCM arrays. The two arrays should be treated as separate memory ranges for burst accesses.

34.7.2.2.4 TCM ECC Configuration

The TCM Controller ECC is SECDED = Single Error Correct, Double Error Detect. The ECC uses a 7-bit ECC code word per word (32-bits) of data. When ECC is enabled, any write of less than a word (32-bits) is converted to a word read-modify-write sequence. In this way, all TCM writes are 32-bit or 64-bit. All TCM reads are also 32-bit or 64-bit. Each 32-bits of data storage has a related 7-bit ECC code word, written at the same time as the related data and read with the related data. ECC code words are stored in additional RAM storage associated with the main TCM storage and do not subtract from the main RAM size. The TCM Controller ECC does not include any address bits in the ECC code word and does not support error injection.

34.7.2.2.5 TCM ECC Enable

The TCM receives separate control inputs to enable ECC generations on writes and to enable ECC checking on reads. This control occurs outside the TCM from system-level control modules.

The TCM data arrays must first be written with good ECC before being read with ECC checking on reads.

34.7.2.2.6 TCM ECC Function

Since the TCM support byte level writes and the ECC is at a word level, when ECC is enabled all write of less than word size are converted to a word read-modify-write sequence. In this way, correct word level ECC is generated.

When TCM ECC generation on writes is enabled, for TCM writes:

- All TCM write generate the needed ECC word code
- The TCM data and associated data ECC word code are written to the data RAM plus data ECC word code RAM at the same time

When TCM ECC read check is enabled, for TCM data reads:

- For every data word read, the data word and its ECC word code are read in parallel
- The ECC is checked, any single bit error is corrected on-the-fly, any single or multi bit error is flagged

Since all single bit ECC errors are corrected on-the-fly, TCM operations continue as normal when only single bit ECC errors occur.

TCM read accesses that get multi bit ECC errors are handled as follows:

- Any access that gets a multi bit error terminates with a bus fault

34.7.2.2.7 TCM ECC Codes

34.7.2.2.7.1 TCM Word Level ECC Code

The TCM word level ECC uses a Hsiao odd-weight column criteria ECC code for ECC generation and checking. The ECC code covers 32-bit data. The same ECC code is used for the upper and lower 32-bit word of the 64-bit wide TCM datapath.

34.7.2.3 Cache Function

The caches on this device are structured as follows. The PC cache and the PS cache have a 2-way set-associative cache structure with a total size of 16 KBytes. The caches have 32-bit address, 64-bit data paths and a 32-byte line size. The cache tags and data storage use single-port, synchronous RAMs.

For these 16-KByte caches, each cache TAG function uses two 256 x 21-bit RAM arrays and the cache DATA function uses two 1024 x 64-bit RAM arrays. The cache TAG entries store 19 bits of upper address as well as a modified and valid bit per cache line. The cache DATA entries store eight bytes of code or data.

All normal cache accesses use physical addresses. This leads to the following cache address use:

CACHE - 16 KByte size = (256 sets) x (32-byte lines) x (2-way set associative)

TAG:

- address[31:13] used in tag for compare (hit) logic
- address[12:5] used to select 1 of 256 sets
- address[4:0] not used

DATA

- address[31:13] not used
- address[12:5] used to select one of 256 sets
- address[4:3] used to select one of four 64-bit words within a set
- address[2:0] used to select the byte within the 64-bit word

34.7.2.4 Cache Control

The Code and System Caches are disabled at reset. Cache tag and data arrays are not cleared at reset. Therefore, to enable the caches, cache commands must be done to clear and initialize the required tag array bits and to configure and enable the caches.

34.7.2.4.1 Cache set commands

The cache set commands may operate on:

- all of way 0,
- all of way 1, or
- all of both ways (complete cache).

Cache set commands are initiated using the upper bits in the PxCCR register. Cache set commands perform their operation on the cache independent of the cache enable bit, PxCCR[ENCACHE].

A cache set command is initiated by setting the PxCCR[GO] bit. This bit also acts as a busy bit for set commands. It stays set while the command is active and is cleared by the hardware when the set command completes.

Supported cache set commands are given in Table 34-4. Set commands work as follows:

- Invalidate – Unconditionally clear valid and modify bits of a cache entry.
- Push – Push a cache entry if it is valid and modified, then clear the modify bit. If entry not valid or not modified, leave as is.
- Clear – Push a cache entry if it is valid and modified, then clear the valid and modify bits. If entry not valid or not modified, clear the valid bit.

Table 34-4. Cache Set Commands

PxCCR[27:24]				Command
PUSHW1	INVW1	PUSHW0	INVW0	
0	0	0	0	NOP
0	0	0	1	Invalidate all way 0
0	0	1	0	Push all way 0
0	0	1	1	Clear all way 0
0	1	0	0	Invalidate all way 1
0	1	0	1	Invalidate all way 1; invalidate all way 0 (invalidate cache)
0	1	1	0	Invalidate all way 1; push all way 0
0	1	1	1	Invalidate all way 1; clear all way 0
1	0	0	0	Push all way 1

Table continues on the next page...

Table 34-4. Cache Set Commands (continued)

PxCCR[27:24]				Command
PUSHW1	INVW1	PUSHW0	INVW0	
1	0	0	1	Push all way 1; invalidate all way 0
1	0	1	0	Push all way 1; push all way 0 (push cache)
1	0	1	1	Push all way 1; clear all way 0
1	1	0	0	Clear all way 1
1	1	0	1	Clear all way 1; invalidate all way 0
1	1	1	0	Clear all way 1; push all way 0
1	1	1	1	Clear all way 1; clear all way 0 (clear cache)

After a reset, complete an invalidate cache command before using the cache. It is possible to combine the cache invalidate command with the cache enable. That is, setting PxCCR to 0x8500_0003 will invalidate the cache and enable the cache and write buffer.

34.7.2.4.2 Cache line commands

Cache line commands operate on a single line in the cache at a time. Cache line commands can be performed using a physical or cache address.

- A cache address consists of a set address and a way select. The line command acts on the specified cache line.
- Cache line commands with physical addresses first search both ways of the cache set specified by the following physical address bits. If they hit, the commands perform their action on the hit way:
  - For Code Cache - [12:5]
  - For System Cache - [12:5]

Cache line commands are specified using the upper bits in the PxCLCR register. Cache line commands perform their operation on the cache independent of the cache enable bit (PxCCR[ENCACHE]). Using a cache address, the command can be completely specified using the PxCLCR register. Using a physical address, the command must also use the PxCSAR register to specify the physical address.

A line cache command is initiated by setting the line command go bit (PxCLCR[LGO] or PxCSAR[LGO]). This bit also acts a a busy bit for line commands. It stays set while the command is active and is cleared by the hardware when the command completes.

The PxCLCR[27:24] bits select the line command as follows:

Table 34-5. Cache Line Commands

PxCLCR[27:24]			Command
LACC	LADSEL	LCMD	
0	0	00	Search by cache address and way
0	0	01	Invalidate by cache address and way
0	0	10	Push by cache address and way
0	0	11	Clear by cache address and way
0	1	00	Search by physical address
0	1	01	Invalidate by physical address
0	1	10	Push by physical address
0	1	11	Clear by physical address
1	0	00	Write by cache address and way
1	0	01	Reserved, NOP
1	0	10	Reserved, NOP
1	0	11	Reserved, NOP
1	1	*xx*	Reserved, NOP

34.7.2.4.2.1 Executing a series of line commands using cache addresses

A series of line commands with incremental cache addresses can be performed by just writing to the PxCLCR.

- Place the command in PxCLCR[27:24],
- Set the way (PxCLCR[WSEL]) and tag/data (PxCLCR[TDSEL]) controls as needed,
- Place the cache address in PxCLCR[CACHEADDR], and
- Set the line command go bit (PxCLCR[LGO]).

When one line command completes, initiate the next command by following these steps:

- Increment the cache address (at bit 3 to step through data or at bit 5 to step through lines), and
- Set the line command go bit (PxCLCR[LGO]).

34.7.2.4.2.2 Executing a series of line commands using physical addresses

Perform a series of line commands with incremental physical addresses using the following steps:

- Write to the PxCLCR.

    - Place the command in PxCLCR[27:24]
    - Set the tag/data (PxCLCR[TDSEL]) control
- Place the physical address in PxCSAR[PHYADDR] and set the line command go bit (PxCSAR[LGO]).

When one line command completes, initiate the next command by following these steps:

- Increment the physical address (at bit 3 to step through data or at bit 5 to step through lines), and
- Set the line command go bit (PxCSAR[LGO]).

The line command go bit is shared between the PxCLCR and PxCSAR registers, so that the above steps can be completed in a single write to the PxCSAR register.

34.7.2.4.2.3 Line command results

At completion of a line command, the PxCLCR register contains information on the initial state of the line targeted by the command. For line commands with cache addresses, this information is read before the line command action is performed from the targeted cache line. For line commands with physical addresses, this information is read on a hit before the line command action is performed from the hit cache line or has initial valid bit cleared if the command misses. In general, if the valid indicator (PxCLCR[LCIVB] is cleared, the targeted line was invalid at the start of the line command and no line operation was performed.

Table 34-6. Line command results

PxCLCR[22:20]			For cache address commands	For physical address commands
LCWAY	LCIMB	LCIVB		
0	0	0	Way 0 line was invalid	No hit
0	0	1	Way 0 valid, not modified	Way 0 valid, not modified
0	1	0	Way 0 line was invalid	No hit
0	1	1	Way 0 valid and modified	Way 0 valid and modified
1	0	0	Way 1 line was invalid	No hit
1	0	1	Way 1 valid, not modified	Way 1 valid, not modified
1	1	0	Way 1 line was invalid	No hit
1	1	1	Way 1 valid and modified	Way 1 valid and modified

At completion of a line command other than a write, the PxCCVR (Cache R/W Value Register) contains information on the initial state of the line tag or data targeted by the command. For line commands, PxCLCR[TDSEL] selects between tag and data. If the line command used a physical address and missed, the data is don't care. For write commands, the PxCCVR holds the write data.

The cache does not have line lock capability. Performance critical code can be loaded in the code TCM controller associated with the low-order address processor code bus.Performance critical data can be loaded in the system TCM controller associated with the upper-order address processor system bus.

34.7.3 Memory Map and Registers

The cache programmer's model provides a variety of registers for configuring and controlling the cache, as well as indirect access paths to all cache tag and data storage.

NOTE

The LMEM registers are accessible in supervisor mode only.

34.7.3.1 LMEM register descriptions

34.7.3.1.1 LMEM memory map

LMEM base address: E008_2000h

34.7.3.1.2.3 Fields

Field	Description
31 GO	Initiate Cache Command Setting this bit initiates the cache command indicated by bits 27-24. Reading this bit indicates if a command is active **NOTE:** This bit stays set until the command completes. Writing zero has no effect. 0 - Write: no effect. Read: no cache command active. 1 - Write: initiate command indicated by bits 27-24. Read: cache command active.
30-28 —	Reserved
27 PUSHW1	Push Way 1 0 - No operation 1 - When setting the GO bit, push all modified lines in way 1
26 INVW1	Invalidate Way 1 **NOTE:** If the PUSHW1 and INVW1 bits are set, then after setting the GO bit, push all modified lines in way 1 and invalidate all lines in way 1 (clear way 1). 0 - No operation 1 - When setting the GO bit, invalidate all lines in way 1
25	Push Way 0

Table continues on the next page...

Field	Description
PUSHW0	0 - No operation 1 - When setting the GO bit, push all modified lines in way 0
24 INVW0	Invalidate Way 0 **NOTE:** If the PUSHW0 and INVW0 bits are set, then after setting the GO bit, push all modified lines in way 0 and invalidate all lines in way 0 (clear way 0). 0 - No operation 1 - When setting the GO bit, invalidate all lines in way 0.
23-4 —	Reserved
3 PCCR3	Forces no allocation on cache misses 0 - Allocation on cache misses 1 - Forces no allocation on cache misses (must also have PCCR2 asserted)
2 PCCR2	Forces all cacheable spaces to write through 0 - Does NOT force all cacheable spaces to write through 1 - Forces all cacheable spaces to write through
1 ENWRBUF	Enable Write Buffer 0 - Write buffer disabled 1 - Write buffer enabled
0 ENCACHE	Cache enable 0 - Cache disabled 1 - Cache enabled

34.7.3.1.3 PC bus Cache line control register (PCCLCR)

This register defines specific line-sized cache operations to be performed using a specific cache line address or a physical address.

If a physical address is specified, both ways of the cache are searched, and the command is only performed on the way which hits.

34.7.3.1.3.1 Offset

34.8 Miscellaneous Control Module (MCM)

The Miscellaneous Control Module (MCM) provides a myriad of miscellaneous control functions.

34.8.1 MCM features

The MCM includes the following features:

- Program-visible information on the platform configuration and revision

34.8.2 MCM Interrupts

The MCM generates the following interrupt requests:

- Non-maskable interrupt
- Normal interrupt

34.8.2.1 Non-maskable interrupt

The MCM's NMI is generated if:

- ISCR[ETBN] is set, when
  - The ETB counter is enabled, ETBCC[CNTEN] = 1
  - The ETB count expires
  - The response to counter expiration is an NMI, MCM_ETBCC[RSPT] = 10

34.8.2.2 Normal interrupt

The MCM's normal interrupt is generated if any of the following is true:

- ISCR[ETBI] is set, when
  - The ETB counter is enabled, ETBCC[CNTEN] = 1
  - The ETB count expires
  - The response to counter expiration is a normal interrupt, ETBCC[RSPT] = 01

34.9.1 SoC-defined platform revision (MCM_PLREV)

The PLREV is a 16-bit read-only register specifying an SoC-defined platform revision number. The state of this register is defined by an platform input signal; it can only be read from the IPS programming model. Any attempted write is ignored.

Address: E008_0000h base + 0h offset = E008_0000h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	PLREV															
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

MCM_PLREV field descriptions

Field	Description
PLREV	The PLREV[15:0] field is specified by an platform input signal to define a software-visible revision number.

34.9.2 Processor core type (MCM_PCT)

The PCT is a 16-bit read-only register specifying the architecture of the processor core within the platform in the device. The state of this register is defined by a module input signal; it can only be read from the IPS programming model. Any attempted write is ignored.

Address: E008_0000h base + 2h offset = E008_0002h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	PCT															
Write																
Reset	1	0	1	0	1	1	0	0	0	1	0	0	0	0	0	0

MCM_PCT field descriptions

Field	Description
PCT	This MCM design supports the ARM Cortex M4 core. The following value identifies this core complex. 0xAC40 ARM Cortex M4

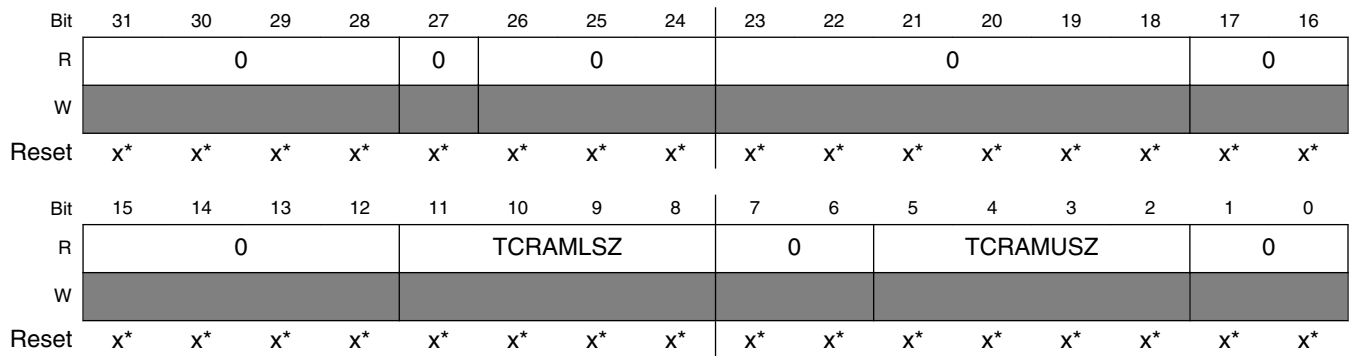
34.9.3 Memory configuration (MCM_MEMCFG)

The CPCFG is a 32-bit read-only register containing information on device memory sizes. The sizes are static and do not change after reset.

NOTE

The reset value depends on the flash and Tightly Coupled Memory (TCM) memory sizes on the specific device.

Address: E008_0000h base + 4h offset = E008_0004h



* Notes:
- x = Undefined at reset.

MCM_MEMCFG field descriptions

Field	Description
31–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11–8 TCRAMLSZ	TCRAML size This field indicates the amount of memory available in the lower TCRAM (code TCM) array.

Total TCM size	TCRAMLSZ	TCRAMUSZ
8 KBytes	0101	0101
16 KBytes	0110	0110

Table continues on the next page...

MCM_MEMCFG field descriptions (continued)

Field	Description		
	Total TCM size	**TCRAMLSZ**	**TCRAMUSZ**
	32 KBytes	0111	0111
	64 KBytes	1000	1000
	128 KBytes	1001	1001
7–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.		
5–2 TCRAMUSZ	TCRAMU size This field indicates the amount of memory available in the upper TCRAM array. See the TCRAMLSZ bit description for encodings.		
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.		

34.9.4 Crossbar Switch (AXBS) Slave Configuration (MCM_PLASC)

PLASC is a 16-bit read-only register identifying the presence/absence of bus slave connections to the device's crossbar switch.

Address: E008_0000h base + 8h offset = E008_0008h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	0								ASC							
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1

MCM_PLASC field descriptions

Field	Description
15–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
ASC	Each bit in the ASC field indicates whether there is a corresponding connection to the crossbar switch's slave input port. 0 A bus slave connection to AXBS input port *n* is absent 1 A bus slave connection to AXBS input port *n* is present

34.9.5 Crossbar Switch (AXBS) Master Configuration (MCM_PLAMC)

PLAMC is a 16-bit read-only register identifying the presence/absence of bus master connections to the device's crossbar switch.

Address: E008_0000h base + Ah offset = E008_000Ah

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	0								AMC							
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1

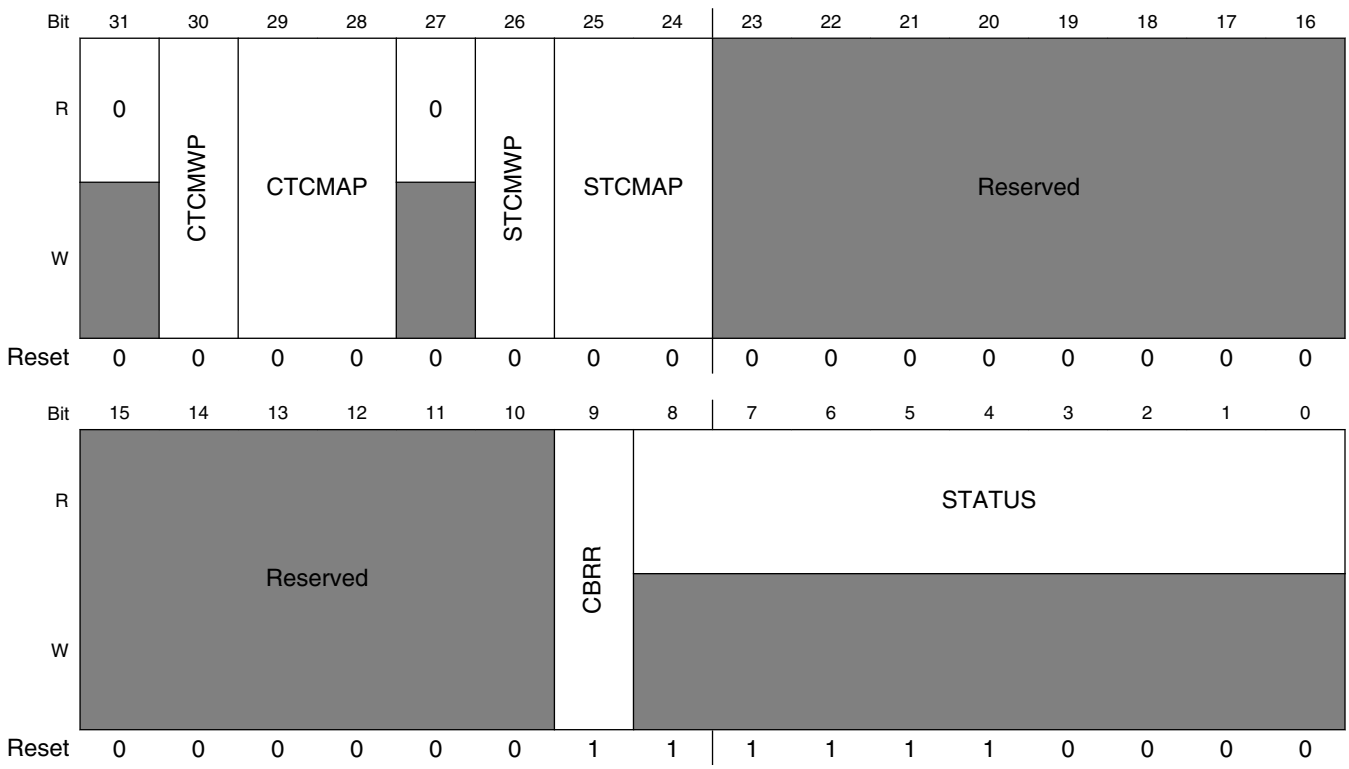
MCM_PLAMC field descriptions

Field	Description
15–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
AMC	Each bit in the AMC field indicates whether there is a corresponding connection to the AXBS master input port. 0 A bus master connection to AXBS input port *n* is absent 1 A bus master connection to AXBS input port *n* is present

34.9.6 Control Register (MCM_CR)

CR defines the arbitration and protection schemes for the two system RAM arrays.

Address: E008_0000h base + Ch offset = E008_000Ch



MCM_CR field descriptions

Field	Description
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 CTCMWP	Code TCM Write Protect When this bit is set, writes to the code TCM array generates a bus error.
29–28 CTCMAP	Code TCM arbitration priority Defines the arbitration scheme and priority for the processor and Tightly Coupled Memory (TCM) backdoor accesses to the code TCM array. 00 Round robin 01 Special round robin (favors TCM backoor accesses over the processor) 10 Fixed priority. Processor has highest, backdoor has lowest 11 Fixed priority. Backdoor has highest, processor has lowest
27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

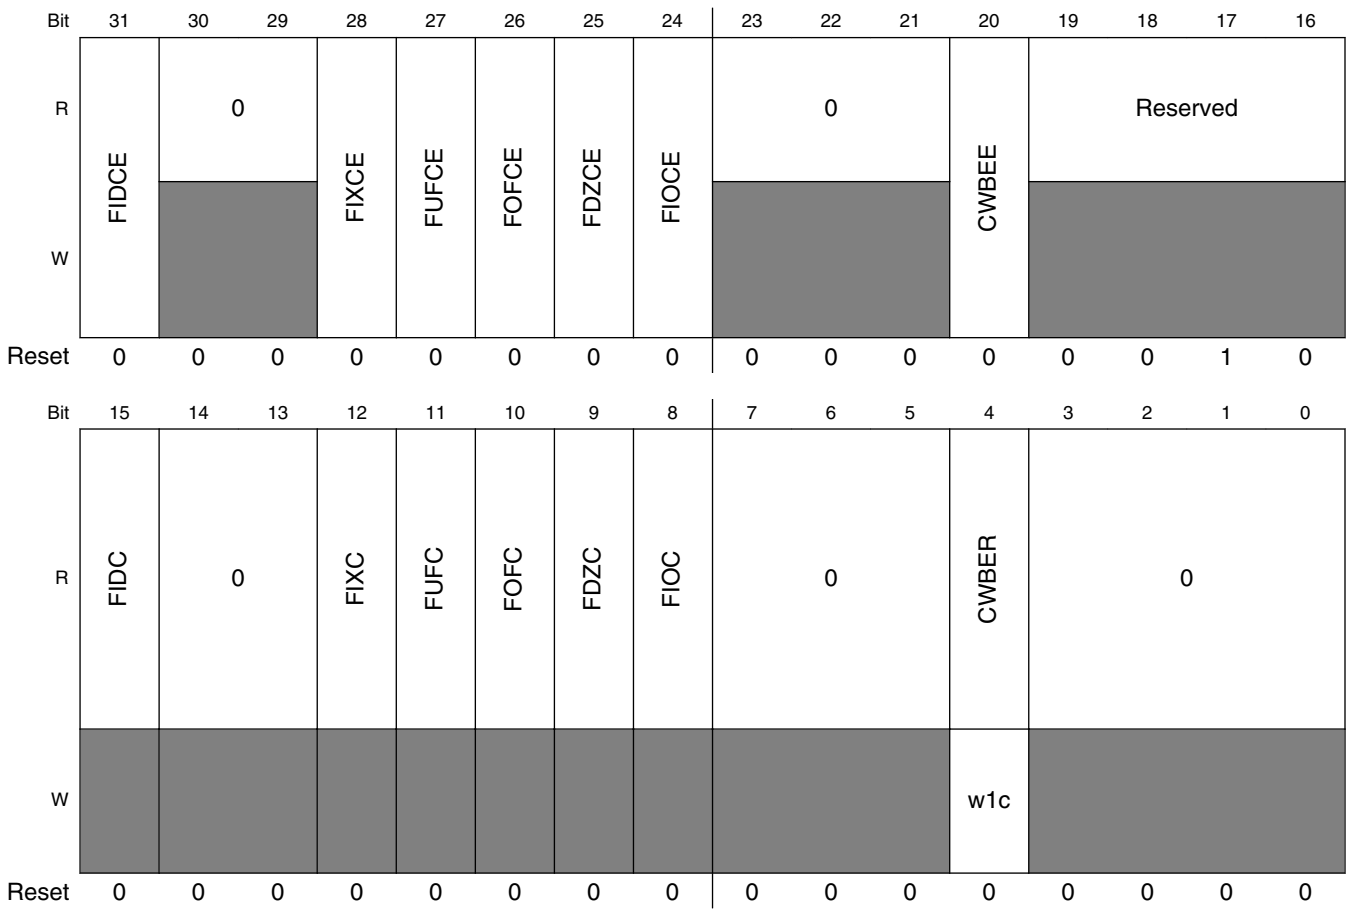
34.9.7 Interrupt Status and Control Register (MCM_ISCR)

The MCM_ISCR register defines the configuration and reports status for a number of core-related interrupt exception conditions. It includes the enable and status bits associated with the core's floating-point exceptions, bus errors associated with the core's cache write buffer, and events associated with the debug ETB module. The individual event indicators are first qualified with their exception enables and then logically summed to form an interrupt request sent to the core's NVIC.

Address: E008_0000h base + 10h offset = E008_0010h



MCM_ISCR field descriptions

Field	Description
31 FIDCE	FPU input denormal interrupt enable 0 Disable interrupt 1 Enable interrupt

Table continues on the next page...

MCM_ISCR field descriptions (continued)

Field	Description
30–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 FIXCE	FPU inexact interrupt enable 0 Disable interrupt 1 Enable interrupt
27 FUFCE	FPU underflow interrupt enable 0 Disable interrupt 1 Enable interrupt
26 FOFCE	FPU overflow interrupt enable 0 Disable interrupt 1 Enable interrupt
25 FDZCE	FPU divide-by-zero interrupt enable 0 Disable interrupt 1 Enable interrupt
24 FIOCE	FPU invalid operation interrupt enable 0 Disable interrupt 1 Enable interrupt
23–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20 CWBEE	Cache write buffer error enable Enables the generation of an interrupt in response to a bus error termination reported on a system bus transfer initiated from the cache's write buffer. 0 Disable error interrupt 1 Enable error interrupt
19–16 Reserved	This field is reserved.
15 FIDC	FPU input denormal interrupt status This read-only bit is a copy of the core's FPSCR[IDC] bit and signals input denormalized number has been detected in the processor's FPU. Once set, this bit remains set until software clears the FPSCR[IDC] bit. 0 No interrupt 1 Interrupt occurred
14–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 FIXC	FPU inexact interrupt status This read-only bit is a copy of the core's FPSCR[IXC] bit and signals an inexact number has been detected in the processor's FPU. Once set, this bit remains set until software clears the FPSCR[IXC] bit. 0 No interrupt 1 Interrupt occurred

Table continues on the next page...

MCM_ISCR field descriptions (continued)

Field	Description
11 FUFC	FPU underflow interrupt status This read-only bit is a copy of the core's FPSCR[UFC] bit and signals an underflow has been detected in the processor's FPU. Once set, this bit remains set until software clears the FPSCR[UFC] bit. 0 No interrupt 1 Interrupt occurred
10 FOFC	FPU overflow interrupt status This read-only bit is a copy of the core's FPSCR[OFC] bit and signals an overflow has been detected in the processor's FPU. Once set, this bit remains set until software clears the FPSCR[OFC] bit. 0 No interrupt 1 Interrupt occurred
9 FDZC	FPU divide-by-zero interrupt status This read-only bit is a copy of the core's FPSCR[DZC] bit and signals a divide by zero has been detected in the processor's FPU. Once set, this bit remains set until software clears the FPSCR[DZC] bit. 0 No interrupt 1 Interrupt occurred
8 FIOC	FPU invalid operation interrupt status This read-only bit is a copy of the core's FPSCR[IOC] bit and signals an illegal operation has been detected in the processor's FPU. Once set, this bit remains set until software clears the FPSCR[IOC] bit. 0 No interrupt 1 Interrupt occurred
7–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 CWBER	Cache write buffer error status Signals a data transfer from the core's cache write buffer was terminated with a bus error. This bit only sets when the corresponding enable bit (CWBEE) is set. The corresponding core fault address, attributes and write data are typically retrieved from the FADR, FATR, and FDR registers during the interrupt service routine before clearing the CWBER flag. 0 No error 1 Error occurred
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

34.9.8 Fault address register (MCM_FADR)

When a properly-enabled cache write buffer error interrupt event is detected, the faulting address is captured in the MCM_FADR register. The MCM logic supports capturing a single cache write buffer bus error event; if a subsequent error is detected before the captured error information has been read from the corresponding registers and the MCM_ISCR[CWBER] indicator cleared, the MCM_FATR[BEOVR] flag is set. However, no additional information is captured.

The bits in this register are set by hardware and signaled by the assertion of MCM_ISCR[CWBER]. Attempted writes to this location are terminated with an error.

Address: E008_0000h base + 20h offset = E008_0020h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

* Notes:
- x = Undefined at reset.

MCM_FADR field descriptions

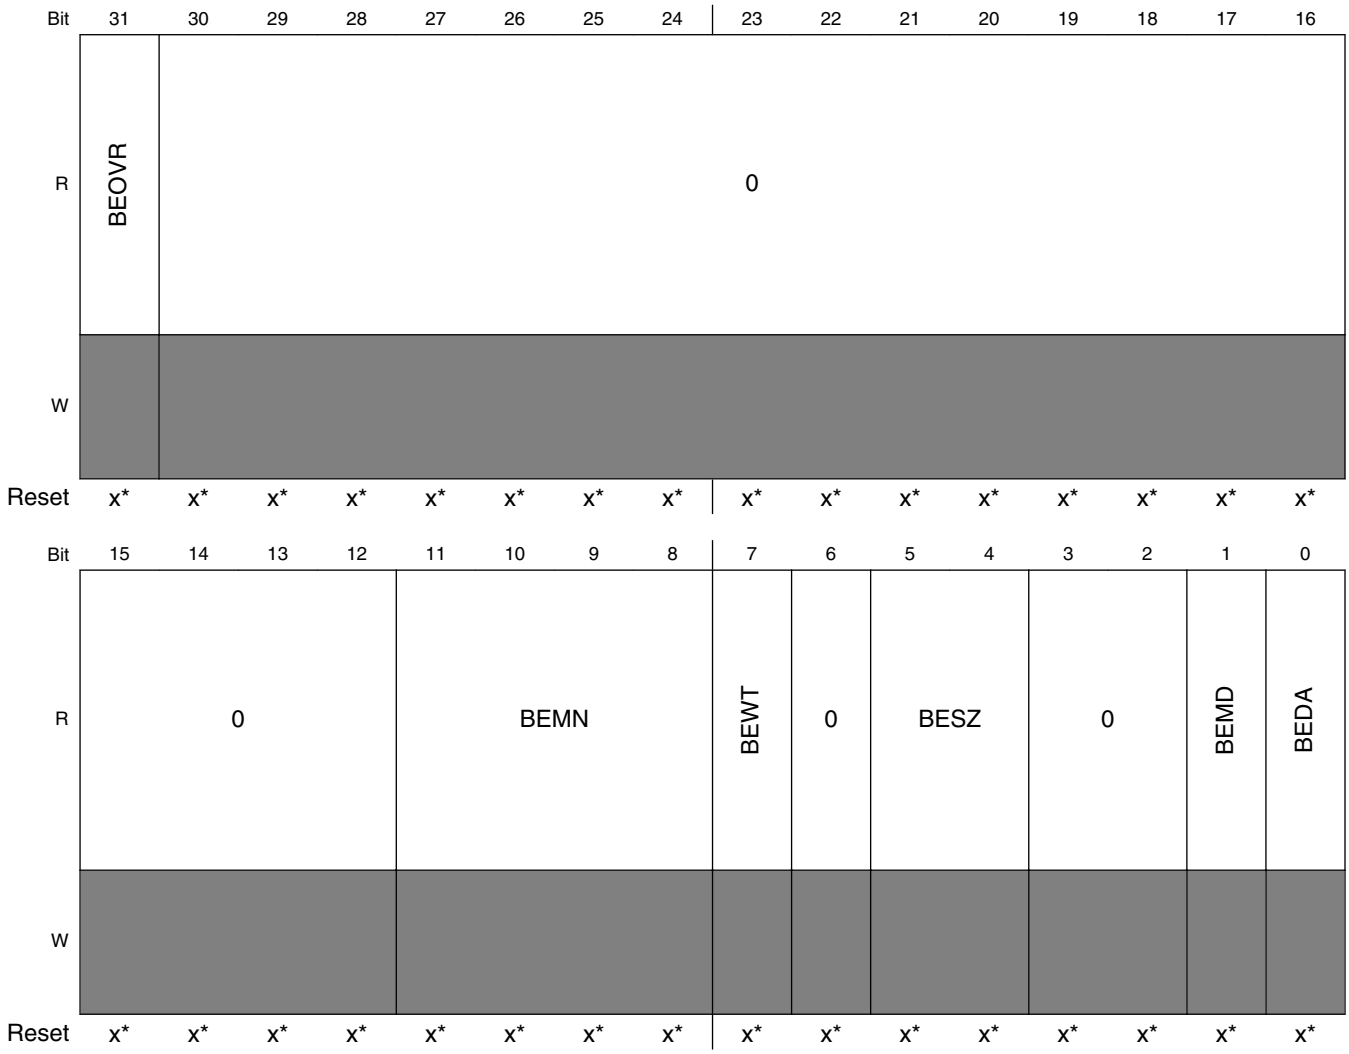
Field	Description
ADDRESS	Fault address

34.9.9 Fault attributes register (MCM_FATR)

When a properly-enabled cache write buffer error interrupt event is detected, the faulting attributes are captured in the MCM_FATR register.

The bits in this register are set by hardware and signaled by the assertion of MCM_ISCR[CWBER]. Attempted writes to this location are terminated with an error.

Address: E008_0000h base + 24h offset = E008_0024h



* Notes:
- x = Undefined at reset.

MCM_FATR field descriptions

Field	Description
31 BEOVR	Bus error overrun Indicates if anothercache write buffer bus error is detected before system software has retrieved all the error information from the original event, this overrun flag is set. The window of time is defined from the detection of the original cache write buffer error termination until the MCM_ISCR[CWBER] is written with a 1 to clear it and rearm the capture logic. This bit is set by the hardware and cleared whenever software writes a 1 to the CWBER bit. 0 No bus error overrun 1 Bus error overrun occurred. The FADR and FDR registers and the other FATR bits are not updated to reflect this new bus error.
30–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

MCM_FATR field descriptions (continued)

Field	Description
11–8 BEMN	Bus error master number Crossbar switch bus master number of the captured cache write buffer bus error. For this device, this value is always 0x1.
7 BEWT	Bus error write Indicates the type of system bus access when the error was detected. Since this logic is monitoring data transfers from the cache write buffer, this bit is always a logical one, signaling a write operation. 0 Read access 1 Write access
6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–4 BESZ	Bus error size Indicates the size of the cache write buffer access when the error was detected. 00 8-bit access 01 16-bit access 10 32-bit access 11 Reserved
3–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 BEMD	Bus error privilege level Indicates the privilege level of the cache write buffer access when the error was detected. 0 User mode 1 Supervisor/privileged mode
0 BEDA	Bus error access type Indicates the type of cache write buffer access when the error was detected. This attribute is always a logical one signaling a data reference. 0 Instruction 1 Data

34.9.10 Fault data register (MCM_FDR)

When a properly-enabled cache write buffer error interrupt event is detected, the faulting data is captured in the MCM_FDR register.

The bits in this register are set by hardware and signaled by the assertion of MCM_ISCR[CWBER]. For byte and halfword writes, only the accessed byte lanes contain valid data; the contents of the other bytes are undefined. Attempted writes to this location are terminated with an error.

Address: E008_0000h base + 28h offset = E008_0028h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

34.9.11 Local Memory Descriptor Register (MCM_LMDR*n*)

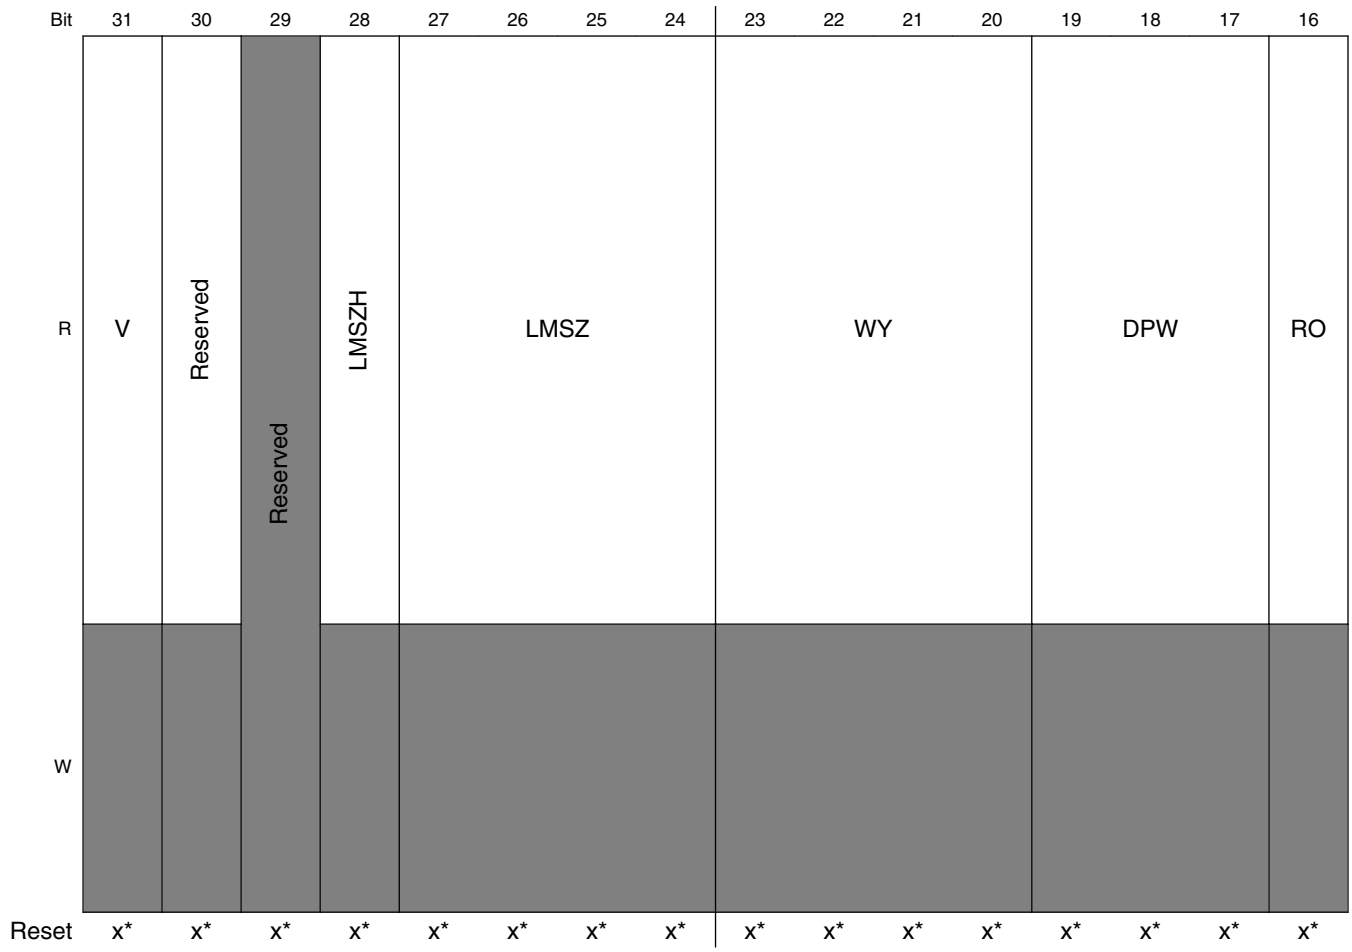
NOTE

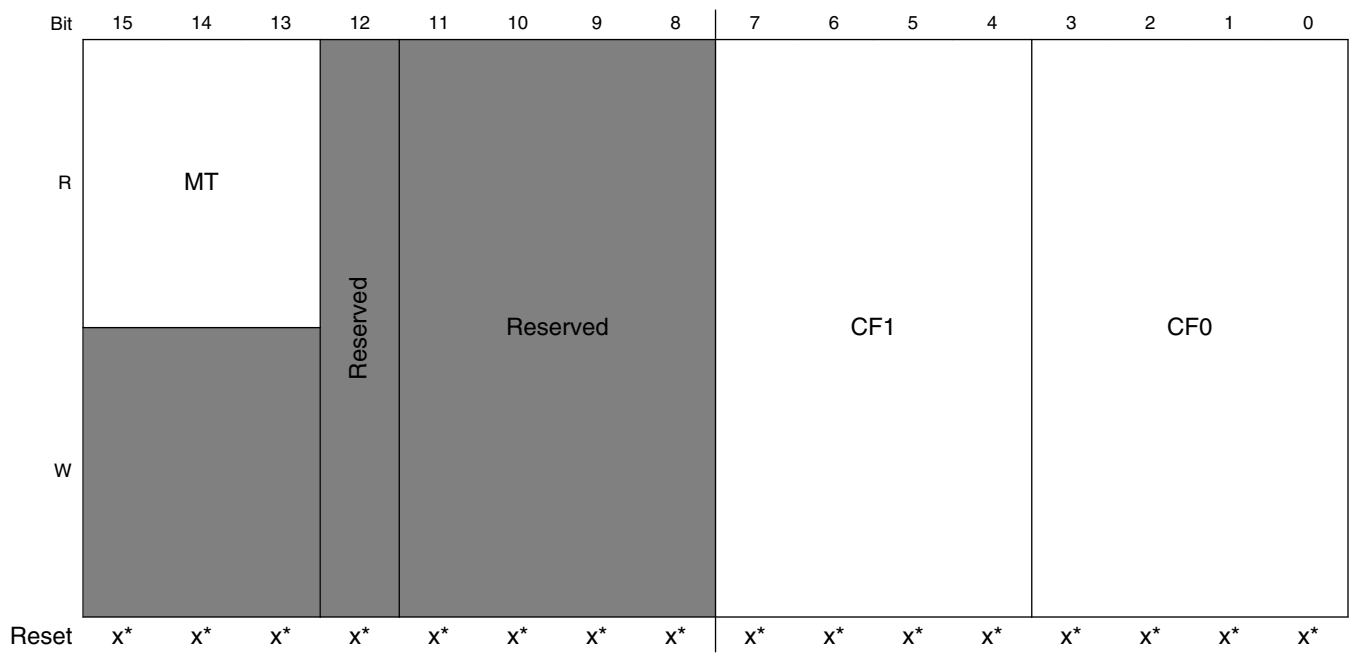
The LMDRn registers mapping to the LMEMs is as follows: LMDR0:code TCM, LMDR1:system TCM, LMDR2:PC Cache, LMDR3: PS Cache.

This section of the programming model is an array of 32-bit generic on-chip memory descriptor registers that provide static information on the attached memories as well as configurable controls (where appropriate).

Privileged 32-bit reads from a processor core or the debugger return the appropriate processor information. Reads from any other bus master return all zeroes. Privileged writes from a processor core or the debugger to writeable registers update the appropriate fields. Privileged writes from other bus masters are ignored. Attempted user mode accesses or any access with a size other than 32 bits are terminated with an error.

Address: E008_0000h base + 400h offset + (4d × i), where i=0d to 3d





* Notes:

- The reset values are different for the individual LMDR registers. LMDR0: 0x8806_0000; LMDR1: 0x8806_2000; LMDR2: 0x8526_4000; LMDR3: 0x8526_6000. x = Undefined at reset.

MCM_LMDR*n* field descriptions

Field	Description
31 V	Local memory Valid bit. This read-only field defines the validity (presence) of the local memory. 0 LMEMn is not present. 1 LMEMn is present.
30 Reserved	This field is reserved.
29 Reserved	This field is reserved.
28 LMSZH	LMEM Size “Hole”. For local memories that are not fully populated, that is, include a memory “hole” in the upper 25% of the address range, this bit is used. 0 LMEMn is a power-of-2 capacity. 1 LMEMn is not a power-of-2, with a capacity is 0.75 × LMSZ.
27–24 LMSZ	LMEM Size. This read-only field provides an encoded value of the local memory size. The capacity of the memory is expressed as Size [bytes] = $2^{(9+SZ)}$ where SZ is non-zero; a SZ = 0 indicates the memory is not present. 0000 no LMEMn (0 KB) 0001 1 KB LMEMn 0010 2 KB LMEMn 0011 4 KB LMEMn 0100 8 KB LMEMn 0101 16 KB LMEMn 0110 32 KB LMEMn 0111 64 KB LMEMn 1000 128 KB LMEMn 1001 256 KB LMEMn 1010 512 KB LMEMn 1011 1024 KB LMEMn 1100 2048 KB LMEMn 1101 4096 KB LMEMn 1110 8192 KB LMEMn 1111 16384 KB LMEMn

Chapter 35
Messaging Unit (MU)

35.1 Chip-specific MU information

Table 35-1. Reference links to related information

Topic	Related module(s)	Reference
System memory map	-	System Memory Map
Clocking	CCM	Clock Management Clock Control Module (CCM)
Power management	PMU	Power Management Power Management Unit
Signal multiplexing	IOMUX	External Signals and Pin Multiplexing IOMUX
Interrupts, DMA Events and XBAR Assignments	-	Interrupts, DMA Events and XBAR Assignments
System Debug	-	System Debug

35.2 Overview

The Messaging Unit (MU) module enables two processors within the SoC to communicate and coordinate by passing messages (e.g. data, status and control) through the MU interface. The MU also provides the ability for one processor to signal the other processor using interrupts.

Because the MU manages the messaging between processors, the MU uses different clocks (from each side of the different peripheral buses). Therefore, the MU must synchronize the accesses from one side to the other. The MU accomplishes synchronization using two sets of matching registers (Processor A-facing, Processor B-facing).

35.2.1 Block Diagram

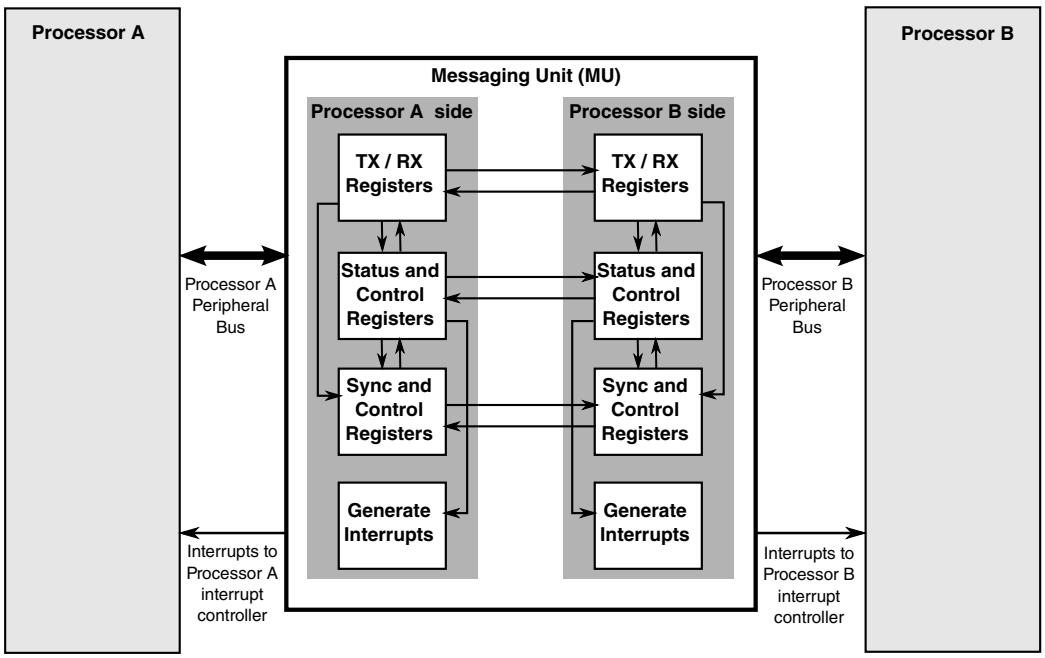

Figure 35-1. MU Block Diagram

35.2.2 Features

The MU includes the following features:

- Messaging control by interrupts or by polling
- Symmetrical processor interfaces with each side supporting the following:
  - Four general-purpose interrupt requests reflected to the other side
  - Three general-purpose flags reflected to the other side [1]
  - Four receive registers with maskable interrupt
  - Four transmit registers with maskable interrupt
- The above interrupts can also be used for waking up the other processor from low-power mode.

NOTE

MU chapter references to Processor A correspond to Core Complex 0 and references to Processor B correspond to Core Complex 1 in this device.

1. For example, MUA (Processor A) can set the flag to MUB (Processor B), and MUB(Processor A) can set the flag to MUA(Processor A).

35.3 Functional Description

Table 35-2. Major Features of the MU

Major Feature	Description
Interprocessor Interrupts	• The MU has 12 interrupt sources on each side (Processor A-side, Processor B-side) that are used for signaling the other processor. The interrupts can be used for notification of RX/TX events and general-purpose signaling between the processors.
MU Reset	• The Processor A can issue a reset to the entire MU, using a control bit (MUR) in the Processor A Control Register (ACR). • The MUR bit is a self-clearing bit.
Status and Control Communications between Core Complexes	• The MU provides a way for the two core complexes to communicate using the status and control registers present on both the Processor B and Processor A sides of the MU. • The status register of one MU side reflects the status of the other MU side. • The control register is used for control operations, such as enabling an interrupt and sending an interrupt to the other processor.
Synchronized Message Transfers between Core Complexes	• The transfer of data messages between core complexes uses transmit empty and receive full flags provided on both sides of the MU. • The update of these transmit and receive flags is accomplished using a synchronization mechanism. There is inherent latency between updating the flag on one side and reflecting its status on other side. For more about latency, see Event Update Timing
Accessing Shared Memory Directly and Avoiding Collisions	• For sending data or messages from one MU-side to the other MU-side, the MU provides 4 transmit registers and 4 receive registers on each side of the MU. • The Processor A or Processor B can access shared memory resources of the SoC directly. However, to avoid simultaneous access to shared memory by both core complexes, the MU provides a method (to prevent simultaneous access) using interrupts and transmit-receive registers for both processors. See Messaging Examples for more information.
Support for Different Clocks in the Two Core Complexes	• The heart of the MU module is the event control mechanism, which synchronizes the access of one MU-side to the other MU-side, because these two MU-sides can operate using different clocks. • Formulated event update latency.
Memory-Mapped Registers	• The MU is connected as a peripheral under the Peripheral bus on both sides—on the Processor A-side, the Processor A Peripheral Bus, and on the Processor B-side, the Processor B Peripheral Bus.

35.3.1 Operating Modes

The MU operates in one of two modes: Run or low power.

35.3.2 Low Power Modes

This section describes the low power operating modes of the MU module.

35.3.2.1 Low Power Clocks and Synchronization

The Processor B and the Processor A clocks operate at different frequencies and from different sources. The MU design does not assume any frequency relationship between the Processor A and the Processor B clocks. Be aware, however, that the frequency relationship affects the MU's throughput performance.

The data buffers and control logic of each MU-side operate with its corresponding clock.

35.3.2.2 Processor Low Power Modes

The Processors have four power modes:

- Run
- WAIT
- STOP
- SUSPEND, can also be called DSM (Deep Sleep Mode)

The Processor can be awakened from a low-power mode by any enabled Processor side MU interrupt, as reflected in the xSR "status" register (RF0–3, TE0–3, GIP0–3 bits are set) and enabled in the xCR control register. Using these bits, the Processor can actively control when to wake the other Processor.

While the Processor is in STOP mode (such that the xSR register bits cannot be updated with events), special logic drives the enabled MU interrupts directly from the other Processor-side (instead of from the xSR register).

While the Processor is in STOP mode, the asynchronous MU interrupt will be asserted to wake the Processor:

- If any transmit data register of the transmitter Processor-side is full, because of a write to it (transmit data register); that is, its "empty" bit in the xSR register is cleared while its corresponding receive interrupt is enabled on the receiver Processor-side.
- If any receive data register of the receiver Processor-side is empty, because of a read on the other Processor -side; that is, its "full" bit in the xSR register is cleared while its corresponding transmit interrupt is enabled on the transmitter Processor-side.
- If any general purpose interrupt bit is set in the xCR register on the other Processor-side while the corresponding interrupt is enabled on the Processor-side.

The logic enables the other Processor to operate independently while the Processor is in any power mode (including STOP). However, the Processor power mode change protocol should be handled with care regarding:

- The interrupts that are enabled on the Processor-side

- The events that could be triggered by the other Processor-side
- The compatibility with the other Processor protocol of entering STOP mode

If the Processor is in STOP mode and an event on the other Processor is triggered, the EP bit (in the xSR register) will remain high until the Processor wakes up.

Before entering STOP mode, the Processor programmer should verify that the EP bit (in the xSR register) is cleared. This check is needed to ensure that all pending updates from the Processor, including the power mode change when STOP or WAIT is executed, will be updated in the xSR register.

- If the other Processor is in STOP mode or DSM mode, the EP bit (in the xSR register) may be stuck high; in this case, the Processor need not check the EP bit before entering STOP mode.

35.3.3 Processor A Side Memory-Mapping

The messaging, control, and status registers of the Processor A-side for the MU are mapped to the Processor A memory as a regular peripheral. The Peripheral bus data is 32 bits wide inside the MU module.

35.3.4 Processor B Side Memory-Mapping

The messaging, control, and status registers of the Processor B-side for the MU are mapped to the Processor B memory as a regular peripheral. The Peripheral bus data is 32 bits wide inside the MU module.

35.3.5 MU Messaging

The MU provides 32-bit status and control registers to the Processor B and Processor A sides for control operations (such as interrupts and reset), and for status checking of the other MU-side.

For messaging, the MU has four, 32-bit write-only transmit registers and four, 32-bit read-only receive registers on the Processor B and Processor A-sides. These registers are used for sending messages to each other. These messages can also be controlled using the 3 general purpose flags provided in the control and status registers of either MU-side.

35.3.5.1 Programmer Model

The messaging logic is used in conjunction with external memory. There are various messaging methods, which can be used to implement a messaging protocol. Some of these messages can mean “a message of N words has just been written, starting at offset X in the memory,” or “a previous data block that was sent has just been read.” Having the messaging logic independent from the memory array does not restrict users to a predefined hardware protocol. On the other hand, the software needed to manage the messaging is short and straightforward.

Most of the messaging mechanisms are symmetric; they are duplicated and are available on both the Processor B-side and the Processor A-side. The messaging mechanisms are:

- Four, 32-bit write-only transmit registers, which are each reflected in four, read-only receive registers in the other processor’s side. Users can use these registers to transfer 32-bit word messages or frame information of messages written to the shared memory (number of words, initial address, and message type code).
- A write to a transmit register on the transmitter side clears a “transmitter empty” bit in the Status Register on the transmitter side, and sets a “receiver full” bit in the Status Register on the receiver side. The setting of the bit at the receiver side can optionally trigger an interrupt at the receiver side (maskable receive interrupt).
- A read of one of the receive registers at the receiver side clears the “receiver full” bit in the Status Register at the receiver side, and sets the “transmitter empty” bit in the Status Register on the transmitter side. The setting of the “transmitter empty” bit can optionally trigger an interrupt at the transmitter side (maskable transmit interrupt).
- Four general purpose flags are reflected in the Status Register on the receiver side
- A read/write access to any reserved location and a write to a read-only register on the Processor A-side of the MU will generate a module transfer error acknowledge to the Processor A.
- A read/write access to any reserved location and write to a read-only register on the Processor B-side of the MU will generate a module transfer error acknowledge to the Processor B.

35.3.5.2 Messaging Examples

The following are messaging examples:

- **Passing short messages:** Transmit register(s) can be used to pass short messages from one to four words in length. For example, when a four-word message is desired, only one of the registers needs to have its corresponding interrupt enable bit set at the receiver side; the message’s first three words are written to the registers whose interrupt is masked, and the fourth word is written to the other register (which triggers an interrupt at the receiver side).

- **Passing frame information:** Transmit registers can be used to pass frame information for long messages written to the shared system memory. Such frame information normally includes a start address, number of words, and perhaps a message type code.
- **Passing event notices and requests:** Events and requests that do not include data words can be signaled from the Processor B to the Processor A using the general interrupts, such as acknowledging that a long message was read from the shared system memory.
- **Passing fixed length data:** Formatted data with a fixed length can be written in predetermined locations in the shared memory. A processor can use a general interrupt (Processor A or Processor B) to signal the other processor that the data is ready.
- **Passing announcements:** The three flags can be used by a processor to announce its current program state or other billboard messages to the other processor.

Figure 35-2 shows the MU registers schematic.

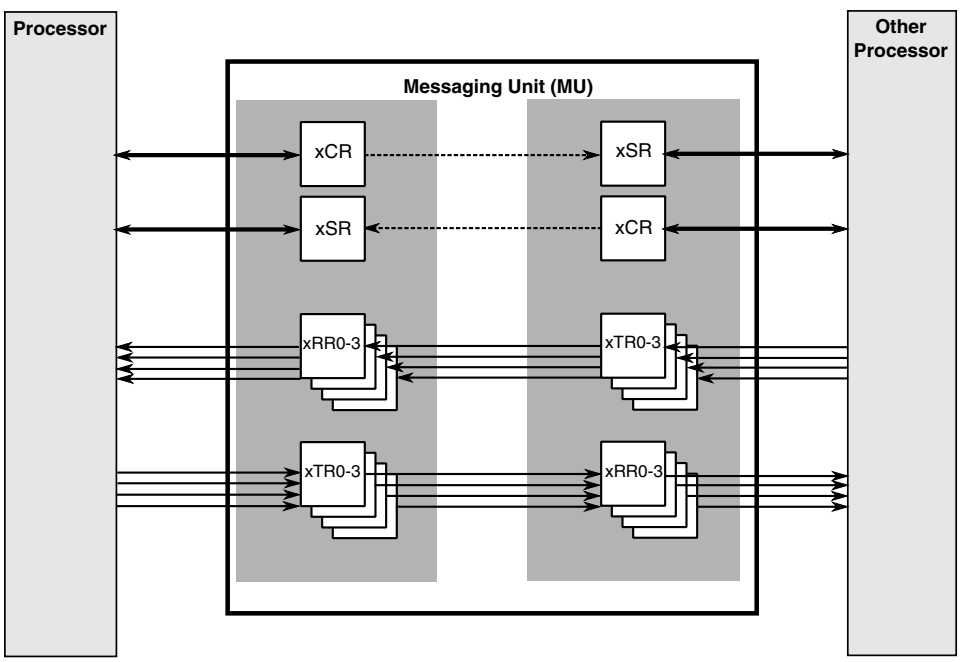

Figure 35-2. MU Registers

35.3.6 Event Update Timing

Each processor's MU messaging side (Processor B or Processor A) has a hardware mechanism to send "event update requests" to the other processor's side. An "event" is considered when any information change should be reflected at the Status Register of the receiving processor. The event update latency is the delay between the event being ready at one processor and the resulting update at the Status Register of the other processor.

- The minimum event latency is "1 clock of the sending side" + "2 1/2 clocks of the receiving side". The minimum case is if there is no event pending when the new event occurs. See clocking chapter for this device for more information about clock sources.
- The maximum event latency is "6 clocks of the sending side" + "6 1/2 clocks of the receiving side." The maximum case is if the event occurred just after a previous event was sent to the other side. The event update latency will vary between the above-mentioned minimum and maximum latencies, depending on the time at which the subsequent event is triggered.

35.3.7 Reset

The MU has two sources of reset, and each reset has a different function from the MU or system perspective.

- One asynchronous system that is connected to both sides of the MU interface.
- One programmable hardware reset (MUR bit) in the ACR register (on the Processor A-side).

Table 35-3. MU programmable resets

Reset	Description
Processor A MU reset	• Processor A MU Reset bit (MUR) of the ACR register • The MUR reset affects the messaging section on both the Processor A and the Processor B sides. The MUR reset causes all control and status registers to return to their default values and all internal states to be cleared. • It is up to the Processor A software to decide whether to use the MUR reset or not. • The instruction immediately following assertion of the MUR bit should not write to MU registers. Such a write may be overwritten by the reset sequence and the register will remain with the reset value. Wait at least one instruction (after assertion of the MUR bit) before attempting a write to MU registers.

After issuing MUR bit reset events, the Processor A programmer can verify that the reset sequence on the Processor B-side has ended, by checking the RS bit in the ASR register.

NOTE

MUR bit assertion is a delicate operation because it affects the other side's registers asynchronously. MUR bit assertion may

cause unpredictable behavior if, for example, the Processor B is concurrently testing an MU register bit (TE bit in Processor B SR register). Before asserting the MUR bit, it should be verified that the Processor B is not presently engaged in an MU signalling activity.

35.3.8 Interrupts

The MU controls the Processor B interrupt requests to the Processor A, and the Processor A interrupt requests to the Processor B. This section describes all the interrupts that the module generates.

35.3.8.1 Interrupts to the Processors

There are 12 interrupt sources from the MU to the Processors:

- Four receive interrupts for each of the receive registers: Asserted when the Processor receive full bits (xSR[RFn]) are set and the xCR[RIEn] bits enabled
- Four transmit interrupts for each of the transmit registers: Asserted when the Processor transmit empty bits (xSR[TEn]) are set and the xCR[TIEn] bits enabled
- Four general purpose interrupts: Asserted when the xSR[GIPn] bits are set and the xCR[GIEn] bits enabled

All the interrupts are maskable in the Processor Control Register (xCR). The MU does not assume any internal priority of these interrupts. Multiple interrupts (for example, Receive 0 and Receive 1 interrupts or any of the transmit and general purpose interrupts) can be asserted at one time. The priority of these interrupts should be resolved by the interrupt controller at the chip level.

The General Purpose Interrupt Pending bits (GIP0, GIP1, GIP2 and GIP3) should be cleared by the software (as part of the interrupt service routine) to de-assert the request to the interrupt controller.

35.3.8.2 General Purpose Interrupt Clearing Sequence

When a Processor writes to the general interrupt bit (GIR), the write event is synchronized to the other Processor clock to set the general interrupt request pending bit (GIP). When the GIP bit is set, and if the general purpose interrupt is enabled on the receiving Processor side (GIE bit is set), then the transmitting Processor general purpose interrupt is issued to the receiving Processor. The receiving Processor clears this interrupt by writing a “1” on the GIP bit. The interrupt is de-asserted as soon as the GIP bit is

written. The write event of the GIP bit is synchronized to the other Processor clock. The synchronized signal clears the GIR bit. The software should not write the GIR bit again until the GIR bit is cleared.

35.3.9 Interrupt Messaging Protocols

35.3.9.1 Messaging Protocols using Interrupts

The example below describes a four-word messaging sequence sent by the Processor to the other Processor.

In this example, the first, second, and third receive interrupts are disabled, and the fourth receive interrupt is enabled. We write registers sequentially for n = 0, 1, 2, 3. For n = 0, 1, 2, the interrupts are disabled, therefore no interrupt will go to the other core complex (although interrupt conditions occur). For n = 3, the interrupt is enabled, and the last Receive Interrupt request is generated.

1. Write Sequence
   - The Processor writes the message information sequentially to its Transmit Registers 0, 1, 2.
   - When the write to the Transmit Register 3 occurs, the RF3 bit of the xSR is set after synchronization, and it immediately trigger the Receive 3 interrupt to the other Processor.
2. Read Sequence
   - The other Processor receives the Receive 3 interrupt and starts reading the message transferred from the receive registers.
   - After Receive Register 3 is read, the interrupt bit is cleared.

Figure 35-3 shows the programmer's model of a messaging protocol using transmit and receive registers. Use Table 35-4 and Figure 35-3 to understand the generalized protocol sequence.

Table 35-4. Interrupt Messaging Protocol (Generalized)

Sequence	Action	Description
1	Processor A Data write	A data write to the ATRn register by Processor A is immediately reflected in the Processor B BRRn register.
2	Clear Tx Empty bit and Set Rx Full bit	The data write to the ATRn register • Clears the transmitter empty bit (TEn) in the Processor A Transmit Status Register • Sets the receiver full bit (RFn) in the Processor B Receive Status Register

Table continues on the next page...

Table 35-4. Interrupt Messaging Protocol (Generalized) (continued)

Sequence	Action	Description
3	Generate Receive Interrupt request	The setting of the receiver full bit (RFn) in the Receive Status Register generates a Receive Interrupt request to Processor B.
4	Processor B Data read	After receiving the Receive Interrupt request, Processor B performs a data read of the BRRn register.
5	Clear Rx Full bit and Set Tx Empty bit	Reading the data out of the BRRn register • Clears the receiver full bit (RFn) in the Processor B Receive Status Register • Sets the transmitter empty bit (TEn) in the Processor A Transmit Status Register
6	Generate Transmit Interrupt request	The setting of the transmitter empty bit (TEn) in the Transmit Status Register generates a Transmit Interrupt request to Processor A.

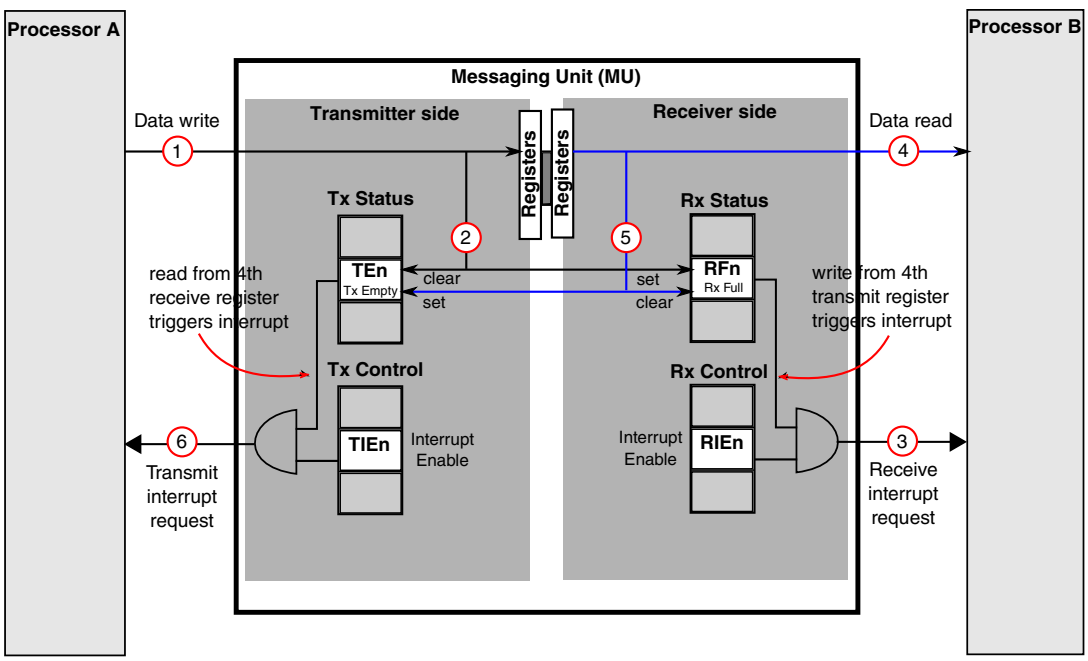

Figure 35-3. Messaging Model Using Transmit and Receive Registers

NOTE

The Transmit registers can be used to pass frame information on long messages written to the shared memory. Such frame information would typically include an initial address, number of words, and perhaps a message type code.

The messaging hardware can be used by software to implement messaging protocols for a wide array of message types. Full support is given for both interrupt and polling management schemes.

35.3.9.2 Messaging Protocols using Event Interrupts

Events and requests that do not include data words can be signaled from the Processor B to the Processor A using the two general interrupts.

Formatted data with a fixed length can be written in predetermined locations in the shared memory. A processor can use a general purpose interrupt to signal the other processor that the data is ready.

The three flags can be used by a processor to announce to the other processor the program state it is currently in, or to announce similar messages.

Table 35-5 and Figure 35-4 describe the event sequence when the Processor triggers an interrupt.

Table 35-5. Interrupt Messaging Protocol (Generalized)

Sequence	Action	Description
1	Processor A sets General Interrupt request bit	Processor A sets its associated General Interrupt request bit (GIRn = 1) in the control register (ACR).
2	General Interrupt Request Pending status bit is set	The General Interrupt Request Pending status bit (GIPn) in the status register (BSR) is set to "1"
3	General Interrupt request to Processor B is generated	Setting the GIPn bit generates the General Interrupt request to Processor B (Interrupt Request Enable bit, GIEn, must be set for Processor B)
4	Processor B reads status register	The Processor B reads the GIPn bit in the BSR register.
5	Processor B services the interrupt	-
6	Processor B sets GIPn bit to clear interrupt	The Processor B writes "1" to the corresponding GIPn bit to clear the interrupt
7	GIRn bit is cleared	Setting the GIPn bit to "1" clears the General Interrupt request bit (GIRn) in the Processor A control register (ACR).

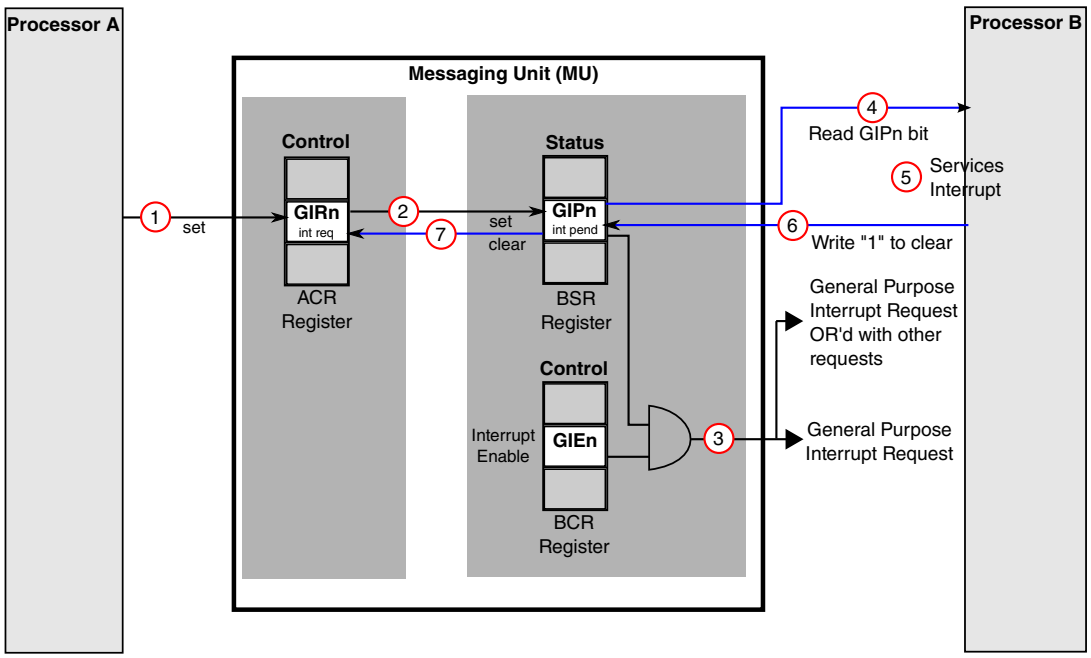

Figure 35-4. Messaging Model Using a General Purpose Interrupt

35.3.10 Exclusive Access to Shared Memory

The MU can be used to signal one processor about its current access to the shared memory, so that the data is not overwritten by the other processor during the exclusive memory access period.

The following tables describe the signaling protocol that the Processor A uses to inform the Processor B about its current access (write) to the shared memory, assuming that the set of bits and registers (GIR0 bit, BRR0 register, BTR0 register, GIR0 bit, ARR0 register, ATR0 register) are reserved to support exclusive access to the shared memory protocol.

Table 35-6. How the Processor A Performs an Exclusive Access to Shared Memory

Sequence	Action	Description
1	Processor A sends GIRn request to Processor B using Processor A control register	When the Processor A wants to perform an exclusive access to the shared memory, the Processor A sends an GIR0 request to the Processor B.
2	Processor A sends an exclusive-access request using a transmit data register (ATRn)	The Processor A will send an exclusive-access request (command, location, and length of target access) to Processor B using a selected transmit data register (ATR0).
3	Processor A waits for a dedicated interrupt from Processor B	The Processor A waits for a dedicated interrupt (as an acknowledgement) triggered by the Processor B before proceeding.

Table continues on the next page...

Table 35-6. How the Processor A Performs an Exclusive Access to Shared Memory (continued)

Sequence	Action	Description
4	Processor A accesses shared memory	After receiving a dedicated interrupt from the Processor B, Processor A proceeds.

Table 35-7. How the Processor B Scans for Transaction Information

Sequence	Action	Description
1	Processor B receives an interrupt from a receive data register (BRRn)	-
2	Processor B reads the receive data register (BRRn)	-
3	Processor B scans the receive data register contents	For transaction information (whether Processor A has requested an exclusive-access)

Table 35-8. How the Processor B Accepts Exclusive Access by Processor A

Sequence	Action	Description
1	Processor B triggers a dedicated interrupt	Processor B acknowledges the Processor A request by triggering a dedicated interrupt (ack) to the Processor A.
2	Processor B sends a code message to Processor A	Along with the acknowledge interrupt, the Processor B sends a code message to the Processor A through the selected transmit register (BTRn). The message informs the Processor A that it can exclusively access the shared memory.

Table 35-9. How the Processor B Rejects Exclusive Access by Processor A

Sequence	Action	Description
1	Processor B ignores Processor A request for exclusive access	If the Processor B does not want to give go-ahead permission to the Processor A, Processor B ignores the exclusive access request.

35.3.11 Packet Data Transfers

The following example describes the packet transfer sequence between the Processor B and Processor A subsystems:

Table 35-10. Packet Data Transfer Sequence

Action	Sequence	Description
Processor B requests DMA	1	The Processor B sends a DMA request to initiate the packet data transfer

Table continues on the next page...

Table 35-10. Packet Data Transfer Sequence (continued)

Action	Sequence	Description
DMA data transfer	2	DMA acknowledges.
	3	DMA starts transferring data from the specified Processor B location to the specified shared memory
	4	DMA interrupts the Processor B to signal that the packet transfer has finished.
Processor B informs Processor A that data is in shared memory	5	Using an MU Processor B-side transmit register, the Processor B sends a packet information message to the Processor A to inform the Processor A of the arrival of new packet data that is stored in shared memory . The message contains the command, location, and length of packet data information.
Processor A receives interrupt	6	The Processor A receives an interrupt (assuming its corresponding Processor A MU-side receive interrupt is enabled), and the pending processing task becomes active and processes packet data from memory.
Processor A reads data, writes data	7	The Processor A reads or processes packet data from shared memory.
	8	The Processor A writes the result from packet processing to a separate buffer.
Processor A informs Processor B that transfer is finished	9	After the processing of the packet data finishes, the Processor A informs the Processor B (using the MU Processor A-side transmit register, ATRn).
Processor A sends interrupt to Processor B (request for more data)	10	The Processor B receives the next interrupt from the Processor A, in which the Processor A requests more packet data.

35.4 External Signals

There are no Messaging Unit signals directly available at the chip boundary of the SoC.

35.5 Initialization

The MU is used for two processors to communicate by passing messages. Below are examples for passing messages:

1. Interrupt mode
    - Processor A:
        - write ATR0;
        - ACR.TIEn[0] = 1;
        - wait for transmit register empty interrupt;
    - Processor B:
        - BCR.RIEn[0] = 1;
        - wait for receive register full interrupt;
        - read BRR0;

2. Polling mode
    - Processor A:
        - write ATR0;
        - while(ASR.TEn[0] != 1) ;
    - Processor B:
        - while(BSR.RFn[0] != 1) ;
        - read BRR0;

See Application Information for details regarding software restrictions.

35.6 Application Information

This section describes certain software restrictions when accessing the MU.

35.6.1 General Restrictions

This section lists the restrictions that apply to both the sides (Processor A, Processor B) of the MU.

35.6.1.1 Write-After-Write to a Transmit Register

A write to a transmit register signals the receiver side that data is ready for retrieval.

- Writing to the transmit register again without verifying that the data was retrieved is prohibited, because the transmitter side has no way of knowing the exact time that the receiver will attempt to retrieve the data.
- Before attempting to write the transmit register again, the transmitter side should wait for a “Transmitter Empty” interrupt, or should poll the “Transmitter Empty” bit in the Status Register.
- Failure to follow this restriction may result in the wrong data being read on the receiver side of the MU.

35.6.1.2 Read-After-Read from a Receive Register

A read of a receive register signals the transmitter side that data can be written to that register. In the same way, the receiver processor should not read a receive register before receiving a “Receiver Full” interrupt or polling the “Receiver Full” bit in the Status Register.

- Reading the receive register again without verifying that the data was written is prohibited, because the receiver side has no way of knowing the exact time that the transmitter will attempt to write the data.
- Before attempting to read the receive register again, the receiver side should wait for a “Receiver Full” interrupt, or should poll the “Receiver Full” bit in the Status Register.
- Failure to follow this restriction may result in the wrong data being written on the transmitter side of the MU.

35.6.2 Processor Restrictions

This section lists the restrictions that apply each side of the processor in the MU.

35.6.2.1 Before Entering Low Power Mode

Before entering Low Power mode, the Processor should verify that the Processor Event Pending (EP) bit in the Status Register is cleared.

- If the Event Pending bit (EP) is still set to “1”, then the Processor should wait and poll the EP bit until it is cleared, before executing the low power mode instruction.
- Note that if the other Processor is in Low Power mode, the EP bit may be stuck high. In this case, the other Processor clock must be turned ON to get the EP bit cleared before the Processor can enter Low Power mode.

35.6.2.2 Before Setting a General Interrupt Request Bit (GIR0–3)

Before setting a General Interrupt Request bit (GIR0–3), verify the GIRn bit is cleared, which means that a general interrupt is not pending. Generally, setting the GIRn bit while the bit is set to “1” will be ignored, but in some cases it may issue a second interrupt. This restriction is meant to prevent this indeterministic behavior.

35.6.2.3 Reset Bit Restrictions

The reset bit (MUR) restrictions are:

- Before asserting the MUR bit in the ACR register, verify that the Processor B-side is not engaged in some MU activity.
- Do not write to an MU register in the instruction immediately after the assertion of the MUR bit in the ACR register, because the written data can be overridden by the reset value.

35.7 MU Processor A-side Memory Map/Register Definition

35.7.1 MUA register descriptions

This section contains the detailed register descriptions for the Processor A-side MU registers.

35.7.1.1 MUA memory map

MUA base address: 40C4_8000h

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)
0	Processor A Transmit Register 0 (TR0)	32	RW	0000_0000
4	Processor A Transmit Register 1 (TR1)	32	RW	0000_0000
8	Processor A Transmit Register 2 (TR2)	32	RW	0000_0000
C	Processor A Transmit Register 3 (TR3)	32	RW	0000_0000
10	Processor A Receive Register 0 (RR0)	32	RO	0000_0000
14	Processor A Receive Register 1 (RR1)	32	RO	0000_0000
18	Processor A Receive Register 2 (RR2)	32	RO	0000_0000
1C	Processor A Receive Register 3 (RR3)	32	RO	0000_0000
20	Processor A Status Register (SR)	32	W1C	00F0_0080
24	Processor A Control Register (CR)	32	RW	0000_0000

35.7.1.2 Processor A Transmit Register 0 (TR0)

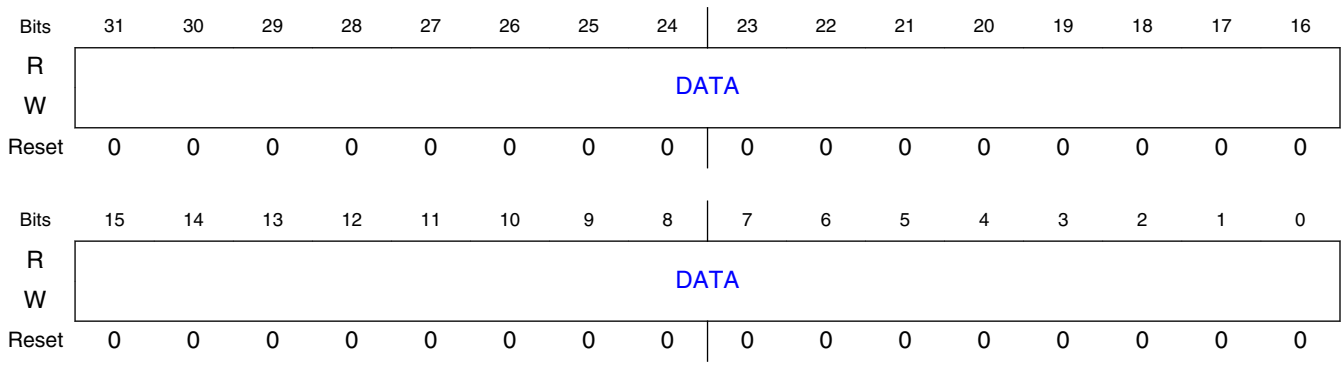
Use Processor A Transmit Register 0 (TR0, 32-bit, write-only) to transmit a message or data to the Processor B.

- Users can only write to the TR0 register when the TE0 bit in SR register is set to "1".
- Reading the TR0 register returns all zeros.

35.7.1.2.1 Offset

Register	Offset
TR0	0h

35.7.1.2.2 Diagram



35.7.1.2.3 Fields

Field	Description
31-0 DATA	TR0 Processor A Transmit Register 0. (Write-only) • Data written to the MUA.TR0 register is reflected on the Processor B-side in the Processor B Receive Register 0 (MUB.RR0). The MUA.TR0 and MUB.RR0 registers are not double-buffered—a write to the MUA.TR0 register overrides the data readable at the MUB.RR0 register. • A write to the transmit register clears a "transmitter empty" bit (TE0) in the Processor A Status Register (MUA.SR) on the transmitter side, and sets a "receiver full" bit (RF0) in the Processor B Status Register (MUB.SR) on the receiver side (optionally triggering an interrupt 0 on the Processor B-side). • Any write to the TR0 register will update all status information.

35.7.1.3 Processor A Transmit Register 1 (TR1)

Use Processor A Transmit Register 1 (TR1, 32-bit, write-only) to transmit a message or data to the Processor B.

- Users can only write to the TR1 register when the TE1 bit in SR register is set to "1".
- Reading the TR1 register returns all zeros.

35.7.1.3.1 Offset

Register	Offset
TR1	4h

35.7.1.3.2 Diagram

35.7.1.3.3 Fields

Field	Description
31-0 DATA	TR1 Processor A Transmit Register 1. (Write-only) • Data written to the MUA.TR1 register is reflected on the Processor B-side in the Processor B Receive Register 1 (MUB.RR1). The TR1 and RR1 registers are not double-buffered—a write to the MUA.TR1 register overrides the data readable at the MUB.RR1 register. • A write to the transmit register clears a "transmitter empty" bit (TE1) in the Processor A Status Register (MUA.SR) on the transmitter side, and sets a "receiver full" bit (RF1) in the Processor B Status Register (MUB.SR) on the receiver side (optionally triggering an interrupt 1 on the Processor B-side). • Any write to the MUA.TR1 register will update all status information.

35.7.1.4 Processor A Transmit Register 2 (TR2)

Use Processor A Transmit Register 2 (TR2, 32-bit, write-only) to transmit a message or data to the Processor B.

- Users can only write to the TR2 register when the TE2 bit in SR register is set to "1".
- Reading the TR2 register returns all zeros.

35.7.1.4.1 Offset

Register	Offset
TR2	8h

35.7.1.5.3 Fields

Field	Description
31-0 DATA	TR3 Processor A Transmit Register 3. (Write-only) • Data written to the MUA.TR3 register is reflected on the Processor B-side in the Processor B Receive Register 3 (MUB.RR3). The TR3 and RR3 registers are not double-buffered—a write to the MUA.TR3 register overrides the data readable at the MUB.RR3 register. • A write to the transmit register clears a "transmitter empty" bit (TE3) in the Processor A Status Register (MUA.SR) on the transmitter side, and sets a "receiver full" bit (RF3) in the Processor B Status Register (MUB.SR) on the receiver side (optionally triggering an interrupt 3 on the Processor B-side). • Any write to the TR3 register will update all status information.

35.7.1.6 Processor A Receive Register 0 (RR0)

Use Processor A Receive Register 0 (RR0, 32-bit, read-only) to receive a message or data from the Processor B.

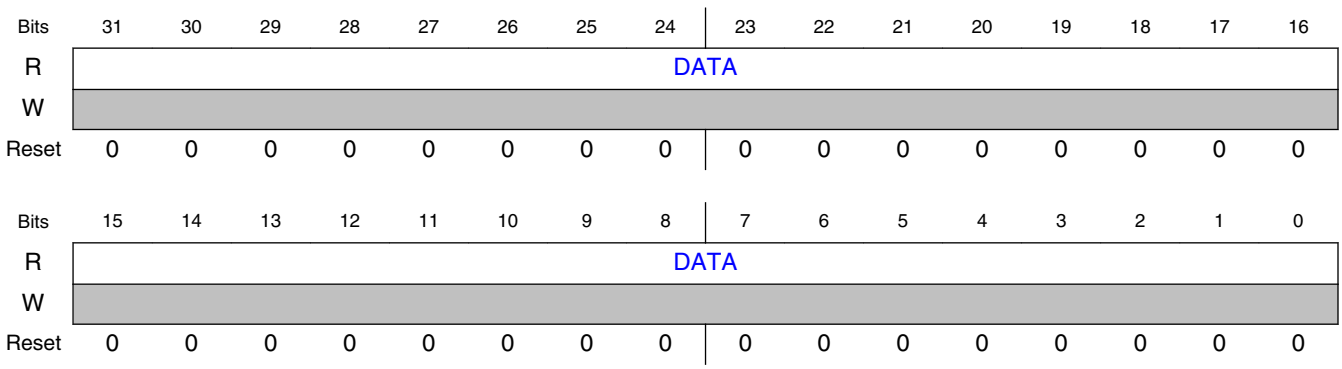
- Data written to the MUB.TR0 register is immediately reflected in the MUA.RR0 register.

- Users can only read the MUA.RR0 register when the RF0 bit in the MUA.SR register is set to "1".
- Writing to the MUA.RR0 register generates an error response to the Processor A.

35.7.1.6.1 Offset

Register	Offset
RR0	10h

35.7.1.6.2 Diagram



35.7.1.6.3 Fields

Field	Description
31-0 DATA	RR0 Processor A Receive Register 0. (Read-only) • Reflects the data written to Processor B Transmit Register 0 (MUB.TR0). • Reading the MUA.RR0 register clears the "receiver full" bit (RF0) in the Processor A Status Register (MUA.SR) on the receiver side, and sets the "transmitter empty" bit (TE0) in the Processor B Status Register on the transmitter side (optionally triggering a transmit interrupt 0 on the Processor B-side). • Any read of the RR0 register will update all status information.

35.7.1.7 Processor A Receive Register 1 (RR1)

Use Processor A Receive Register 1 (RR1, 32-bit, read-only) to receive a message or data from the Processor B.

- Data written to the MUB.TR1 register is immediately reflected in the MUA.RR1 register.
- Users can only read the MUA.RR1 register when the RF1 bit in the MUA.SR register is set to "1".
- Writing to the RR1 register generates an error response to the Processor A.

35.7.1.7.1 Offset

Register	Offset

35.7.1.7.3 Fields

Field	Description
31-0 DATA	RR1 Processor A Receive Register 1. (Read-only) • Reflects the data written to Processor B Transmit Register 1 (MUB.TR1). • Reading the RR1 register clears the "receiver full" bit (RF1) in the Processor A Status Register (MUA.SR) on the receiver side, and sets the "transmitter empty" bit (TE1) in the Processor B Status Register on the transmitter side (optionally triggering a transmit interrupt 1 on the Processor B-side). • Any read of the RR1 register will update all status information.

35.7.1.8 Processor A Receive Register 2 (RR2)

Use Processor A Receive Register 2 (RR2, 32-bit, read-only) to receive a message or data from the Processor B.

- Data written to the MUB.TR2 register is immediately reflected in the MUA.RR2 register.
- Users can only read the MUA.RR2 register when the RF2 bit in the MUA.SR register is set to "1".
- Writing to the RR2 register generates an error response to the Processor A.

35.7.1.8.3 Fields

Field	Description
31-0 DATA	RR2 Processor A Receive Register 2. (Read-only) • Reflects the data written to Processor B Transmit Register 1 (MUB.TR2). • Reading the MUA.RR2 register clears the "receiver full" bit (RF2) in the Processor A Status Register (MUA.SR) on the receiver side, and sets the "transmitter empty" bit (TE2) in the Processor B Status Register on the transmitter side (optionally triggering a transmit interrupt 2 on the Processor B-side). • Any read of the RR2 register will update all status information.

35.7.1.9 Processor A Receive Register 3 (RR3)

Use Processor A Receive Register 3 (RR3, 32-bit, read-only) to receive a message or data from the Processor B.

- Data written to the MUB.TR3 register is immediately reflected in the MUA.RR3 register.
- Users can only read the MUA.RR3 register when the RF3 bit in the MUA.SR register is set to "1".
- Writing to the RR3 register generates an error response to the Processor A.

35.7.1.9.3 Fields

Field	Description
31-0 DATA	RR3 Processor A Receive Register 3. (Read-only) • Reflects the data written to Processor B Transmit Register 3 (MUB.TR3). • Reading the MUA.RR3 register clears the "receiver full" bit (RF3) in the Processor A Status Register (MUA.SR) on the receiver side, and sets the "transmitter empty" bit (TE3) in the Processor B Status Register on the transmitter side (optionally triggering a transmit interrupt 3 on the Processor B-side). • Any read of the RR3 register will update all status information.

35.7.1.10 Processor A Status Register (SR)

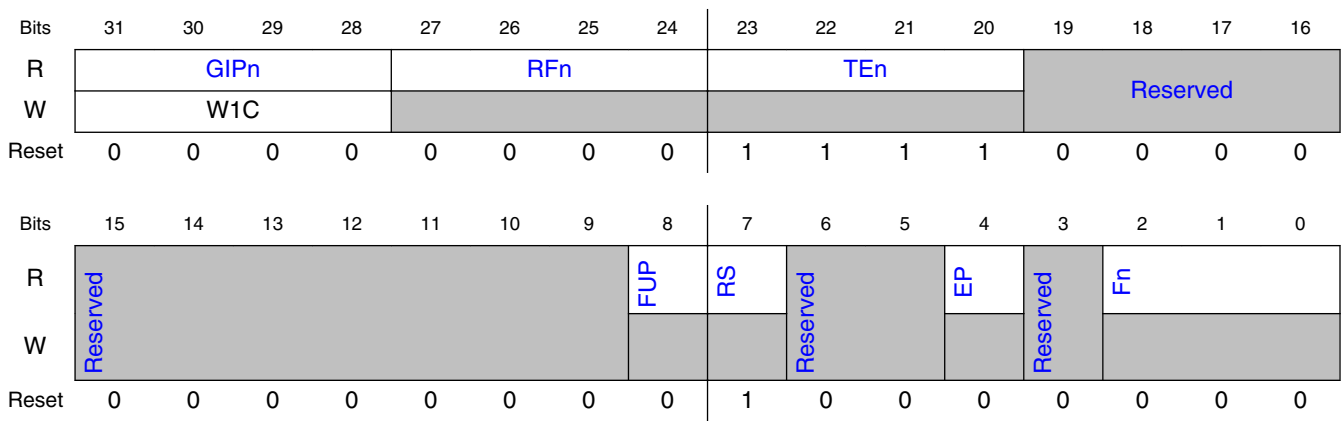
Use the Processor A Status Register (SR, 32-bit, read-write) to show interrupt status from the Processor B, general purpose flags, and to set dual function control-status bits.

- Some dual-purpose bits are set by the MU logic, and cleared by the Processor A-side programmer
- Other dual-purpose bits are set by the Processor A-side programmer, and cleared by the MU logic.

35.7.1.10.1 Offset

Register	Offset
SR	20h

35.7.1.10.2 Diagram



35.7.1.10.3 Fields

Field	Description
31-28 GIPn	GIPn For n = {0, 1, 2, 3} Processor A General Interrupt Request n Pending. (Read-Write) • GIPn bit signals the Processor A that the GIRn bit in the MUB.CR register on the Processor B-side was set from "0" to "1". If the GIEn bit in the MUA.CR register is set to "1", a General Interrupt n request is issued.

Table continues on the next page...

Field	Description
	• The GIPn bit is cleared by writing it back as "1". Writing "0", or writing "1" when the GIPn bit is cleared is ignored. Use this feature in the interrupt routine, where the GIPn bit is cleared in order to de-assert the interrupt request source at the interrupt controller. The proper bit clearing sequence is: clear an Processor A register, set the desired bit in it (Processor A register), and write it to the MUA.SR register, thus clearing the GIPn bit. • GIPn bit is cleared when the MU is reset. 0000 - Processor A general purpose interrupt n is not pending. (default) 0001 - Processor A general purpose interrupt n is pending.
27-24 RFn	RFn For n = {0, 1, 2, 3} Processor A Receive Register n Full. (Read-only) • The RFn bit is set to "1" when the MUB.TRn register is written on the Processor B-side. • After the RFn bit is set to "1", the RFn bit signals the Processor A-side that new data is ready to be read by the Processor A in the MUA.RRn register, and a Receive n interrupt is issued on the Processor A-side (if the RIEn bit in the CR register has been set to "1"). • RFn bit is cleared when the MUA.RRn register is read, and when the MU is reset. 0000 - MUA.RRn register is not full (default). 0001 - MUA.RRn register has received data from MUB.TRn register and is ready to be read by the Processor A.
23-20 TEn	TEn For n = {0, 1, 2, 3} Processor A Transmit Register n Empty. (Read-only) • The TEn bit is set to "1" after the BRRn register is read on the Processor B-side. • After the TEn bit is set to "1", the TEn bit signals the Processor A-side that the MUA.TRn register is ready to be written on the Processor A-side, and a Transmit n interrupt is issued on the Processor A-side (if the TEn bit in the MUA.CR register is set to "1"). • TEn bit is cleared after the MUA.TRn register is written on the Processor A-side. • TEn bit is set to "1" when the MU is reset. 0000 - MUA.TRn register is not empty. 0001 - MUA.TRn register is empty (default).
19-9 —	- Reserved
8 FUP	FUP Processor A Flags Update Pending. (Read-only) • FUP bit is set to "1" when the Processor A-side sends a Flags Update request to the Processor B-side. • A Flags Update request is generated when the ABF[2:0] bits of the CR register change. No flag update changes are allowed while the FUP bit is set to "1". Any write to the ABF[2:0] bits, while the FUP bit is set to "1", will not generate a Flags Update event, and the ABF[2:0] bits will stay unchanged. • FUP bit is cleared when this Flags Update request is internally acknowledged (that the flag is updated) from the MU Processor B-side, and during MU reset. 0 - No flags updated, initiated by the Processor A, in progress (default) 1 - Processor A initiated flags update, processing
7 RS	RS Processor B-side Reset State. (Read-only) • RS bit indicates if the Processor B-side of the MU is in a reset state or not. • If the RS bit is set to "1", then the Processor B-side of the MU is still in the reset state. • If the RS bit is cleared, then the Processor B-side of the MU are out of reset.

Table continues on the next page...

Field	Description
	• The RS bit is set to "1" during: a Processor B system reset, or an MU reset (caused by setting the MUR bit at the MUA.CR register). • The RS bit is cleared when the reset sequence on the Processor B-side of the MU ends. After issuing any of the reset events mentioned previously, verify that the RS bit is cleared before starting any accesses. • When Processor A side of MU comes out of reset RS bit has value "1"(default).Then Processor A sees the status of Processor B-side and if Processor B-side has come out of reset then RS bit goes low. This takes 5-6 clock cycles. If the RS bit is read now it shows as low although its reset value was "1" . 0 - The Processor B-side of the MU is not in reset. 1 - The Processor B-side of the MU is in reset.
6-5 —	- Reserved
4 EP	EP Processor A-Side Event Pending. (Read-only) • EP bit is set to "1" when the Processor A-side mechanism sends an event update request to the Processor B-side. • EP bit is cleared when the event update acknowledge is received. An "event" is any hardware message that is reflected in the MUB.SR register on the Processor B-side (for example, "transmit register 0 written"). During normal operations, users do not have to deal with the state of the EP bit because the event update mechanism works automatically. • To ensure events have been posted to Processor B before entering STOP mode, verify that the EP bit is cleared. If EP bit is set to "1", wait and continue to poll it (EP bit) before entering STOP mode. • Reading the SR register (to check the EP bit) should be the last access to the MU that should be performed before entering STOP or WAIT modes; otherwise, the EP bit may be set by subsequent additional actions. • The EP bit is cleared when the MU resets. 0 - The Processor A-side event is not pending (default). 1 - The Processor A-side event is pending.
3 —	- Reserved
2-0 Fn	Fn For n = {0, 1, 2} Processor A-Side Flag n. (Read-only) • Fn bit is the Processor A-side flag that reflects the values written to the BAFn bit in the Processor B control register. • Every time that the BAFn bit is written, the BAFn bit write event updates the Fn bit after the event update latency, which is measured in terms of the number of clocks of the Processor B and the Processor A. 000 - BAFn bit in MUB.CR register is written 0 (default). 001 - BAFn bit in MUB.CR register is written 1.

35.7.1.11 Processor A Control Register (CR)

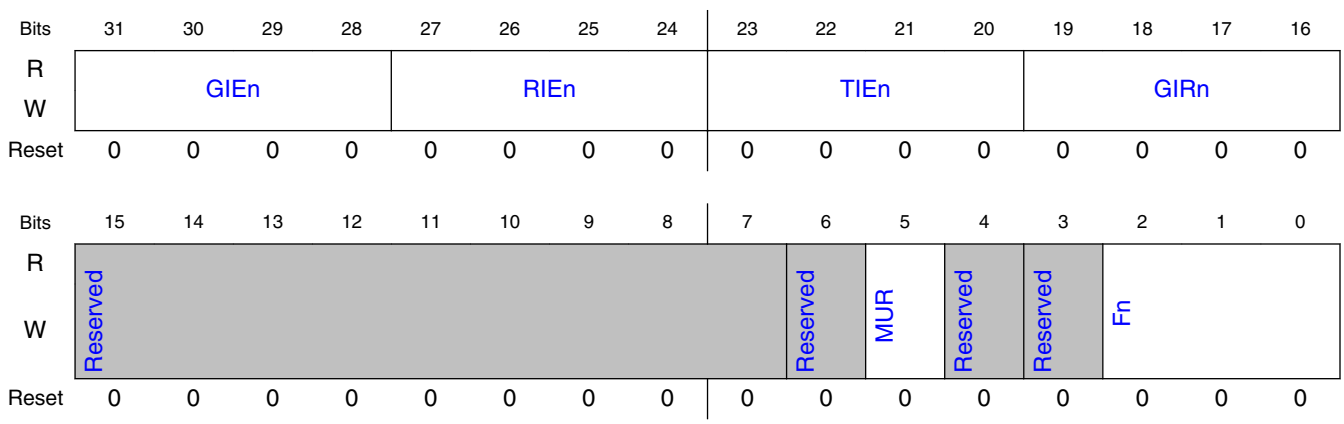
Use the Processor A Control Register (CR, 32-bit, read-write) to enable the MU interrupts on the Processor A-side, and trigger events and interrupts on the Processor B-side (general purpose interrupt, flag update).

For the fields GIEn, RIEn, TIEn and GIRn, n=0 corresponds to the high order bit and n=3 corresponds to the low order bit.

35.7.1.11.1 Offset

Register	Offset
CR	24h

35.7.1.11.2 Diagram



35.7.1.11.3 Fields

Field	Description
31-28 GIEn	GIEn For n = {0, 1, 2, 3} Processor A General Purpose Interrupt Enable n. (Read-Write) When GIEn=0 corresponds to the high order bit and GIE3 corresponds to the low order bit. • GIEn bit enables Processor A General Interrupt n. • If GIEn bit is set to "1" (enabled), then a General Interrupt n request is issued when the GIPn bit in the MUA.SR register is set to "1". • If GIEn is cleared (disabled), then the value of the GIPn bit is ignored and no General Interrupt n request will be issued. • GIEn bit is cleared when the MU resets. 0000 - Disables Processor A General Interrupt n. (default) 0001 - Enables Processor A General Interrupt n.
27-24	RIEn

Table continues on the next page...

Field	Description
RIEn	For n = {0, 1, 2, 3} Processor A Receive Interrupt Enable n. (Read-Write) • RIEn bit enables Processor A Receive Interrupt n. • If RIEn bit is set to "1" (enabled), then an Processor A Receive Interrupt n request is issued when the RFn bit in the MUA.SR register is set to "1". • If RIEn bit is cleared (disabled), then the value of the RFn bit is ignored and no Processor A Receive Interrupt n request will be issued. • RIEn bit is cleared when the MU resets. 0000 - Disables Processor A Receive Interrupt n. (default) 0001 - Enables Processor A Receive Interrupt n.
23-20 TIEn	TIEn For n = {0, 1, 2, 3} Processor A Transmit Interrupt Enable n. (Read-Write) • TIEn bit enables Processor A Transmit Interrupt n. • If TIEn bit is set to "1" (enabled), then an Processor A Transmit Interrupt n request is issued when the TEn bit in the MUA.SR register is set to "1". • If TIEn bit is cleared (disabled), then the value of the TEn bit is ignored and no Processor A Transmit Interrupt n request will be issued. • TIEn bit is cleared when the MU resets. 0000 - Disables Processor A Transmit Interrupt n. (default) 0001 - Enables Processor A Transmit Interrupt n.
19-16 GIRn	GIRn For n = {0, 1, 2, 3} Processor A General Purpose Interrupt Request n. (Read-Write) • Writing "1" to the GIRn bit sets the GIPn bit in the MUB.SR register on the Processor B-side. If the GIEn bit in the MUB.CR register is set to "1" on the Processor B-side, a General Purpose Interrupt n request is triggered. • The GIRn bit is cleared if the GIPn bit (in the MUB.SR register on the Processor B-side) is cleared by writing it (GIPn bit) as "1", thereby signalling the Processor A that the interrupt was accepted (cleared by the software). The GIPn bit cannot be written as "0" on the Processor A-side. • To ensure proper operations, verify that the GIRn bit is cleared (meaning that there is no pending interrupt) before setting it (GIRn bit). • GIRn bit is cleared when the MU resets. 0000 - Processor A General Interrupt n is not requested to the Processor B (default). 0001 - Processor A General Interrupt n is requested to the Processor B.
15-7 —	- Reserved
6 —	- Reserved
5 MUR	MUR Processor A MU Reset. • Setting MUR bit to "1" resets both the Processor B and the Processor A sides of the MU module, forcing all control and status registers to return to their default values (except the HR bit in the MUA.CR register and HRM bit in MUB.CR register), and all internal states to be cleared. • Before setting the MUR bit to "1", it is advisable to interrupt the Processor B, because setting the MUR bit may affect the ongoing Processor B program. • After setting the MUR bit, monitor the value of the RS bit in the MUA.SR register to know when the reset sequence on the Processor B-side has ended. • MUR bit can only be written as "1". • MUR bit is always read as "0". • MUR bit is cleared during the MU reset sequence.

Table continues on the next page...

Field	Description
	0 - N/A. Self clearing bit (default). 1 - Asserts the Processor A MU reset.
4 —	- Reserved
3 —	- Reserved
2-0 Fn	Fn For n = {0, 1, 2} Processor A to Processor B Flag n. (Read-Write) • Fn bit is a read-write flag that is reflected in Fn bit in the MUB.SR register on the Processor B-side. • Fn bit is cleared when the MU resets. 000 - N/A. Self clearing bit (default). 001 - Asserts the Processor A MU reset.

35.8 MU Processor B-side Memory Map/Register Definition

35.8.1 MUB register descriptions

This section contains the detailed register descriptions for the Processor B-side MU registers.

35.8.1.1 MUB memory map

MUB base address: 40C4_C000h

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)
0	Processor B Transmit Register 0 (TR0)	32	RW	0000_0000
4	Processor B Transmit Register 1 (TR1)	32	RW	0000_0000
8	Processor B Transmit Register 2 (TR2)	32	RW	0000_0000
C	Processor B Transmit Register 3 (TR3)	32	RW	0000_0000
10	Processor B Receive Register 0 (RR0)	32	RO	0000_0000
14	Processor B Receive Register 1 (RR1)	32	RO	0000_0000
18	Processor B Receive Register 2 (RR2)	32	RO	0000_0000
1C	Processor B Receive Register 3 (RR3)	32	RO	0000_0000
20	Processor B Status Register (SR)	32	W1C	00F0_0080

Table continues on the next page...

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)
24	Processor B Control Register (CR)	32	RW	0000_0000

35.8.1.2 Processor B Transmit Register 0 (TR0)

Use Processor B Transmit Register 0 (TR0, 32-bit, write-only) to transmit a message or data to the Processor A.

- The TR0 register can only be written when the TE0 bit in SR register is set to "1".
- Reading the TR0 register returns all zeros.

35.8.1.2.1 Offset

Register	Offset
TR0	0h

35.8.1.2.2 Diagram

35.8.1.2.3 Fields

Field	Description
31-0 DATA	TR0 Processor B Transmit Register 0. (Write-only) • Data written to the MUB.TR0 register is reflected on the Processor A-side in the Processor A Receive Register 0 (MUA.RR0). The MUB.TR0 and MUA.RR0 registers are not double-buffered—a write to the MUB.TR0 register overrides the data readable at the MUA.RR0 register.

Field	Description
	• A write to the transmit register clears a "transmitter empty" bit (TE0) in the Processor B Status Register (MUB.SR) on the transmitter side, and sets a "receiver full" bit (RF0) in the Processor A Status Register (MUA.SR) on the receiver side (optionally triggering an interrupt 0 on the Processor A-side). • Any write to the TR0 register will update all status information.

35.8.1.3 Processor B Transmit Register 1 (TR1)

Use Processor B Transmit Register 1 (TR1, 32-bit, write-only) to transmit a message or data to the Processor A.

- The TR1 register can only be written when the TE1 bit in SR register is set to "1".
- Reading the TR1 register returns all zeros.

35.8.1.3.1 Offset

Register	Offset
TR1	4h

35.8.1.3.3 Fields

Field	Description
31-0 DATA	TR1 Processor B Transmit Register 1. (Write-only)

Field	Description
	• Data written to the MUB.TR1 register is reflected on the Processor A-side in the Processor A Receive Register 1 (MUA.RR1). The MUB.TR1 and MUA.RR1 registers are not double-buffered—a write to the MUB.TR1 register overrides the data readable at the MUA.RR1 register. • A write to the transmit register clears a "transmitter empty" bit (TE1) in the Processor B Status Register (MUB.SR) on the transmitter side, and sets a "receiver full" bit (RF1) in the Processor A Status Register (MUA.SR) on the receiver side (optionally triggering an interrupt 1 on the Processor A-side). • Any write to the TR1 register will update all status information.

35.8.1.4 Processor B Transmit Register 2 (TR2)

Use Processor B Transmit Register 2 (TR2, 32-bit, write-only) to transmit a message or data to the Processor A.

- The TR2 register can only be written when the TE2 bit in SR register is set to "1".
- Reading the TR2 register returns all zeros.

35.8.1.4.3 Fields

Field	Description
31-0	TR2

Field	Description
DATA	Processor B Transmit Register 2. (Write-only) • Data written to the MUB.TR2 register is reflected on the Processor A-side in the Processor A Receive Register 2 (MUA.RR2). The MUB.TR2 and MUA.RR2 registers are not double-buffered—a write to the MUB.TR2 register overrides the data readable at the MUA.RR2 register. • A write to the transmit register clears a "transmitter empty" bit (TE2) in the Processor B Status Register (MUB.SR) on the transmitter side, and sets a "receiver full" bit (RF2) in the Processor A Status Register (MUA.SR) on the receiver side (optionally triggering an interrupt 2 on the Processor A-side). • Any write to the TR2 register will update all status information.

35.8.1.5 Processor B Transmit Register 3 (TR3)

Use Processor B Transmit Register 3 (TR3, 32-bit, write-only) to transmit a message or data to the Processor A.

- The TR3 register can only be written when the TE3 bit in SR register is set to "1".
- Reading the TR3 register returns all zeros.

35.8.1.5.3 Fields

Field	Description
31-0	TR3

Field	Description
DATA	Processor B Transmit Register 3. (Write-only) • Data written to the TR3 register is reflected on the Processor A-side in the Processor A Receive Register 3 (MUA.RR3). The MUB.TR3 and MUA.RR3 registers are not double-buffered—a write to the TR3 register overrides the data readable at the MUA.RR3 register. • A write to the transmit register clears a "transmitter empty" bit (TE3) in the Processor B Status Register (MUB.SR) on the transmitter side, and sets a "receiver full" bit (RF3) in the Processor A Status Register (MUA.SR) on the receiver side (optionally triggering an interrupt 3 on the Processor A-side). • Any write to the TR3 register will update all status information.

35.8.1.6 Processor B Receive Register 0 (RR0)

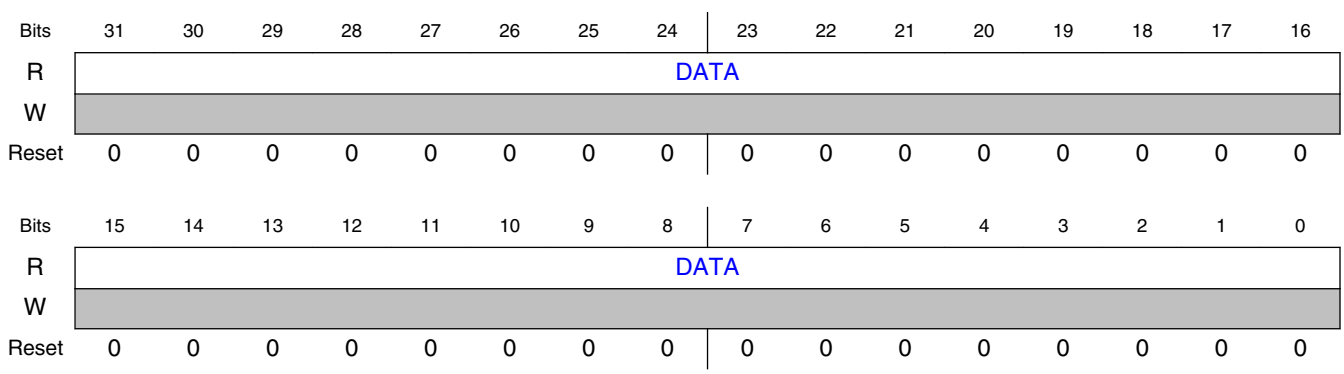
Use Processor B Receive Register 0 (RR0, 32-bit, read-only) to receive a message or data from the Processor A.

- Data written to the MUA.TR0 register is immediately reflected in the MUB.RR0 register.
- The MUB.RR0 register can only be read when the RF0 bit in the MUB.SR register is set to "1".
- Writing to the MUB.RR0 register generates an error response to the Processor B.

35.8.1.6.1 Offset

Register	Offset
RR0	10h

35.8.1.6.2 Diagram



35.8.1.6.3 Fields

Field	Description
31-0 DATA	RR0 Processor B Receive Register 0. (Read-only) • Reflects the data written to Processor A Transmit Register 0 (MUA.TR0). • Reading the MUB.RR0 register clears the "receiver full" bit (RF0) in the Processor B Status Register (MUB.SR) on the receiver side, and sets the "transmitter empty" bit (TE0) in the Processor A Status Register on the transmitter side (optionally triggering a transmit interrupt 0 on the Processor A-side). • Any read of the RR0 register will update all status information.

35.8.1.7 Processor B Receive Register 1 (RR1)

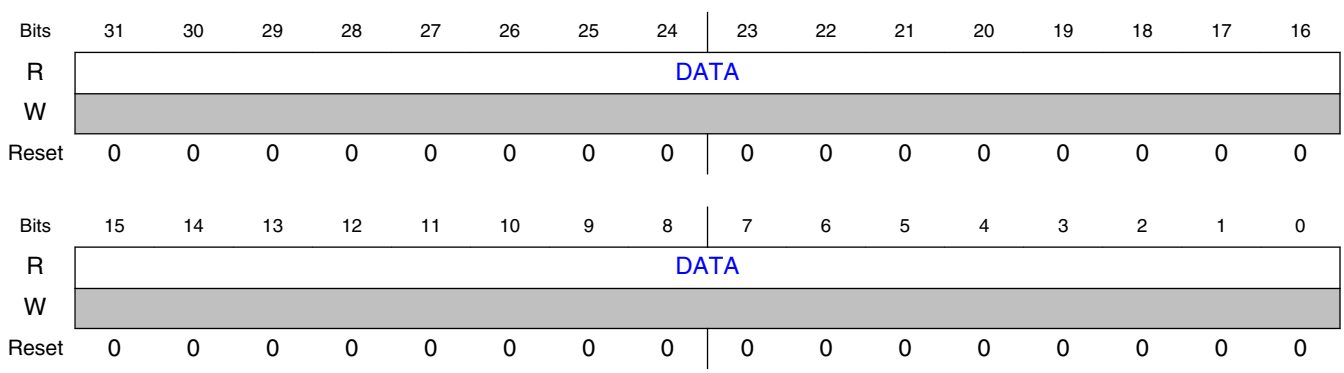
Use Processor B Receive Register 1 (RR1, 32-bit, read-only) to receive a message or data from the Processor A.

- Data written to the MUA.TR1 register is immediately reflected in the MUB.RR1 register.
- The MUB.RR1 register can only be read when the RF1 bit in the MUB.SR register is set to "1".
- Writing to the MUB.RR1 register generates an error response to the Processor B.

35.8.1.7.1 Offset

Register	Offset
RR1	14h

35.8.1.7.2 Diagram



35.8.1.7.3 Fields

Field	Description
31-0 DATA	RR1 Processor B Receive Register 1. (Read-only) • Reflects the data written to Processor A Transmit Register 1 (MUA.TR1). • Reading the MUB.RR1 register clears the "receiver full" bit (RF1) in the Processor B Status Register (MUB.SR) on the receiver side, and sets the "transmitter empty" bit (TE1) in the Processor A Status Register on the transmitter side (optionally triggering a transmit interrupt 1 on the Processor A-side). • Any read of the RR1 register will update all status information.

35.8.1.8 Processor B Receive Register 2 (RR2)

Use Processor B Receive Register 2 (RR2, 32-bit, read-only) to receive a message or data from the Processor A.

- Data written to the MUA.TR2 register is immediately reflected in the MUB.RR2 register.
- The MUB.RR2 register can only be read when the RF2 bit in the MUB.SR register is set to "1".
- Writing to the MUB.RR2 register generates an error response to the Processor B.

35.8.1.8.1 Offset

35.8.1.8.3 Fields

Field	Description
31-0 DATA	RR2 Processor B Receive Register 2. (Read-only) • Reflects the data written to Processor A Transmit Register 1 (MUA.TR2). • Reading the MUB.RR2 register clears the "receiver full" bit (RF2) in the Processor B Status Register (MUB.SR) on the receiver side, and sets the "transmitter empty" bit (TE2) in the Processor A Status Register on the transmitter side (optionally triggering a transmit interrupt 2 on the Processor A-side). • Any read of the RR2 register will update all status information.

35.8.1.9 Processor B Receive Register 3 (RR3)

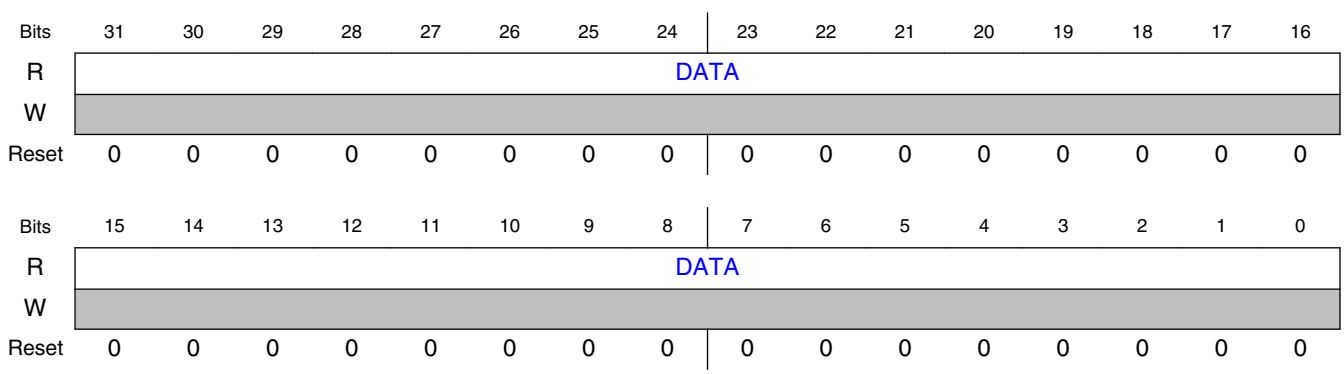
Use Processor B Receive Register 3 (RR3, 32-bit, read-only) to receive a message or data from the Processor A.

- Data written to the MUA.TR3 register is immediately reflected in the MUB.RR3 register.
- The MUB.RR3 register can only be read when the RF3 bit in the MUB.SR register is set to "1".
- Writing to the MUB.RR3 register generates an error response to the Processor B.

35.8.1.9.1 Offset

Register	Offset
RR3	1Ch

35.8.1.9.2 Diagram



35.8.1.9.3 Fields

Field	Description
31-0 DATA	RR3 Processor B Receive Register 3. (Read-only) • Reflects the data written to Processor A Transmit Register 3 (MUA.TR3). • Reading the MUB.RR3 register clears the "receiver full" bit (RF3) in the Processor B Status Register (MUB.SR) on the receiver side, and sets the "transmitter empty" bit (TE3) in the Processor A Status Register on the transmitter side (optionally triggering a transmit interrupt 3 on the Processor A-side). • Any read of the RR3 register will update all status information.

35.8.1.10 Processor B Status Register (SR)

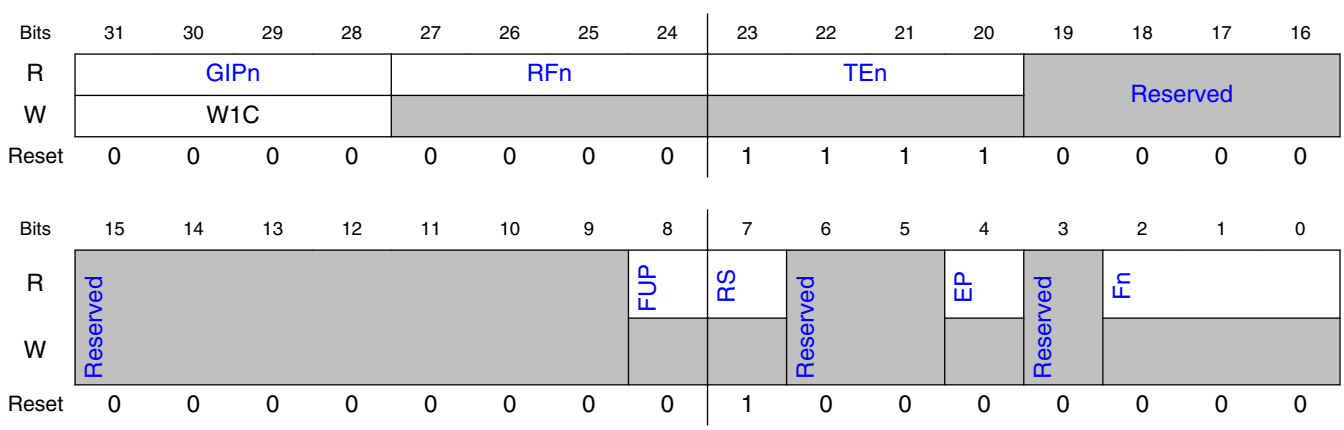
Use the Processor B Status Register (SR, 32-bit, read-write) to show interrupt status from the Processor B, general purpose flags, and to set dual function control-status bits.

- Dual-purpose bits are set by the Processor B-side programmer, and cleared by the MU logic.

35.8.1.10.1 Offset

Register	Offset
SR	20h

35.8.1.10.2 Diagram



35.8.1.10.3 Fields

Field	Description
31-28 GIPn	GIPn For n = {0, 1, 2, 3} Processor B General Interrupt Request n Pending. (Read-Write) • GIPn bit signals the Processor B that the GIRn bit in the MUA.CR register on the Processor A-side was set from "0" to "1". If the GIEn bit in the MUB.CR register is set to "1", a General Interrupt n request is issued. • The GIPn bit is cleared by writing it back as "1". Writing "0", or writing "1" when the GIPn bit is cleared is ignored. Use this feature in the interrupt routine, where the GIPn bit is cleared in order to de-assert the interrupt request source at the interrupt controller. • GIPn bit is cleared when the MU is reset. 0000 - Processor B general purpose interrupt n is not pending. (default) 0001 - Processor B general purpose interrupt n is pending.
27-24 RFn	RFn For n = {0, 1, 2, 3} Processor B Receive Register n Full. (Read-only) • RFn bit signals to the Processor B-side that new data was written by the Processor A to the MUA.TRn register, and is ready to be read by the Processor B in the MUB.RRn register. • The RFn bit is set to "1" when the MUA.TRn register is written on the Processor A-side. • After the RFn bit is set to "1", the RFn bit signals the Processor B-side that new data is ready to be read by the Processor B in the MUB.RRn register, and a Receive n interrupt is issued on the Processor A-side (if the RIEn bit in the MUB.CR register has been set to "1"). • RFn bit is cleared when the MUB.RRn register is read, and when the MU is reset. 0000 - MUB.RRn register is not full (default). 0001 - MUB.RRn register has received data from MUA.TRn register and is ready to be read by the Processor B.
23-20 TEn	TEn For n = {0, 1, 2, 3} Processor B Transmit Register n Empty. (Read-only) • When TEn = "1", it signals to the Processor B-side that the MUB.TRn register is ready to be written on the Processor B-side. • The TEn bit is set to "1" after the MUA.RRn register is read on the Processor A-side. • Setting TEn bit will issue a transmit n interrupt on the Processor B-side (if the TIEn bit in the MUB.CR register is set to "1". • TEn bit is cleared after the MUB.TRn register is written on the Processor B-side. • TEn bit is set to "1" when the MU is reset. 0000 - MUB.TRn register is not empty. 0001 - MUB.TRn register is empty (default).
19-9 —	Reserved
8 FUP	FUP Processor B Flags Update Pending. (Read-only) • FUP bit is set to "1" when the Processor B-side sends a Flags Update request to the Processor A-side. • A Flags Update request is generated when the BAF[2:0] bits of the MUB.CR register change. No flag update changes are allowed while the FUP bit is set to "1". Any write to the BAF[2:0] bits, while the FUP bit is set to "1", will not generate a Flags Update event, and the BAF[2:0] bits will stay unchanged. • FUP bit is cleared when this Flags Update request is internally acknowledged (that the flag is updated) from the MU Processor A-side, and during MU reset.

Table continues on the next page...

Field	Description
	0 - No flags updated, initiated by the Processor B, in progress (default) 1 - Processor B initiated flags update, processing
7 RS	RS Processor A Reset State. (Read-only) • RS bit indicates if the Processor A-side of the MU is in a reset state or not. • If the RS bit is set to "1", then the Processor A-side of the MU is still in the reset state. • If the RS bit is cleared, then both the Processor A and the Processor A-side of the MU are out of reset. • The RS bit is set to "1" during: a Processor A system reset, or an MU reset (caused by setting the MUR bit at the MUB.CR register). • The RS bit is cleared when the reset sequence on the Processor A-side of the MU ends. After issuing any of the three reset events mentioned previously, it should be verified that the RS bit is cleared before starting any accesses. • When Processor B side of MU comes out of reset RS bit has value "1"(default).Then Processor B sees the status of Processor A side and if Processor A has come out of reset then RS bit goes low. This takes 5-6 clock cycles. If the RS bit is read now it is low although its reset value was "1" . 0 - The Processor A or the Processor A-side of the MU is not in reset. 1 - The Processor A or the Processor A-side of the MU is in reset.
6-5 —	- Reserved
4 EP	EP Processor B-Side Event Pending. (Read-only) • EP bit is set to "1" when the Processor B-side mechanism sends an event update request to the Processor A-side. • EP bit is cleared when the event update acknowledge is received. An "event" is any hardware message that is reflected in the MUA.SR register on the Processor A-side (for example, "transmit register 0 written"). During normal operations, the state of the EP bit does not need to be updated manually because the event update mechanism works automatically. • To ensure events have been posted to Processor A before entering STOP mode, it should be verified that the EP bit is cleared. If EP bit is set to "1", continue to poll it (EP bit) before entering STOP mode. • Reading the SR register (to check the EP bit) should be the last access to the MU that should be performed before entering STOP mode; otherwise, the EP bit may be set by subsequent additional actions. • Due to Processor B pipeline effects, three NOP operations (or their timing equivalent) should be given after an instruction that sets an event before the EP bit can reflect this event. • The EP bit is cleared when the MU resets. 0 - The Processor B-side event is not pending (default). 1 - The Processor B-side event is pending.
3 —	Reserved
2-0 Fn	Fn For n = {0, 1, 2} Processor B-Side Flag n. (Read-only) • Fn bit is the Processor B-side flag that reflects the values written to the ABFn bit in the Processor A control register. • Every time that the ABFn bit is written, the ABFn bit write event updates the Fn bit after the event update latency, which is measured in terms of the number of clocks of the Processor A and the Processor B.

Field	Description
	000 - ABFn bit in MUA.CR register is written 0 (default). 001 - ABFn bit in MUA.CR register is written 1.

35.8.1.11 Processor B Control Register (CR)

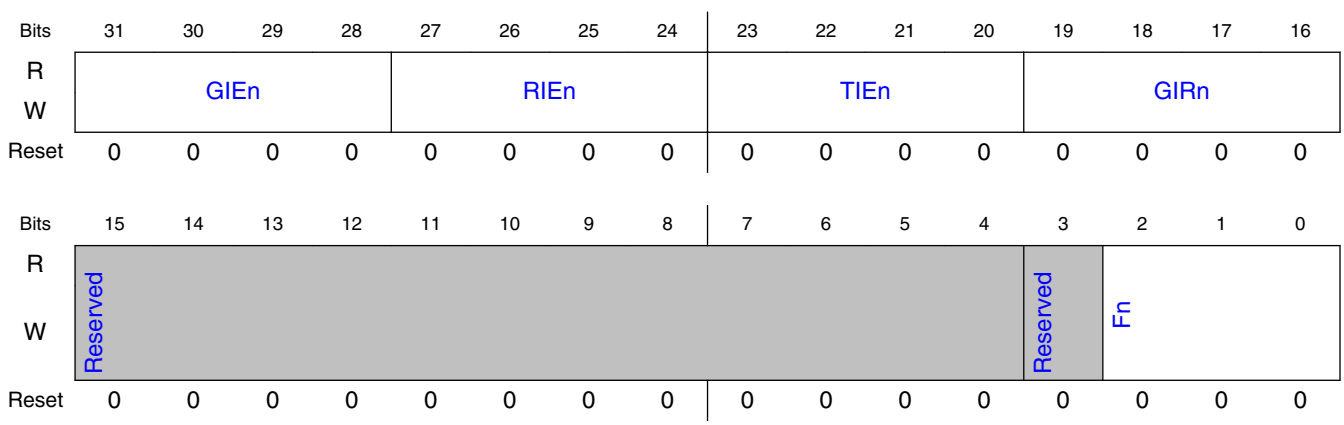
Use the Processor B Control Register (CR, 32-bit, read-write) to enable the MU interrupts on the Processor B-side, and trigger events and interrupts on the Processor A-side (wake from STOP, hardware reset, flag update).

For the fields GIEn, RIEn, TIEn and GIRn, n=0 corresponds to the high order bit and n=3 corresponds to the low order bit.

35.8.1.11.1 Offset

Register	Offset
CR	24h

35.8.1.11.2 Diagram



35.8.1.11.3 Fields

Field	Description
31-28 GIEn	GIEn For n = {0, 1, 2, 3} Processor B General Purpose Interrupt Enable n. (Read-Write)

Table continues on the next page...

Field	Description
	• GIEn bit enables Processor B General Interrupt n. • If GIEn bit is set to "1" (enabled), then a General Interrupt n request is issued when the GIPn bit in the MUB.SR register is set to "1". • If GIEn is cleared (disabled), then the value of the GIPn bit is ignored and no General Interrupt n request will be issued. • GIEn bit is cleared when the MU resets. 0000 - Disables Processor B General Interrupt n. (default) 0001 - Enables Processor B General Interrupt n.
27-24 RIEn	RIEn For n = {0, 1, 2, 3} Processor B Receive Interrupt Enable n. (Read-Write) • RIEn bit enables Processor B Receive Interrupt n. • If RIEn bit is set to "1" (enabled), then an Processor B Receive Interrupt n request is issued when the RFn bit in the MUB.SR register is set to "1". • If RIEn bit is cleared (disabled), then the value of the RFn bit is ignored and no Processor B Receive Interrupt n request will be issued. • RIEn bit is cleared when the MU resets. 0000 - Disables Processor B Receive Interrupt n. (default) 0001 - Enables Processor B Receive Interrupt n.
23-20 TIEn	TIEn For n = {0, 1, 2, 3} Processor B Transmit Interrupt Enable n. (Read-Write) • TIEn bit enables Processor B Transmit Interrupt n. • If TIEn bit is set to "1" (enabled), then an Processor B Transmit Interrupt n request is issued when the TEn bit in the MUB.SR register is set to "1". • If TIEn bit is cleared (disabled), then the value of the TEn bit is ignored and no Processor B Transmit Interrupt n request will be issued. • TIEn bit is cleared when the MU resets. 0000 - Disables Processor B Transmit Interrupt n. (default) 0001 - Enables Processor B Transmit Interrupt n.
19-16 GIRn	GIRn For n = {0, 1, 2, 3} Processor B General Purpose Interrupt Request n. (Read-Write) • Writing "1" to the GIRn bit sets the GIPn bit in the MUA.SR register on the Processor A-side. If the GIEn bit in the ACR register is set to "1" on the Processor A-side, a General Purpose Interrupt n request is triggered. • The GIRn bit is cleared if the GIPn bit (in the MUA.SR register on the Processor A-side) is cleared by writing it (GIPn bit) as "1", thereby signalling the Processor B that the interrupt was accepted (cleared by the software). The GIPn bit cannot be written as "0" on the Processor B-side. • To ensure proper operations, it must be verified that the GIRn bit is cleared (meaning that there is no pending interrupt) before setting it (GIRn bit). • GIRn bit is cleared when the MU resets. 0000 - Processor B General Interrupt n is not requested to the Processor A (default). 0001 - Processor B General Interrupt n is requested to the Processor A.
15-4 —	Reserved
3 —	Reserved
2-0	Fn

Field	Description
Fn	For n = {0, 1, 2} Processor B to Processor A Flag n. (Read-Write) • Fn bit is a read-write flag that is reflected in Fn bit in the MUA.SR register on the Processor A-side. • Fn bit is cleared when the MU resets. 000 - Clears the Fn bit in the MUA.SR register. 001 - Sets the Fn bit in the MUA.SR register.

Chapter 36
Network Interconnect Bus System (NIC-301)

36.2 Overview

This section provides an overview of the

- NIC-301 (Network Inter-Connect) AXI arbiter IP

  The NIC-301 (by Arm Ltd.) is a configurable AXI arbiter between several masters and slaves. The NIC-301 IP is designed so that many configuration options are selected at the hardware design stage, determined by SoC characteristics and needs, while several other configuration options are software-controlled.

This chapter covers in brief the NIC-301 while providing configuration details on the NIC-301 instances used in the chip. For complete details on the NIC-301 design, see the Arm specification, *AMBA® Network Interconnect (NIC-301) Technical Reference Manual, version r2p3*.

NOTE

The NIC-301 default settings, in most cases, should not be modified by the customer. The default settings have gone through exhaustive testing during the validation of the part, and have proven to work well for the part's intended target applications. Changes to the default settings may result in a degradation in system performance.

36.2.1 NIC-301 Main Features

Key features of the NIC-301 module include the following:

- Address space memory mapping.
- Programmer's view, for software-configured parameters, via internal "GPV" ports.
- Support for cross-clock domain synchronization.

36.2.2 Modes and Operations

The NIC-301 supports a normal functional mode only.

36.3 External Signals

There are no external I/O interfaces for NIC-301.

36.4 Memory Map and Register Definition

The bus system is composed of the several instances that have GPV registers, which are helpful for bus arbitration and performance. For detailed descriptions of these registers, see the Arm document: *DDI0397I_corelink_network_interconnect_nic301_r2p3_trm.pdf*.

1. **SIM_DISP registers**

   The SIM_DISP GPV base address is GPV0_BASE = 0x41000000. The following registers are implemented in this NIC.

Register Name	Port Name	Module Name	Absolute Address	Reset Value	Descriptions
read_qos	m_a_0	GC355	GPV0_BASE + 0x42000 + 0x100	6	Set the priority of master's read. The priority level would be used when the master's read transaction is being arbitrated by the NIC. Legal programmable values are from 0 to 15. Higher number sets higher priority (0: the lowest arbitration priority; 15: the highest priority).
read_qos	m_a_1	PXP	GPV0_BASE + 0x45000 + 0x100	6	Same as above
read_qos	m_a_2	LCDIF	GPV0_BASE + 0x46000 + 0x100	12	Same as above
read_qos	m_a_3	LCDIFv2	GPV0_BASE + 0x47000 + 0x100	12	Same as above
read_qos	m_a_4	CSI	GPV0_BASE + 0x48000 + 0x100	14	Same as above
write_qos	m_a_0	GC355	GPV0_BASE + 0x42000 + 0x104	6	Set the priority of master's write. The priority level would be used when the master's write transaction is being arbitrated by the NIC. Legal programmable values are from 0 to 15. Higher number sets higher priority (0: the lowest arbitration priority; 15: the highest priority).
write_qos	m_a_1	PXP	GPV0_BASE + 0x45000 + 0x104	6	Same as above
write_qos	m_a_2	LCDIF	GPV0_BASE + 0x46000 + 0x104	12	Same as above
write_qos	m_a_3	LCDIFv2	GPV0_BASE + 0x47000 + 0x104	12	Same as above
write_qos	m_a_4	CSI	GPV0_BASE + 0x48000 + 0x104	14	Same as above
fn_mod	m_a_0	GC355	GPV0_BASE + 0x42000 + 0x108	0	Issuing functionality modification register. This register sets the block issuing capability to one outstanding transaction. Legal programmable values are 0, 1, 2 and 3. NOTE: It is recommended to keep its reset value to obtain the best performance. 0: Default setting 1: Set read issuing capability to one outstanding transaction 2: Set write issuing capability to one outstanding transaction 3: Set both read and write issuing capability to one outstanding transaction
fn_mod	m_a_1	PXP	GPV0_BASE + 0x45000 + 0x108	0	Same as above
fn_mod	m_a_2	LCDIF	GPV0_BASE + 0x46000 + 0x108	0	Same as above

Table continues on the next page...

Register Name	Port Name	Module Name	Absolute Address	Reset Value	Descriptions
fn_mod	m_a_3	LCDIFv2	GPV0_BASE + 0x47000 + 0x108	0	Same as above
fn_mod	m_a_4	CSI	GPV0_BASE + 0x48000 + 0x108	0	Same as above

2. SIM_M registers

The SIM_M GPV base address is GPV1_BASE = 0x41100000. The following registers are implemented in this NIC.

Register Name	Port Name	Module Name	Absolute Address	Reset Value	Descriptions
fn_mod_ahb	m_c_3	ENET	GPV1_BASE + 0x45000 + 0x028	0	This register has 3 control bits. Bit 0: rd_incr_override. Writting 1 to this bit forces NIC to convert all AHB read transactions to a series of AXI singles. Bit 1: wr_incr_override. Writting 1 to this bit forces NIC to convert all AHB write transactions to a series of AXI singles. Bit 2: lock_override. Writting 1 to this bit forces NIC not to create any AXI lock transactions. NOTE: It is recommended to keep its reset value to obtain the best performance.
read_qos	m_c_0	CAAM	GPV1_BASE + 0x42000 + 0x100	6	Set the priority of master's read. The priority level would be used when the master's read transaction is being arbitrated by the NIC. Legal programmable values are from 0 to 15. Higher number sets higher priority (0: the lowest arbitration priority; 15: the highest priority).
read_qos	m_c_1	ENET1GRX	GPV1_BASE + 0x43000 + 0x100	6	Same as above
read_qos	m_c_2	ENET1GTX	GPV1_BASE + 0x44000 + 0x100	6	Same as above
read_qos	m_c_3	ENET	GPV1_BASE + 0x45000 + 0x100	6	Same as above
read_qos	m_c_4	USBO2	GPV1_BASE + 0x46000 + 0x100	12	Same as above
read_qos	m_c_5	USDHC1	GPV1_BASE + 0x47000 + 0x100	12	Same as above
read_qos	m_c_6	USDHC2	GPV1_BASE + 0x48000 + 0x100	14	Same as above
read_qos	m_c_8	ENET_QOS	GPV1_BASE + 0x4A000 + 0x100	0	Same as above
write_qos	m_c_0	CAAM	GPV1_BASE + 0x42000 + 0x104	6	Set the priority of master's write. The priority level would be used when the master's write

Table continues on the next page...

Register Name	Port Name	Module Name	Absolute Address	Reset Value	Descriptions
					transaction is being arbitrated by the NIC. Legal programmable values are from 0 to 15. Higher number sets higher priority (0: the lowest arbitration priority; 15: the highest priority).
write_qos	m_c_1	ENET1G RX	GPV1_BASE + 0x43000 + 0x104	6	Same as above
write_qos	m_c_2	ENET1G TX	GPV1_BASE + 0x44000 + 0x104	6	Same as above
write_qos	m_c_3	ENET	GPV1_BASE + 0x45000 + 0x104	6	Same as above
write_qos	m_c_4	USBO2	GPV1_BASE + 0x46000 + 0x104	12	Same as above
write_qos	m_c_5	USDHC1	GPV1_BASE + 0x47000 + 0x104	12	Same as above
write_qos	m_c_6	USDHC2	GPV1_BASE + 0x48000 + 0x104	14	Same as above
write_qos	m_c_8	ENET_QOS	GPV1_BASE + 0x4A000 + 0x104	0	
fn_mod	m_c_0	CAAM	GPV1_BASE + 0x42000 + 0x108	0	Issuing functionality modification register. This register sets the block issuing capability to one outstanding transaction. Legal programmable values are 0, 1, 2 and 3. NOTE: It is recommended to keep its reset value to obtain the best performance. 0: Default setting 1: Set read issuing capability to one outstanding transaction 2: Set write issuing capability to one outstanding transaction 3: Set both read and write issuing capability to one outstanding transaction
fn_mod	m_c_1	ENET1G RX	GPV1_BASE + 0x43000 + 0x108	0	Same as above
fn_mod	m_c_2	ENET1G TX	GPV1_BASE + 0x44000 + 0x108	0	Same as above
fn_mod	m_c_3	ENET	GPV1_BASE + 0x45000 + 0x108	0	Same as above
fn_mod	m_c_4	USBO2	GPV1_BASE + 0x46000 + 0x108	0	Same as above
fn_mod	m_c_5	USDHC1	GPV1_BASE + 0x47000 + 0x108	0	Same as above
fn_mod	m_c_6	USDHC2	GPV1_BASE + 0x48000 + 0x108	0	Same as above
fn_mod	m_c_8	ENET_QOS	GPV1_BASE + 0x4A000 + 0x108	0	Same as above

3. SIM_M7 registers

The SIM_M7 GPV base address is GPV4_BASE = 0x41400000. The following registers are implemented in this NIC.

Register Name	Port Name	Module Name	Absolute Address	Reset Value	Descriptions
fn_mod_ahb	m_b_5	DMA	GPV4_BASE + 0x47000 + 0x028	0	This register has 3 control bits. Bit 0: rd_incr_override. Writting 1 to this bit forces NIC to convert all AHB read transactions to a series of AXI singles. Bit 1: wr_incr_override. Writting 1 to this bit forces NIC to convert all AHB write transactions to a series of AXI singles. Bit 2: lock_override. Writting 1 to this bit forces NIC not to create any AXI lock transactions. NOTE: It is recommended to keep its reset value to obtain the best performance.
wr_tidemark	m_b_4	LPSRMIX masters	GPV4_BASE + 0x46000 + 0x040	4	The WFIFO depth is 8, so the valid programmable values to this register are 0 to 8. This is a tidemark level that stalls the release of the transaction until: The NIC receives the WLAST beat. The write FIFO becomes full. The number of occupied slots in the write data FIFO exceeds the write tidemark.
read_qos	m_b_0	CORTEXM7	GPV4_BASE + 0x42000 + 0x100	6	Set the priority of master's read. The priority level would be used when the master's read transaction is being arbitrated by the NIC. Legal programmable values are from 0 to 15. Higher number sets higher priority (0: the lowest arbitration priority; 15: the highest priority).
read_qos	m_b_5	DMA	GPV4_BASE + 0x47000 + 0x100	6	Same as above
read_qos	m_b_6	IEE	GPV4_BASE + 0x48000 + 0x100	0	Same as above
write_qos	m_b_0	CORTEXM7	GPV4_BASE + 0x42000 + 0x104	6	Set the priority of master's write. The priority level would be used when the master's write transaction is being arbitrated by the NIC. Legal programmable values are from 0 to 15. Higher number sets higher priority (0: the lowest arbitration priority; 15: the highest priority).
write_qos	m_b_5	DMA	GPV4_BASE + 0x47000 + 0x104	6	Same as above
write_qos	m_b_6	IEE	GPV4_BASE + 0x48000 + 0x104	0	Same as above

Table continues on the next page...

Register Name	Port Name	Module Name	Absolute Address	Reset Value	Descriptions
fn_mod	m_b_0	CORTEXM 7	GPV4_BASE + 0x42000 + 0x108	0	Issuing functionality modification register. This register sets the block issuing capability to one outstanding transaction. Legal programmable values are 0, 1, 2 and 3. NOTE: It is recommended to keep its reset value to obtain the best performance. 0: Default setting 1: Set read issuing capability to one outstanding transaction 2: Set write issuing capability to one outstanding transaction 3: Set both read and write issuing capability to one outstanding transaction
fn_mod	m_b_5	DMA	GPV4_BASE + 0x47000 + 0x108	0	Same as above
fn_mod	m_b_6	IEE	GPV4_BASE + 0x48000 + 0x108	0	Same as above

4. **IB registers**

   There are no IB registers implemented in this chip.

5. **Address region control registers**

   There are not such type of registers implemented in this chip.

6. **Peripheral ID registers**

   The peripheral ID registers are implemented in the SIM_DISP, SIM_M, and SIM_M7. For more details, please see the Arm document: *DDI0397I_corelink_network_interconnect_nic301_r2p3_trm.pdf*.

Chapter 37
On-Chip RAM Memory Controller (OCRAM)

37.1 Chip-specific OCRAM information

Table 37-1. Reference links to related information

Interrupts, DMA Events and XBAR Assignments	-	Interrupts, DMA Events and XBAR Assignments

37.2 Overview

NOTE

For the M7 OCRAM (within FlexRAM module), see the FlexRAM chapter for introduction and details.

There are two OCRAM modules (OCRAM1 and OCRAM2), with dedicated 1.125 MB RAM in total, implemented in the chip. For each instance, there is 576 KB RAM[1], including 512 KB general data RAM and 64 KB cipher RAM.

NOTE

The OCRAM minimum size is 128 KB in default.

1. • When ECC enabled, total valid RAM is 512 KB.
   • When ECC disabled, total valid RAM is 576 KB.

The OCRAM block is implemented as an slave module on the 64-bit system AXI bus. Designed as a simple on-chip memory controller, it supports only one AXI port with memory banks. For the AXI port, the read and write transactions are handled by two independent modules. As it is possible to have simultaneous read and write request from the AXI bus, each memory bank has an arbiter with round-robin scheme. After arbitration, the granted read or write access command can then be issued to the memory cell through a read/write MUX.

The memory banks are organized with the lower 2 bits of the address which is the AXI bus address and is 64 bits aligned interleaved. This allows a read access and a write access to be processed at the same time if they are targeted to different memory banks.

Various options are provided for adding a pipeline in a read/write access, in order to ensure flexible timing control at both high and low frequencies.

37.2.1 Block diagram

The OCRAM block diagram is shown in the figure below.

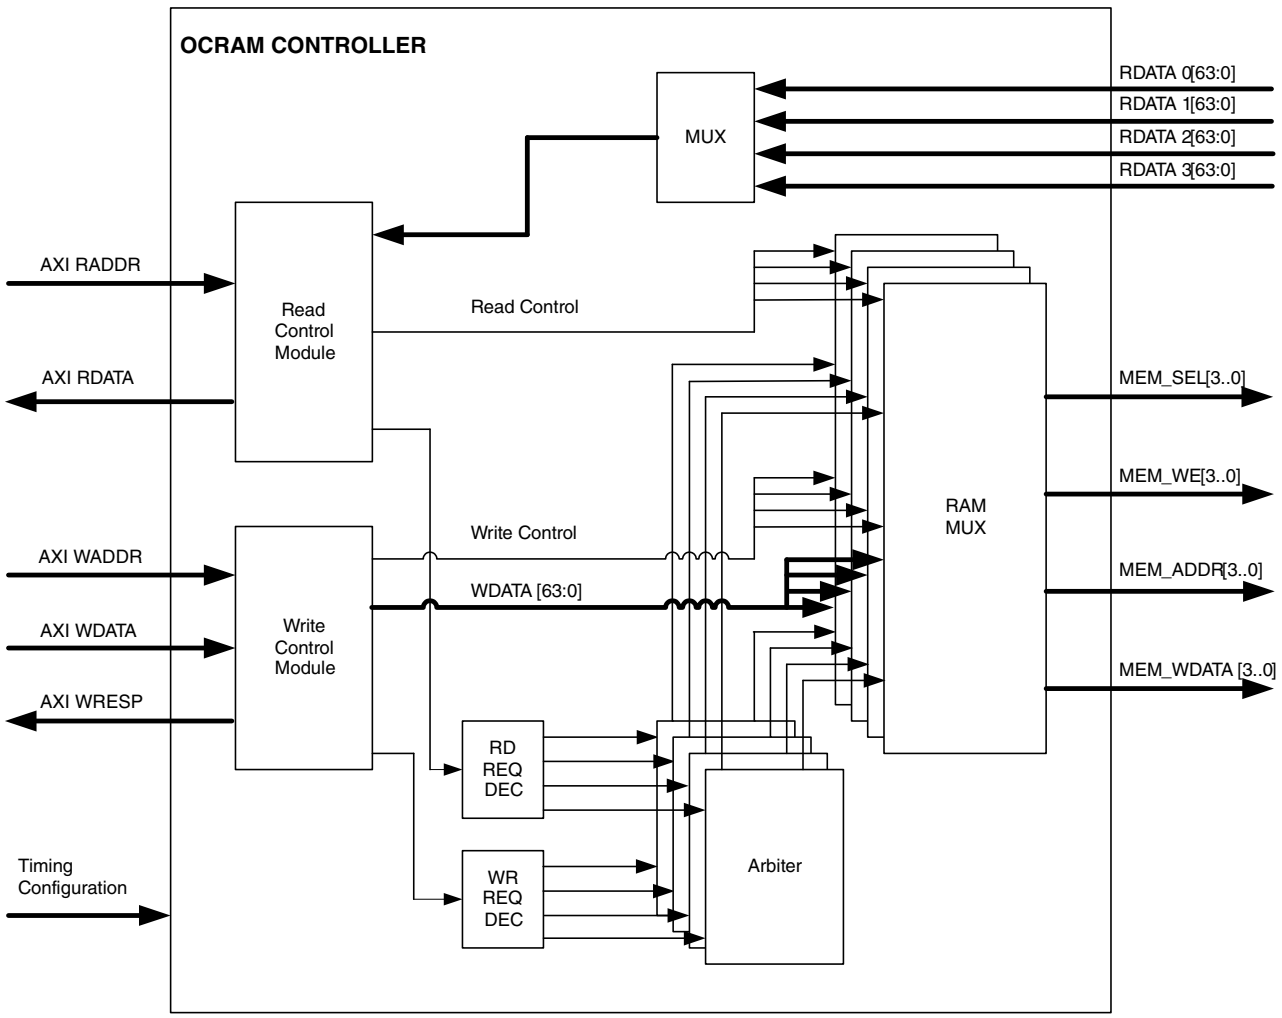

Figure 37-1. OCRAM Block Diagram

37.3 Functional Description

37.3.1 Read/Write Arbitration

The detailed rules used in arbitration are as follows:

- If there is no granted read or write in the last cycle, and there is only a read request or a write request, the request will be granted.
- If there is no granted read or write in the last cycle, and there are both read or write requests coming in at the same time, the read request will be granted first.

- If a granted read/write transaction has just finished, the write/read request will have the higher priority in the next cycle.
- If the first read/write access request in a transaction is granted, all the data transfer in this burst will be finished before the next arbitration begins, that is, the round-robin arbitration mechanism is based on AXI transaction, not data access.

Chapter 38
MECC64

38.1 Chip-specific MECC information

Table 38-1. Reference links to related information

Topic	Related module(s)	Reference
System memory map	-	System Memory Map
Clocking	CCM	Clock Management Clock Control Module (CCM)
Power management	PMU	Power Management Power Management Unit
Signal multiplexing	IOMUX	External Signals and Pin Multiplexing IOMUX
Interrupts, DMA Events and XBAR Assignments	-	Interrupts, DMA Events and XBAR Assignments

NOTE

ROM code will set the ECC enable bit (PIPE_ECC_EN[ECC_EN]) when MECC fuse is burnt.

38.2 Overview

The Memory ECC Controller (MECC64) module supports Single Error Correction and Double Error Detection (SEC-DED) ECC functions to On-Chip RAM (OCRAM) access. It can generate a 8-bit ECC code by Hsiao Hamming algorithm for 64-bit data. Corresponding OCRAM space is available to store ECC code. When ECC function is disabled, ECC OCRAM can also be used to store data.

38.2.1 Block diagram

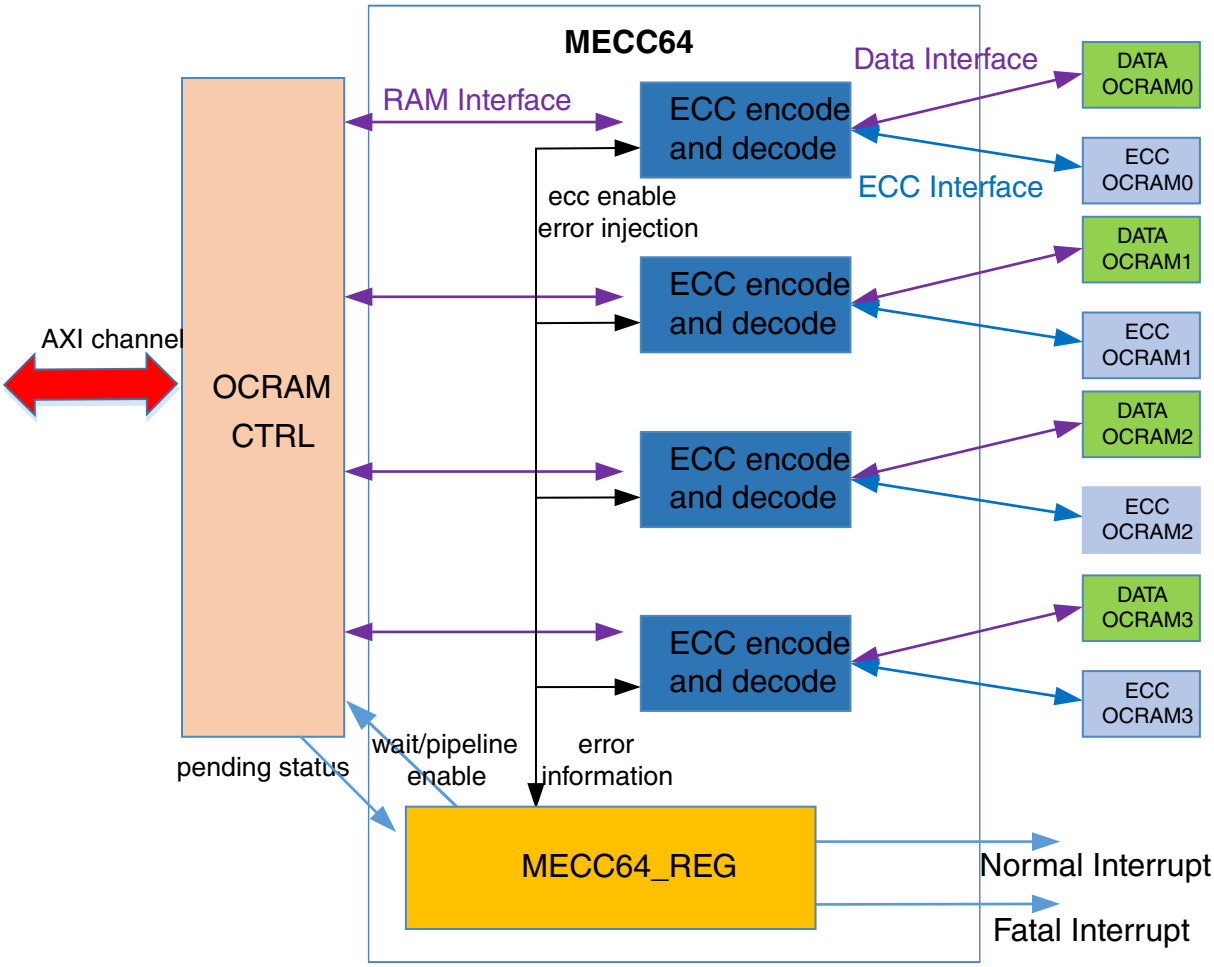

Figure 38-1. MECC64 block diagram

The following list shows detailed register/bitfield correspondance in the block diagram.

- ecc enable:
  - PIPE_ECC_EN[ECC_EN]
- error injection:
  - ERR_DATA_INJ_LOW/HIGH*n*
  - ERR_ECC_INJ*n*
- error information:
  - SINGLE_ERR_ADDR_ECC*n*
  - SINGLE_ERR_DATA_LOW/HIGH*n*
  - SINGLE_ERR_POS_LOW/HIGH*n*
  - MULTI_ERR_ADDR_ECC*n*
  - MULTI_ERR_DATA_LOW/HIGH*n*
- pending status:
  - PENDING_STAT

- wait/pipeline enable:
  - PIPE_ECC_EN[READ_DATA_WAIT_EN]
  - PIPE_ECC_EN[READ_ADDR_PIPE_EN]
  - PIPE_ECC_EN[WRITE_DATA_PIPE_EN]
  - PIPE_ECC_EN[WRITE_ADDR_PIPE_EN]

38.2.2 Features

The MECC64 includes the following features:

- Generates a 8-bit ECC code for 64-bit write data. Write data and ECC code are written into seperate OCRAM banks.
- Supports SEC-DED function for 64-bit read data and 8-bit ECC code.
- Integrate 4 banks OCRAM controller for converting AXI transaction to RAM interface.
- Error injection on write data and ECC code for debug purpose.
- Two different interrupt types: Normal and Fatal.

38.3 Functional description

The MECC64 converts AXI interface to RAM interface signals, and provides ECC encode/decode function for OCRAM write/read. For each data in OCRAM bank, corresponding space in ECC OCRAM banks is available to store ECC code when ECC function is enabled. When ECC function is disabled, ECC OCRAM banks can also be used to store data.

The OCRAM bank address allocation is as below:

- Bank0: ocram_base_address+0x20*i
- Bank1: ocram_base_address+0x20*i+0x8
- Bank2: ocram_base_address+0x20*i+0x10
- Bank3: ocram_base_address+0x20*i+0x18

where i = 0,1,2,3,4,...

38.3.1 Interface Conversion

The MECC64 integrates 4 banks OCRAM controller which converts AXI master interface signals to 4 groups of OCRAM interface signals (see OCRAM chapter for details). The 4 OCRAM banks are organized with lower 2 bits of address interleaved.

This allows a read access and a write access to be processed at the same time if they are targeted to different OCRAM banks. OCRAM controller can support to add pipeline or wait-state in read/write access by register configuration.

38.3.2 ECC encode

When ECC is enabled, the 4 groups of OCRAM write access will enter into seperate ECC encode channels. In a ECC encode channel, it will generate 8 bits ECC code for 64 bits OCRAM write data. Then 64 bits OCRAM write access will split into one 64 bits data write and one 8 bits ECC code write. The 64 bits data will be written into one of the DATA OCRAM banks according to address, and 8 bits ECC code will be written simutaneously into the corresponding ECC OCRAM bank.

When ECC is disabled, 4 ECC OCRAM banks can also be used to store data. The ECC OCRAM banks space address is after DATA OCRAM banks.

38.3.3 Error injection

The MECC64 can inject error in write data and ECC code by configuring ERR_DATA_INJ* and ERR_ECC_INJ* registers. The 64 bits write data and 8 bits ECC code can be inverted if corresponding bits in ERR_DATA_INJ* and ERR_ECC_INJ* registers are set. Each OCRAM bank has separate error injection registers. This feature is mainly used for debug.

38.3.4 ECC decode

When ECC is enabled, the 64 bits OCRAM read access will be split into one 64 bits data read and one 8 bits ECC code read. After getting read data from DATA OCRAM and ECC code from the corresponding ECC OCRAM, ECC decode channel can report single bit error or multiple bits error if ECC check is failed. At the same time, the error information will be saved in the module's error registers for debug. When single bit error is detected on read data, the error bit in read data will be corrected. In this case, AXI master will get read data correctly. When multiple bits error is detected on read data, error read data will not be corrected. In this case, master will get read data in error. When single bit error or multiple bits error happens, interrupt will be asserted if the corresponding enable bits are set in ERROR_STAT_EN and ERROR_SIG_EN registers. Each OCRAM bank has separate error and interrupt registers.

When ECC is disabled, 4 ECC OCRAM banks can also be used to store data. The ECC OCRAM banks can be read by using the address after DATA OCRAM banks.

NOTE

- If read access is 64-bit, the MECC64 will generate single or multi error interrupt once when meeting ECC error.
- If read access is 32-bit (or 16-bit/8-bit), the MECC64 will generate interrupt twice when meeting ECC error, once each in both the low 32 bits and the high 32 bits, even if it has a bit error in only the low 32 bits or the high 32 bits. This is because the ECC function will do ECC code validation on the full 64 bits for one read access.

38.3.5 Interrupts

The MECC64 can generate two kinds of interrupts:

- Normal interrupt can be generated for the following cases:
  - Single bit error is corrected for read;
  - AXI access address exceeds OCRAM address range;
  - AXI write access to OCRAM bank is not full size (wstrb=0xff).
- Fatal interrupt can be generated when 'multiple bits error' is detected for read.

38.3.6 Clocks

There are two clocks in MECC64:

Clock	Description
clk	Main clock
ips_clk	This is for IPS bus, used for register write/read.

There are no special requirements for these two clocks.

38.4 Signals

There are no external signals for MECC.

38.5 Initialization

The steps for initialization process is as below:

1. Enable MECC function (set PIPE_ECC_EN[ECC_EN] = 1).
2. Enable interrupts (set ERR_STAT_EN = 0xFFFF, ERR_SIG_EN = 0xFFFF).

NOTE

- When the MECC function is enabled, the OCRAM memory region can be initialized with 0x00 or 0xFF (initialization data for the first ECC encode), to generate ECC code within OCRAM ECC code region.
  - Initialization is required because the MECC64 needs a complete OCRAM and OCRAM ECC data. When initialized, it generates ECC code depending on initialization data, store data and its ECC code in OCRAM and OCRAM ECC memory.
  - Do such initialization with 64 bits access, with STRD or STMIA instruction. Do not use memset() API, which is STR instruction, in software coding level.
- OCRAM memory with ECC should be non-cacheable, or cacheable with write through, to assure data in OCRAM memory at the write time. It may have different methods to achieve this goal, such as Memory Protection Unit (MPU) or disable cache.

38.6 Application information

There are no application pseudocode examples for MECC64.

38.7 Memory Map and register definition

This section includes the MECC64 module memory map and detailed descriptions of all registers.

38.7.1 MECC64 register descriptions

38.7.1.2.3 Fields

Field	Description
31-16 —	Reserved
15 ADDR_ERR3	OCRAM Access Error On Bank3 When OCRAM access unallocated address on bank3, this bit will be asserted if corresponding status enable bit in ERR_STAT_EN register is set. 0 - OCRAM access error does not happen on OCRAM bank3. 1 - OCRAM access error happens on OCRAM bank3.
14 ADDR_ERR2	OCRAM Access Error On Bank2 When OCRAM access unallocated address on bank2, this bit will be asserted if corresponding status enable bit in ERR_STAT_EN register is set. 0 - OCRAM access error does not happen on OCRAM bank2. 1 - OCRAM access error happens on OCRAM bank2.
13 ADDR_ERR1	OCRAM Access Error On Bank1 When OCRAM access unallocated address on bank1, this bit will be asserted if corresponding status enable bit in ERR_STAT_EN register is set.

Table continues on the next page...

Field	Description
	0 - OCRAM access error does not happen on OCRAM bank1. 1 - OCRAM access error happens on OCRAM bank1.
12 ADDR_ERR0	OCRAM Access Error On Bank0 When OCRAM access unallocated address on bank0, this bit will be asserted if corresponding status enable bit in ERR_STAT_EN register is set. 0 - OCRAM access error does not happen on OCRAM bank0. 1 - OCRAM access error happens on OCRAM bank0.
11 STRB_ERR3	AXI Strobe Error On OCRAM Bank3 When AXI write access to OCRAM bank3 is not full size(wstrb=0xff), this bit will be asserted if corresponding status enable bit in ERR_STAT_EN register is set. 0 - AXI strobe error does not happen on OCRAM bank3. 1 - AXI strobe error happens on OCRAM bank3.
10 STRB_ERR2	AXI Strobe Error On OCRAM Bank2 When AXI write access to OCRAM bank2 is not full size(wstrb=0xff), this bit will be asserted if corresponding status enable bit in ERR_STAT_EN register is set. 0 - AXI strobe error does not happen on OCRAM bank2. 1 - AXI strobe error happens on OCRAM bank2.
9 STRB_ERR1	AXI Strobe Error On OCRAM Bank1 When AXI write access to OCRAM bank1 is not full size(wstrb=0xff), this bit will be asserted if corresponding status enable bit in ERR_STAT_EN register is set. 0 - AXI strobe error does not happen on OCRAM bank1. 1 - AXI strobe error happens on OCRAM bank1.
8 STRB_ERR0	AXI Strobe Error On OCRAM Bank0 When AXI write access to OCRAM bank0 is not full size(wstrb=0xff), this bit will be asserted if corresponding status enable bit in ERR_STAT_EN register is set. 0 - AXI strobe error does not happen on OCRAM bank0. 1 - AXI strobe error happens on OCRAM bank0.
7 MULTI_ERR3	Multiple Bits Error On OCRAM Bank3 When detect multiple bits error on read data from OCRAM bank3, this bit will be asserted if corresponding status enable bit in ERR_STAT_EN register is set. 0 - Multiple bits error does not happen on OCRAM bank3. 1 - Multiple bits error happens on OCRAM bank3.
6 MULTI_ERR2	Multiple Bits Error On OCRAM Bank2 When detect multiple bits error on read data from OCRAM bank2, this bit will be asserted if corresponding status enable bit in ERR_STAT_EN register is set. 0 - Multiple bits error does not happen on OCRAM bank2. 1 - Multiple bits error happens on OCRAM bank2.
5 MULTI_ERR1	Multiple Bits Error On OCRAM Bank1 When detect multiple bits error on read data from OCRAM bank1, this bit will be asserted if corresponding status enable bit in ERR_STAT_EN register is set. 0 - Multiple bits error does not happen on OCRAM bank1. 1 - Multiple bits error happens on OCRAM bank1.

Table continues on the next page...

Field	Description
4 MULTI_ERR0	Multiple Bits Error On OCRAM Bank0 When detect multiple bits error on read data from OCRAM bank0, this bit will be asserted if corresponding status enable bit in ERR_STAT_EN register is set. 0 - Multiple bits error does not happen on OCRAM bank0. 1 - Multiple bits error happens on OCRAM bank0.
3 SINGLE_ERR3	Single Bit Error On OCRAM Bank3 When detect single bit error on read data from OCRAM bank3, this bit will be asserted if corresponding status enable bit in ERR_STAT_EN register is set. 0 - Single bit error does not happen on OCRAM bank3. 1 - Single bit error happens on OCRAM bank3.
2 SINGLE_ERR2	Single Bit Error On OCRAM Bank2 When detect single bit error on read data from OCRAM bank2, this bit will be asserted if corresponding status enable bit in ERR_STAT_EN register is set. 0 - Single bit error does not happen on OCRAM bank2. 1 - Single bit error happens on OCRAM bank2.
1 SINGLE_ERR1	Single Bit Error On OCRAM Bank1 When detect single bit error on read data from OCRAM bank1, this bit will be asserted if corresponding status enable bit in ERR_STAT_EN register is set. 0 - Single bit error does not happen on OCRAM bank1. 1 - Single bit error happens on OCRAM bank1.
0 SINGLE_ERR0	Single Bit Error On OCRAM Bank0 When detect single bit error on read data from OCRAM bank0, this bit will be asserted if corresponding status enable bit in ERR_STAT_EN register is set. 0 - Single bit error does not happen on OCRAM bank0. 1 - Single bit error happens on OCRAM bank0.

38.7.1.3 Error Interrupt Status Enable Register (ERR_STAT_EN)

Setting the bits in this register to 1 enables the corresponding Error Interrupt Status to be set by the specified event.

For additional information see application note AN12077: Using the i.MX RT FlexRAM. This document describes the flexible memory array available on the i.MX RT MCUs. It includes the following information:

- Configuration of the bank array
- Memory type size definition
- Available memory controllers
- Power domains and clocks
- Interrupt request generation
- Example of FlexRAM configuration usage on a specific application use case

39.2 Overview

The Flexible RAM Controller (FLEXRAM) provides access control, as well as Single-bit Error Correction and Dual-bit Error Detection (SEC-DED) ECC, from TCM/OCRAM to 512KB of on-chip RAM. Another 128KB of on-chip RAM is allocated to store ECC cipher or used by OCRAM to store normal data.

39.2.1 Block diagram

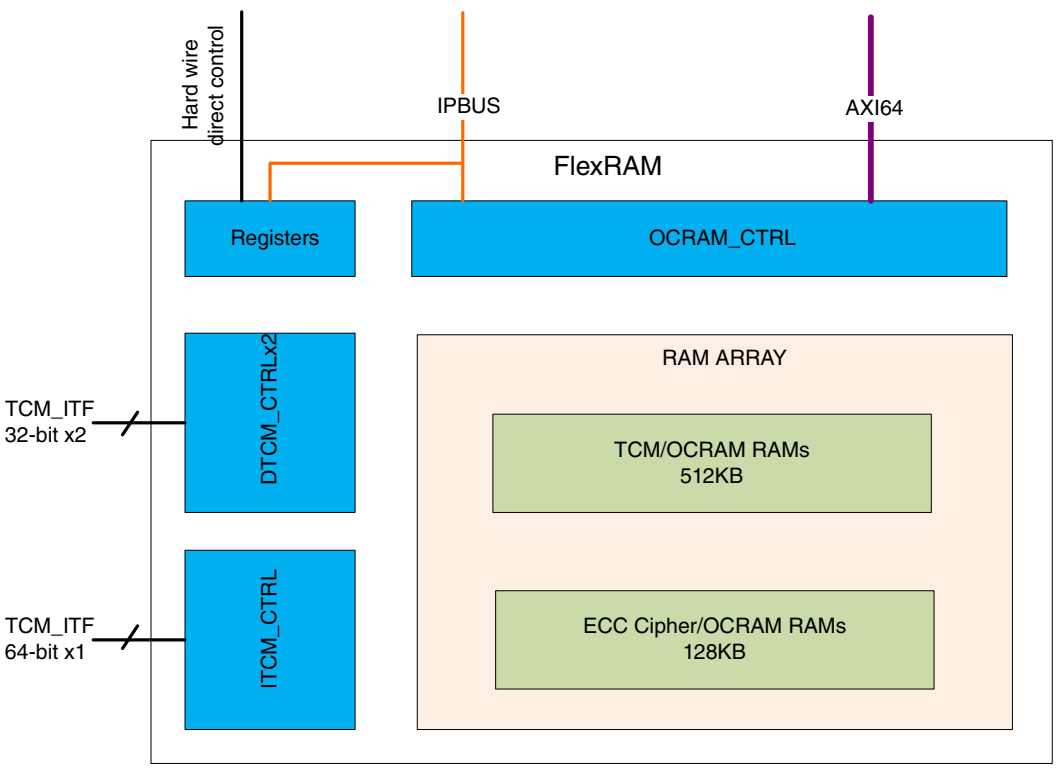

Figure 39-1. FLEXRAM block diagram

39.2.2 Features

FLEXRAM includes the following features:

- Integrated I-TCM and D-TCM RAM controller:
  - 64-bit I-TCM interface and 2x 32-bit D-TCM interfaces
  - Supports 512 KB TCM (for both ITCM and DTCM) space
  - Supports two access modes:

    - Fast mode: RAM access is expected to be finished in 1-cycle for both read and write.
    - Wait mode: RAM access is expected to be finished in 2-cycle. Wait mode for read and write path can be enabled separately.
  - Synchronous interface to the Cortex-M7 Core, run at the same frequency as the core
  - Automatic clock gating control to reduce power consumption
- Integrated OCRAM controller:
  - Single SRAM bank controller
  - Supports 640 KB SRAM size
  - Synchronous to the system bus, runs at the same frequency as bus fabric
- Parametrized RAM array:
  - Supports 640 KB total memory space
  - Support 64 blocks of 32-bit RAM
- RAM array portioning:
  - RAM size of ITCM, DTCM and OCRAM can be configured separately
  - Step of the RAM size partitioning for ITCM, DTCM and OCRAM is (Total RAM SIZE)/16
  - Flexible RAM bank organization include 16 banks with size of 32KB and 16 banks with size of 8KB. The first 16 banks can be allocated for ITCM, DTCM and OCRAM separately for master data storage, while the latter 16 banks (smaller sized) can only store data for OCRAM or store ECC for ITCM, DTCM and OCRAM.
- Flexible power mode:
  - Run mode: All RAM banks are powered on
  - Retention mode: Only one (bank0) out of the 16 RAM banks is on while the rest banks are powered off
  - Partial mode: 16 out of the 32 RAM banks (bank8 to bank15, and bank24 to bank31) can be powered off dynamically
- Bank8 to bank15, and bank24 to bank 31 can be disabled with hardware fuse setting. When the fuse is set, total RAM size will be limit to 320 KB
- Generates interrupt upon TCM, OCRAM access out of the configured RAM range
- Generates interrupt when access to pre-configured OCRAM, ITCM and DTCM address occurs
  - Independent address control for OCRAM, ITCM and DTCM
  - Interrupt generation on read or write access based register settings

39.3 Functional description

FLEXRAM converts AXI and TCM interface signals to RAM interface signals, and implements MUX control for OCRAM , DTCM and ITCM access to on-chip RAM. FLEXRAM supports Single-bit Error Correction and Dual-bit Error Detection ECC (SEC-DED) for both OCRAM and TCM.

39.3.1 Interface Conversion

FLEXRAM integrates OCRAM controller which converts AXI master interface signals to RAM interface signals (Please see the OCRAM chapter for more details). OCRAM controller can support to add pipeline or wait-state in read/write access by setting FLEXRAM_CTRL register.

FLEXRAM also implements TCM controller module to convert DTCM/ITCM interface to RAM interface. TCM read/write access can be extended to 2 cycles by setting TCM_CTRL register. When DTCM and ITCM access unallocated RAM address, TCM controller can send TCM_ERR signa to DTCM/ITCM interface.

If TCM ECC is enabled and ECC Error is detected on a read access, the subsequent valid access in the error detection cycle would be re-aligned. TCM_RETRY signal would be sent to ITCM/DTCM, and if the Error is a single-bit ECC error, TCM controller would scrub the address with corrected data.

39.3.2 RAM Bank Allocation

There are two parts of RAM can be accessed through FlexRAM, 512 KB data RAM and 128 KB ECC RAM.

Software can configure data RAM array size for OCRAM, DTCM and ITCM by GPR16 and GPR17 in IOMUX. The RAM size step is 32KB.

ECC RAM array can be configured by GPR16 and GPR17 in IOMUX, FLEXRAM_CTRL and two fuse bits (fuse_tcm_ECC_disable and fuse_ocram_ECC_disable).

The allocated RAM bank cannot be overlapped for OCRAM, DTCM and ITCM.

The following table shows an example of a 128KB ITCM, 128KB DTCM and 256KB OCRAM configuration for data RAM.

Table 39-2. FLEXRAM Partitioning Example

	ITCM	DTCM	OCRAM
Bank0	0	0	1
Bank1	0	0	1
Bank2	0	0	1
Bank3	0	0	1
Bank4	1	0	0
Bank5	1	0	0
Bank6	0	1	0
Bank7	0	1	0
Bank8	0	0	1
Bank9	0	0	1
Bank10	0	0	1
Bank11	0	0	1
Bank12	1	0	0
Bank13	1	0	0
Bank14	0	1	0
Bank15	0	1	0

Each RAM bank has 2 bits bank configuration signal (e.g. from IOMUX GPR17).

Table 39-3. RAM Bank Configuration

	RAM Bank Configuration
00	Not used
01	OCRAM
10	DTCM
11	ITCM

The left 128KB RAM, taken as bank16 to bank31, can be used as data RAM for OCRAM or as ECC RAM shared by OCRAM, ITCM and DTCM based on the configuration of FLEXRAM_CTRL, GPR (ram_bank_config) and fuse bits (fuse_tcm_ECC_disable and fuse_ocram_ECC_disable). If the fuse bit is set, then corresponding ECC function would be disabled regardless of the setting in FLEXRAM_CTRL register. While if fuse bit is 0, FLEXRAM_CTRL setting determines whether ECC function is turned on. Generally, there would be 4 scenarios:

- TCM ECC enabled & OCRAM ECC enabled
- TCM ECC enabled & OCRAM ECC disabled
- TCM ECC disabled & OCRAM ECC enabled
- TCM ECC disabled & OCRAM ECC disabled

If both TCM ECC and OCRAM ECC are enabled, then the 128KB would be allocated just similarly as the 512KB data RAM, but with step size 8KB and used as ECC RAM for OCRAM and TCM. The following table shows the corresponding ECC RAM bank allocation in this case: bank16~19 and bank24~27 are allocated as OCRAM ECC RAM, bank20,21,28,29 (32KB) are allocates as ITCM ECC RAM, and bank22,23,30,31 (32KB) are allocated as DTCM ECC RAM.

Table 39-4. FLEXRAM ECC RAM Partitioning Example

	ITCM ECC	DTCM ECC	OCRAM ECC
Bank16	0	0	1
Bank17	0	0	1
Bank18	0	0	1
Bank19	0	0	1
Bank20	1	0	0
Bank21	1	0	0
Bank22	0	1	0
Bank23	0	1	0
Bank24	0	0	1
Bank25	0	0	1
Bank26	0	0	1
Bank27	0	0	1
Bank28	1	0	0
Bank29	1	0	0
Bank30	0	1	0
Bank31	0	1	0

If TCM ECC is enabled and OCRAM ECC is disabled, RAM partition would also be aligned with corresponding data RAM bank. If configured for OCRAM, they would be used as OCRAM data RAM addressed after normal OCRAM data RAM. Take the table above as an example, the RAM partition for the 128KB would be just similar as shown in the table: only bank16~19 and bank24~27 would be used as OCRAM data RAM. This 64K space can be addressed after bank11.

If TCM ECC is disabled and OCRAM ECC is enabled, partition of the 128KB RAM would be decided by which bank of bank0~15 is configured for OCRAM. Take the table above as an example, under such configuration, bank16~19 and bank24~27 would be used as OCRAM ECC RAM, while bank20~23 and bank28~31 cannot be addressed.

If both OCRAM ECC and TCM ECC are disabled, then the whole 128KB RAM would be used for OCRAM data RAM, no matter what value the GPR (ram_bank_config) is configured.

39.3.3 Low power modes

FLEXRAM has input fuse control signal to control OCRAM bank8~15 and bank24~31 interface access. When the fuse bit is programmed, bank8~15 and bank24~31 cannot be accessed again and can be powered down.

39.3.4 Clocks

The following table lists the clock sources of the FlexRAM module.

Table 39-5. FlexRAM Clocks

Clock name	Description
core_clk	Arm core clock
axi_clk	AXI bus clock
ipg_clk	Peripheral clock
ipg_clk_s	Peripheral access clock for register accesses

39.3.5 Reset

FLEXRAM has 2 reset signals. One is used for OCRAM interface and in always-on power domain. The other one is used for TCM interface and in core power domain.

39.3.6 Interrupts

FLEXRAM can generate interrupt in the following cases:

- OCRAM, DTCM or ITCM access the RAM address which is not allocated.
- OCRAM, DTCM or ITCM access the RAM address which is assigned in *_MAGIC_ADDR register.
- ECC error is detected in a read access from OCRAM, DTCM or ITCM. Multi-bit ECC error and single-bit ECC error interrupt would be asserted separately.
- Partial write is launched by OCRAM, and the corresponding ECC_EN is set to 1'b1.

39.3.7 Lookup Table

Syndrome for single-bit ECC can be used to locate the Error bit. For OCRAM or ITCM single-bit ECC Error Information Register, see "Lookup table for 64-bit data ECC syndrome". For D0TCM or D1TCM single-bit ECC Error Information Register, see "Lookup table for 32-bit data ECC syndrome".

39.4.1.8 Interrupt Enable Register (INT_SIG_EN)

39.4.1.8.1 Offset

Register	Offset
INT_SIG_EN	18h

39.4.1.8.2 Function

This register is used to select which interrupt status is indicated to the Host System as the interrupt. These status bits all share the same interrupt line. Setting any of these bits to 1 enables interrupt generation. The corresponding Status register bit will generate an interrupt when the corresponding interrupt signal enable bit is set.

39.4.1.16.4 Fields

Field	Function
31-0 OCRAM_ECCM_ERRED_DATA_MSB	OCRAM multi-bit ECC error data [63:32]

39.4.1.17 ITCM single-bit ECC Error Information Register (ITCM_ECC_SINGLE_ERROR_INFO)

39.4.1.17.1 Offset

Register	Offset
ITCM_ECC_SINGLE_ERROR_INFO	3Ch

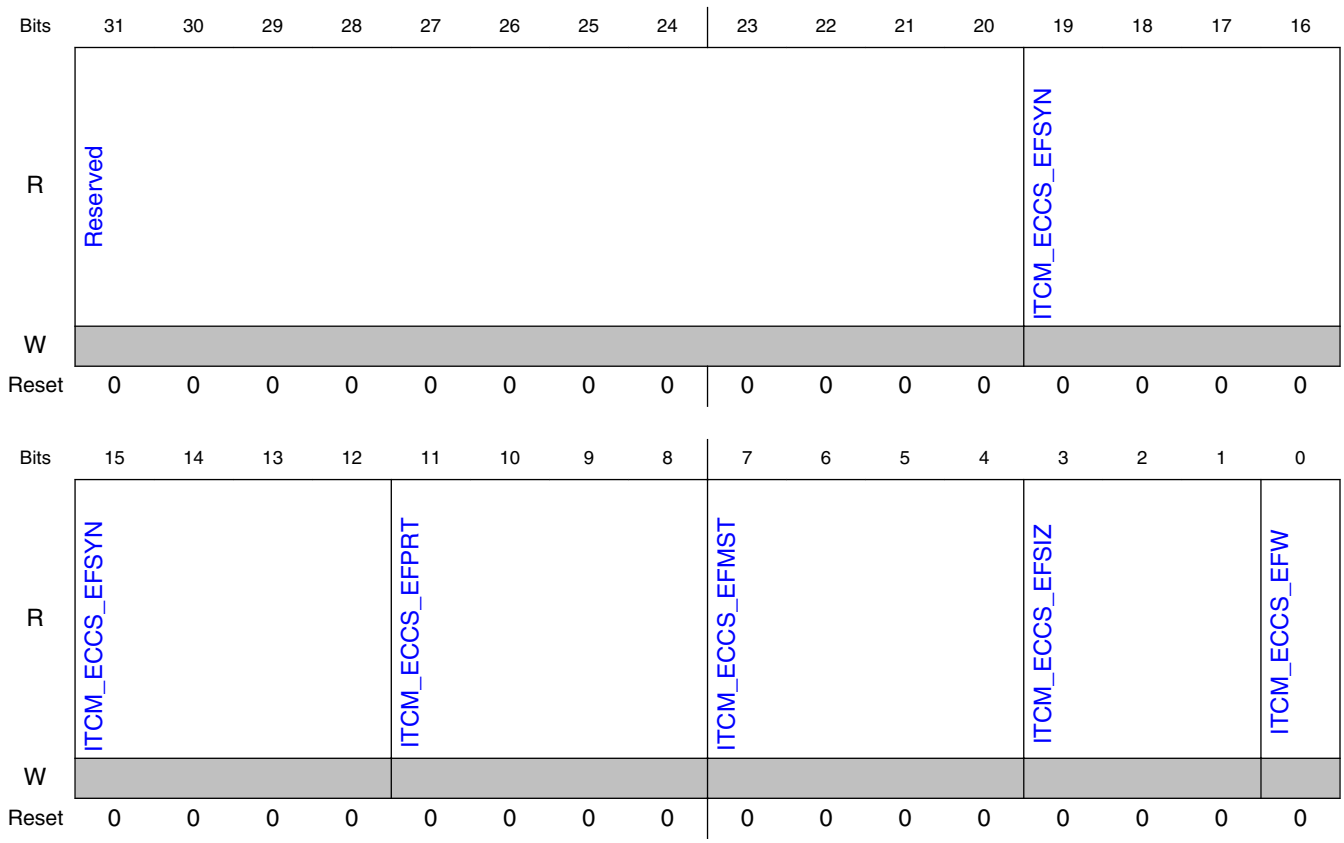
39.4.1.17.2 Function

This register is used to store detail error information for corresponding ITCM single-bit ECC interrupt if the interrupt is enabled.

NOTE

For TCM_PRIV, TCM_WR and TCM_MASTER, they are interface signals defined by Arm TCM bus protocol. ITCM, D0TCM and D1TCM have their respective sets of these signals.

39.4.1.17.3 Diagram



39.4.1.17.4 Fields

Field	Function
31-20 Reserved	Reserved
19-12 ITCM_ECCS_EFSYN	ITCM single-bit ECC error corresponding syndrome ECC syndrome can be used to locate the Error bit using a look-up table (see "Lookup table for 64-bit data ECC syndrome")
11-8 ITCM_ECCS_EFPRT	ITCM single-bit ECC error corresponding TCM_PRIV. TCM_PRIV is to tell the privilege level of access.
7-4	ITCM single-bit ECC error corresponding TCM_MASTER.

Table continues on the next page...

Field	Function
ITCM_ECCS_EFMST	TCM_MASTER is to tell the requester of the current access. For TCM_MASTER, the following list shows the encoding of the access requestor. • 4'b0000 Instruction fetch • 4'b0001 Data access • 4'b0010 Vector fetch on automated exception entry • 4'b0011 AHB slave access • 4'b0100 Debugger access • 4'b0101 MBIST access • 4'b1001 Software data access from sequence queue • 4'b1011 AHB slave access from sequence queue • 4'b1100 Debugger access from sequence queue
3-1 ITCM_ECCS_EFSIZ	ITCM single-bit ECC error corresponding TCM size For ITCM, this value should be 3 (64bit).
0 ITCM_ECCS_EFW	ITCM single-bit ECC error corresponding TCM_WR value. TCM_WR is to tell whether it is a write access(1'b1) or a read access(1'b0).

39.4.1.18 ITCM single-bit ECC Error Address Register (ITCM_ECC_SINGLE_ERROR_ADDR)

39.4.1.18.1 Offset

Register	Offset
ITCM_ECC_SINGLE_ERROR_ADDR	40h

39.4.1.18.2 Function

This register is used to store the errored address for corresponding ITCM single-bit ECC interrupt if the interrupt is enabled.

Chapter 40
AHB to IP Bridge (AIPS Lite)

40.1 Chip-specific AIPS Lite information

Table 40-1. Reference links to related information

Topic	Related module(s)	Reference
System memory map	-	System Memory Map
Clocking	CCM	Clock Management Clock Control Module (CCM)
Power management	PMU	Power Management Power Management Unit

40.2 Overview

The peripheral bridge (AIPS Lite) converts the crossbar switch interface to an interface that can access most of the slave peripherals on this chip. The peripheral bridge occupies 4MB of the address space, which is divided into peripheral slots of 16KB.

NOTE

Not all peripheral slots might be in use. See the memory map chapter for details on slot assignments.

40.3 Functional Description

The slave devices connected to the peripheral bridge are modules which contain a programming model of control and status registers. The system masters read and write these registers through the peripheral bridge.

The peripheral bridge manages all transactions destined for the attached slave devices and generates select signals for modules on the peripheral bus by decoding accesses within the attached address space.

It supports peripheral slots with 8, 16, and 32-bit data width. All accesses to the peripheral slot must be sized less than or equal to the designated peripheral slot size. If an access is attempted that is larger than the targeted port, and error response is generated.

40.3.1 Clocks

The clock roots of AIPS1, AIPS2 and AIPS3 use BUS_CLK_ROOT, while AIPS4 uses BUS_LPSR_CLK_ROOT. Please see the "System Clocks" section of CCM chapter for clock setting, configuration and gating information.

40.4 Memory Map/Register Definition

This module does not contain any user programmable registers.

Chapter 41
Semaphores (SEMA4)

In this device, core processor 0 (logical processor number=0) is Cortex-M7 processor, and core processor 1 (logical processor number=1) is Cortex-M4 processor.

NOTE

This device only supports two master IDs for SEMA4. CM7 master ID is 0, CM4 master ID is 1. All the other masters should not access SEMA4.

41.2 Overview

The Semaphores (SEMA4) module provides a platform IPS slave device which implements 16 hardware-enforced gates.

41.2.1 Block Diagram

A simplified block diagram of the Semaphores module is shown in Figure 41-1. This is a dual-processor configuration, where cp0 is core processor 0 and cp1 is core processor 1. In the diagram, the register blocks named gate0, gate1,…, gate 15 include the finite state machines (FSM) implementing the semaphore gates plus the interrupt notification logic.

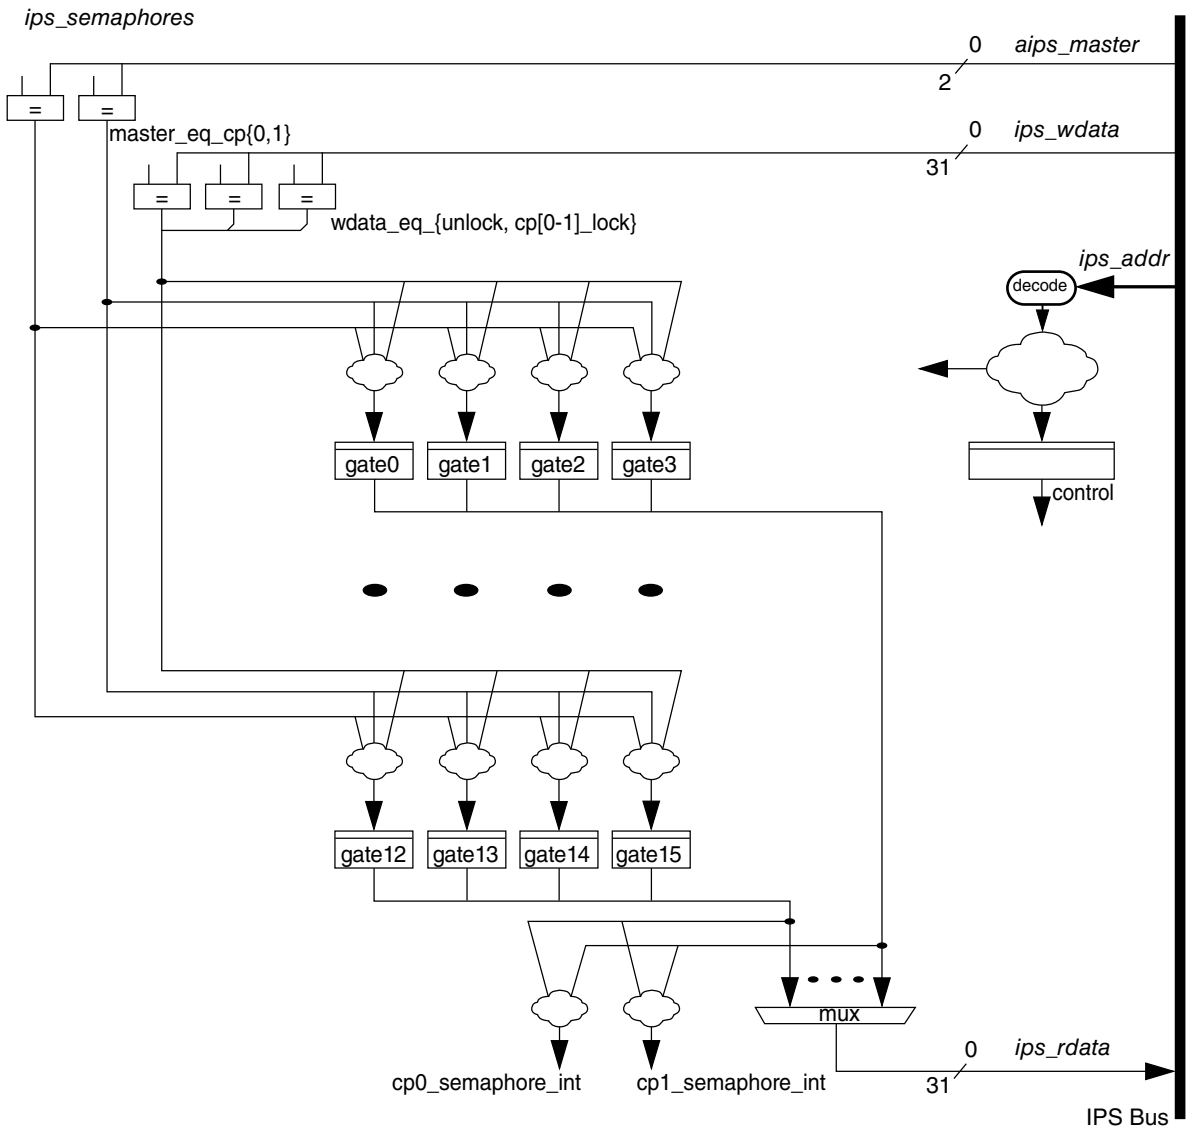

Figure 41-1. Semaphores Block Diagram

41.2.2 Features

The Semaphores module implements hardware-enforced semaphores as an IPS-mapped slave peripheral device. The feature set includes:

- Support for 16 hardware-enforced gates in a dual-processor configuration

- Each hardware gate appears as a 3-state, 2-bit state machine, with all 16 gates mapped as a byte-size array
  - Processors lock gates by writing "processor_number+1" to the appropriate gate and must read back the gate value to verify the lock operation was successful.

    3-state implementation:

    if gate = 0b00, then state = unlocked
    if gate = 0b01, then state = locked by processor 0
    if gate = 0b10, then state = locked by processor 1
  - Uses the bus master number/ID as a reference attribute plus the specified data patterns to validate all write operations
  - Once locked, the gate can (and must) be unlocked by a write of zeroes from the locking processor
- Optional interrupt notification after a failed lock write provides a mechanism to indicate when the gate is unlocked
- Secure reset mechanisms are supported to clear the contents of individual gates or notification logic, as well as a clear_all capability

- Memory-mapped IPS slave peripheral platform module
  - Interface to the IPS bus for programming-model accesses
  - Two outputs (one per processor) for interrupt notification of failed lock writes

41.3 Functional Description

In this section, the functional operation of the Semaphores module, specifically the state machines of the SEMA4_GATEn and SEMA4_CPnNTF registers are detailed.

41.3.1 Modes of Operation

The Semaphores module does not support any special modes of operation. As a slave peripheral memory-mapped device located on the platform's IPS slave bus, it responds based strictly on the memory addresses of the connected bus. The IPS bus is used to access the Semaphores' programming model.

41.3.2 SEMA4_GATEn Operation

Recall each of the SEMA4_GATEn registers implements a 2-bit, 3-state machine. The state transitions for each gate are shown in the following figure.

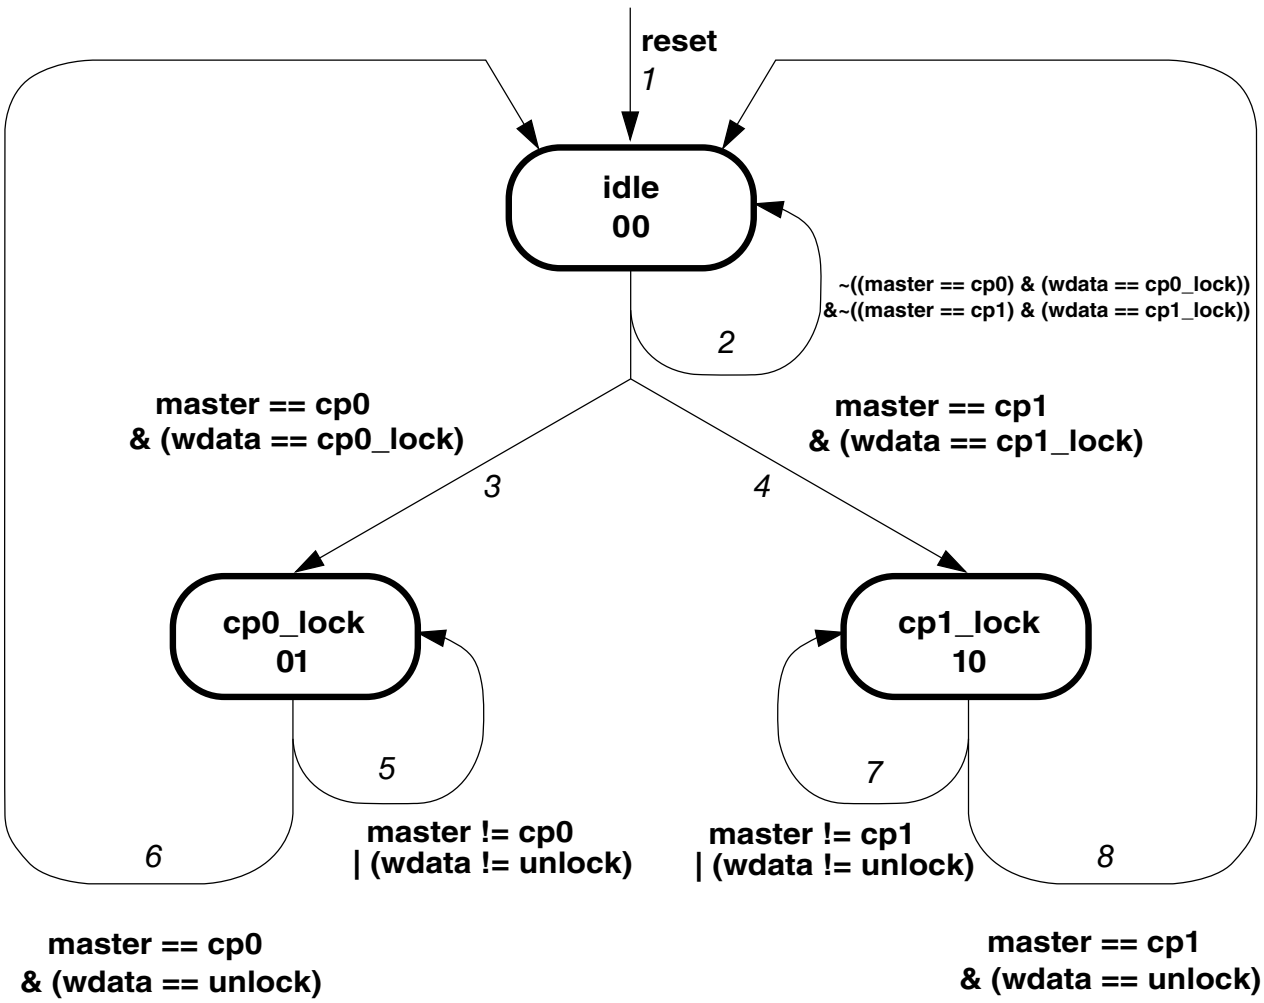

Figure 41-2. SEMA4_GATEn State Machine

The bus master number/ID is used to identify core processor 0 (cp0) or core processor 1 (cp1).

The state transitions for SEMA4_GATEn are defined in the following table.

Table 41-2. SEMA4_GATEn State Transitions

Current State	Next State	Transition	Description
–	idle	1	Any reset, whether a system reset or an individual gate reset, unconditionally forces the gate into the idle state.

Table continues on the next page...

Table 41-2. SEMA4_GATEn State Transitions (continued)

Current State	Next State	Transition	Description
idle	idle	2	Unless a write of the appropriate lock value from the corresponding processor occurs, the gate remains in the idle state.
idle	cp0_lock	3	When a write of the "cp0_lock" data value is initiated by processor 0, the gate transitions into the cp0_lock state.
idle	cp1_lock	4	When a write of the "cp1_lock" value is initiated by processor 1, the gate transitions into the cp1_lock state.
cp0_lock	cp0_lock	5	Once in this state, the gate remains here if any attempted write is not from cp0 with the unlock data value.
cp0_lock	idle	6	The gate returns to the idle (unlocked) state once a write from cp0 with the unlock data value occurs.
cp1_lock	cp1_lock	7	Once in this state, the gate remains here if any attempted write is not from cp1 with the unlock data value.
cp1_lock	idle	8	The gate returns to the idle (unlocked) state once a write from cp1 with the unlock data value occurs.

41.3.3 SEMA4_CPnNTF Operation

The failed lock write notification interrupt request is implemented in a 3-bit, 5-state machine which records failed lock attempts and transitions based on gate locking and unlocking. Two specific states are encoded and program-visible as SEMA4_CP0NTF[GNn] and SEMA4_CP1NTF[GNn]. See the following figure.

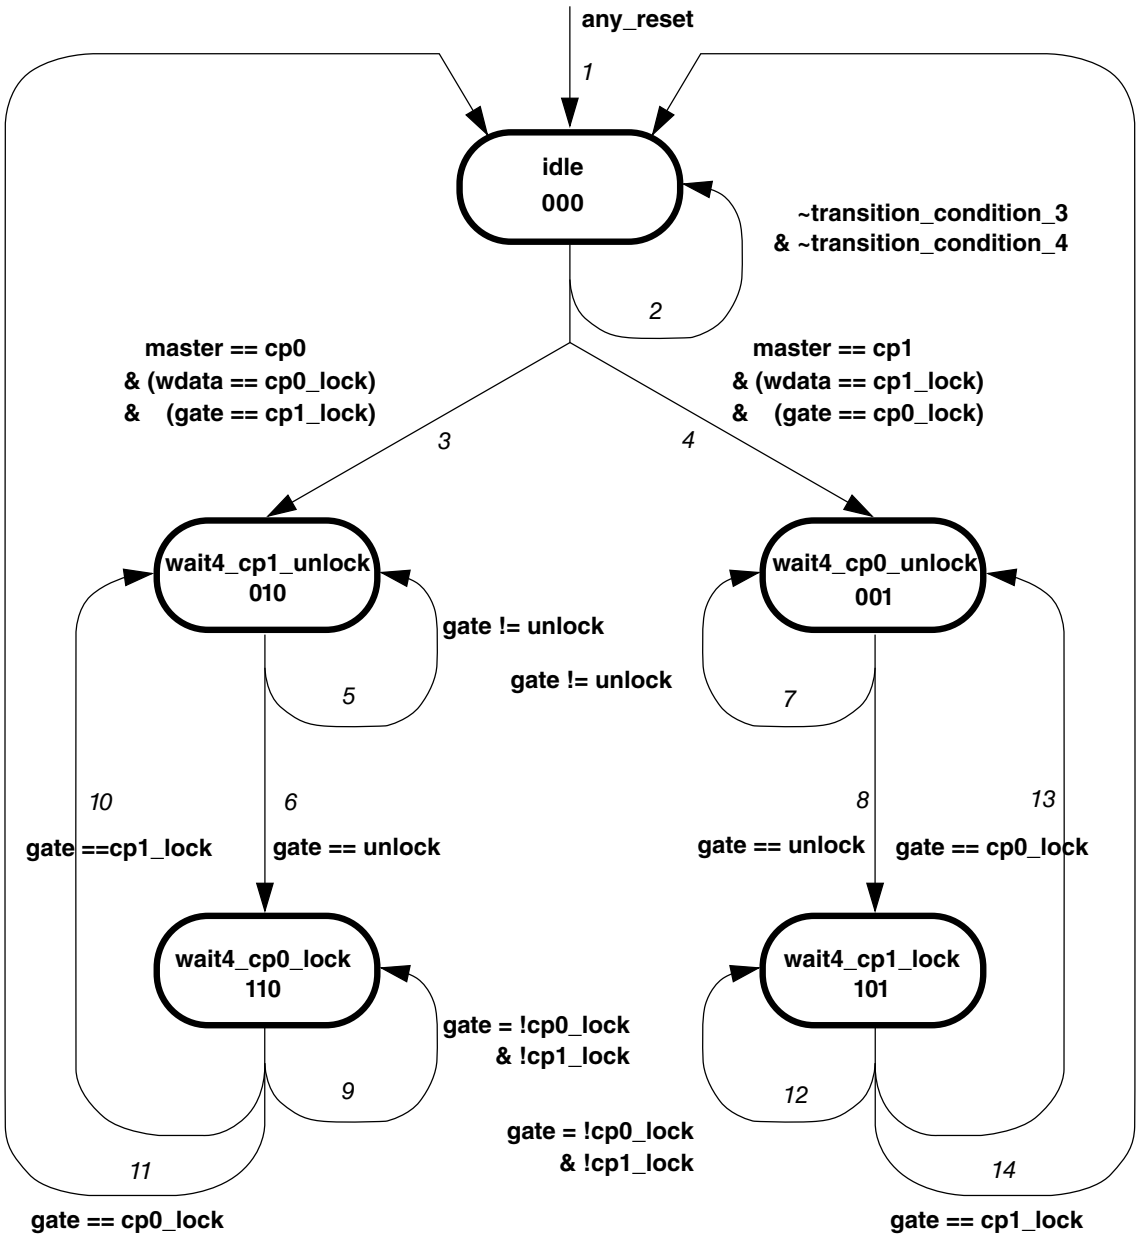

Figure 41-3. IRQ Notification State Machine

The state transitions of the IRQ notification function are defined in the following table. Specific states of this machine are program-visible as the SEMA4_CPnNTF registers. In particular, two states are program-visible:

```
if state = wait4_cp0_lock (0b110) // generate cp0_semaphore_int if properly enabled
then SEMA4_CP0NTF[GNn] = 1;
else SEMA4_CP0NTF[GNn] = 0

if state = wait4_cp1_lock (0b101) // generate cp1_semaphore_int if properly enabled
then SEMA4_CP1NTF[GNn] = 1;
else SEMA4_CP1NTF[GNn] = 0
```

Table 41-3. IRQ Notification State Transitions

Current State	Next State	Transition	Description
–	idle	1	Any reset, including a system reset or an individual notification or secure gate reset, unconditionally forces the machine into the idle state.
idle	idle	2	Unless a write of the appropriate lock value from the corresponding processor to an already-locked gate occurs, the machine remains in the idle state.
idle	wait4_cp1_unlock	3	When a write of the "cp0_lock" data value is initiated by processor 0 but the gate is already locked by cp1, the machine transitions into this state, where it waits for cp1 to unlock the gate.
idle	wait4_cp0_unlock	4	When a write of the "cp1_lock" data value is initiated by processor 1but the gate is already locked by cp0, the machine transitions into this state, where it waits for cp0 to unlock the gate
wait4_cp1_unlock	wait4_cp1_unlock	5	Once in this state, the machine remains here until the gate is unlocked.
wait4_cp1_unlock	wait4_cp0_lock	6	From this state, the machine transitions into the next state, waiting for cp0 to lock the gate, once it has been unlocked.
wait4_cp0_unlock	wait4_cp0_unlock	7	Once in this state, the machine remains here until the gate is unlocked.
wait4_cp0_unlock	wait4_cp1_lock	8	From this state, the machine transitions into the next state, waiting for cp1 to lock the gate, once it has been unlocked.
wait4_cp0_lock	wait4_cp0_lock	9	In this state, the machine generates the notification interrupt (if properly-enabled) and remains here until the gate is locked by processor 0 or the gate is again locked by processor 1.
wait4_cp0_lock	wait4_cp1_unlock	10	In this state, the machine generates the notification interrupt (if properly-enabled) and transitions if the gate is again locked by processor 1. With this transition, the notification interrupt request is negated.
wait4_cp0_lock	idle	11	In this state, the machine generates the notification interrupt (if properly-enabled) and transitions if the gate is finally locked by processor 0. With this transition, the notification interrupt request is negated.
wait4_cp1_lock	wait4_cp1_lock	12	In this state, the machine generates the notification interrupt (if properly-enabled) and remains here until the gate is locked by processor 1or the gate is again locked by processor 0.
wait4_cp1_lock	wait4_cp0_unlock	13	In this state, the machine generates the notification interrupt (if properly-enabled) and transitions if the gate is again locked by processor 0. With this transition, the notification interrupt request is negated.
wait4_cp1_lock	idle	14	In this state, the machine generates the notification interrupt (if properly-enabled) and transitions if the gate is finally locked by processor 1. With this transition, the notification interrupt request is negated.

The Semaphores module generates two interrupt request output signals, one per processor, combining the SEMA4_CPnINE and SEMA4_CPnNTF registers, where the boolean equations are:

```
cp0_semaphore_int
    =    SEMA4_CP0INE[INE0]    &    SEMA4_CP0NTF[GN0]
    |    SEMA4_CP0INE[INE1]    &    SEMA4_CP0NTF[GN1]
    |    SEMA4_CP0INE[INE2]    &    SEMA4_CP0NTF[GN2]
    ...
    |    SEMA4_CP0INE[INE15]    &    SEMA4_CP0NTF[GN15]
cp1_semaphore_int
    =    SEMA4_CP1INE[INE0]    &    SEMA4_CP1NTF[GN0]
    |    SEMA4_CP1INE[INE1]    &    SEMA4_CP1NTF[GN1]
    |    SEMA4_CP1INE[INE2]    &    SEMA4_CP1NTF[GN2]
    ...
    |    SEMA4_CP1INE[INE15]    &    SEMA4_CP1NTF[GN15]
```

41.4 External Signal Description

The Semaphores module does not include any external interfaces.

41.5 Initialization Information

The reset state of the Semaphores module allows it to begin operation without the need for any further initialization. All the internal state machines are cleared by any reset event, allowing the module to immediately begin operation.

41.6 Application Information

In an operational multi-core system, most interactions involving the Semaphores module involves reads and writes to the SEMA4_GATEn registers for implementation of the hardware-enforced software gate functions. Typical code segments for gate functions perform the following operations:

- To lock (close) a gate
  - The processor performs a byte write of "logical_processor_number + 1" to gate[i]
  - The processor reads back gate[i] and checks for a value of "logical_processor_number + 1"

If the compare indicates the expected value, then the gate is locked; proceed with the protected code segment. If the compare does not indicate the expected value, the lock operation failed; repeat the process beginning with byte write to gate[i] in spin-wait loop, or proceed with another execution path and wait for failed lock interrupt notification.

A simple C-language example of a `gateLock` function is shown in the following figure.

```
#define UNLOCK     0
#define CP0_LOCK   1
#define CP1_LOCK   2

void gateLock (n)
int   n;                                          /* gate number to lock */
{
   int i;
   int current_value;
   int locked_value;

   i = processor_number();  /* obtain logical CPU number */

   if (i == 0)
      locked_value = CP0_LOCK;
   else
      locked_value = CP1_LOCK;

   /* read the current value of the gate and wait until the state == UNLOCK */
   do {
        current_value = gate[n];
   } while (current_value != UNLOCK);

   /* the current value of the gate == UNLOCK. attempt to lock the gate for this
        processor. spin-wait in this loop until gate ownership is obtained */
   do {
      gate[n] = locked_value;  /* write gate with processor_number + 1 */
      current_value = gate[n]; /* read gate to verify ownership was obtained */
   } while (current_value != locked_value);
```

Figure 41-4. Sample gateLock Function

- To unlock (open) a gate
    - After completing the protected code segment, the locking processor performs a byte write of zeroes to gate[i], opening (unlocking) the gate

A few comments on the logical CPU number are appropriate. In this example, a reference to `processor_number()` is used to retrieve this hardware configuration value. Typically, the logical processor numbers are defined by a hardwired input vector to the individual cores. The exact method for accessing the logical processor number varies by architecture.

If the optional failed lock IRQ notification mechanisms are used, then accesses to the related registers (SEMA4_CPnINE, SEMA4_ CPnNTF) are required. Note that there is no required negation of the failed lock write notification interrupt, as the request is automatically cleared by the Semaphores module once the gate has been successfully locked by the "failing" processor.

Finally, in the event a system state requires a software-controlled reset of a gate or IRQ notification register(s), accesses to the secure reset control registers (SEMA4_RSTGT, SEMA4_RSTNTF) are required. For these situations, it is recommended that the

appropriate IRQ notification enable (SEMA4_CPnINE) bits should be disabled *before* initiating the secure reset 2-write sequence (write RSTGT and write RSTNTF), to avoid any race conditions involving spurious notification interrupt requests.

41.7 Memory map and register definition

The Semaphores module provides an IPS programming model mapped to an on-platform 16 KB space. The description here specifies a dual-core configuration with 16 semaphore gates. All the register names are prefixed with "SEMA4" as an abbreviation for the full module name.

The programming model is referenced using 8-, 16- and 32-bit accesses. Reads can use any reference size, while writes are generally restricted to the size of the register. Exceptions to the write size restrictions are detailed in the individual register descriptions. Attempted references using inappropriate access sizes, to undefined (reserved) addresses, or with a non-supported access type (for example, a write to a read-only register) generate an IPS error termination.

The 16 KB Semaphores programming model map is shown in the following table.

SEMA4 memory map

41.7.1 Semaphores Gate n Register (SEMA4_Gate*n*)

Each semaphore gate is implemented in a 2-bit finite state machine (FSM), right-justified in a byte data structure. The hardware uses the bus master number in conjunction with the data patterns to validate all attempted write operations. Only processor bus masters can modify the gate registers. Once locked, a gate can (and must) be opened (unlocked) by the locking processor core.

Multiple gate values can be read in a single access, but only a single gate can be updated via a write operation at a time. 16- and 32-bit writes to multiple gates are allowed, but the write data operand must only update the state of a single gate. A byte write data value of 0x03 is defined as "no operation" and does not affect the state of the corresponding gate register. Attempts to write multiple gates in a single aligned access with a size larger than an 8-bit (byte) reference generate an error termination and do not allow any gate state changes

Field	Description
	Gate Finite State Machine. The hardware gate is maintained in a 3-state implementation-unlocked, locked by processor 0 or locked by processor 1. For more details, see SEMA4_GATEn Operation . **NOTE:** The state of the gate reflects the last processor that locked it, which can be useful during system debug. 00 The gate is unlocked (free). 01 The gate has been locked by processor 0. 10 The gate has been locked by processor 1. 11 This state encoding is never used and therefore reserved. Attempted writes of 0x03 are treated as "no operation" and do not affect the gate state machine.

41.7.2 Semaphores Processor n IRQ Notification Enable (SEMA4_CP*n*INE)

The application of a hardware semaphore module provides an opportunity for implementation of helpful system-level features. An example is an optional mechanism to generate a processor interrupt after a failed lock attempt. Recall traditional software gate functions execute a spin-wait loop in an effort to obtain and lock the referenced gate. With this module, the processor that fails in the lock attempt could continue with other tasks and allow a properly-enabled notification interrupt to return its execution to the original lock function.

The optional notification interrupt function consists of two registers for each processor: an interrupt notification enable register (SEMA4_CPnINE) and the interrupt request register (SEMA4_CPnNTF). To support implementations with more than 16 gates, these registers can be referenced with aligned 16- or 32-bit accesses. For the SEMA4_CPnINE registers, unimplemented bits read as zeroes, and writes are ignored.

41.7.3 Semaphores Processor n IRQ Notification (SEMA4_CP*n*NTF)

The Semaphores module optionally allows the processor that fails in the lock attempt to continue with other tasks and allow a properly-enabled notification interrupt to return its execution to the original lock function rather than simply execute in a spin-wait loop.

The optional notification interrupt mechanism consists of two registers for each processor: an interrupt notification enable register (SEMA4_CPnINE) and the read-only notification interrupt request register (SEMA4_CPnNTF). To support implementations with more than 16 gates, these registers can be referenced with aligned 16- or 32-bit accesses. For the SEMA4_CPnNTF registers, unimplemented bits read as zeroes.

The notification interrupt is generated via a unique finite state machine (FSM), one per hardware gate. This machine operates in the following manner:

1. When an attempted lock fails, the FSM enters a first state where it waits until the gate is unlocked.

2. Once unlocked, the FSM enters a second state where it generates an interrupt request to the “failed lock” processor.
3. When the “failed lock” processor succeeds in locking the gate, the IRQ is automatically cleared and the FSM returns to the idle state. However, if the other processor again locks the gate, the FSM returns to the first state, clears the interrupt request, and then waits for the gate to be unlocked (again).

The notification interrupt request is implemented in a 3-bit, 5-state machine, where two specific states are encoded and program-visible as SEMA4_CP0NTF[GNn] and SEMA4_CP1NTF[GNn].

41.7.4 Semaphores (Secure) Reset Gate n (SEMA4_RSTGT)

Although the intent of the hardware gate implementation specifies a protocol where the locking processor must unlock the gate, it is recognized that system operation may require a reset function to re-initialize the state of any gate(s) without requiring a system-level reset.

To support this special gate reset requirement, the Semaphores module implements a "secure" reset mechanism which allows a hardware gate (or all the gates) to be initialized by following a specific dual-write access pattern. Using a technique similar to that required for the servicing of a software watchdog timer, the secure gate reset requires two consecutive writes with predefined data patterns from the same processor to force the clearing of the specified gate(s). The required access pattern is:

1. A processor performs a 16-bit write to the SEMA4_RSTGT memory location. The least significant byte (SEMA4_RSTGT[RSTGDP]) must be 0xe2; the most significant byte is a "don't_care" for this reference.
2. The same processor then performs a second 16-bit write to the SEMA4_RSTGT location. For this write, the lower byte (SEMA4_RSTGT[RSTGDP]) is the logical complement of the first data pattern (0x1d) and the upper byte (SEMA4_RSTGT[RSTGTN]) specifies the gate(s) to be reset. This gate field can specify a single gate be cleared, or that all gates are cleared.
3. Reads of the SEMA4_RSTGT location return information on the 2-bit state machine (SEMA4_RSTGT[RSTGSM]) which implements this function, the bus master performing the reset (SEMA4_RSTGT[RSTGMS]) and the gate number(s) last cleared (SEMA4_RSTGT[RSTGTN]). Reads of the SEMA4_RSTGT register do not affect the secure reset finite state machine in any manner.

Address: 40CC_8000h base + 100h offset = 40CC_8100h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read Write	RSTGTN								RSTGSM_RSTGMS_RSTGDP							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SEMA4_RSTGT field descriptions

Field	Description
15–8 RSTGTN	Reset Gate Number. This 8-bit field specifies the specific hardware gate to be reset. This field is updated by the second write. This field contains the hexidecimal value of the gate number. If RSTGTN < 64, then reset the single gate defined by RSTGTN, else reset all the gates. The corresponding secure IRQ notification state machine(s) are also reset.
RSTGSM_ RSTGMS_ RSTGDP	**NOTE:** This field contains sub-fields that vary depending on whether it is being read or written. Sub-fields indicated as having read access are valid only for read operations. Sub-fields indicated as having write access are valid only for write operations. Bit numbering in the descriptions begins with the most significant bit numbered 0. See the following table for details.

Access	Sub-Field	Description
Read-Only	7-6 Reserved	Reserved. Always reads 0.
	5-4 RSTGSM	Reset Gate Finite State Machine. Reads of the SEMA4_RSTGT register return the encoded state machine value. The reset state machine is maintained in a 2-bit, 3-state implementation, defined as: 00 Idle, waiting for the first data pattern write. 01 Waiting for the second data pattern write. 10 The 2-write sequence has completed. Generate the specified gate reset(s). After the reset is performed, this machine returns to the idle (waiting for first data pattern write) state. Note that the RSTGSM = 0b10 state is valid for only a single machine cycle, so it is impossible for a read to return this value 11 This state encoding is never used and therefore reserved.
	3 Reserved	Reserved. Always reads 0.
	2-0 RSTGMS	Reset Gate Bus Master. This 3-bit read-only field records the logical number of the bus master performing the gate reset function. The reset function requires that the two consecutive writes to this register be initiated by the same bus master to succeed. This field is updated each time a write to this register occurs. The association between system bus master port numbers, the associated bus master device and the logical processor number is SoC-specific. See the chip-specific information section.
Write-Only	7-0 RSTGDP	Reset Gate Data Pattern. This write-only field is accessed with the specified data patterns on the two consecutive writes to enable the gate reset mechanism. For the first write, RSTGDP = 0xe2 while the second write requires RSTGDP = 0x1d.

41.7.5 Semaphores (Secure) Reset IRQ Notification (SEMA4_RSTNTF)

As with the case of the secure reset function of the hardware gates, it is recognized that system operation may require a reset function to re-initialize the state of the IRQ notification logic without requiring a system-level reset.

To support this special notification reset requirement, the Semaphores module implements a "secure" reset mechanism which allows an IRQ notification (or all the notifications) to be initialized by following a specific dual-write access pattern. When successful, the specified IRQ notification state machine(s) are reset. Using a technique similar to that required for the servicing of a software watchdog timer, the secure reset mechanism requires two consecutive writes with predefined data patterns from the same processor to force the clearing of the IRQ notification(s). The required access pattern is:

1. A processor performs a 16-bit write to the SEMA4_RSTNTF memory location. The least significant byte (SEMA4_RSTNTF[RSTNDP]) must be 0x47; the most significant byte is a "don't_care" for this reference.
2. The same processor then performs a second 16-bit write to the SEMA4_RSTNTF location. For this write, the lower byte (SEMA4_RSTNTF[RSTNDP]) is the logical complement of the first data pattern (0xb8) and the upper byte (SEMA4_RSTNTF[RSTNTN]) specifies the notification(s) to be reset. This field can specify a single notification be cleared, or that all notifications are cleared.
3. Reads of the SEMA4_RSTNTF location return information on the 2-bit state machine (SEMA4_RSTNTF[RSTNSM]) which implements this function, the bus master performing the reset (SEMA4_RSTNTF[RSTNMS]) and the notification number(s) last cleared (SEMA4_RSTNTF[RSTNTN]). Reads of the SEMA4_RSTNTF register do not affect the secure reset finite state machine in any manner.

Address: 40CC_8000h base + 104h offset = 40CC_8104h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Power management	PMU	Power Management Power Management Unit
Signal multiplexing	IOMUX	External Signals and Pin Multiplexing IOMUX
Interrupts, DMA Events and XBAR Assignments	-	Interrupts, DMA Events and XBAR Assignments

NOTE

In this device, only Cortex-M7 and Cortex-M4 are supported to use SEMA42 (within RDC) or SEMA4. Domain ID is used to distinguish CM7 and CM4, and no master index is used.

NOTE

RDC is not available or accessible on single core versions of RT117x (RT1172 and RT1171).

NOTE

RDC configuration by ROM is not supported.

NOTE

When a buffered write from the CM4 is restricted by an RDC policy, the write operation is blocked but does not generate a bus fault.

42.2 Overview

The Resource Domain Controller (RDC) provides robust support for the isolation of destination memory mapped locations such as peripherals and memory to a single cluster, a bus master, or set of clusters and bus masters.

42.2.1 Block Diagram

Many of today's processors have multiple clusters for increased performance and flexibility. In some cases, the clusters serve different functions (for example, user level applications versus real time machine control) and in such cases the software for each cluster may be developed by different providers.

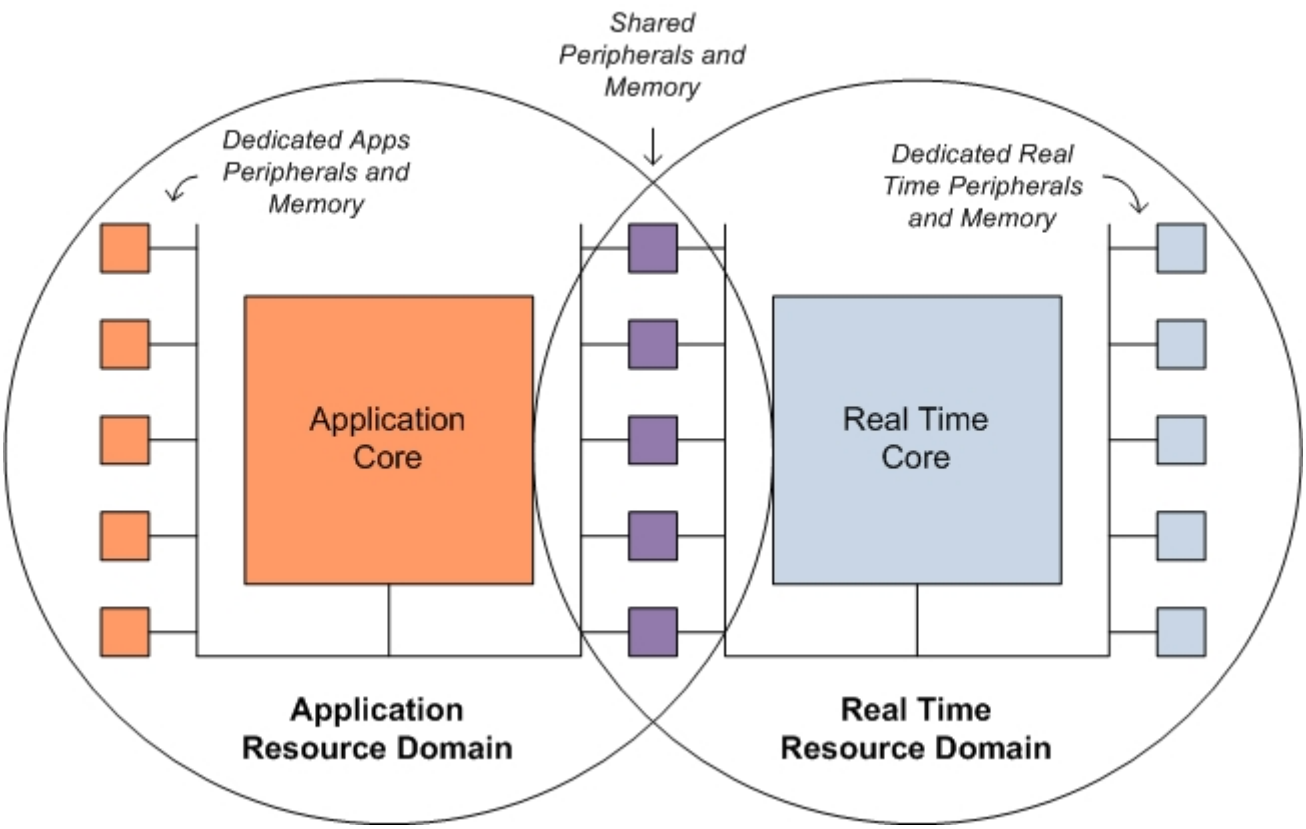

Figure 42-1. Dedicated and Shared Peripherals

For efficiency reasons the code on the clusters may share chip resources such as peripherals and memory. The sharing of chip resources between the somewhat independent processing domains allows for the opportunity of data collisions where

information stored in peripherals or memory by a process on one cluster is overwritten by software running on another cluster. Without careful collaboration between the two operating systems inadvertent malfunction or degradation in performance may result.

The RDC provides a mechanism to allow boot time configuration code to establish resource domains by assigning clusters, bus masters, peripherals and memory regions to domain identifiers. Once configured, bus transactions are monitored to restrict accesses initiated by clusters and bus masters to their respective peripherals and memory.

For shared peripherals, the RDC provides a semaphore-based locking mechanism to provide for temporary exclusivity while the domain software uses the peripheral. Once the software of one domain has finished the task and finished with the peripheral then it may release the semaphore making the peripheral available to the other domain.

42.2.2 Features

Resource domain subsystem has the following features:

- Assignment of clusters, bus masters, peripherals, and memory regions to a resource domain
- Fixed memory resolution of 128 Bytes for small address spaces and 4 KB for large address spaces
- Two resource domain identifiers (DIDs)
- Memory read/write access controls for each resource domain and region
- Optional semaphore-based, hardware-enforced exclusive access of shared peripherals to a resource domain
- Prioritized access permissions for overlapping memory regions
- Automatic restoration of resource domain access permissions to memory regions in the power-down domain

42.3 Functional Description

The RDC is the central location for creation of isolated resource domains and for the enablement of semaphore-based access also known as “safe sharing”. Configuration software assigns one of resource domain identifiers to each cluster and bus master, and allocates each memory region and peripheral to one or more resource domains.

Memory Read or Write access privileges for each resource domain are declared for each memory region. In addition, the software configuration determines which shared peripherals (those peripherals allocated to more than one domain) require safe sharing by setting the semaphore-required configuration for each peripheral.

The RDC configuration information is sent to the fabric ports, memories gaskets, semaphore controller, and peripherals to control access based on domain assignments. The fabric uses the domain identifier associated with each port to include this information along with the bus transaction. When the slave gasket encounters a bus transaction, it makes a comparison of the transaction domain ID to the RDC-provided list of allowed domains. If the transaction domain ID is on the list, then access may be permitted.

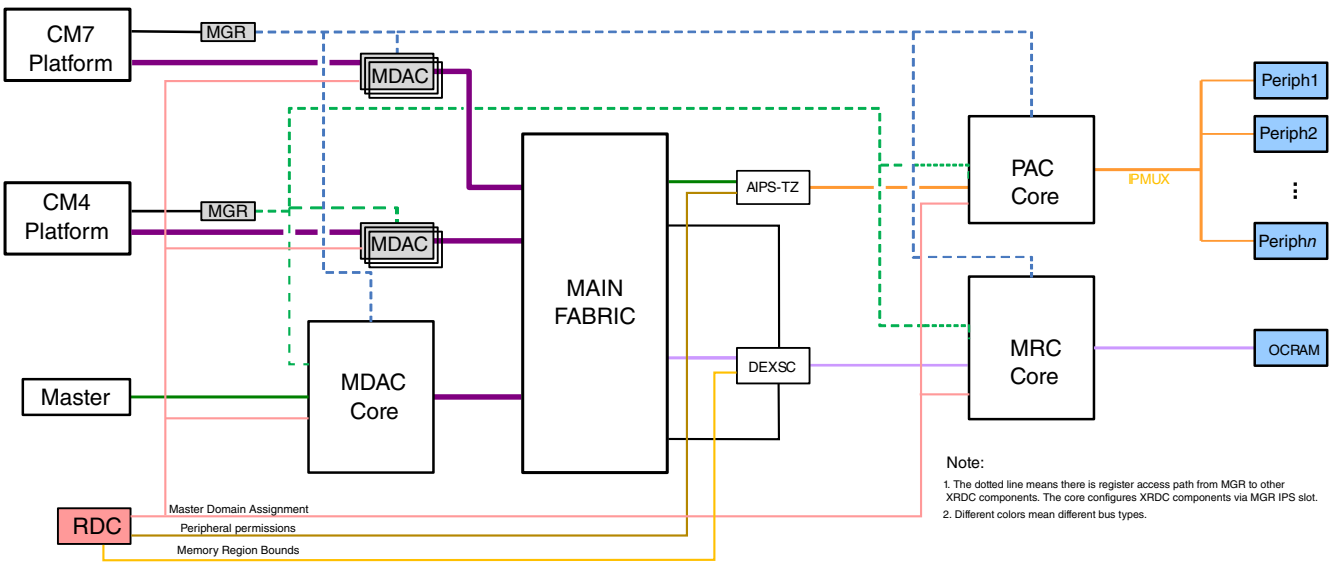

Figure 42-2. Example RDC Connections

For shared peripherals, RDC permits more than one domain access to a single peripheral. RDC also provides three ways to control synchronized use of shared peripherals. These methods include hardware-enforced synchronization, software-based semaphores, or no synchronization. The latter may be suitable for well-tuned multi-cluster operating systems that handle synchronization in the cluster platform, for instance.

For hardware-enforced synchronization, also known as "safe sharing", ownership of the peripheral must be claimed in the semaphore controller before access is allowed to the shared peripheral. Each shared peripheral has a corresponding Peripheral Domain Access Permissions (PDAP) register. When the Semaphore Required (SREQ) bit in a PDAP register is set, a master cannot access this shared peripheral until obtaining a semaphore. During the time that the domain has the semaphore in possession, its bus masters have exclusive access to the peripheral.

When the semaphore is released, then no domain masters have access until the semaphore is obtained again. When the SREQ bit is set, RDC module does not allow masters to obtain semaphores of peripherals to which the domain is not allocated; the master must have designated access in the D-bits of the corresponding PDAP register (for example, D1R bit set for Domain 1 access of the shared peripheral). There is a one-to-one mapping

between the semaphore controller gate and the resource domain controller peripheral. The mapping of PDAP registers and peripherals can be found in the Peripheral Map section of the RDC chapter.

42.3.1 Domain ID

The RDC provides for an isolation of domain resources by use of an identifier called the Domain ID (DID). A cluster and its resources including memory, bus masters, and peripherals are all associated with a single DID. When software or a DMA attempts to access a peripheral or memory, the corresponding bus transaction includes the DID along with the other bus control information such as Read, Write, and privilege mode.

42.3.2 Resource Assignment

The RDC allows assignment of peripherals and memories to one or more domains while each bus master or cluster is placed in one of several domains. The masters are assigned a domain in the Master Domain Assignment (MDA) register. A peripheral is given R/W access permissions to each domain in the PDAP register. Memory regions are bound by address space in start and end registers, i.e. MRSA and MREA. Each memory region is assigned one or more allowed domains and R/W permissions in the Memory Region Control (MRC) register. Memory regions must be enabled before the permissions are active. Otherwise the permissions are not restricted.

The RDC itself should be isolated to ensure that only a trustworthy resource manager can configure the RDC registers. This process may either be present initially during secure boot, or during the runtime in the secure world, for example. If the operating system does not support a runtime trusted execution, then during the secure boot process the RDC configuration can be locked to prevent further modification after the operating systems are running.

NOTE

The CCM supports multi-cluster awareness based on resource domain assignments programmed into the RDC. Refer to the CCM chapter regarding the relationship between cluster resource domains and their respective CCM resources. Failing to follow the proper sequence when updating the resource domain assignments of the cluster can result in clocks being inadvertently gated.

42.3.3 Safe Sharing

For shared peripherals, the RDC can be configured to require a domain to obtain a semaphore lock before access to the peripheral is allowed. This feature helps prevent collisions from processes on separate clusters that may want to use the same peripheral at the same time. The RDC sends a list of eligible domains to the semaphore module for each gate/peripheral. The eligible domains are those that are set in the peripheral domain access permissions (PDAP) registers. There is a one-to-one correspondence between semaphore gates and peripherals so each gate in the semaphore block represents a peripheral. The RDC receives semaphore locks from the hardware semaphore module (SEMA42). A semaphore lock is acquired when a cluster or bus master from a given domain requests a lock for a particular gate. The semaphore module compares the request's domain ID against the list of eligible domain IDs. If the domain ID is on the list and the lock is available then the lock is set and a signal is sent back to the RDC module indicating a lock has been acquired for a particular gate and a domain ID the lock belongs to. The RDC then restricts access to the corresponding peripheral to only transactions originating from the domain that has the lock. Another domain, though on the shared list to access the peripheral, must then wait until the lock is released before acquiring the lock and gaining access to the peripheral. To enable this feature of hardware enforcement for the semaphore locks, the SREQ bit is set in the RDC resource register.

If the SREQ is set, then when a process determines it needs a shared peripheral, it must first lock the resource in the semaphore module. Once the resource is locked, the semaphore module sends a signal to the RDC indicating the domain has access to the resource. The RDC will then set the access permissions to allow that domain access to the peripheral.

For a domain to acquire a lock on a peripheral, the domain must have been assigned to the peripheral in the RDC Peripheral Domain Access Permissions register (PDAP). The semaphore module only allows safe-sharing locks for those domains that are assigned to the peripheral. The semaphore module does not consider the access type (Read or Write) when allowing domains to acquire locks.

The SEMA42 module implements hardware-enforced semaphores as an IPS-mapped slave peripheral device. The feature set includes:

- Module definition supporting 64 hardware-enforced gates in a multi-processor configuration, where up to 15 processors can be supported; cp*X* is meant to represent cluster processor *X*
    - Gates appear as an *n*-entry byte-size array with read and write accesses ($n = 64$).

- Processors lock gates by writing logic 1 to the appropriate gate and must read back the gate value to verify the lock operation was successful. Also note that after locking, the gate register contains the value of the locking domain (in the field LDOM).
- Once locked, the gate is unlocked by a write of zeroes from the locking processor.
- The number of implemented gates is specified by a hardware configuration define.

- Each hardware gate appears as a 16-state, 4-bit state machine.
  - 16-state implementation

    if gate = 0x0, then state = unlocked
    if gate = 0x1, then state = locked by processor (master_index) 0
    if gate = 0x2, then state = locked by processor (master_index) 1
    …
    if gate = 0xF, then state = locked by processor (master_index) 14
  - Uses the logical bus master number (master_index) as a reference attribute plus the specified data patterns to validate all write operations.
  - Once locked, the gate can (and must) be unlocked by a write of zeroes from the locking processor.
- Secure reset mechanisms are supported to clear the contents of individual gates, as well as a clear_all capability.

- Memory-mapped IPS slave peripheral platform module
  - Interface to the IPS bus for programming-model accesses

42.3.4 Resource Domain Control and Security Considerations

Conceptually, the RDC configuration is independent of the processor privilege mode and security domain. It is intended to allow for isolation between cluster processing environments to prevent collisions and increase reliability. Access between resource domains is mutually exclusive and each domain should be in control of its own privilege modes and access rights.

However, it is important to realize multi-cluster processors may have a multiple resource domains but only one overarching security domain. Chip security controls reside in one resource domain. In this configuration, a domain can affect at least one level of access privileges in the other domain. This may be acceptable but clarity and care is needed to ensure expected functionality.

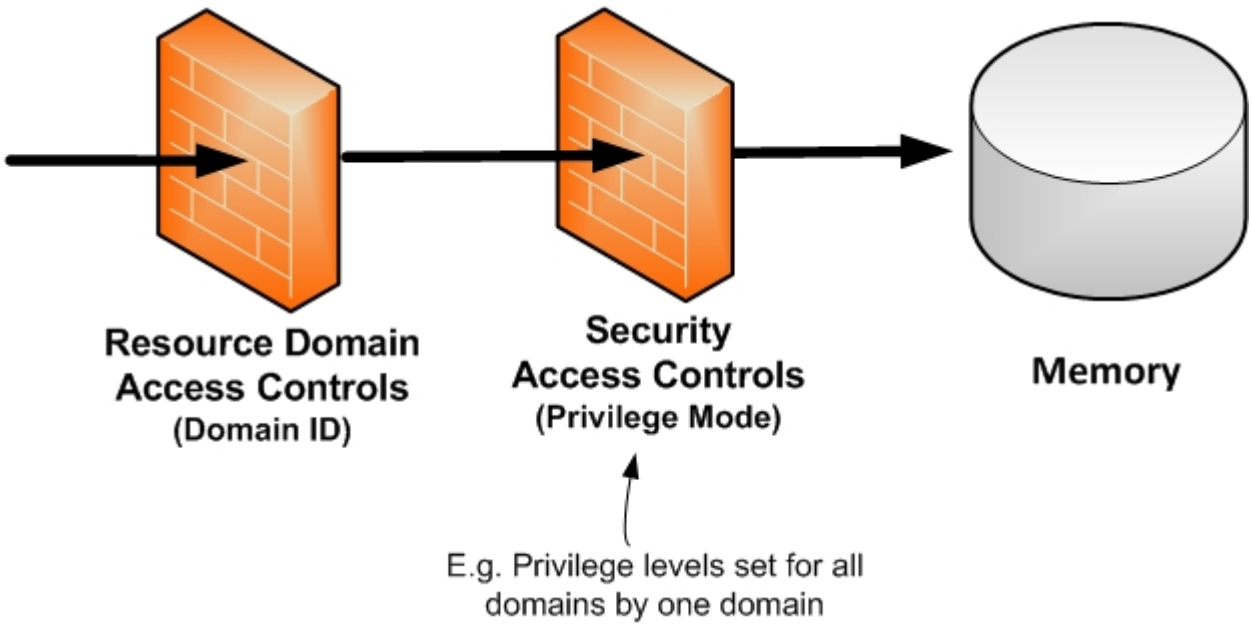

Figure 42-3. Access Control to Memory

Therefore, access to the security controls should be restricted to the most trustworthy operating mode of the cluster and privilege levels should be coordinated to ensure that shared peripherals and memory regions are accessible by both clusters. For instance, if a memory region is designated for secure accesses then all domain masters that share that region must have secure privileges.

42.3.5 Modes of Operation

The RDC provides access controls to the resource domain subsystem. When the device is in a low power mode then some memory regions in the subsystem may be powered off. RDC responds to the impacted memory regions by automatically reconfiguring the memory regions once power returns and blocking access to those memory regions until the reconfiguration process is complete.

42.3.5.1 Low Power Modes

The RDC loads configuration information for memory regions (MRSA, MRSE, MRC) into access control mechanisms (gaskets) at the memory interface. The location of this configuration information may reside inside power domains that lose power during sleep modes for energy savings. To restore configuration information upon return from sleep mode, the RDC receives a global power control signal indicating power is restored. The RDC then automatically reconfigures the memory regions with the configuration information.

During reconfiguration, access is blocked to the previously powered down memories. When the RDC completes reconfiguration it issues an interrupt and allows access to the memory regions. Only the powered down regions are blocked during the reconfiguration. Memory regions in the "always-on" power domain (still powered during sleep mode) remain available according to the programmed access rights. If no memory regions were enabled then the powered down regions are available immediately when power is restored.

The figure below shows the Global Power Control signal which RDC uses to invalidate the configuration upon deassertion and to restore the configuration when re-asserted. The configuration is valid and bus transactions allowed once the memory regions have been restored.

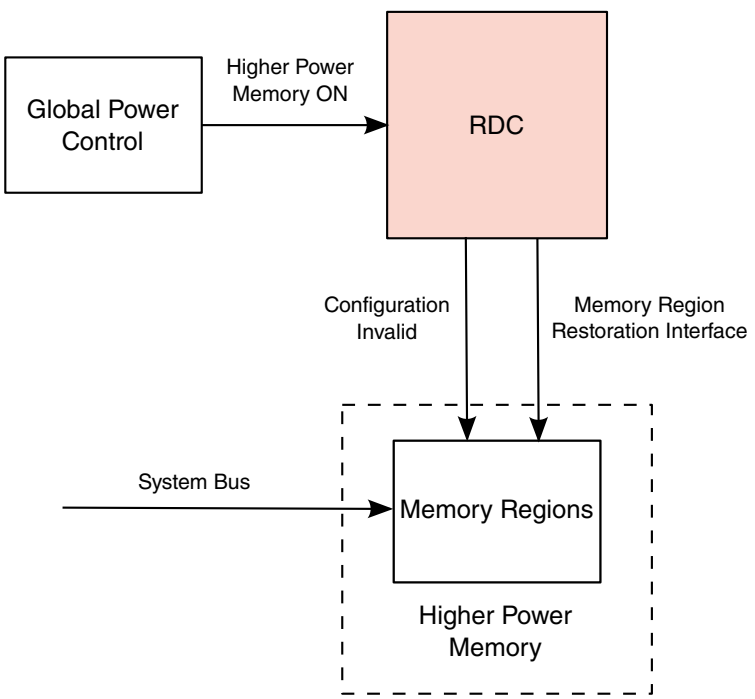

Figure 42-4. Memory Restoration Signaling

42.4 External Signals

RDC has no external signals pinned out.

42.5 Programming Interface

This section provides product specific details describing the mapping of resources - peripherals, bus masters, and memory regions - to corresponding resource domain controls RDC registers.

The RDC and RDC_SEMA42 register maps are combined in this chapter. The base address for the one RDC map and two SEMA42 maps are each separated by 4KB. While there are two SEMA42 submodules and therefore two sets of SEMA42 registers, this chapter describes one. Please refer to the peripheral memory map for the base addresses of the RDC and SEMA42 modules.

42.5.1 Master Assignment Registers

Table 42-2. Master Assignment Mapping

Master	RDC MDA register/Tied Value/Other Source
CM7	Tied to 0
CM7 DMA	Tied to 0

42.5.3 Memory Region Map

The number of memories with domain isolation support varies per device. The number of memory regions for a particular memory and the size of those regions varies per memory gasket. Each region of memory has a set of registers to define the boundaries of the region based on start and end addresses, a control register to set the domain access permissions and enable the region, and a status register to determin if access was denied to a region.

For this device, refer to the table below to determine the memories with domain support, the number of regions for each memory, the region resolution, the identifying numbers for the sets of memory region registers, and the addresses of the RDC registers to access the sets of Memory Region registers.

Table 42-4. Memory Region Mapping

Memory/Port	Regions	Region Resolution	MEM Region register set	Register Addr Range	DEXSC/DSEC Parameters
SEMC	8	4KB	0-7	0x800 – 0x87C	DEXSC_START_ADDR 11'h000
					NUM_OF_SECTIONS 8
					MEM_ADDR_WIDTH 20
FlexSPI1	8	4KB	8-15	0x880 – 0x8FC	DEXSC_START_ADDR 11'h080
					NUM_OF_SECTIONS 8
					MEM_ADDR_WIDTH 20
FlexSPI2	8	4KB	16-23	0x900 – 0x97C	DEXSC_START_ADDR 11'h100
					NUM_OF_SECTIONS 8
					MEM_ADDR_WIDTH 20
OCRAM1	8	128B	24-31	0x980 – 0x9FC	DEXSC_START_ADDR 11'h180
					NUM_OF_SECTIONS 8
					MEM_ADDR_WIDTH 25
OCRAM2	8	128B	32-39	0xA00 – 0xA7C	DEXSC_START_ADDR 11'h200
					NUM_OF_SECTIONS 8
					MEM_ADDR_WIDTH 25

Table continues on the next page...

Table 42-4. Memory Region Mapping (continued)

Memory/Port	Regions	Region Resolution	MEM Region register set	Register Addr Range	DEXSC/DSEC Parameters
M7 OCRAM	4	128B	40-43	0xA80 – 0xABC	DEXSC_START_ADDR 11'h280
					NUM_OF_SECTIONS 4
					MEM_ADDR_WIDTH 25
M4 OCRAM	4	128B	44-47	0xAC0 – 0xAFC	DEXSC_START_ADDR 11'h2C0
					NUM_OF_SECTIONS 4
					MEM_ADDR_WIDTH 25
CAAM	8	8KB	48-55	0xB00 – 0xB7C	DEXSC_START_ADDR 11'h300
					NUM_OF_SECTIONS 8
					MEM_ADDR_WIDTH 19
GPV	3	1MB	56-58	0xB80 – 0xBAC	DEXSC_START_ADDR 11'h380
					NUM_OF_SECTIONS 3

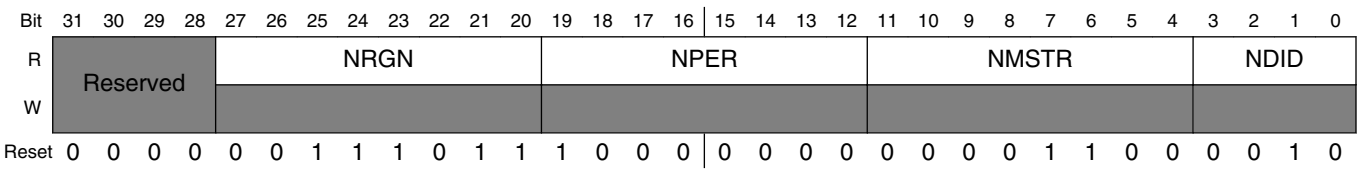
42.6.1 Version Information (RDC_VIR)

The VIR provides version information including the number of domains, number of master slots, number of peripheral slots, and number of memory regions.

Address: 40C7_8000h base + 0h offset = 40C7_8000h

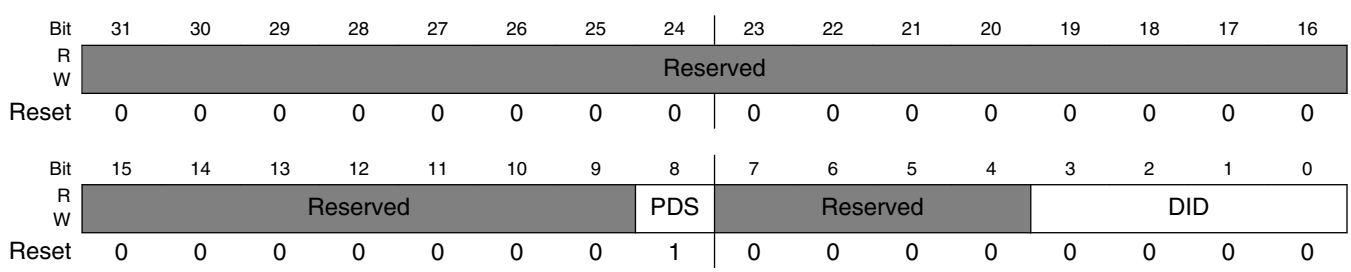


RDC_VIR field descriptions

Field	Description
31–28 Reserved	This field is reserved.
27–20 NRGN	Number of Memory Regions Indicates the number of memory regions in this instance of the RDC.
19–12 NPER	Number of Peripherals Indicates the number of peripherals that can be isolated or safe-shared.
11–4 NMSTR	Number of Masters Indicates the number of masters supported by this instance of RDC.
NDID	Number of Domains Indicates the number of domain IDs supported by this instance of the RDC. For example, value '0010' means the actual number of domains is 2.

42.6.2 Status (RDC_STAT)

Address: 40C7_8000h base + 24h offset = 40C7_8024h

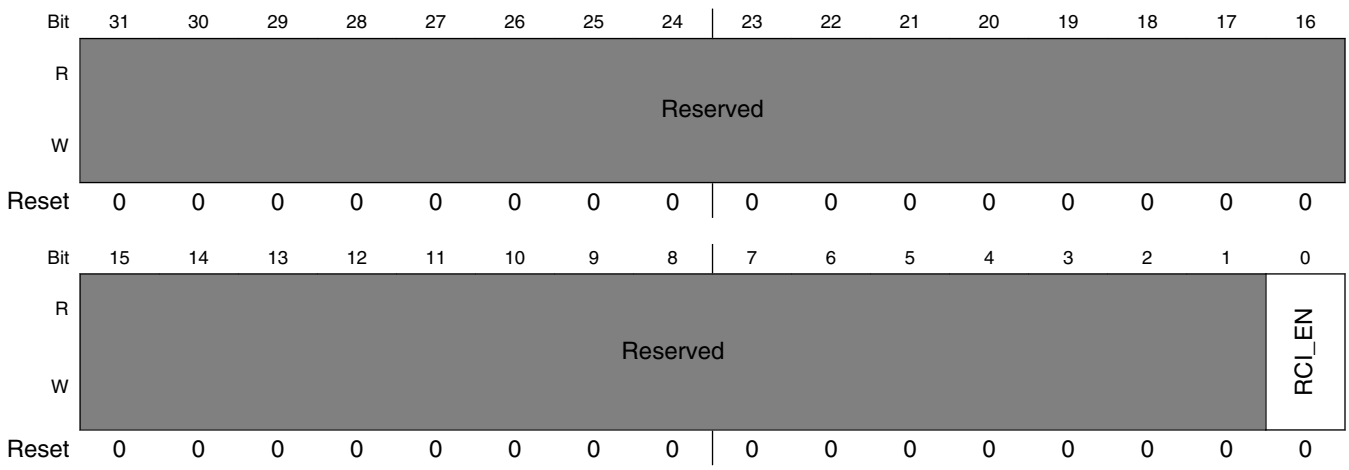


RDC_STAT field descriptions

Field	Description
31–9 Reserved	This field is reserved.
8 PDS	Power Domain Status Indicates if the "Power Down" memory regions are powered and available. Power Down memory regions are only those memory regions susceptible to power outage for power savings are unavailable if this is zero. "Always-On" memory regions remain available. Always On memory regions are those regions that are not powered down unless the entire SoC is powered down. This signal remains low until all access controls have been restored to the domain. 0 Power Down Domain is OFF 1 Power Down Domain is ON
7–4 Reserved	This field is reserved.
DID	Domain ID The Domain ID of the core or bus master that is reading this. The value is different for requests from different domains.

42.6.3 Interrupt and Control (RDC_INTCTRL)

Address: 40C7_8000h base + 28h offset = 40C7_8028h



RDC_INTCTRL field descriptions

Field	Description
31–1 Reserved	This field is reserved.
0 RCI_EN	Restoration Complete Interrupt Interrupt generated when the RDC has completed restoring state to a recently re-powered memory regions.

Table continues on the next page...

RDC_INTCTRL field descriptions (continued)

Field	Description
	0 Interrupt Disabled 1 Interrupt Enabled

42.6.4 Interrupt Status (RDC_INTSTAT)

Indication of Interrupt Pending for State Restoration

Address: 40C7_8000h base + 2Ch offset = 40C7_802Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

RDC_MREA*n* field descriptions

Field	Description
31–7 EADR	Upper bound for memory region Upper bound (exclusive) modulo the defined granularity byte size of a region. The region size (granularity) is defined for each Memory/Port in the Memory Region Map section. Region boundaries are aligned to the minimum possible region size for the Memory/Port.
Reserved	This field is reserved.

42.6.9 Memory Region Control (RDC_MRC*n*)

Address: 40C7_8000h base + 808h offset + (16d × i), where i=0d to 58d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

RDC_MRC*n* field descriptions

Field	Description
31 LCK	Region Lock Locks all region fields from further modification except ENA, which can be set but not reset after LCK is set. LCK is a sticky bit. 0 No Lock. All fields in this register may be modified. 1 Locked. No fields in this register may be modified except ENA, which may be set but not cleared.
30 ENA	Region Enable Activates the memory region. If the region is not activated then the permissions and address boundaries have not affect and the region will be fully accessible.

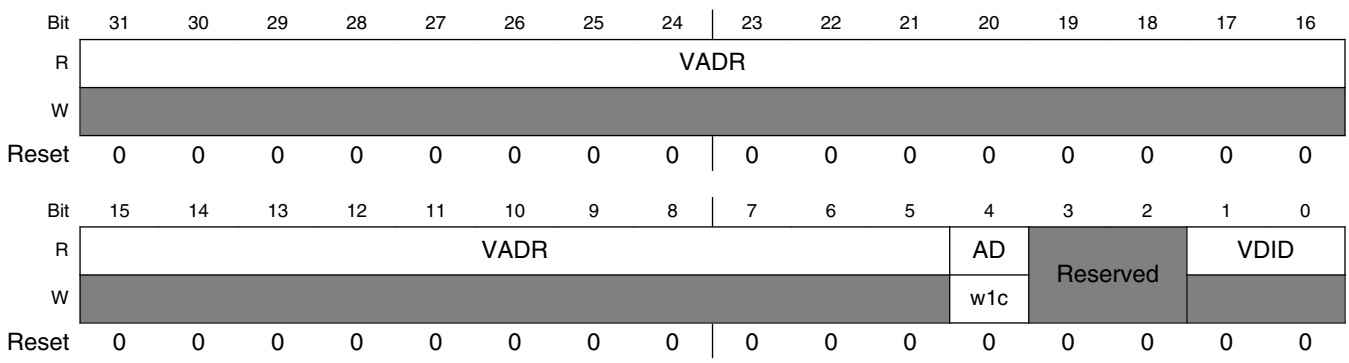
Table continues on the next page...

RDC_MRC*n* field descriptions (continued)

Field	Description
	0 Memory region is not defined or restricted. 1 Memory boundaries, domain permissions and controls are in effect.
29–8 Reserved	This field is reserved.
7–4 Reserved	This field is reserved.
3 D1R	Domain 1 Read Access to Region 0 Processing Domain 1 does not have Read access to the memory region 1 Processing Domain 1 has Read access to the memory region
2 D1W	Domain 1 Write Access to Region 0 Processing Domain 1 does not have Write access to the memory region 1 Processing Domain 1 has Write access to the memory region
1 D0R	Domain 0 Read Access to Region 0 Processing Domain 0 does not have Read access to the memory region 1 Processing Domain 0 has Read access to the memory region
0 D0W	Domain 0 Write Access to Region 0 Processing Domain 0 does not have Write access to the memory region 1 Processing Domain 0 has Write access to the memory region

42.6.10 Memory Region Violation Status (RDC_MRVS*n*)

Address: 40C7_8000h base + 80Ch offset + (16d × i), where i=0d to 58d



RDC_MRVS*n* field descriptions

Field	Description
31–5 VADR	Violating Address The address of the denied access. The first access violation is captured. Subsequent violations are ignored until the status register is cleared. Contents are cleared upon reading the register. Clearing of contents occurs only when the status is read by the memory region's associated domain ID (s).

Table continues on the next page...

RDC_MRVS*n* field descriptions (continued)

Field	Description
4 AD	Access Denied Access to a memory region denied. This bit is cleared when this bit is written by one of the allowed domains.
3–2 Reserved	This field is reserved.
VDID	Violating Domain ID The domain ID of the denied access. The first access violation is captured. Subsequent violations are ignored until the status register is cleared. Contents are cleared upon reading the register. 00 Processing Domain 0 01 Processing Domain 1 10 Reserved 11 Reserved

42.7 RDC SEMA42 Memory Map/Register Definition

Only Supervisor Mode accesses are allowed on these registers. User accesses generate an error termination.

42.7.1 Gate Register (RDC_SEMAPHORE*x*_GATE*n*)

Each semaphore gate is implemented in a 4-bit finite state machine, right-justified in a byte data structure. The hardware uses the logical bus master number (master_index) in conjunction with the data patterns to validate all attempted write operations. Only processor bus masters can modify the gate registers. Once locked, a gate can (and must) be opened (unlocked) by the locking processor core.

Multiple gate values can be read in a single access, but only a single gate can be updated via a write operation at a time. Attempted writes with a data value that is neither the unlock value nor the appropriate lock value (master_index + 1) are simply treated as "no operation" and do not affect any gate state. Attempts to write multiple gates in a single aligned access with a size larger than an 8-bit (byte) reference generate an error termination and do not allow any gate state changes.

Address: Base address + 0h offset + (1d × i), where i=0d to 63d

Field	Description
7–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–4 LDOM	Read-only bits. They indicate which domain had currently locked the gate. 00 The gate is locked by domain 0. (True if the field GTFSM does not equal to 0000.) 01 The gate has been locked by domain 1. 10 Reserved 11 Reserved
GTFSM	Gate Finite State Machine. The state of the gate reflects the last processor that locked it, which can be useful during system debug. The hardware gate is maintained in a 16-state implementation, defined as:

Table continues on the next page...

RDC_SEMAPHORE*x*_GATE*n* field descriptions (continued)

Field	Description
	0000 The gate is unlocked (free). 0001 The gate has been locked by processor with master_index = 0. 0010 The gate has been locked by processor with master_index = 1. 0011 The gate has been locked by processor with master_index = 2. 0100 The gate has been locked by processor with master_index = 3. 0101 The gate has been locked by processor with master_index = 4. 0110 The gate has been locked by processor with master_index = 5. 0111 The gate has been locked by processor with master_index = 6. 1000 The gate has been locked by processor with master_index = 7. 1001 The gate has been locked by processor with master_index = 8. 1010 The gate has been locked by processor with master_index = 9. 1011 The gate has been locked by processor with master_index = 10. 1100 The gate has been locked by processor with master_index = 11. 1101 The gate has been locked by processor with master_index = 12. 1110 The gate has been locked by processor with master_index = 13. 1111 The gate has been locked by processor with master_index = 14.

42.7.2 Reset Gate Write (RDC_SEMAPHORE*x*_RSTGT_W)

Although the intent of the hardware gate implementation specifies a protocol where the locking processor must unlock the gate, it is recognized that system operation may require a reset function to re-initialize the state of any gate(s) without requiring a system-level reset.

To support this special gate reset requirement, the RDC Semaphores module implements a "secure" reset mechanism that allows a hardware gate (or all the gates) to be initialized by following a specific dual-write access pattern. Using a technique similar to that required for the servicing of a software watchdog timer, the secure gate reset requires two consecutive writes with predefined data patterns from the same processor to force the clearing of the specified gate(s). The required access pattern is:

1. A processor performs a 16-bit write to the RDC_SEMA42RSTGT memory location. The least significant byte (RDC_SEMA42RSTGT[RSTGDP]) must be 0xE2; the most significant byte is a "don't_care" for this reference.
2. The same processor then performs a second 16-bit write to the RDC_SEMA42RSTGT location. For this write, the lower byte (RDC_SEMA42RSTGT[RSTGDP]) is the logical complement of the first data pattern (0x1D) and the upper byte (RDC_SEMA42RSTGT[RSTGTN]) specifies the gate(s) to be reset. This gate field can specify a single gate be cleared, or else that all gates are to be cleared. If the same processor writes incorrect data on the second access or another processor performs the second write access, the special gate reset sequence is aborted and no error signal will be asserted.

3. Reads of the RDC_SEMA42RSTGT location return information on the 2-bit state machine (RDC_SEMA42RSTGT[RSTGSM]) that implements this function, the bus master performing the reset (RDC_SEMA42RSTGT[RSTGMS]), and the gate number(s) last cleared (RDC_SEMA42RSTGT[RSTGTN]). Reads of the RDC_SEMA42RSTGT register do not affect the secure reset finite state machine in any manner.

Address: Base address + 42h offset

Read	RSTGTN								0							
Write									RSTGDP							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

RDC_SEMAPHOREx_RSTGT_W field descriptions

Field	Description
15–8 RSTGTN	Reset Gate Number. This 8-bit field specifies the specific hardware gate to be reset. This field is updated by the second write. This field contains the hexidecimal value of the gate number. If RSTGTN < 64, then reset the single gate defined by RSTGTN, else reset all the gates.
RSTGDP	Reset Gate Data Pattern. This write-only field is accessed with the specified data patterns on the two consecutive writes to enable the gate reset mechanism. For the first write, RSTGDP = 0xE2 while the second write requires RSTGDP = 0x1D.

42.7.3 Reset Gate Read (RDC_SEMAPHOREx_RSTGT_R)

Although the intent of the hardware gate implementation specifies a protocol where the locking processor must unlock the gate, it is recognized that system operation may require a reset function to re-initialize the state of any gate(s) without requiring a system-level reset.

To support this special gate reset requirement, the RDC Semaphores module implements a "secure" reset mechanism that allows a hardware gate (or all the gates) to be initialized by following a specific dual-write access pattern. Using a technique similar to that required for the servicing of a software watchdog timer, the secure gate reset requires two consecutive writes with predefined data patterns from the same processor to force the clearing of the specified gate(s). The required access pattern is:

1. A processor performs a 16-bit write to the RDC_SEMA42RSTGT memory location. The least significant byte (RDC_SEMA42RSTGT[RSTGDP]) must be 0xE2; the most significant byte is a "don't_care" for this reference.
2. The same processor then performs a second 16-bit write to the RDC_SEMA42RSTGT location. For this write, the lower byte (RDC_SEMA42RSTGT[RSTGDP]) is the logical complement of the first data

pattern (0x1D) and the upper byte (RDC_SEMA42RSTGT[RSTGTN]) specifies the gate(s) to be reset. This gate field can specify a single gate be cleared, or else that all gates are to be cleared. If the same processor writes incorrect data on the second access or another processor performs the second write access, the special gate reset sequence is aborted and no error signal will be asserted.

3. Reads of the RDC_SEMA42RSTGT location return information on the 2-bit state machine (RDC_SEMA42RSTGT[RSTGSM]) that implements this function, the bus master performing the reset (RDC_SEMA42RSTGT[RSTGMS]), and the gate number(s) last cleared (RDC_SEMA42RSTGT[RSTGTN]). Reads of the RDC_SEMA42RSTGT register do not affect the secure reset finite state machine in any manner.

Address: Base address + 42h offset

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	RSTGTN								0		RSTGSM		RSTGMS			
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

RDC_SEMAPHOREx_RSTGT_R field descriptions

Field	Description
15–8 RSTGTN	Reset Gate Number. This 8-bit field specifies the specific hardware gate to be reset. This field is updated by the second write. This field contains the hexidecimal value of the gate number. If RSTGTN < 64, then reset the single gate defined by RSTGTN, else reset all the gates.
7–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–4 RSTGSM	Reset Gate Finite State Machine. Reads of the RDC_SEMA42RSTGT register return the encoded state machine value. Note the RSTGSM = 10 state is valid for only a single machine cycle, so it is impossible for a read to return this value. The reset state machine is maintained in a 2-bit, 3-state implementation, defined as: 00 Idle, waiting for the first data pattern write. 01 Waiting for the second data pattern write. 10 The 2-write sequence has completed. Generate the specified gate reset(s). After the reset is performed, this machine returns to the idle (waiting for first data pattern write) state. The "01" state persists for only one clock cycle. Software will never be able to observe this state. 11 This state encoding is never used and therefore reserved.
RSTGMS	Reset Gate Bus Master. This 4-bit read-only field records the logical number of the bus master performing the gate reset function. The reset function requires that the two consecutive writes to this register must be initiated by the same bus master to succeed. This field is updated each time a write to this register occurs. The association between system bus master port numbers, the associated bus master device, and the logical processor number is SoC-specific. See the chip-specific information section before the Semaphores (SEMA4) chapter for more details.

Chapter 43
Extended Resource Domain Controller 2 (XRDC2)

43.1 Chip-specific XRDC2 information

Table 43-1. Reference links to related information

Topic	Related module(s)	Reference
System memory map	-	System Memory Map
Clocking	CCM	Clock Management Clock Control Module (CCM)
Power management	PMU	Power Management Power Management Unit
Signal multiplexing	IOMUX	External Signals and Pin Multiplexing IOMUX
Interrupts, DMA Events and XBAR Assignments	-	Interrupts, DMA Events and XBAR Assignments

The XRDC2 is used in RT1170 to support both single-core and multi-core use cases with max flexible resource management.

XRDC2 is used as second-level control (RDC is used as first-level control). Protect the access to resources within one CPU based on access type:

- Secure/non-secure access
- Privileged/user access

Each CPU has its own XRDC2, which has up to 16 domains.

Below is the diagram to show resource management concept in i.MX RT1170.

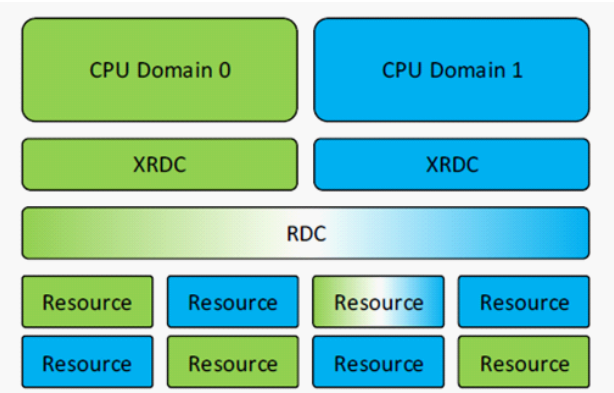

Figure 43-1. Resource Management Concept in i.MX RT1170

The following tables show the i.MX RT1170 XRDC2 configuration details.

Table 43-2. i.MX RT1170 XRDC2 MDAC Details

Table 43-2. i.MX RT1170 XRDC2 MDAC Details (continued)

MDAC	j	i in MGR for M7	i in MGR for M4	MATCH
Reserved	-	13	13	-
SSARC MDAC	N/A	14	14	No match input
USB MDAC	0~7	15	15	MATCH[11:0]= {AWXID[5:0],ARXID[5:0]}
USDHC1 MDAC	0~7	16	16	MATCH[11:0]= {AWXID[5:0],ARXID[5:0]}
USDHC2 MDAC	0~7	17	17	MATCH[11:0]= {AWXID[5:0],ARXID[5:0]}

ID information:

- XID: AHB bus version of the Extended ID format
- AWXID/ARXID: AXI bus version of the Extended ID format
- AWUSER/ ARUSER: AXI bus user bits
- AWICID/ARICID: AXI Write/Read Isolation Context Identifiers(ICID) from CAAM
- PID: Process id from M4 MCM. See the Arm Cortex M4 Platform chapter for more information
- CHANNEL_ID: channel id from EDMA, indicates DMA channel index
- HMASTER: Master id from EDMA, indicates the master id of master that programmed the DMA channel that is active

Table 43-3. Extended ID

Extended ID	Field Name	Description
[7:6]	RDC domain ID[1:0]	Transmit CID from input to output transparently
[5]	Instruction Fetch Flag	Indicates if the access is instruction fetch. In AHB bus version, it is equal to ~HPROT[0], In AXI bus version, it is equal to ARPORT[2]
[4]	Reserved	-
[3]	Access Region Match	Indicate if ADDR is in defined 8 regions. See APC IOMUXC GPR register descriptions for more information
[2:0]	Access Region ID[2:0]	Indicates ADDR is in which region. See APC chapter for more information

43.2 Overview

The Extended Resource Domain Controller 2 (XRDC2) provides an integrated, scalable architectural framework for access control, system memory protection and peripheral isolation. It allows software to assign chip resources including processor cores, non-core bus masters, memory regions and slave peripherals to processing domains to support enforcement of robust operational environments.

The XRDC2 is a second generation design that has the same core functions and shares many conventions with the original XRDC. However, the XRDC2 programming model is not compatible with original XRDC. For the sake of brevity, this document uses the generic XRDC2 to refer to the second generation design.

43.2.1 Block diagram

The XRDC2 implementation is distributed across multiple submodules instantiated throughout the device. The XRDC2 submodules include:

- Manager (MGR) coordinates all programming model reads and writes
- Master Domain Assignment Controller (MDAC) is responsible for the generation of the DID, nonsecure and privileged attributes for every system bus transaction in the device based on pre-programmed Master Domain Assignment (MDA) registers
- Memory Region Controller (MRC) implements the access controls for slave memories based on the pre-programmed Memory Region Descriptor (MRGD) registers
- Peripheral Access Controller (PAC) implements the access controls for slave peripherals based on the pre-programmed Peripheral Domain Access Control (PDAC) registers
- Memory Slot Controller (MSC) implements the access controls for a memory or peripheral based on the pre-programmed Memory Slot Access Control (MSAC) registers

See Figure 43-2 for a simplified XRDC2 block diagram focusing on topology and connections.

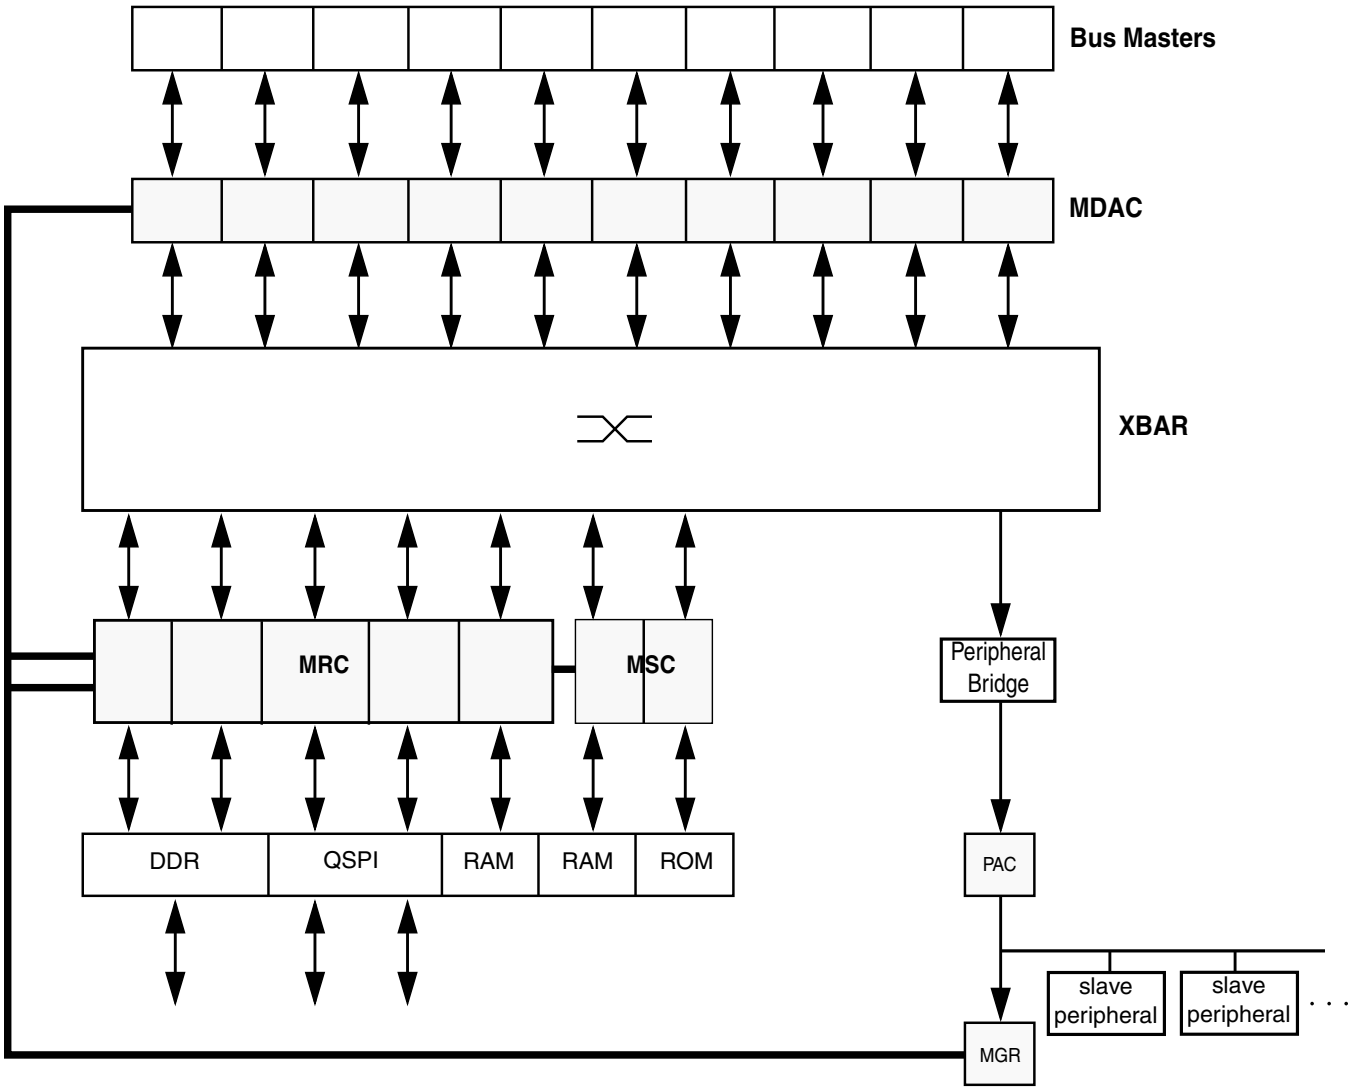

Figure 43-2. Simplified XRDC2 Block Diagram

43.2.2 Features

The key features of the XRDC2 include:

- Assignment of chip resources to processing “domains”
  - Each processing domain is assigned a unique domain identifier (DID)
  - DID is a new attribute associated with every system bus transaction
  - DID used in conjunction with user/privileged, secure/nonsecure attributes for access control
- Access rights to slave memory and peripheral targets defined by region or memory slot descriptors
- Supports sharing of a memory regions and peripherals with exclusive access locks to dynamically determine access rights

- Built upon a 4-level hierarchical access control model
  - SecurePriv(ileged) > SecureUser > NonsecurePriv(ileged) > NonsecureUser
  - Encoded into a 3-bit per-domain access control policy (ACP) used throughout the XRDC2
- Global and individual descriptor locking of configuration registers
- Programming model and hardware implementation is distributed across multiple submodules
  - Supports a broad, highly-configurable architecture definition
- Very configurable hardware design and implementation
  - Scalable across a wide spectrum of SoC devices

43.3 Functional description

The XRDC2 memory protection scheme has two components. First each bus mastering resource has an associated Master Domain Assignment Controller (MDAC) for assigning a domain identifier (DID) attribute to each bus transaction. Second each memory and peripheral has an associated access control submodule that enforces access control policies based on the DID and privilege level of the transaction. The XRDC2 access control submodules are the Memory Region Controller (MRC), Peripheral Access Controller (PAC) and Memory Slot Controller (MSC). All accesses throughout the device are monitored concurrently to determine the validity of each and every access. If a reference from a given domain has sufficient access rights, it is allowed to continue, else the access is denied and a bus error is generated.

The access control scheme defined by the XRDC2 supports a 4-level model, combining the traditional privileged (also known as supervisor) and user modes with an additional signal defining the secure, nonsecure attributes of each memory reference. The result is a 4-level hierarchical access control mechanism, where:

```
SecurePriv(ileged) > SecureUser > NonsecurePriv(ileged) > NonsecureUser
```

with different access control policies based on read and write references. Combined with the DID, the user/privileged and secure/nonsecure attributes are the basis for implementation of the XRDC2's access control mechanisms.

Access to shared memory regions and slave peripherals can be dynamically controlled with hardware exclusive access locks. This capability allows the access control policy for a given resource to be dynamically revised based on lock ownership.

43.3.1 Modes of Operation

The XRDC2 module does not support any special modes of operation. The XRDC2 responds based only on the memory addresses of the connected system buses. Domain assignment and access control functions are evaluated on a transfer-by-transfer basis using the addresses and attributes of each transfer. The implementation of the XRDC2 supports AMBA-AHB, AMBA-AXI, AMBA-APB and IPS bus protocols.

43.3.2 Manager (MGR)

The MGR submodule is responsible for coordinating XRDC2's programming model reads and writes.

The complete programming model is large, requiring a 64 Kbyte slave peripheral address space slot, although most devices define a sparsely populated subset. The MGR submodule implements the global registers. Other registers are distributed across the various submodule instances (MSC, PAC, MDAC, MRC). The MGR submodule provides the required hardware management for all programming model accesses, generating and distributing the appropriate address decodes and write data to the MSC, PAC, MDAC and MRC submodule instances, collecting and combining all the register read data buses and responses.

43.3.3 Master Domain Assignment Controller (MDAC)

The MDAC submodule is responsible for the generation of the DID, nonsecure and privileged attributes for every system bus transaction in the device. The MDAC compares its *match* input to the MATCH field for each enabled MDA descriptor for each bus transaction. If the MDAC *match* input is equal to the MATCH field for all bit positions which are a zero in the MASK field, the MDA generates a hit. The highest priority MDA with a hit takes precedence and its DID, PA, SA field values determine the DID, secure and privilege attributes for the bus transaction. See Master Domain Assignment (MDAC 0_MDA0_W0 - MDAC31_MDA31_W0) for details.

The MDAC is a configurable submodule, both in terms of hardware configurability options and software programmability. Internally, the MDACi_MDAj_Wk registers are implemented in this submodule. Each instance also supports a number of hardware parameters that are device-specific. These include parameters defining the number of

implemented domains, *match* input size, and the number of MDA descriptors. The MDAC can also optionally support multiple bus master ports with a single set of MDA descriptors.

43.3.4 DxACP Evaluation

Fundamental to the XRDC2's operation is the actual access violation check performed by the memory region (MRC), memory slot controller (MSC) and peripheral access (PAC) controllers.

Previous descriptions have detailed the domain assignment mechanisms and the tracking of the domain identifier as an address attribute through the system bus switching fabric(s). As transactions reach the slave memory and peripheral controllers, the address is used to select the appropriate memory region descriptor or access control descriptor. Once the appropriate descriptor has been selected, the next function is the actual access evaluation.

For this step, the DID of the current transaction selects the appropriate 3-bit DxACP (domain "x" access control policy) from the source register. The DxACP field defines the access rights for the domain based on the 4-level model combined with the transaction's access attributes (read = 0/write = 1, secure = 0/nonsecure = 1, user = 0/privileged = 1).

The 4-level model is defined by the concatenation of two address attributes: secure/nonsecure and user/privileged attributes. These two attribute signals (nonsecure, privileged) and the resulting access levels are defined as:

```
if {nonsecure, privileged} == 0b01, then level = SecurePriv(ileged)
if {nonsecure, privileged} == 0b00, then level = SecureUser
if {nonsecure, privileged} == 0b11, then level = NonsecurePriv(ileged)
if {nonsecure, privileged} == 0b10, then level = NonsecureUser
```

Recall the resulting hierarchical access control model specifies:

```
SecurePriv(ileged) > SecureUser > NonsecurePriv(ileged) > NonsecureUser
```

The XRDC2's evaluation of the access control policy is defined by the following Table 43-8 table.

Table 43-8. Domain x Access Control Policy Definition

	Allowable Accesses			
Policy	Secure Priv	Secure User	Nonsecure Priv	Nonsecure User
111	r, w	r, w	r, w	r, w
110	r, w	r, w	r, w	none
101	r, w	r, w	r	r
100	r, w	r, w	r	none
011	r, w	r, w	none	none
010	r, w	none	none	none
001	r	r	none	none
000	none	none	none	none

Unimplemented domains default to an all-zero DxACP field providing no access rights. After the DxACP evaluation is complete, the transaction is allowed to continue if it has sufficient access rights, else the access is denied and a bus error is generated. The XRDC2 also supports the inclusion of an exclusive access lock to dynamically alter the write permissions of a memory region or peripheral access. See Exclusive Access Lock for details.

43.3.5 Exclusive Access Lock

The exclusive access lock is a hardware mechanism to dynamically modify the DxACP permission evaluation such that only one domain has access to a peripheral or memory region at any given time. Once an exclusive access lock is enabled, it is enabled until the next reset and the lock must be acquired by a domain to enable its access permissions. Only one domain can own the lock at a time and only the lock owner's access permissions are enabled, read and write permissions for all other domains are revoked.

Owning an exclusive access lock only enables permissions granted by the DxACP field, it does not grant permissions. Only domains with some read or write permissions (non-zero DxACP value) can acquire or release a lock. A lock can be held indefinitely. Typically a lock is released after required accesses are completed to allow other domains to acquire the lock as needed. In normal operation, only the domain that owns the lock can release it. There is a safeguarded means for a domain which does not own a lock to force a lock release.

The exclusive access lock is enabled, acquired and released by writing to the 2-bit Exclusive Access Lock (EAL) descriptor field. Neither the global configuration lock nor the descriptor lock apply to this field. The EAL field can be written to independently of

the rest of the descriptor fields. Non-zero writes (01,10,11) to the EAL field do not affect other fields of the register. Likewise, a write of 00 does not affect the exclusive access lock and other fields of the register are updated. This convention eliminates the need to perform a read, modify, write operation to control the exclusive access lock. For devices without the exclusive access lock feature, the EAL field is a read only, reserved space and register writes are not affected by non-zero writes to the EAL field.

The EAL values are shown in the following table.

Table 43-9. Exclusive Access Lock (EAL)

EAL	Lock Enabled	Lock State	Access Permissions	Allowed Transitions
00	No	---	Per DxACP evaluation.	01 disable lock 10 enable lock
01	No	---	Per DxACP evaluation.	None
10	Yes	Available	Read and write permissions revoked for all domains.	11 acquire lock
11	Yes	Not Available	Per DxACP evaluation for the domain that owns the lock, read and write permissions revoked for all other domains.	10 release lock

If EAL=11, the owner of the lock is indicated by the 4-bit, read only EALO field. The EALO field is used in the lock acquisition procedure to determine when the lock acquisition is successful. Domains with a DxACP field value of 000 can not acquire or release the lock.

The EAL field has a reset value of 00 which disables the exclusive access lock. The lock is disabled until the next reset by writing 0x01000000 to the W1 register (PAC/MSC) or W6 register (MRC) which sets EAL=01. Alternatively, the exclusive access lock is enabled until the next reset and set to the available state by writing 0x02000000 to the W1 register (PAC/MSC) or W6 register (MRC) which sets EAL=10.

Once the exclusive access lock is enabled, domains must acquire the lock to enable their access permissions. Only one domain can own the lock at a time. The procedure for acquiring the lock is as follows:

1. Set EAL = 11 by writing 0x03000000 to the W1 register (PAC/MSC) or W6 register (MRC)
2. Read EALO
3. If EALO = DID then the lock is acquired, else delay and repeat steps 1-3.

The DID value can be determined by reading the Status Register (SR).

The exclusive access lock is released by writing 0x02000000 to the W1 register (PAC/MSC) or W6 register (MRC) which sets EAL=10. Only the domain that owns the lock (EALO=DID) may release the lock with the normal lock release write.

A lock can be forced to the available state (EAL=10) by a domain that does not own the lock through the forced lock release procedure. The procedure to force an exclusive access lock release is as follows:

1. Write 0x02000046 to W1 register (PAC/MSC) or W6 register (MRC)
2. Write 0x02000052 to W1 register (PAC/MSC) or W6 register (MRC)

Only the EAL field and the least significant byte of the forced release writes are significant and detected by hardware. The two writes must be consecutive, any intervening write to the register resets the sequence. No other register fields are affected by the forced release write. Once the lock is released, it can be acquired by any domain. As a convention, normal lock release writes should use 0x02000000 to clearly distinguish normal release writes from other configuration register writes and forced release writes.

43.3.6 Memory Region Controller (MRC)

The Memory Region Controller (MRC) provides domain-based, hardware access control for all system bus references targeted at non-peripheral memory spaces. Using pre-programmed Memory Region Descriptors (MRGDs) which define memory spaces and their associated access rights per domain identifier, the MRC concurrently monitors system bus transactions and evaluates the appropriateness of each transfer. Memory references that have sufficient access control rights are allowed to complete, while references that are not mapped to any defined memory region or have insufficient rights are terminated with a bus error.

The XRDC2 architectural framework supports up to 32 MRC instances, where each MRC instance can support up to 32 region descriptors and monitors one AHB or AXI slave port.

When MCR[GVLDC]=1, the MRC submodules evaluate memory access addresses versus the enabled MRGDs to determine which regions have a hit. To determine if the current reference hits in a given region, two magnitude comparators are used in conjunction with the region's start and end addresses. The equation for the hit determination is as follows:

```
region_hitj = (addr[35:12] >= srtaddrj) & (addr[35:12] <= endaddrj) & vldj
```

where addr[35:0] is the current system reference address, srtaddr and endaddr are the start and end address fields, and vld is the valid bit, all from the memory region descriptor j.

There are no hardware checks to verify that endaddr > srtaddr, software must ensure proper values are loaded into these fields of the region descriptor. Regions can be disabled via system power mode controls, see the appropriate section of the reference manual for details. The use of region addresses aligned to 4 kB boundaries matches the AXI bus specification which prohibits bus transactions from crossing a 4 kB boundary.

If a transfer hits one or more regions, it is evaluated with the highest priority MRGD with a hit. MRGDs have a fixed priority order starting with index j=0 as the lowest priority, index j=1 next highest, etc. Using the highest priority MRGD and the transfer attributes {DID, write, nonsecure, privileged} the transfer is evaluated as described in DxACP Evaluation. If the access has sufficient rights based on the DxACP evaluation and the exclusive access lock, it is allowed to continue, otherwise the access is denied and a bus error is generated. If a transfer does not hit any region, the access is denied and a bus error is generated.

43.3.7 Memory Slot Controller (MSC)

The Memory Slot Controller (MSC) performs access control for a peripheral or memory space with a fixed address range. For accesses within that address range the MSC uses the DID associated with the access to select the appropriate DxACP field in the MSAC descriptor. The selected DxACP field is then evaluated against the attributes associated with the memory transaction to determine the validity of the access. See DxACP Evaluation for more details. If the access has sufficient rights based on the DxACP evaluation and the exclusive access lock, it is allowed to continue, else the access is denied and a bus error is generated.

43.3.8 Peripheral Access Controller (PAC)

The Peripheral Access Controller (PAC) submodule performs access control for a set of peripherals connected to a peripheral bus bridge or integrated into a peripheral subsystem. The PAC selects the PDAC descriptor based on the peripheral slot accessed and then uses the DID associated with the access to select the appropriate DxACP field. The selected DxACP field is then evaluated against the attributes associated with the memory transaction to determine the validity of the access. See DxACP Evaluation for more details. If the access has sufficient rights based on the DxACP evaluation and the exclusive access lock, it is allowed to continue, else the access is denied and a bus error is generated. Unimplemented peripheral slots allow all accesses to continue without any protection controls.

43.4 External Signals

The XRDC2 module does not directly support any external interfaces.

The internal interfaces include a standard 32-bit slave bus for all programming model accesses, connections to the address phase signals associated with AHB and/or AXI system buses and connections to the slave peripheral buses as shown in the Figure 43-2.

43.5 Initialization

Out of reset, MCR[GVLDM] and MCR[GVLDC] are cleared and XRDC2 disabled allowing secure privileged startup code to configure the entire programming model. The initialization process typically is performed in 3 steps:

1. Program all of the domain assignment (MDACi_MDAj_Wk), memory region (MRCi_MRGDj_Wk), peripheral domain access control (PACi_PDACj_Wk) and memory slot access control (MSCi_Wk) descriptors. There are individual valid bits included in all these registers which typically would be asserted. Additionally, there are also lock mechanisms available if register settings need to be configured and marked as read-only.
2. Once the XRDC2 programming model is loaded, the MCR[GVLDM] bit is set.
3. After a delay to account for the maximum latency through the system bus fabric the MCR[GVLDC] bit is set and the XRDC2 is fully operational.

43.6 Application information

As described in the Overview, the XRDC2 architecture is intended to provide a broad, highly-capable framework for access control, system memory protection and peripheral isolation. The resulting microarchitecture implementation is distributed throughout the SoC, highly configurable via hardware design parameters and software programmability. The considerable number of hardware design parameters allows the XRDC2 architecture to be a very scalable solution, able to service a wide spectrum of SoC devices.

43.6.1 Master Domain Assignments

The typical use case related to master domain assignments is to include one (or more) processor core(s) in a single domain, possibly coupled with other bus master devices like DMA, etc. The definition of a domain may be static, based simply on the combination of a processor and other optional bus masters. Alternatively, the processor's operation may be configured to dynamically select between a very small number of domains. For example, "critical" tasks, whether safety-critical, performance-critical, etc. can be grouped together in one domain and all other tasks into a second domain. The various submodule descriptors all have lock features that allow the register resources to be converted into read-only resources to protect the written configuration.

43.6.2 Memory Region Descriptor Management

There are two important concepts to consider in managing the memory region descriptors.

First, recall that the association between each MRCi instance and the slave memory regions it monitors is SoC-dependent. The device-specific configuration specifies the number of implemented memory region descriptors in a given instance and the specific port numbers associated with the slave memories being monitored.

Second, as detailed in the section, Memory Region Controller (MRC), recall that, once the XRDC2 is enabled, *every memory reference must hit in one or more regions*, else a bus error is generated. MRGD0(lowest priority) can be programmed to cover the entire address space to provide a default set of access permissions.

43.7 Memory Map and register definition

The XRDC2 module supports a large number of architecturally-defined, program-visible registers distributed across a 64 Kbyte peripheral address slot. The actual registers present in any given device are application (and SoC) specific.

The programming model registers can be accessed via 8-, 16- or 32-bit reads and 32-bit write references. Attempted accesses using unsupported write data sizes, writes to read-only resources, or to reserved spaces are terminated with an error. The XRDC2 programming model is partitioned into 5 groups of registers:

- Global Registers
- Memory Slot Access Control (MSAC) Registers
- Master Domain Assignment (MDA) Registers
- Peripheral Domain Access Control (PDAC) Registers
- Memory Region Descriptor (MRGD) Registers

The MSAC, PDAC, MDA and MRGD registers are organized as 3-dimensional data structures with the following format {submodule instance}_{descriptor instance}_{word index} as shown in the following table, Table 43-10. There is only one MSAC descriptor instance for each MSC. The PDAC, MSAC, and MDA descriptors are 2 words in length. The MRGD descriptor is 8 words in length.

Table 43-10. XRDC2 Register Address Offsets

Submodule	Descriptor Registers	Address Offset
MSC	MSCi_MSAC_Wk	0x1000 + 8*i + 4*k
MDAC	MDACi_MDAj_Wk	0x2000 + 0x100*i + 8*j + 4*k
PAC	PACi_PDACj_Wk	0x4000 + 0x800*i + 8*j + 4*k
MRC	MRCi_MRGDj_Wk	0x8000 + 0x400*i + 32*j + 4*k

The architectural definition of the complete XRDC2 programming model is presented in the XRDC2 memory map table below. Each implementation is SoC-specific and highly dependent on the device requirements.

43.7.1 XRDC2 register descriptions

43.7.1.1 XRDC2 memory map

XRDC2_D0 base address: 40CE_0000h

XRDC2_D1 base address: 40CD_0000h

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)

8018 - FFF8	Memory Region Descriptor (MRC0_MRGD0_W6 - MRC31_MRGD31_W6)	32	RW	0000_0000

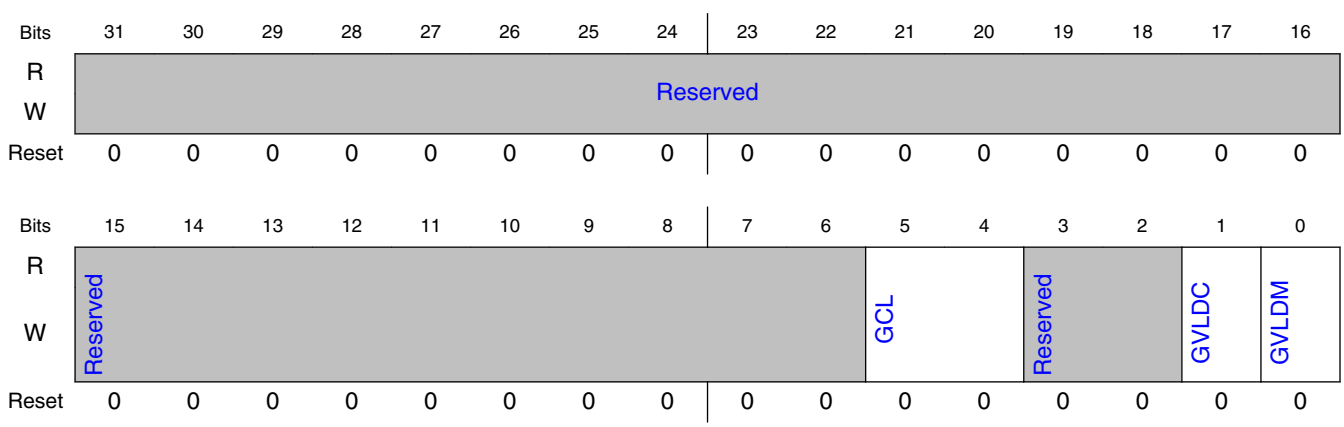
43.7.1.2 Module Control Register (MCR)

The MCR provides the global enables for the XRDC2.

43.7.1.2.1 Offset

Register	Offset
MCR	0h

43.7.1.2.2 Diagram



43.7.1.2.3 Fields

Field	Description
31-6 —	Reserved
5-4 GCL	Global Configuration Lock This 2-bit field provides a mechanism to limit write access to all registers. Once set to a non-zero value, this field can't be modified until the next reset. Exclusive access locks are not affected by the the global configuration lock. 00 - Lock disabled, registers can be written by any domain. 01 - Lock disabled until the next reset, registers can be written by any domain. 10 - Lock enabled, only the global configuration lock owner (SR[GCLO]) can write to registers. 11 - Lock enabled, all registers are read only until the next reset.
3-2 —	Reserved
1 GVLDC	Global Valid Access Control 0 - Access controls are disabled, XRDC2 allows all transactions. 1 - Access controls are enabled.
0 GVLDM	Global Valid MDAC 0 - DID set to 0 for all transactions. 1 - MDACs are enabled.

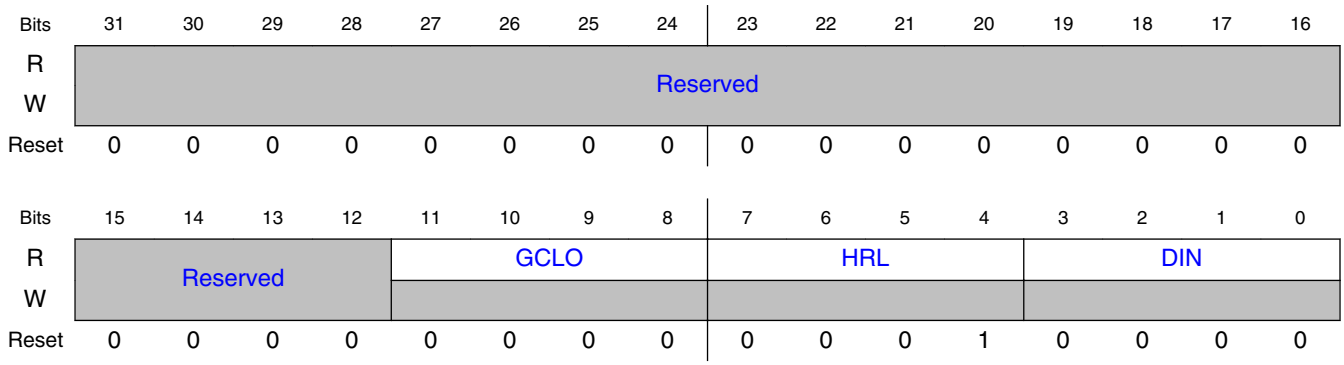
43.7.1.3 Status Register (SR)

The SR provides read-only status about the XRDC2.

43.7.1.3.1 Offset

Register	Offset
SR	4h

43.7.1.3.2 Diagram



43.7.1.3.3 Fields

Field	Description
31-12 —	Reserved
11-8 GCLO	Global Configuration Lock Owner This 4-bit read only field is set to the DID of the domain that set MCR[GCL]=10. When MCR[GCL]=10 this field indicates which domain owns the global configuration lock and is the only domain that can write to registers. GCLO values are defined as follows: • 0000: global configuration lock owner is domain 0 • 0001: global configuration lock owner is domian id 1 • ... • 1111: global configuration lock owenr is domain id 15
7-4 HRL	Hardware Revision Level This 4-bit read-only field specifies the XRDC2's hardware and definition revision level. It can be read by software to determine the functional definition of the module. It is hardwired to 1 as it represents the first XRDC2 implementation. HRL values are defined as follows: • 0000: version 0 • 0001: version 1 • .... • 1111: version 15
3-0 DIN	Domain Identifier Number This field provides the domain number [0-15] of the requesting bus master. DIN values are defined as follows: • 0000: domain id number is 0 • 0001: domain id number is 1 • ... • 1111: domain id number is 15

43.7.1.4 Memory Slot Access Control (MSC0_MSAC_W0 - MSC127_MSAC_W0)

The MSCi_MSAC_Wk registers hold the MSAC descriptors used by the MSC submodules to enforce access control policies for memories and peripherals. Each MSAC descriptor is formed by two 32-bit registers (MSCi_MSAC_W0/W1). Each MSC is assigned to one peripheral or memory and has one MSAC descriptor.

This device includes an exclusive access lock in the MSAC descriptor. The exclusive access lock provides a mechanism to dynamically modify the DxACP permission evaluation such that only one domain has access permissions at a time. The exclusive access lock is controlled by writing to the EAL field. The EAL field is written independently of the other W1 register fields. Writes with a non-zero EAL value do not update other fields of the W1 register. Writes with a 00 EAL value update other W1 register fields but do not affect the write access lock. See Exclusive Access Lock for details.

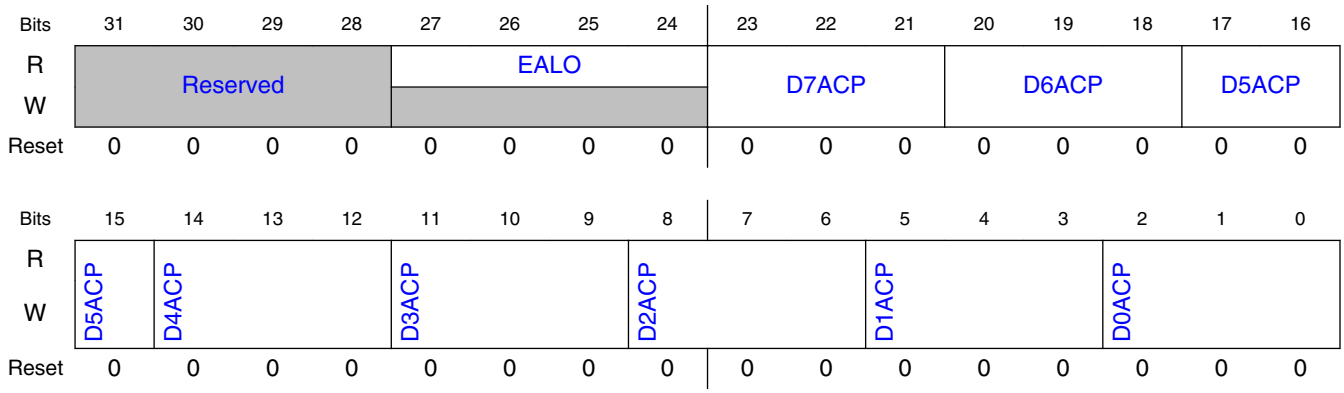
A MSC submodule is associated with one peripheral or memory with a fixed address range. For accesses within that address range the MSC uses the DID associated with the access to select the appropriate DxACP field. The selected DxACP field is then evaluated against the attributes associated with the memory transaction to determine the validity of the access. See DxACP Evaluation for more details. If the access has sufficient rights, it is allowed to continue, else the access is denied and a bus error is generated.

43.7.1.4.1 Offset

For i = 0 to 127:

Register	Offset
MSCi_MSAC_W0	1000h + (i × 8h)

43.7.1.4.2 Diagram



43.7.1.4.3 Fields

Field	Description
31-28 —	Reserved
27-24 EALO	Exclusive Access Lock Owner When EAL=11, this 4-bit read-only field indicates which domain owns the exclusive access lock. See Exclusive Access Lock for details on usage of the exclusive access lock.
23-21 D7ACP	Domain “x” access control policy This 3-bit field defines the access control rights for the selected domain. The encodings specify read and write access capabilities based on the 4 operating states. These fields are only implemented for supported DIDs; unsupported DIDs are not implemented and default to a zero value providing no access rights. Refer to Table 43-8
20-18 D6ACP	Domain “x” access control policy Refer to Table 43-8
17-15 D5ACP	Domain “x” access control policy Refer to Table 43-8
14-12 D4ACP	Domain “x” access control policy Refer to Table 43-8
11-9 D3ACP	Domain “x” access control policy Refer to Table 43-8
8-6 D2ACP	Domain “x” access control policy Refer to Table 43-8
5-3 D1ACP	Domain “x” access control policy Refer to Table 43-8
2-0 D0ACP	Domain “x” access control policy Refer to Table 43-8

43.7.1.5 Memory Slot Access Control (MSC0_MSAC_W1 - MSC127_MSAC_W1)

Refer to Memory Slot Access Control (MSC0_MSAC_W0 - MSC127_MSAC_W0) for description.

43.7.1.5.1 Offset

For i = 0 to 127:

Register	Offset
MSCi_MSAC_W1	1004h + (i × 8h)

43.7.1.5.3 Fields

Field	Description
31 VLD	Valid This field indicates the memory slot access control definition is valid. It is further qualified by MCR[GVLDC] = 1. If either MCR[GVLDC] or the VLD flag is cleared, all accesses to the memory or peripheral are allowed.. 0 - The MSAC assignment is invalid. 1 - The MSAC assignment is valid.
30-29 DL2	Descriptor Lock

Table continues on the next page...

Field	Description
	This 2-bit field provides a mechanism to limit writes to the MSAC descriptor to protect its contents. Once set to a non-zero value, this field can't be modified until the next reset. This lock is in addition to the global configuration lock, both locks must grant permissions to write to the MSAC descriptor. Neither lock applies to the EAL field. 00 - Lock disabled, descriptor registers can be written. 01 - Lock disabled until the next reset, descriptor registers can be written. 10 - Lock enabled, only domain "x" can only update the DxACP field; no other fields can be written. 11 - Lock enabled, descriptor registers are read-only until the next reset.
28-26 —	Reserved
25-24 EAL	Exclusive Access Lock This 2-bit field provides a mechanism to dynamically modify the DxACP permission evaluation such that only one domain has access permissions at a time. This field is written independently of the rest of the W1 register. Writes with a value of 00 do not affect the exclusive access lock and are used to update other fields of the W1 register. Writes with a non-zero value do not update other fields of the W1 register. Neither the global configuration lock nor the descriptor lock apply to this field. See Exclusive Access Lock for details on usage of the exclusive access lock. 00 - Lock disabled. 01 - Lock disabled until next reset. 10 - Lock enabled, lock state = available. 11 - Lock enabled, lock state = not available.
23-21 D15ACP	Domain "x" access control policy This 3-bit field defines the access control rights for the selected domain. The encodings specify read and write access capabilities based on the 4 operating states. These fields are only implemented for supported DIDs; unsupported DIDs are not implemented and default to a zero value providing no access rights. Refer to Table 43-8
20-18 D14ACP	Domain "x" access control policy Refer to Table 43-8
17-15 D13ACP	Domain "x" access control policy Refer to Table 43-8
14-12 D12ACP	Domain "x" access control policy Refer to Table 43-8
11-9 D11ACP	Domain "x" access control policy Refer to Table 43-8
8-6 D10ACP	Domain "x" access control policy Refer to Table 43-8
5-3 D9ACP	Domain "x" access control policy Refer to Table 43-8
2-0 D8ACP	Domain "x" access control policy Refer to Table 43-8

43.7.1.6 Master Domain Assignment (MDAC0_MDA0_W0 - MDAC31_MDA31_W0)

The MDACi_MDAj_Wk registers hold the MDA descriptors used by the MDAC submodules to assign the DID, secure and privilege attributes to bus transactions. Each MDA descriptor is formed by two 32-bit registers (MDACi_MDAj_W0/W1). Each bus master port is assigned to a MDAC submodule that can have up to 32 MDAs. The number of implemented MDAs varies per MDAC instance. See chip-specific XRDC information for details. An MDAC instance may support multiple master ports. The MDA descriptor includes the MATCH, MASK, VLD, DL, SA, PA, and DID fields as shown below in the register diagram.

When MCR[GVLDM]=1, setting the VLD bit enables comparison of the MDAC *match* input to the MATCH field for each bus transaction. If the MDAC *match* input is equal to the MATCH field for all bit positions which are a zero in the MASK field, the MDA generates a hit. The highest priority MDA with a hit takes precedence and its DID, SA, PA field values determine the DID, secure and privilege attributes for the bus transaction. MDAs have a fixed priority order starting with index j=0 as the lowest priority, index j=1 next highest, etc. If MCR[GVLDM]=0 or there are no MDA hits then the DID attributes are set to zero and the secure and privilege attributes from the master are assigned to the transaction.

The *match* input, MATCH and corresponding MASK fields vary in width from 0 to 16 bits by MDAC instance. Likewise the signals used for the *match* input vary by master. See chip-specific XRDC information for more details. A MDAC may have only one MDA descriptor with a MATCH width of 0 bits. In this case the programmed DID, SA and PA values are associated with every transaction and any access to the MDAC_MDA_W0 register will result in a bus error. The MASK field for MDA index j=0 can be set to all ones to create a default set of DID, SA, and PA values to be applied if there are no other MDA hits.

43.7.1.6.1 Offset

For i = 0 to 31; j = 0 to 31:

Register	Offset
MDACi_MDAj_W0	2000h + (i × 100h) + (j × 8h)

43.7.1.6.2 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	MASK															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

43.7.1.6.3 Fields

Field	Description
31-16 MATCH	Match The MATCH field specifies the reference value for the comparison with the MDAC *match* input. The MATCH field width varies by MDAC instance from 0 to 16 bits. Unimplemented bits are read as 0. A size of 0 bits generates a hit on all comparisons.
15-0 MASK	Mask The MASK field specifies which bits are valid for the MATCH comparison. Only bit positions in which the MASK value is zero are compared. The MASK field width is the same as the MATCH field which varies by MDAC instance from 0 to 16 bits. A MASK value of all ones generates a hit on all comparisons.

43.7.1.7 Master Domain Assignment (MDAC0_MDA0_W1 - MDAC31_MDA31_W1)

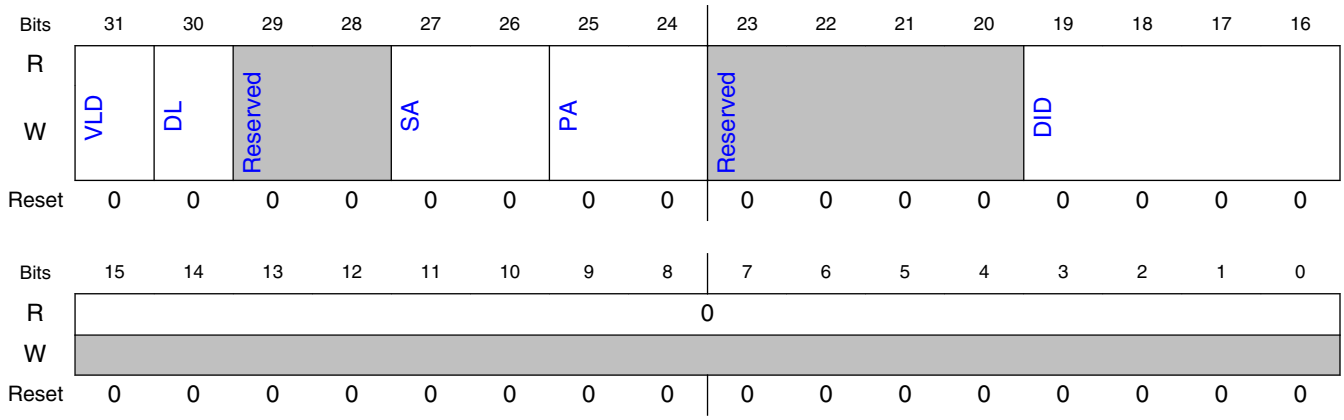
Refer to Master Domain Assignment (MDAC0_MDA0_W0 - MDAC31_MDA31_W0) for description.

43.7.1.7.1 Offset

For i = 0 to 31; j = 0 to 31:

Register	Offset
MDACi_MDAj_W1	2004h + (i × 100h) + (j × 8h)

43.7.1.7.2 Diagram



43.7.1.7.3 Fields

Field	Description
31 VLD	Valid This field indicates if the MDA descriptor is valid. When MCR[GVLDM]=1, setting the VLD bit enables comparison of the MDAC *match* input to the MATCH field for each bus transaction. A write to the W0 register clears the VLD bit so a coherent register state can be supported. 0 - The MDA is invalid. 1 - The MDA is valid.
30 DL	Descriptor Lock The DL bit provides a means to make the MDA descriptor registers read only. Once set, this bit remains asserted until the next reset. 0 - Lock disabled, registers can be written. 1 - Lock enabled, registers are read-only until the next reset.
29-28 —	Reserved
27-26 SA	Secure attribute This 2-bit field defines the secure/nonsecure attribute output on a hit. 00 - Use the bus master's secure/nonsecure attribute directly. 01 - Use the bus master's secure/nonsecure attribute directly. 10 - Force the bus attribute for this master to secure. 11 - Force the bus attribute for this master to nonsecure.
25-24 PA	Privileged attribute This 2-bit field defines the privileged/user attribute on a hit. 00 - Use the bus master's privileged/user attribute directly. 01 - Use the bus master's privileged/user attribute directly. 10 - Force the bus attribute for this master to user. 11 - Force the bus attribute for this master to privileged.

Table continues on the next page...

Field	Description
23-20 —	Reserved
19-16 DID	Domain Identifier This field defines the Domain Identifier (DID) attribute on a hit.
15-0 —	Reserved

43.7.1.8 Peripheral Domain Access Control (PAC0_PDAC0_W0 - PAC7_PDAC255_W0)

The PACi_PDACj_Wk registers hold the PDAC descriptors used by the PAC submodules to enforce access control policies for peripherals. Each PDAC descriptor is formed by two 32-bit registers (PACi_PDACj_W0/W1). Each peripheral bridge or peripheral subsystem is assigned to a PAC submodule that can have up to 256 PDAC descriptors, one per peripheral slot. In some PAC hardware configurations, certain slots may be mirror slots that use the PDAC descriptor of other slots. For example, slots 8 to 15 could be mirror slots that use the PDAC descriptors from slots 0 to 7, with slot 8 using PDAC0, slot 9 using PDAC1, etc. See chip-specific XRDC information for the PAC configurations used.

This device includes an exclusive access lock in the PDAC descriptor. The exclusive access lock provides a mechanism to dynamically modify the DxACP permission evaluation such that only one domain has access permissions at a time. The exclusive access lock is controlled by writing to the EAL field. The EAL field is written independently of the other W1 register fields. Writes with a non-zero EAL value do not update other fields of the W1 register. Writes with a 00 EAL value update other W1 register fields but do not affect the exclusive access lock. See Exclusive Access Lock for details on usage of the exclusive access lock.

The PAC submodule uses the peripheral access address to select the appropriate PDAC descriptor, and then uses the DID associated with the access to select the appropriate DxACP field. The selected DxACP field is then evaluated against the attributes associated with the memory transaction to determine the validity of the access. See DxACP Evaluation for more details. If the access has sufficient rights, it is allowed to continue, else the access is denied and a bus error is generated.

43.7.1.8.1 Offset

For i = 0 to 7; j = 0 to 255:

Register	Offset
PACi_PDACj_W0	4000h + (i × 800h) + (j × 8h)

43.7.1.10 Memory Region Descriptor (MRC0_MRGD0_W0 - MRC31_MRGD31_W0)

The MRCi_MRGDj_Wk registers hold the Memory Region Descriptors (MRGD) used by the MRC submodules to enforce access control policies for memories. Each MRGD is formed by a set of seven 32-bit registers (MRCi_MRGDj_W0-W6) which specify the start address, end address and access permissions for a region of memory. Each slave memory port is assigned to an MRC submodule that can have up to 32 memory regions and associated MRGDs. The number of implemented MRGDs varies per MRC instance, please see the appropriate section of the reference manual for details.

This device includes an exclusive access lock in the MRGD.The exclusive access lock provides a mechanism to dynamically modify the DxACP permission evaluation such that only one domain has access permissions at a time. The exclusive access lock is controlled by writing to the EAL field. The EAL field is written independently of the other W6 register fields. Writes with a non-zero EAL value do not update other fields of the W6 register. Writes with a 00 EAL value update other W6 register fields but do not affect the exclusive access lock. See Exclusive Access Lock for details on usage of the exclusive access lock.

When MCR[GVLDC]=1, the MRC submodules evaluate memory access addresses versus the enabled MRGDs to determine which regions have a hit. The MRC uses the domain identifier associated with the access to select the appropriate DxACP field from the highest priority MRGD that has a hit. MRGDs have a fixed priority order starting with index j=0 as the lowest priority, index j=1 next highest, etc. The selected DxACP field is evaluated against the attributes associated with the memory transaction to determine the validity of the access. See Memory Region Controller (MRC) for details. If the access has sufficient rights, it is allowed to continue, else the access is denied and a

bus error is generated. If an access has no region hits the access is denied and a bus error is generated. MRGD0 can be programmed to cover the entire memory space to provide default permissions if no other MRGDs hit.

Chapter 44
Display And Camera Overview

44.1 Overview

The following modules are a part of the Display and Camera system:

- CMOS Sensor Interface (CSI): Support for 8/16/24-bit data port for YCbCr, YUV, or RGB data input
- MIPI Serial Interface (MIPI CSI2): Camera interface that supports 80 Mbps to 1.5 Gbps data rate in high speed mode, and 10Mbps in low power mode
- Enhanced LCD Interface (eLCDIF): 8/16/18/24-bit RGB LCD interface
- LCD Interface v2 (LCDIFv2): Advanced LCD interface with multi-layer blending
- MIPI Display Serial Interface (MIPI DSI): Display interface that support MIPI DSI-compliant interfaces
- Video Multiplexer (VIDEO_MUX): Mux controls between supported display and camera interfaces
    - Digital Content Integrity Checker (DCIC): Verifies that display data is not corrupted (supports up to 24-bit pixel data)
- PXP pixel pipeline: 2D graphics and pixel/image processing
- Graphics Processing Unit (GPU2D): 2D Graphics engine that supports raster and vector graphics encompassing the majority of the embedded graphics use-case scenarios

The following figure shows the high-level integration scheme of the chip display and camera system.

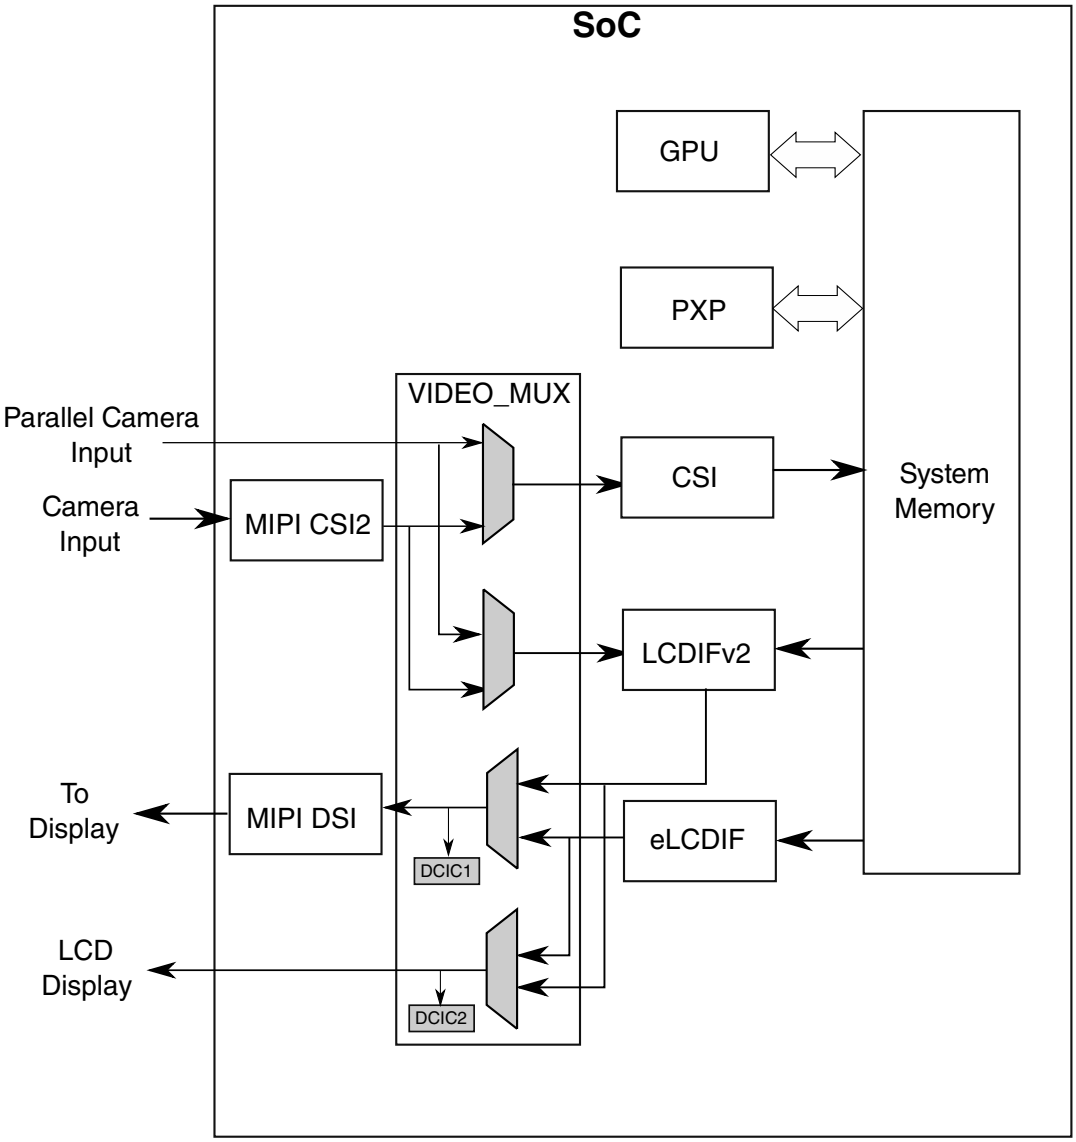

Figure 44-1. High-level Integration block diagram

NOTE

The camera input to the CSI module can be chosen from either Parallel Camera or MIPI CSI2. However, the display output can be fed to MIPI DSI and/or eLCDIF.

The LCDIFv2 acts as the primary LCD controller, while the eLCDIF acts as the secondary/backup controller.

The GPU2D is a vector engine and PXP acts as the blending accelerator.

44.1.1 CMOS Sensor Interface (CSI)

The CSI enables the chip to connect directly to external CMOS image sensors. CMOS image sensors are separated into two classes, dumb and smart. Dumb sensors are those that support only traditional sensor timing (Vertical SYNC, Horizontal SYNC), and output RGB, YUV, YCbCr, RAW formats, as well as Bayer and statistics data. The smart sensors support BT.656 video decoder formats and perform additional processing of the image (for example, image compression, image pre-filtering, and various data output formats).

44.1.2 MIPI Camera Serial Interface 2 (MIPI_CSI2)

The MIPI CSI2 is a camera interface that supports two data lanes, and one clock input between all data lanes. It provides support for virtual channels.

44.1.3 Enhanced LCD Interface (eLCDIF)

The eLCDIF is a general purpose display controller that is used to drive a wide range of display devices. These displays can vary in size and capability. There are other popular displays that support moving pictures and require the RGB interface mode (called DOTCLK interface in this document) for high-speed data transfers.

The block has several major features:

- Bus master interface to source frame buffer data for display refresh and a DMA interface to manage input data transfers from the LCD requiring minimal CPU overhead.
- 8/16/18/24 bit LCD data bus support available depending on I/O mux options.
- Programmable timing and parameters for DOTCLK LCD interfaces to support a wide variety of displays.

44.1.4 LCD Interface v2 (LCDIFv2)

The LCDIFv2 controller blends graphics from memory in real time, and output the data to a display interface.

It includes the following features:

- CRC check for configurable region on the final display output after alpha blending

- Eight layers of alpha blending
- Write-back channel to save the final output into memory

44.1.5 MIPI Display Serial Interface (MIPI_DSI)

MIPI DSI is a display interface that provides an interface to connect to MIPI DSI-compliant peripherals. It provides support for command and video modes, and virtual channels.

The MIPI DSI controller is associated with a MIPI D-PHY which complies with the MIPI D-PHY 1.1 standard. It supports two data lanes and one clock lane.

44.1.6 Video Multiplexer (VIDEO_MUX)

Video Multiplexer is a mux that lets the user choose between several camera and display interfaces. It also includes a Digital Content Integrity Checker (DCIC) to check for data corruption.

44.1.7 Pixel Processing Pipeline (PXP)

The pixel processing pipeline is used to perform image processing on image/video buffers before sending to an LCD display.

The main features of PXP include:

- Multiple input/output format support, including YUV/RGB/Grayscale
- Supports both RGB/YUV scaling
- Supports overlay with Alpha blending
- Supports Rotation of 0, 90, 180, and 270 degrees in conjunction with vertical and horizontal flip options

44.1.8 Graphics Processing Unit (GPU2D)

The 2D GPU comprises of several components like Tessellation engine, Vector Graphics Engine, Imaging Engine that perform various processing. It supports OpenVG 1.1 API Standard for VGA and VGLite Graphics API.

45.2 Overview

This chapter presents the CMOS Sensor Interface (CSI) architecture, operation principles, and programming model. The CSI enables the chip to connect directly to external CMOS image sensors.

CMOS image sensors are separated into two classes, dumb and smart. Dumb sensors are those that support only traditional sensor timing (Vertical SYNC and Horizontal SYNC) and output only RGB, YUV, and Bayer and statistics data, while smart sensors support ITU-R BT.656 video decoder formats and perform additional processing of the image (for example, image compression, image pre-filtering, and various data output formats). Statistics only work for Bayer data is 8-bit per pixel format.

45.2.1 Block Diagram

The block diagram of the CSI module is shown below:

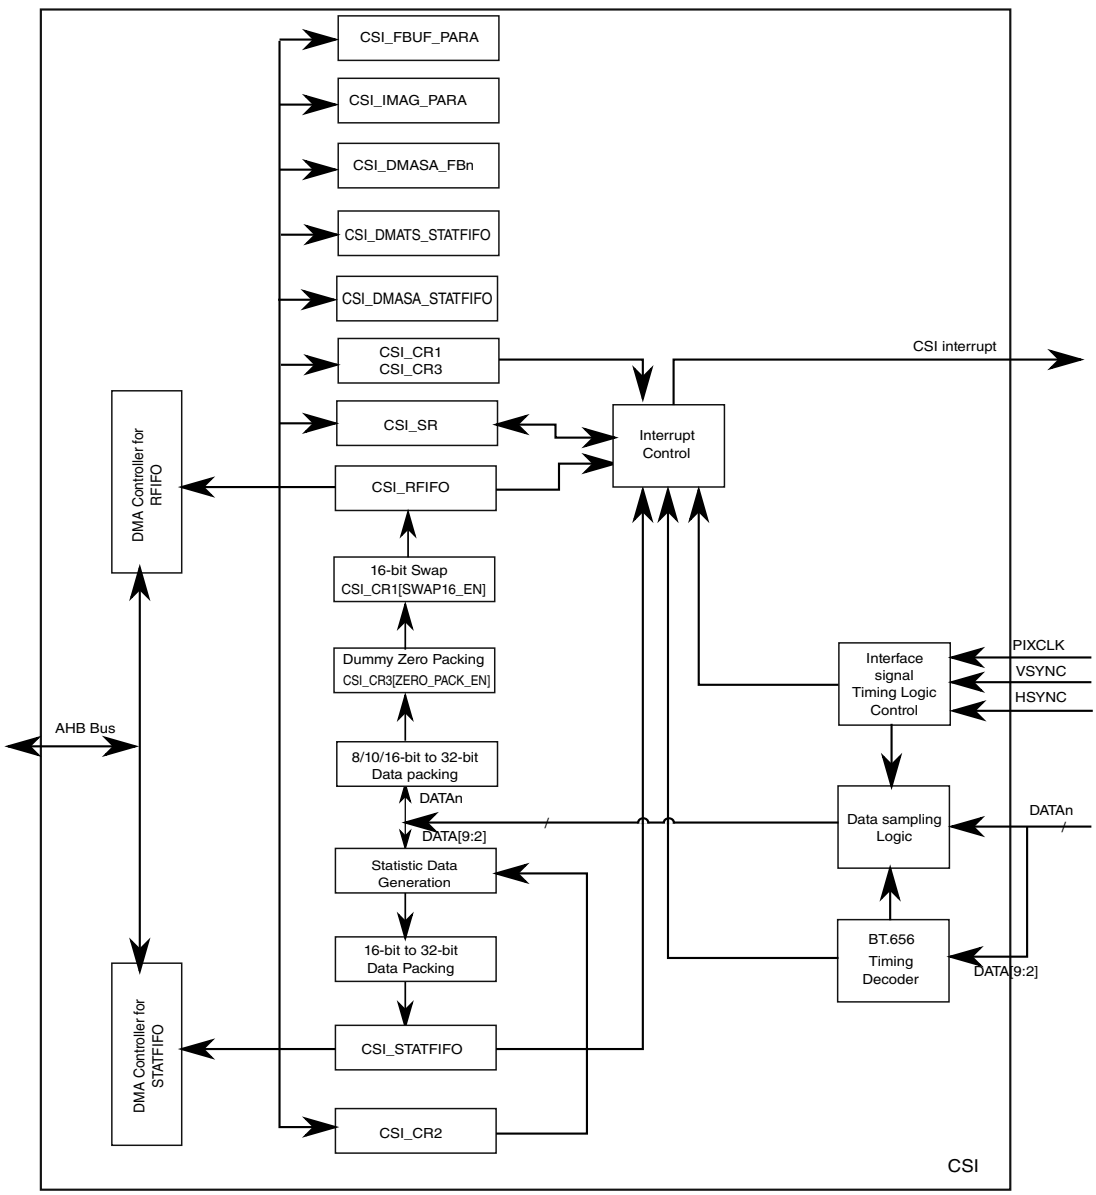

Figure 45-1. Block Diagram

45.2.2 Features

The features of the CSI include:

- Configurable interface logic to support most commonly available CMOS sensors.

- Support for ITU-R BT.656 video interface as well as traditional sensor interface.
- 8-bit / 16-bit / 24-bit data port for YCbCr, YUV, or RGB data input.
- 8-bit / 10-bit / 16-bit data port for Bayer data input.
- Full control of 8-bit/pixel, 10-bit/pixel or 16-bit / pixel data format to 64-bit receive FIFO packing.
- 256 x 64 FIFO to store received image pixel data.
- Statistic FIFO size of 64x32 bits
- Receive FIFO overrun protection mechanism.
- Embedded DMA controllers to transfer data from receive FIFO or statistic FIFO through AHB bus.
- Support 2D (data is chosen as x/y coordinate) DMA transfer from the receive FIFO to the frame buffers
- Support double buffering two frames in the external memory.
- Single interrupt source to interrupt controller from maskable interrupt sources: Start of Frame, End of Frame, Change of Field, FIFO full, FIFO overrun, DMA transfer done, BT.656 error and AHB bus response error.
- Configurable master clock frequency output to sensor.
- Support decoloring and binarization to accelerate image processing and recognition, and barcode/QR code decoding applications. It reduces memory space required and bus loading.

45.3 Functional Description

45.3.1 Principles of Operation

The information found here describes the modes of operation of the sensor interface.

The CSI is designed to support generic sensor interface timing as well as ITU-R BT.656 video interface timing. Traditional CMOS sensors typically use VSYNC (SOF), HSYNC (BLANK), and PIXCLK signals to output Bayer, RGB or YUV data. Smart CMOS sensors, that come with on-chip imaging processing, usually support video mode transfer. They use an embedded timing codec to replace the VSYNC and HSYNC signal. The timing codec is defined by the ITU-R BT.656 standard.

The CSI can support connection with the sensor as follows.

- To connect with one 8-bit sensor, the sensor data interface should connect to CSI_DATA[9:2].
- To connect with one 10-bit sensor, the sensor data interface should connect to CSI_DATA[9:0].

- To connect with one 12-bit sensor, the sensor data interface should connect to CSI_DATA[11:0].
- To connect with one 16-bit sensor, the sensor data interface should connect to CSI_DATA[15:0].
- To connect with one 24-bit sensor, connect the sensor data interface to CSI_DATA[23:0].

45.3.1.1 Data Transfer with the Embedded DMA Controllers

The CSI has two embedded DMA controllers, one for the receive FIFO and the other for the statistic FIFO. It supports 2D DMA transfer from the receive FIFO to the frame buffers in the external memory and linear DMA transfer from the statistic FIFO.

NOTE

One word = 4 bytes

Double words = 8 bytes

To transfer data from the RxFIFO to the external memory, the user should set the start address in the frame buffer where the transferred data is stored, the parameters of the frame buffers, and the parameters of the image coming from the sensor. The user can have two frame buffers in the external memory. Each one will store a frame of image coming from the sensor. The embedded DMA controller will first write the frame buffer1 and then frame buffer2. These two frame buffers will be written by turns. The start address should be aligned in double words and set in the CSI_DMASA-FB1 and CSI_DMASA-FB2 registers. In the CSI_FBUF_PARA register, the user should set the stride of the frame buffer to show how many double words to skip before starting to write the next row of the image. In the CSI_IMAG_PARA register, the user should set the width and height of the image coming from the sensor. The CSI_CR3[RxFF_LEVEL] and CSI_CR3[DMA_REQ_EN_RFF] bits also need to be set before the data transfer starts. When the number of the data in the RxFIFO reaches the trigger level, a DMA request will be sent to the embedded DMA controller and the data will be read out from the RxFIFO and written through AHB bus into the external frame buffers. The burst type of transfer can be INCR4, INCR8 and INCR16 by setting CSI_CR2[DMA_BURST_TYPE_RFF] bits. INCR4/INCR8/INCR16 are AHB protocols. After all data in an image frame are transferred, the CSI_SR[DMA_TSF_DONE_FB1] or CSI_SR[DMA_TSF_DONE_FB2] bit will be set and the interrupt can be triggered if the corresponding enable bit is set in CSI_CR1 register. The CSI_CR3[DMA_REFLASH_RFF] bit can be used to activate or restart the embedded DMA controller.

The RxFIFO has the overrun protection mechanism in case the RxFIFO is overrun during data transfer. If the RxFIFO is full and more data needs to be received during the data transfer, the RxFIFO will be overwritten continuously and all 128 words of data in the RxFIFO before overrun occurred will be discarded; the corresponding 128 words memory space in the frame buffer will keep the previous values. In other words, the DMA will skip the 128 word space fragment as if data is written.

To transfer data from the statistic FIFO to the external memory, the user should set the start address of the external memory where the transferred data is stored and the total transfer sizes. The start address and the transfer sizes are all aligned in double words and should be set in the CSIDMASA-STATFIFO and CSIDMATS-STATFIFO registers. The CSI_CR3[STATFF_LEVEL] and CSI_CR3[DMA_REQ_EN_SFF] bits should also be set before the data transfer starts. When the number of the data in the CSI_STATFIFO register reaches the trigger level, a dma request will be sent to the embedded DMA controller and the data will be read out from the STATFIFO and written through AHB

bus into the external memory. The burst type of transfer can be INCR4, INCR8 and INCR16 by setting CSI_CR2[DMA_BURST_TYPE_SFF] bit. After all expected data (defined by the total transfer sizes) are transferred, the CSI_SR[DMA_TSF_DONE_SFF] bit will be set and an interrupt can be triggered if the CSI_CR1[SFF_DMA_DONE_INTEN] is enabled. The CSI_CR3[DMA_REFLASH_SFF] bit can be used to activate or re-start the embedded DMA controller.

45.3.1.2 Gated Clock Mode

VSYNC, HSYNC, and PIXCLK signals are used in gated clock mode.

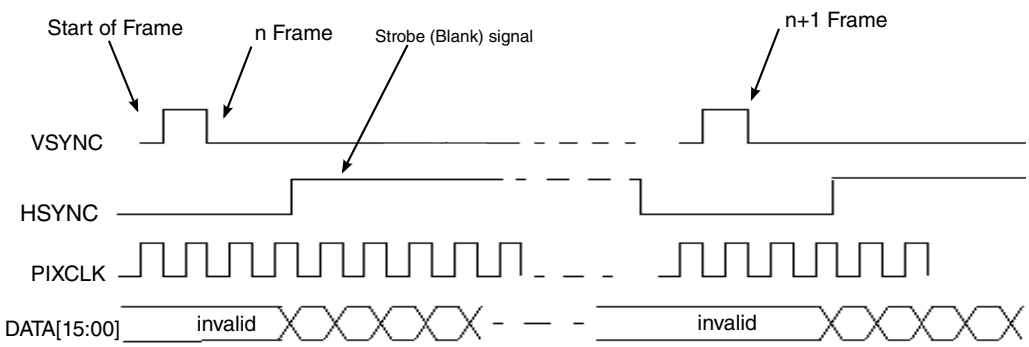

Figure 45-2. Gated Clock Mode Timing Diagram

NOTE

The CSI can be programmed to support rising/falling-edge triggered VSYNC through CSI_CR1[SOF_POL], active-high/low HSYNC using CSI_CR1[HSYNC_POL], and rising/falling-edge triggered PIXCLK through CSI_CR1[REDGE]. The configuration chosen by the user is referred to as an active edge.

A frame starts with an active edge on VSYNC, then HSYNC asserts and holds for the entire line. The Pixel clock is valid as long as HSYNC is asserted. Data is latched at the active edge of the valid pixel clocks. HSYNC deasserts at the end of line. Pixel clocks then become invalid and CSI stops receiving data from the stream. For the next line the HSYNC timing repeats. For the next frame the VSYNC timing repeats.

45.3.1.3 Non-Gated Clock Mode

In non-gated clock mode, only the VSYNC and PIXCLK signals are used; the HSYNC signal is ignored.

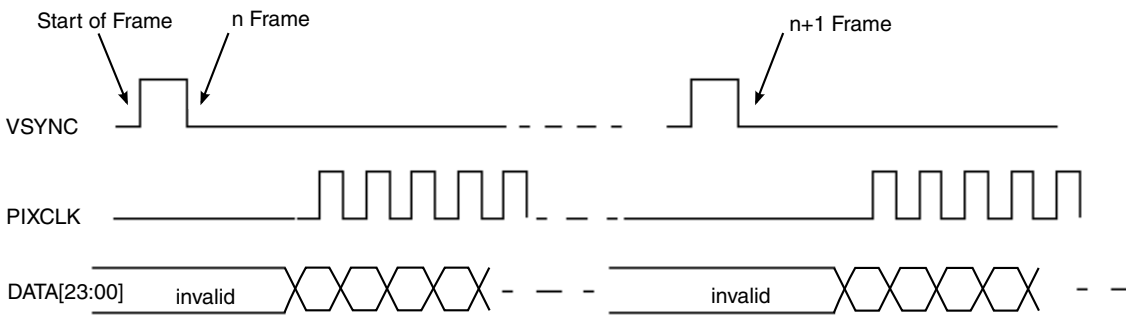

Figure 45-3. Non-Gated Clock Mode Timing Diagram

The overall timing of non-gated mode is the same as the gated-clock mode, except for the HSYNC signal. HSYNC signal is ignored by the CSI. All incoming pixel clocks are valid and cause data to be latched into RxFIFO. The PIXCLK signal is inactive (states low) until valid data is ready to be transmitted over the bus.

Figure 45-3 shows the timing of a typical sensor. Other sensors may have the slightly different timing from that shown. The CSI can be programed to support rising/falling-edge triggered VSYNC, active-high/low HSYNC, and rising/falling-edge triggered PIXCLK.

Below is the TV Decoder input mode timing diagram.

45.3.1.4 ITU-R BT.656 Interlace Mode

In interlace mode, an even field and an odd field are interlaced to create a frame. An even field consists of even-numbered lines (0,2,4,6, etc.), and an odd field consist of odd-numbered lines (1,3,5,7,etc.). Some vertical and horizontal blanking data is also added to the fields.

In BT.656 interlace mode, only the PIXCLK and CSI_DATA[9:2] signals are used. The start of frame and blank signals are replaced by a timing code which is embedded in the data stream. Each active line starts with an Start of Active Video (SAV) code and ends with an End of Active Video (EAV) code. In some cases, digital blanking is inserted in between EAV and SAV code. The CSI decodes and filters out the timing-coding from the data stream, recovering VSYNC and HSYNC signals for internal use, such as statistical

block control. Data is forwarded to the data receive and packing block in a sequential manner without reordering-that is, field 1 followed by field 2. The fields must be reordered in software to get back the original image.

Change of Field (COF) interrupt is triggered upon every field change. The interrupt service routine reads the status register to check for the current field.

According to the BT.656 specification, the image must be in 625/50 PAL or 525/60 NTSC format. Data must be in YCbCr422 format, each pixel contains 2 bytes, either Y + Cr or Y + Cb. These requirements are set for TV systems. The CSI module supports PAL and NTSC format only.

The following figure describes the frame structure in PAL system, showing vertical and horizontal blanking.

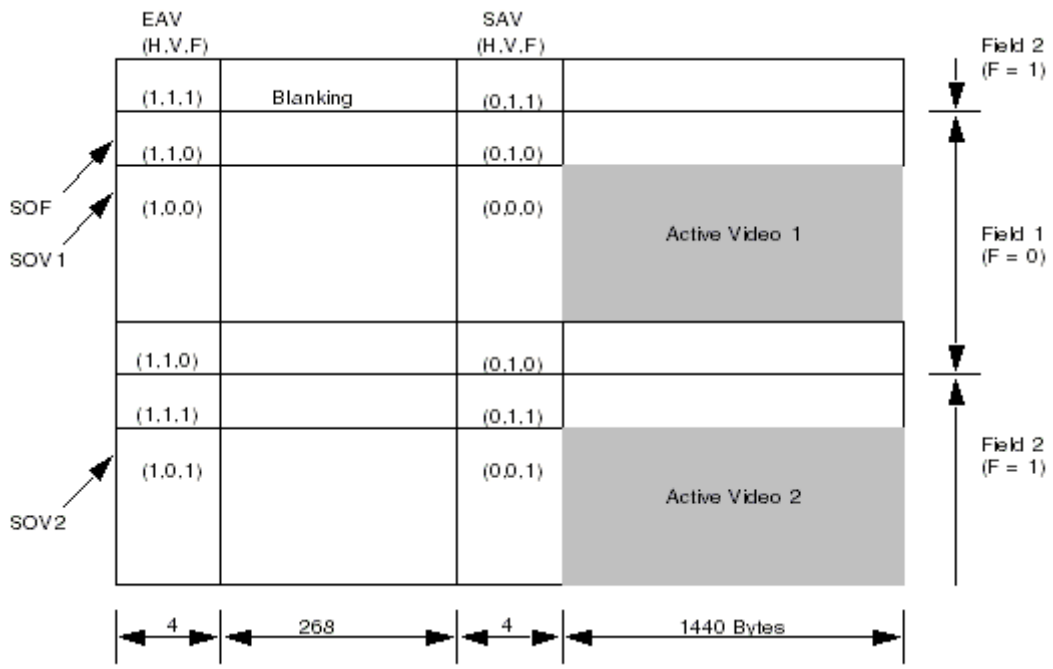

Figure 45-4. BT.656 Interlace Mode (PAL)

The following figure describes the general timing for a single line, showing SAV and EAV.

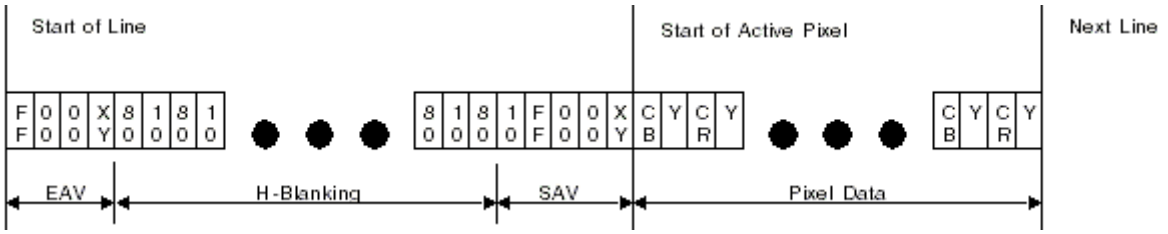

Figure 45-5. BT.656 General Line Timing

The coding tables recommended by the BT.656 specification are shown below. It is used in the BT.656 mode to decode the video stream. An interrupt is generated for SOF, which is decoded from the embedded timing codec.

Table 45-3. Coding for SAV and EAV

Data Bit Number	1st Byte 0xFF	2nd Byte 0x00	3rd Byte 0x00	4th Byte 0xXY
7 (MSB)	1	0	0	1
6	1	0	0	F
5	1	0	0	V
4	1	0	0	H
3	1	0	0	P3
2	1	0	0	P2
1	1	0	0	P1
0	1	0	0	P0

Table 45-4. Codes with Protection bits for Error Detection/Correction

F	V	H	P3	P2	P1	P0
0	0	0	0	0	0	0
0	0	1	1	1	0	1
0	1	0	1	0	1	1
0	1	1	0	1	1	0
1	0	0	0	1	1	1
1	0	1	1	0	1	0
1	1	0	1	1	0	0
1	1	1	0	0	0	1

Table 45-5. Representations by F-Bit

F-Bit	Representations
0	ODD FIELD (FIELD 1)
1	EVEN FIELD (FIELD 2)

45.3.1.5 ITU-R BT.656 Progressive Mode

For a CMOS camera system of VGA or CIF resolution, strict adherence to the interlace requirements stated in the BT.656 standard is not required.

The image is considered to have only 1 active field which is scanned in a progressive manner. This active field is regarded as field 1 and the F-bit in the timing codec is ignored by the decoder. Most sensors support BT.656 timing in this mode (progressive) by default.

The following figure shows the typical flow of progressive mode.

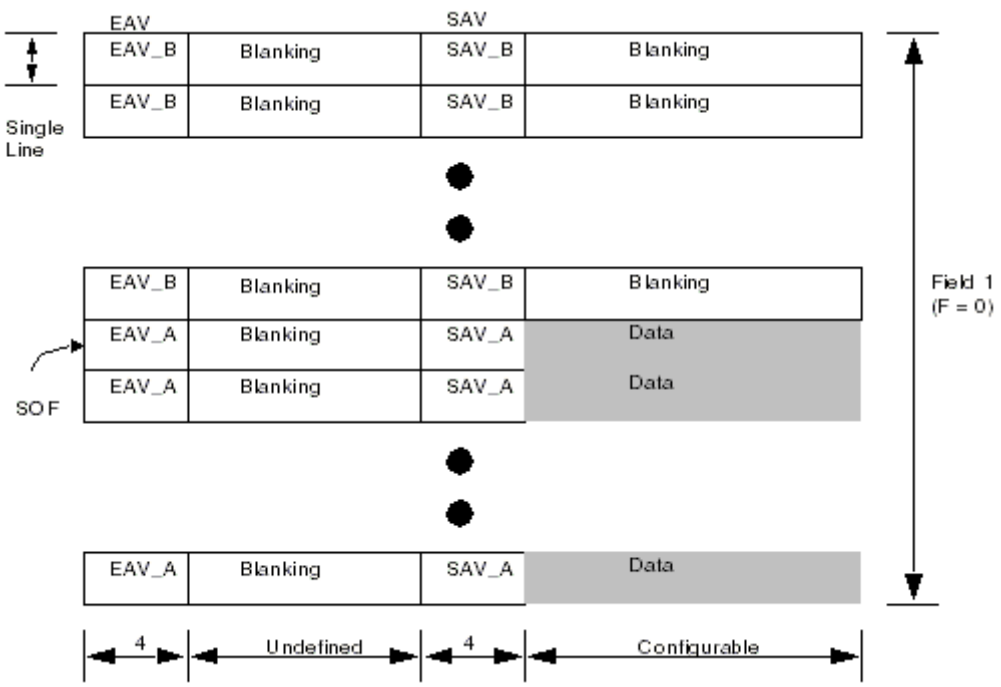

Figure 45-6. BT.656 Progressive Mode (General Case)

An interrupt is generated for SOF but not for COF. In the general case, when SOF information is retrieved from the embedded coding, it is known as internal VSYNC mode. In other cases, when the VSYNC signal is provided by the sensor, it is known as external VSYNC mode. The CSI can be operated in internal or external VSYNC mode.

45.3.1.6 Error Correction for ITU-R BT.656 Coding

According to the algorithm for BT.656 coding, protection bits in the SAV and EAV are encoded in the way that allows a 1-bit error to be corrected, or a 2-bit error to be detected by the decoder. This feature is supported by the interlace mode BT.656 decoder in CSI.

For the 1-bit error case, users can select the error to be corrected automatically, or simply shown as a status flag instead. For the 2-bit error case, because the decoder is unable to make a correction, the error would be shown as a status flag only.

An interrupt can be generated upon the detection of an error. This signal can be enabled or disabled without affecting the operation of the status bit.

45.3.1.7 Deinterlacer

Deinterlacing is the process of converting interlaced video, such as ITU-R BT.656 input or TV Decoder (VADC) input, into a non-interlaced form.

The CSI uses the weaving method to do deinterlacing. Weaving is done by adding consecutive fields together. CSI uses top-field detection function. No matter input is NTSC or PAL mode, the combined frame will always put the top-field first and then bottom-field.

45.3.2 Decoloring and Binarization

CSI involves the decoloring and binarization function and cooperates with SW to enormously accelerate the decoloring and binarization scanner speed and reduce the memory size.

45.3.2.1 Decoloring and Binarization Introduction

A barcode, including 1 dimensional (1-D) and 2 dimensional (2-D), can be read by an imaging device such as a camera and appropriately interpreted by process module.

Before detector and decoder, a decoloring and binarization scanner needs to convert the image to binary format. Previous chips usually use CPU to do such work (as shown in the figure below):

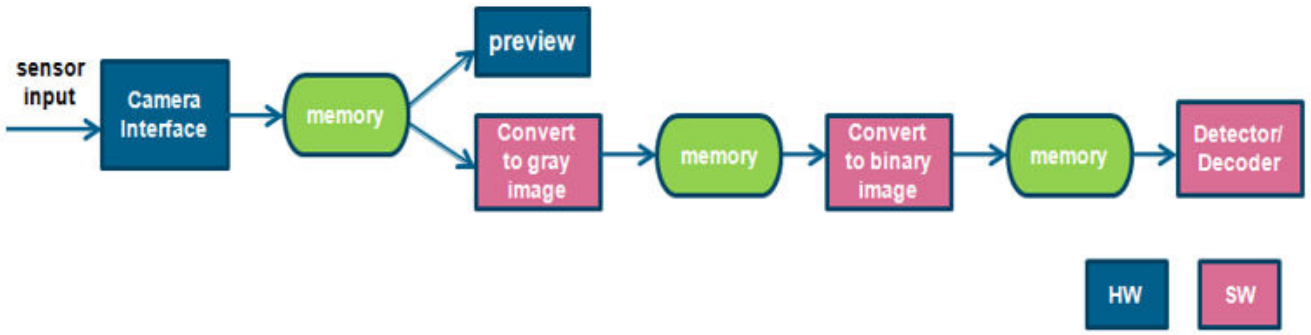

Figure 45-7. Previous Flow of Decoloring and Binarization Scanner

CSI is directly connected to external camera and synchronizes and processes the input image before storing to memory. After CSI, displayer will fetch the data from memory and display for customer review, meanwhile, CPU will fetch the data and convert the YUV data to binary data through two times memory read and write.

Using above architecture, previous barcode scanner flow not only consumes big memory size but also decrease the barcode scanner speed. Due to above disadvantage, upgraded CSI combines normal image preview and Decoloring and binarization together (as shown in the figure below).

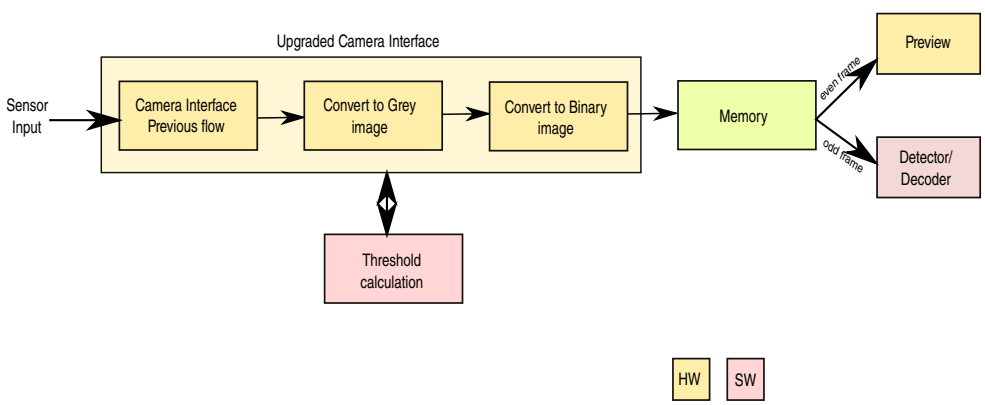

Figure 45-8. Updated Flow of Decoloring and Binarization Scanner

In a real-time camera sensor input, there is no much difference between two continuous frames, thus we can use the threshold calculated by SW based on the histogram of previous frame to do the binarization in current frame.

Upgraded flow combines the Decoloring and Binarization scanner binarization and preview to one flow. Even frame stores image to memory for preview while statistics the gray level histogram and sends to SW; odd frame uses the SW computed threshold based on previous gray level histogram and coverts the image to binary format before storing to memory for the scanner detector and decoder.

Using HW to take some binary work instead of SW can enormously accelerates the scanner speed and meanwhile reduces the memory size.

45.3.2.2 Upgraded CSI module

The upgraded architecture can help to achieve preview and binarization. The preview can be achieved using even frame and binarization using an odd frame. It takes maximum advantage of the normal SYNC, FIFO and DMA modules. By inserting the Binarization and Histogram modules between the sensor input and memory, the conversion of a YUV image to Binary is completed in a single pipeline.

The detailed diagram is shown below:

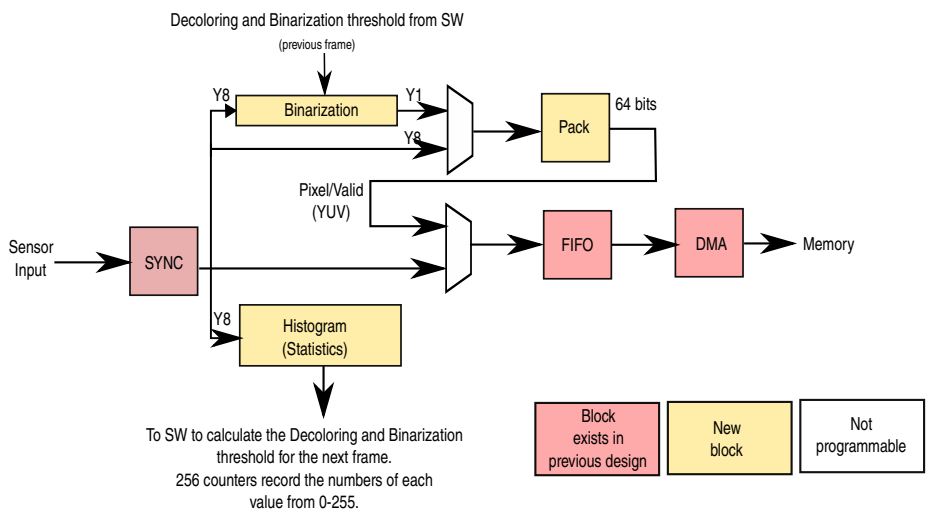

Figure 45-9. Upgraded CSI block diagram

The Binarization module utilizes a threshold based on grey level histogram to transform the image into black and white pixels. Y1 and Y8 data will be muxed together in the Pack module and packed to 32/64/128 bits per cycle as a system requires. Then it is muxed with normal image input. The output gets stored to the FIFO, read out by the DMA engine, and then stored in the external memory.

This upgraded method greatly reduces memory utilization.

The Even Frame data path is shown below:

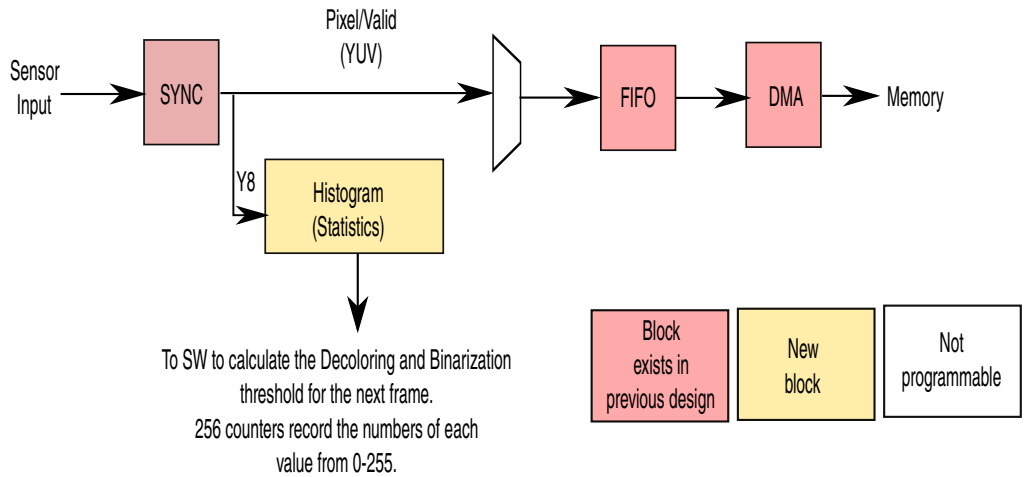

Figure 45-10. Even Frame Path

The Odd Frame data path is shown below:

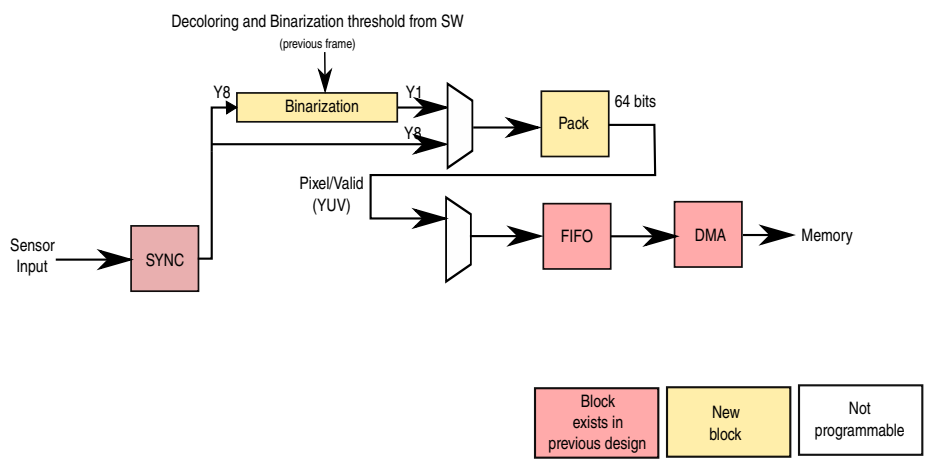

Figure 45-11. Odd Frame Path

Through above pipeline, an image, from YUV422 CMOS sensor, with 600KB size, will be transformed to 600K/16=37.5KB size. Only 1/16 memory needed using upgraded CSI IP compared to previous one. Besides, deleting two times read/write memory will

significantly accelerate the Decoloring and Binarization scanner speed. The color data is always saved to FB2, and gray scaled data always saved to FB1 in case of grey scale mode.

45.3.2.2.1 Decoloring and Binarization Histogram

Decoloring and Binarization uses a threshold to define the boundary between black and white pixels. The threshold is based on the image gray level histogram. Decoloring and Binarization histogram calculation consists of three steps as shown below:

- Extracting Y8 component from various data formats
- Counting each value (0~255) pixel numbers and storing to 256 counter registers
- Generating calculated done interrupt

When SW receives the calculated done interrupt, it reads out the 256 counter registers and chooses the suitable threshold by a certain algorithm based on the histogram and re-sends it to CSI module.

45.3.2.2.2 Binarization

Binarization transforms the Y8 data into 1-bit value (0 or 1) by comparing the value with the threshold configured by SW, and then sends output to the packing module.

Alternatively, the Y8 data can bypass the binarization module and stored directly to memory for backup function.

45.3.2.2.3 Limitation

Decoloring and Binarization scanner histogram starts at the start of a frame and stops as soon as the end of a frame is reached in order to leave maximum time period for SW involvement. It computes the threshold using this data. Due to camera video blanking limitation, it only works well in systems that satisfies hard real-time constraints, such as bare metal or real-time Operating Systems (OS).

45.3.3 Data Packing Style

Careful attention to endianess is needed given the different port sizes at different stages of the image capture path.

To enable flexible packing of image data before storage in the FIFOs, the CSI module can swap data fields by use of the CSI_CR1[PACK_DIR] and CSI_CR1[SWAP16_EN]).

The CSI module accepts 8-bit, 10-bit or 16-bit data from the sensor by configuring CSI_CR1[PIXEL_BIT] and CSI_CR3[SENSOR_16BITS]. The input data is packed according to the setting of CSI_CR1[PACK_DIR] bit. The packed data is stored in the RX FIFO according to the setting of the CSI_CR1[SWAP16_EN].

For 10-bit per pixel data format, each pixel is expanded to 16 bits by appending 6 zeros bits to the most significant bit.

When gray scale mode (CSI_CR20[QRCODE_EN]==1'b1) and Binary mode (CSI_CR20[BINARY_EN] == 1'b1) are enabled, data from sensor input will be converted from YUV to binary Y and packed to memory.

When gray scale mode (CSI_CR20[QRCODE_EN]==1'b1) and Y8 mode (CSI_CR20[BINARY_EN] == 1'b0) are enabled, data from sensor input will be converted from YUV to Y8 and packed to memory.

In binary mode, number of bits per pixel is 1. In Y8 mode, the number of bits per pixel is 8.

45.3.3.1 RX FIFO Path

45.3.3.1.1 Bayer Data

Bayer data is a type of raw data from the image sensor. This byte-wide data must be converted to the RGB space or YUV space by software. The data path for Bayer data is from the CSI to memory. If the system is in little endian, then the CSI_CR1[PACK_DIR] bit should be set to 0. 8-bit data format from a sensor is packed to 64 bits as P7.P6.P5.P4.P3.P2.P1.P0, where P0 is the pixel coming in time slot 0 (first data) and P3 is the pixel coming in time slot 3 . When the data is addressed as bytes by software, P0 is transferred first, P1 is transferred next, and so on. 10-bit data format is packed to 64 bits as 000000.P3.000000.P2.000000.P1.000000.P0, where P0 is the 10-bit data coming in time slot 0 (first pixel) and P3 is the 10-bit data coming in time slot 3 (fourth pixel). 16-bit data is packed to 64 bits as P3.P2.P1.P0, where P0-P3 are 16-bit data.

45.3.3.1.2 RGB565 Data

RGB565 data is processed data from the image sensor, which can be put directly into the display buffer. The data is 16 bits wide. The data path is from CSI to memory. It could be directed to the display controller from the memory. On the sensor side, data must be transmitted as P0 first, followed by P1, and so on. For each pixel, whether the MSB or LSB is sent first depends on the endianness of the sensor. Data is 16 bits wide with the MSB labeled RG, and the LSB labeled GB. P0 is represented as RG0 and GB0.

CSI receives data in one of the following sequence:

- RG0, GB0, RG1, GB1, while RG0 comes out at time slot 0 (first data), and GB1 comes out at time slot 3 (last data)
- GB0, RG0, GB1, RG1

Using the first sequence as an example, and assuming the system is running in little endian, the data is presented as:

- 8-bit data from sensor: RG0, GB0, RG1, GB1, …
- 64-bit data before storage in the CSI RX FIFO (PACK_DIR bit = 1): RG0GB0RG1GB1RG2GB2RG3GB3
- 64-bitdata in CSI RX FIFO (SWAP16_EN bit enabled): RG3GB3RG2GB2RG1GB1RG0GB0
- 64-bit transfer to system memory: RG3GB3RG2GB2RG1GB1RG0GB0
- 16-bit read by display controller: RG0GB0, RG1GB1

45.3.3.1.3 RGB888 Data

This is another kind of processed data from image sensor, which can be used for further image processing directly. Each of the data consist of 8-bit Red, 8-bit Green, and 8-bit Blue data. An example of timing scheme is shown in the following figure.

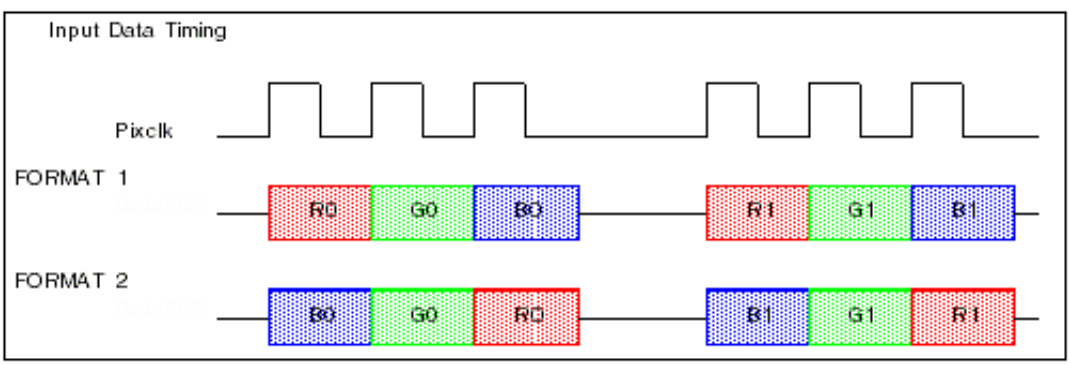

Figure 45-12. Sample Timing Diagram for RGB888 8 bits/cycle Data

An optional scheme to pack a dummy byte is provided. For every group of 3 bytes data, a dummy zero is packed to form a 32-bit word as shown in the following figure. The dummy zero can be packed at the LSB position or MSB position. Using RGB888A_FORMAT_SEL in CSI_CSICR18[18] to determine to put the dummy bytes packed at LSB or MSB position.

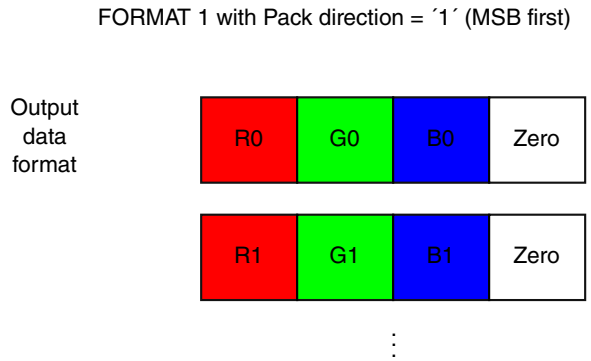

Figure 45-13. Dummy Byte Packing Scheme

45.3.3.1.4 Binary Data

This is one of processed data formats from the image sensor. For Y1 (Binary) mode (CSI_CR20[BINARY_EN] = 1), when grey scale mode is enabled, the data will be packed as {Y63,Y62,.....Y0} if CSI_CR20[BIG_EN]=1. Alternatively, if CSI_CR20[BIG_END]=0, the data will be packed as{Y0,Y1,... , Y63}. In this case, one pixel is 1 bit.

For Y8 mode (CSI_CR20[BINARY_EN]=0), when grey scale mode is enabled, the data will be packed as {Y7,Y6,.....Y0} if CSI_CR20[BIG_END] =1. Alternatively, if CSI_CR20[BIG_END]=0, the data will be packed as {Y0,Y1,... , Y7}. In this case, one pixel is 8 bits.

NOTE

The data is packed as 8 bits per byte.

45.3.3.2 STAT FIFO Path

Statistics only works for Bayer data in 8-bit per pixel format. It generates 16-bit statistical output from the 8-bit Bayer input (CSI_DATA[13:6]). The outputs are Sum of Green (G), Sum of Red (R), Sum of Blue (B), and Auto Focus (F). Each output is 16-bits wide.

The settings of CSI_CR1[PACK_DIR] and CSI_CR1[SWAP16_EN] bits have no effect on the input path. The CSI_CR1[PACK_DIR] only controls how the 16-bit stat output is packed into the 32-bit STAT FIFO.

When the CSI_CR1[PACK_DIR] = 1, the stat data is packed as:

First 32-bit: RG

Second 32-bit: BF

…

When the CSI_CR1[PACK_DIR] = 0, the stat data is packed as:

First 32-bit: GR

Second 32-bit: FB

...

The diagram shows how 16-bit data stat output is packed into 32-bit STATFIFO register:

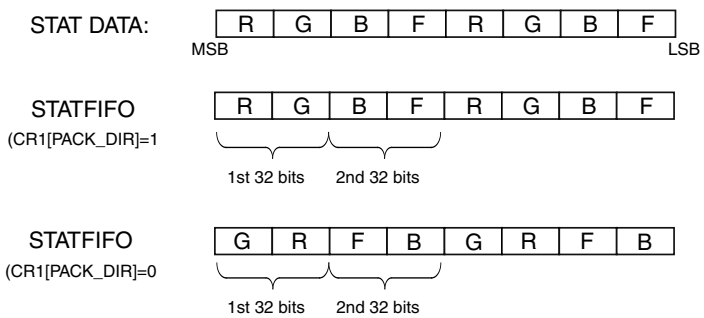

Figure 45-14. Data Packing

45.3.4 Clocks

The following table describes the clock sources for CSI. Please see Clock Controller Module (CCM) for clock setting, configuration and gating information.

Table 45-6. Clocks

Clock	Description
hclk	Module clock
ipg_clk	Peripheral clock
ipg_clk_s	Peripheral access clock
ipg_clk_s_raw	Peripheral raw data clock

45.3.5 Reset

CSI has one hardware reset. When set, it will reset all the logic and registers to their default values.

To re-enable CSI without using the hardware reset, follow the steps below:

1. Disable CSI by setting CSI_CR18[CSI_ENABLE]=0
2. Reflash the DMA controller for RFIFO by setting CSI_CR3[DMA_REFLASH_RFF]=1

3. Enable CSI by setting CSI_CR18[CSI_ENABLE]=1

45.3.6 Interrupt Generation

The information found here describes CSI events that generate interrupts.

45.3.6.1 Start Of Frame Interrupt (SOF_INT)

The source of an SOF interrupt is dependent on the mode of operation.

In traditional mode, VSYNC signal is taken from sensor and SOF_INT is generated at the rising or falling edge (programmable) of VSYNC.

In BT.656 interlace mode, the SOF interrupt information is retrieved from the embedded coding and SOF_INT is generated.

In BT.656 progressive mode, there are two sources of an SOF interrupt:

- In *internal* VSYNC mode, SOF is retrieved from the embedded coding.
- In *external* VSYNC mode, VSYNC is taken from the sensor and SOF is generated at the rising edge of VSYNC.

45.3.6.2 End Of Frame Interrupt (EOF_INT)

An EOF interrupt is generated when the frame ends and the complete frame data in RXFIFO is read.

The EOF event triggering works with the RX count register (CSIRXCNT). Software sets the RX count register to the frame size (in words). The CSI RX logic then counts the number of pixel data being received and compares it with the RX count. If the preset value is reached, an EOF interrupt is generated and the data in the RXFIFO are read. If a SOF event is detected before this happens, the EOF interrupt is not generated.

45.3.6.3 Change Of Field Interrupt (COF_INT)

The Change of Field interrupt is only valid in BT.656 Interlace mode. The COF interrupt is generated when the field toggles, either from field 1 to field 2, or field 2 to field 1.

Software should first check CSI_SR[COF_INT] bit before checking that F1_INT or F2_INT is turned on.

In PAL systems, the field changes at the beginning of the frame and coincides with SOF. For the first field, a COF interrupt is not generated, only an SOF. The COF interrupt is generated for the second field.

45.3.6.4 BT.656 Error Interrupt (ECC_INT)

The BT.656 Error Interrupt is only valid for BT.656 Interlace mode. An ECC interrupt is generated when an error is found on the SAV or EAV codes in the incoming stream. When this happens, the CSI_SR[ECC_INT] status bit is set.

45.3.6.5 RxFIFO Full Interrupt (RxFF_INT)

A RxFIFO full interrupt is generated when the number of data in RXFIFO reaches the water mark defined by RxFF_LEVEL in CSICR3.

45.3.6.6 Statistic FIFO Full Interrupt (STATFF_INT)

A StatFIFO full interrupt is generated when the number of data in STATFIFO reaches the water mark defined by STATFF_LEVEL in CSICR3.

45.3.6.7 RxFIFO Overrun Interrupt (RFF_OR_INT)

A RxFIFO Overrun interrupt is generated when the RxFIFO has 128 words data and more data is being written in.

45.3.6.8 Statistic FIFO Overrun Interrupt (SFF_OR_INT)

A StatFIFO Overrun interrupt is generated when the STATFIFO has 64 words data and more data is being written in.

45.3.6.9 Frame Buffer1 DMA Transfer Done Interrupt (DMA_TSF_DONE_FB1)

A DMA transfer done interrupt of frame buffer1 is generated when one frame of data are transferred from RxFIFO to the frame buffer1 in the external memory.

45.3.6.10 Frame Buffer2 DMA Transfer Done Interrupt (DMA_TSF_DONE_FB2)

A DMA transfer done interrupt of frame buffer2 is generated when one frame of data are transferred from RxFIFO to the frame buffer2 in the external memory.

45.3.6.11 Statistic FIFO DMA Transfer Done Interrupt (DMA_TSF_DONE_SFF)

A StatFIFO DMA transfer done interrupt is generated when all the data are transferred from StatFIFO to the external memory. The transfer size is defined in the STATFIFO DMA Transfer Size Register.

45.3.6.12 AHB Bus Response Error Interrupt (HRESP_ERR_INT)

An AHB Bus response error interrupt is generated when a bus error is detected.

This error can occur if an address is wrong. For more details, refer to AHB protocol.

45.3.6.13 Histogram Calculation Done Interrupt (HISTOGRAM_CALC_DONE)

A histogram calculation interrupt is generated when all the data are calculated by the histogram module. When this interrupt happens, driver can read the final statistic value for further process.

45.3.6.14 DMA Field 0 Transfer Done Interrupt (DMA_FIELD0_DONE)

A DMA transfer done interrupt of field 0 is generated when one field of data are transferred from RxFIFO to the frame buffer in external memory. This signal should work on interlaced mode.

45.3.6.15 DMA Field 1 Transfer Done Interrupt (DMA_FIELD1_DONE)

A DMA transfer done interrupt of field 1 is generated when one field of data are transferred from RxFIFO to the frame buffer in external memory. This signal should work on interlaced mode.

45.3.6.16 Base Address Change Error Interrupt (BASEADDR_CHANGE_ERROR)

A Base Address change error is generated when the base address changed while the last frame data transfer are not finished.

45.4 External Signals

The table below describes the external signals for the CSI. The external signals are tied between the CSI module and an external CMOS sensor.

Table 45-7. CSI External Signals

Signal	Description	Direction
DATAn	Data Sensor Signal, part of 16-bit Sensor Data Bus (Bayer, YUV, YCrCb, RGB)	I
FIELD	CSI Field Signal	I
HSYNC	Horizontal Sync (Blank Signal)	I
MCLK	CMOS Sensor Master Clock Note: MCLK is provided by the CCM module directly, not from the CSI module itself	O
PIXCLK	Pixel Clock	I
VSYNC	Vertical Sync (Start Of Frame)	I

NOTE

DATA[1:0] cannot be used for 8-bit bus.

45.5 Initialization

To initialize CSI, follow the steps below:

1. Enable the external sensor
2. Configure the CSI registers
3. Enable CSI by setting CSI_CR18[CSI_ENABLE]=1

The steps 1 and 2 can be interchanged.

45.6 CSI Memory Map/Register Definition

All the 32-bit registers of the CSI module are summarized in the Memory Map below:

CSI memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4080_0000	CSI Control Register 1 (CSI_CR1)	32	R/W	4000_0800h	45.6.1/2983
4080_0004	CSI Control Register 2 (CSI_CR2)	32	R/W	0000_0000h	45.6.2/2987
4080_0008	CSI Control Register 3 (CSI_CR3)	32	R/W	0000_0000h	45.6.3/2989
4080_000C	CSI Statistic FIFO Register (CSI_STATFIFO)	32	R	0000_0000h	45.6.4/2991
4080_0010	CSI RX FIFO Register (CSI_RFIFO)	32	R	0000_0000h	45.6.5/2992
4080_0014	CSI RX Count Register (CSI_RXCNT)	32	R/W	0000_9600h	45.6.6/2992
4080_0018	CSI Status Register (CSI_SR)	32	R/W	8000_4000h	45.6.7/2993
4080_0020	CSI DMA Start Address Register - for STATFIFO (CSI_DMASA_STATFIFO)	32	R/W	0000_0000h	45.6.8/2996
4080_0024	CSI DMA Transfer Size Register - for STATFIFO (CSI_DMATS_STATFIFO)	32	R/W	0000_0000h	45.6.9/2996
4080_0028	CSI DMA Start Address Register - for Frame Buffer1 (CSI_DMASA_FB1)	32	R/W	0000_0000h	45.6.10/ 2997
4080_002C	CSI DMA Transfer Size Register - for Frame Buffer2 (CSI_DMASA_FB2)	32	R/W	0000_0000h	45.6.11/ 2998
4080_0030	CSI Frame Buffer Parameter Register (CSI_FBUF_PARA)	32	R/W	0000_0000h	45.6.12/ 2998
4080_0034	CSI Image Parameter Register (CSI_IMAG_PARA)	32	R/W	0000_0000h	45.6.13/ 2999
4080_0048	CSI Control Register 18 (CSI_CR18)	32	R/W	0002_D000h	45.6.14/ 3000
4080_004C	CSI Control Register 19 (CSI_CR19)	32	R/W	0000_0000h	45.6.15/ 3003
4080_0050	CSI Control Register 20 (CSI_CR20)	32	R/W	0000_0000h	45.6.16/ 3004
4080_0054	CSI Control Register (CSI_CR21)	32	R/W	0000_0000h	45.6.17/ 3005
4080_0058	CSI Control Register (CSI_CR22)	32	R/W	0000_0000h	45.6.17/ 3005
4080_005C	CSI Control Register (CSI_CR23)	32	R/W	0000_0000h	45.6.17/ 3005
4080_0060	CSI Control Register (CSI_CR24)	32	R/W	0000_0000h	45.6.17/ 3005
4080_0064	CSI Control Register (CSI_CR25)	32	R/W	0000_0000h	45.6.17/ 3005
4080_0068	CSI Control Register (CSI_CR26)	32	R/W	0000_0000h	45.6.17/ 3005

Table continues on the next page...

CSI memory map (continued)

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page

45.6.1 CSI Control Register 1 (CSI_CR1)

This register controls the sensor interface timing and interrupt generation. The interrupt enable bits in this register control the interrupt signals and the status bits. That means status bits will only function when the corresponding interrupt bits are enabled.

Address: 4080_0000h base + 0h offset = 4080_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

CSI_CR1 field descriptions

Field	Description
31 SWAP16_EN	SWAP 16-Bit Enable. This bit enables the swapping of 16-bit data. Data is packed from 8-bit or 10-bit to 32-bit first (according to the setting of PACK_DIR) and then swapped as 16-bit words before being put into the RX FIFO. The action of the bit only affects the RX FIFO and has no affect on the STAT FIFO. **NOTE:** Example of swapping enabled: Data input to FIFO = 0x11223344 Data in RX FIFO = 0x 33441122 **NOTE:** Example of swapping disabled: Data input to FIFO = 0x11223344 Data in RX FIFO = 0x11223344

Table continues on the next page...

CSI_CR1 field descriptions (continued)

Field	Description
	0 Disable swapping 1 Enable swapping
30 EXT_VSYNC	External VSYNC Enable. This bit controls the operational VSYNC mode. **NOTE:** This only works when the CSI is in BT.656 progressive mode. 0 Internal VSYNC mode 1 External VSYNC mode
29 EOF_INT_EN	End-of-Frame Interrupt Enable. This bit enables and disables the EOF interrupt. 0 EOF interrupt is disabled. 1 EOF interrupt is generated when RX count value is reached.
28 Reserved	This field is reserved.
27 VIDEO_MODE	Video mode select. This bit controls the video mode in BT.656 mode and TV decoder input. 0 Progressive mode is selected 1 Interlace mode is selected
26 COF_INT_EN	Change Of Image Field (COF) Interrupt Enable. This bit enables the COF interrupt. This bit works only in BT.656 interlace mode which is when CCIR_EN = 1 and CCIR_MODE = 1. 0 COF interrupt is disabled 1 COF interrupt is enabled
25 SF_OR_INTEN	STAT FIFO Overrun Interrupt Enable. This bit enables the STATFIFO overrun interrupt. 0 STATFIFO overrun interrupt is disabled 1 STATFIFO overrun interrupt is enabled
24 RF_OR_INTEN	RxFIFO Overrun Interrupt Enable. This bit enables the RX FIFO overrun interrupt. 0 RxFIFO overrun interrupt is disabled 1 RxFIFO overrun interrupt is enabled
23 Reserved	This field is reserved. This bit should read 0.
22 SFF_DMA_ DONE_INTEN	STATFIFO DMA Transfer Done Interrupt Enable. This bit enables the interrupt of STATFIFO DMA transfer done. 0 STATFIFO DMA Transfer Done interrupt disable 1 STATFIFO DMA Transfer Done interrupt enable
21 STATFF_INTEN	STATFIFO Full Interrupt Enable. This bit enables the STAT FIFO interrupt. 0 STATFIFO full interrupt disable 1 STATFIFO full interrupt enable
20 FB2_DMA_ DONE_INTEN	Frame Buffer2 DMA Transfer Done Interrupt Enable. This bit enables the interrupt of Frame Buffer2 DMA transfer done. 0 Frame Buffer2 DMA Transfer Done interrupt disable 1 Frame Buffer2 DMA Transfer Done interrupt enable

Table continues on the next page...

CSI_CR1 field descriptions (continued)

Field	Description
19 FB1_DMA_ DONE_INTEN	Frame Buffer1 DMA Transfer Done Interrupt Enable. This bit enables the interrupt of Frame Buffer1 DMA transfer done. 0 Frame Buffer1 DMA Transfer Done interrupt disable 1 Frame Buffer1 DMA Transfer Done interrupt enable
18 RXFF_INTEN	RxFIFO Full Interrupt Enable. This bit enables the RxFIFO full interrupt. 0 RxFIFO full interrupt disable 1 RxFIFO full interrupt enable
17 SOF_POL	SOF Interrupt Polarity. This bit controls the condition that generates an SOF interrupt. 0 SOF interrupt is generated on SOF falling edge 1 SOF interrupt is generated on SOF rising edge
16 SOF_INTEN	Start Of Frame (SOF) Interrupt Enable. This bit enables the SOF interrupt. 0 SOF interrupt disable 1 SOF interrupt enable
15–13 Reserved	This field is reserved.
12 HISTOGRAM_ CALC_DONE_IE	Histogram Interrupt Enable 0 Histogram done interrupt disable 1 Histogram done interrupt enable
11 HSYNC_POL	HSYNC Polarity Select. This bit controls the polarity of HSYNC. This bit only works in gated-clock-that is, GCLK_MODE = 1 and CCIR_EN = 0. 0 HSYNC is active low 1 HSYNC is active high
10 CCIR_EN	BT.656 Interface Enable. This bit selects the type of interface used. 0 Traditional interface is selected. 1 BT.656 interface is selected.
9 Reserved	This field is reserved.
8 FCC	FIFO Clear Control. This bit determines how the RXFIFO and STATFIFO are cleared. When Synchronous FIFO clear is selected the RXFIFO and STATFIFO are cleared, and STAT block is reset, on every SOF. FIFOs and STAT block restarts immediately after reset. For information on the operation when Asynchronous FIFO clear is selected, refer to the descriptions for the CLR_RXFIFO and CLR_STATFIFO bits. 0 Asynchronous FIFO clear is selected. 1 Synchronous FIFO clear is selected.
7 PACK_DIR	Data Packing Direction. This bit Controls how 8-bit/10-bit image data is packed into 32-bit RX FIFO, and how 16-bit statistical data is packed into 32-bit STAT FIFO. 0 Pack from LSB first. For image data, 0x11, 0x22, 0x33, 0x44, it will appear as 0x44332211 in RX FIFO. For stat data, 0xAAAA, 0xBBBB, it will appear as 0xBBBBAAAA in STAT FIFO. 1 Pack from MSB first. For image data, 0x11, 0x22, 0x33, 0x44, it will appear as 0x11223344 in RX FIFO. For stat data, 0xAAAA, 0xBBBB, it will appear as 0xAAAABBBB in STAT FIFO.

Table continues on the next page...

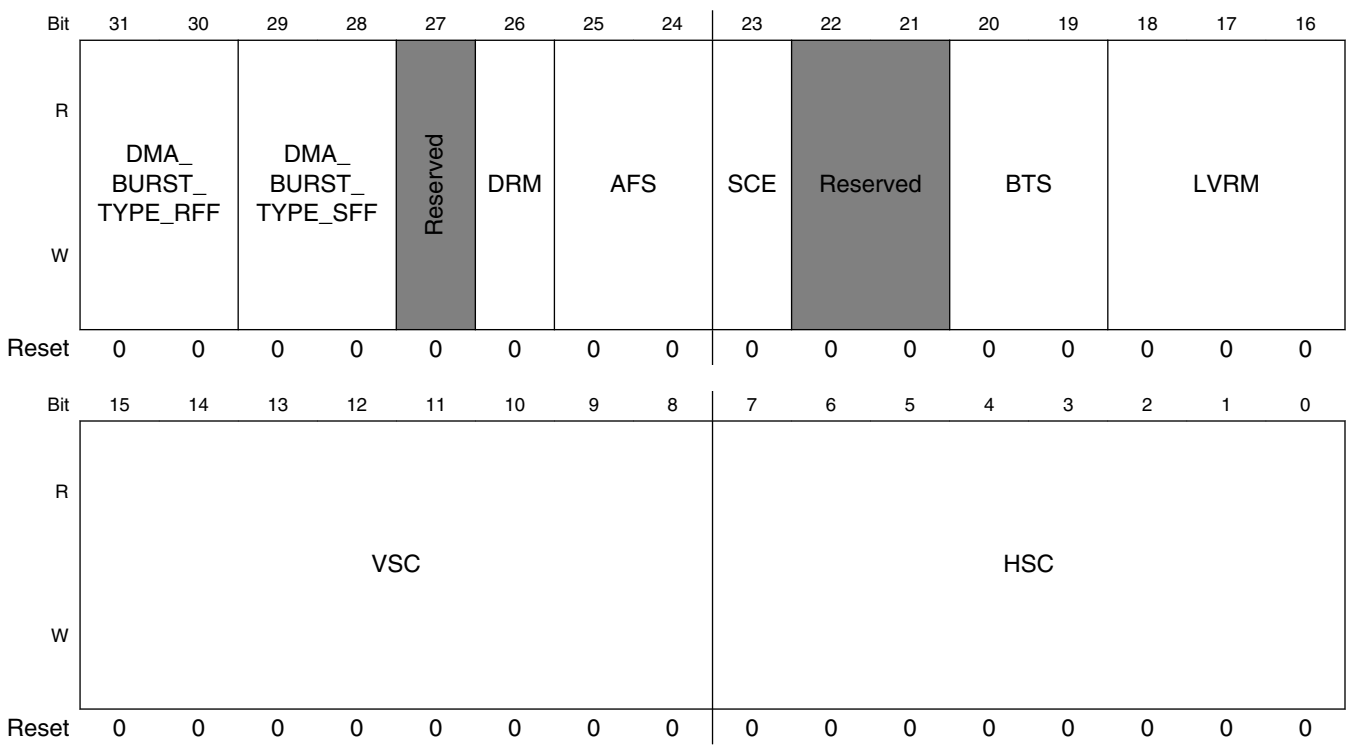
CSI_CR1 field descriptions (continued)

Field	Description
6 CLR_STATFIFO	Asynchronous STATFIFO Clear. This bit clears the STATFIFO and Reset STAT block. This bit works only in async FIFO clear mode-that is, FCC = 0. Otherwise this bit is ignored. Writing 1 will clear STATFIFO and reset STAT block immediately, STATFIFO and STAT block then wait and restart after the arrival of next SOF. The bit is restored to 0 automatically after finish. Normally reads 0.
5 CLR_RXFIFO	Asynchronous RXFIFO Clear. This bit clears the RXFIFO. This bit works only in async FIFO clear mode-that is, FCC = 0. Otherwise this bit is ignored. Writing 1 clears the RXFIFO immediately, RXFIFO restarts immediately after that. The bit is restored to 0 automatically after finish. Normally reads 0.
4 GCLK_MODE	Gated Clock Mode Enable. Controls if CSI is working in gated or non-gated mode. This bit works only in traditional mode-that is, CCIR_EN = 0. Otherwise this bit is ignored. 0 Non-gated clock mode. All incoming pixel clocks are valid. HSYNC is ignored. 1 Gated clock mode. Pixel clock signal is valid only when HSYNC is active.
3 INV_DATA	Invert Data Input. This bit enables or disables internal inverters on the data lines. 0 CSI_D[7:0] data lines are directly applied to internal circuitry 1 CSI_D[7:0] data lines are inverted before applied to internal circuitry
2 INV_PCLK	Invert Pixel Clock Input. This bit determines if the Pixel Clock (CSI_PIXCLK) is inverted before it is applied to the CSI module. 0 CSI_PIXCLK is directly applied to internal circuitry 1 CSI_PIXCLK is inverted before applied to internal circuitry
1 REDGE	Valid Pixel Clock Edge Select. Selects which edge of the CSI_PIXCLK is used to latch the pixel data. 0 Pixel data is latched at the falling edge of CSI_PIXCLK 1 Pixel data is latched at the rising edge of CSI_PIXCLK
0 PIXEL_BIT	Pixel Bit. This bit indicates the bayer data width for each pixel. This bit should be configured before activating or re-starting the embedded DMA controller. 0 8-bit data for each pixel 1 10-bit data for each pixel

45.6.2 CSI Control Register 2 (CSI_CR2)

This register provides the statistic block with data about which live view (sensor input) resolution is being used, and the starting sensor pixel of the Bayer pattern. It also contains the horizontal and vertical count used to determine the number of pixels to skip between the 64 x 64 blocks of statistics when generating statistics on live view image that are greater than 512 x 384.

Address: 4080_0000h base + 4h offset = 4080_0004h



CSI_CR2 field descriptions

Field	Description
31–30 DMA_BURST_ TYPE_RFF	Burst Type of DMA Transfer from RxFIFO. Selects the burst type of DMA transfer from RxFIFO. X0 INCR8 01 INCR4 11 INCR16
29–28 DMA_BURST_ TYPE_SFF	Burst Type of DMA Transfer from STATFIFO. Selects the burst type of DMA transfer from STATFIFO. X0 INCR8 01 INCR4 11 INCR16

Table continues on the next page...

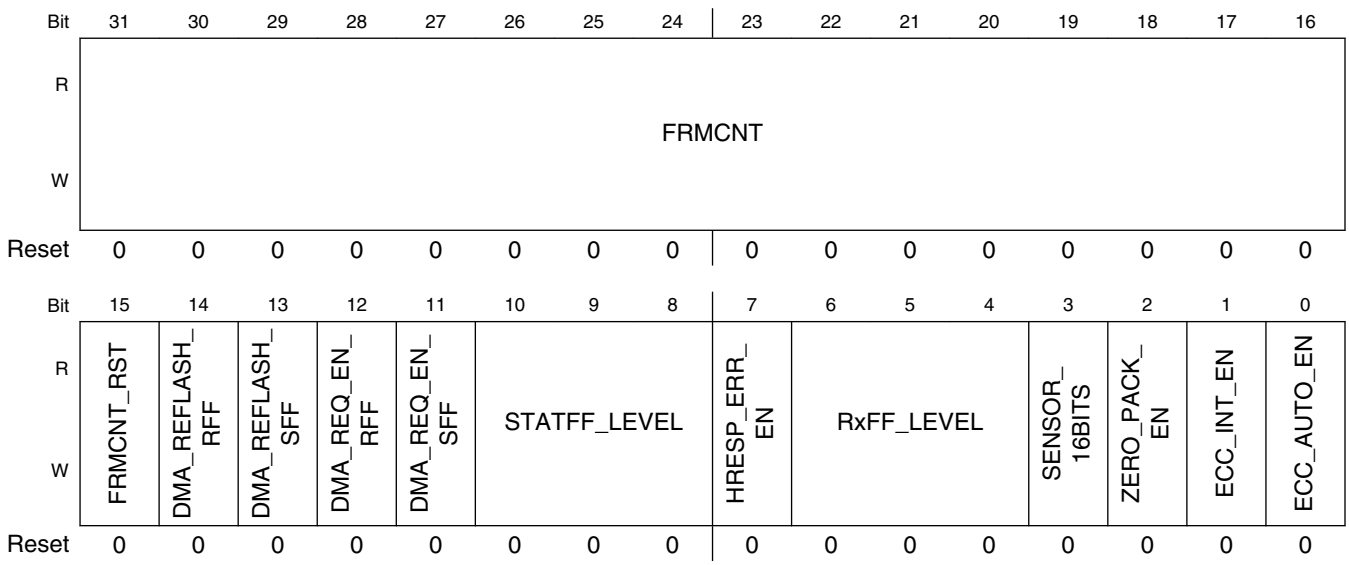
CSI_CR2 field descriptions (continued)

Field	Description
27 Reserved	This field is reserved. This bit should read 0
26 DRM	Double Resolution Mode. Controls size of statistics grid. 0 Stats grid of 8 x 6 1 Stats grid of 8 x 12
25–24 AFS	Auto Focus Spread. Selects which green pixels are used for auto-focus. 00 Abs Diff on consecutive green pixels 01 Abs Diff on every third green pixels 1x Abs Diff on every four green pixels
23 SCE	Skip Count Enable. Skip count is the number of pixels to skip between the 64x64 blocks of statistics. 0 Skip count disable 1 Skip count enable
22–21 Reserved	This field is reserved. These bits should read 0.
20–19 BTS	Bayer Tile Start. Controls the Bayer pattern starting point. 00 GR 01 RG 10 BG 11 GB
18–16 LVRM	Live View Resolution Mode. Selects the grid size used for live view resolution. 0 512 x 384 1 448 x 336 2 384 x 288 3 384 x 256 4 320 x 240 5 288 x 216 6 400 x 300
15–8 VSC	Vertical Skip Count. Contains the number of rows to skip. SCE must be 1, otherwise VSC is ignored. 0-255 Number of rows to skip minus 1
HSC	Horizontal Skip Count. Contains the number of pixels to skip. SCE must be 1, otherwise HSC is ignored. 0-255 Number of pixels to skip minus 1

45.6.3 CSI Control Register 3 (CSI_CR3)

This read/write register acts as an extension of the functionality of the CSI Control register 1, adding additional control and features.

Address: 4080_0000h base + 8h offset = 4080_0008h



CSI_CR3 field descriptions

Field	Description
31–16 FRMCNT	Frame Counter. This is a 16-bit Frame Counter (Wraps around automatically after reaching the maximum)
15 FRMCNT_RST	Frame Count Reset. Resets the Frame Counter. (Cleared automatically after reset is done) 0 Do not reset 1 Reset frame counter immediately
14 DMA_ REFLASH_RFF	Reflash DMA Controller for RxFIFO. This bit reflash the embedded DMA controller for RxFIFO. It should be reflashed before the embedded DMA controller starts to work. (Cleared automatically after reflashing is done) 0 No reflashing 1 Reflash the embedded DMA controller
13 DMA_ REFLASH_SFF	Reflash DMA Controller for STATFIFO. This bit reflash the embedded DMA controller for STATFIFO. It should be reflashed before the embedded DMA controller starts to work. (Cleared automatically after reflashing is done) 0 No reflashing 1 Reflash the embedded DMA controller

Table continues on the next page...

CSI_CR3 field descriptions (continued)

Field	Description
12 DMA_REQ_EN_RFF	DMA Request Enable for RxFIFO. This bit enables the dma request from RxFIFO to the embedded DMA controller. 0 Disable the dma request 1 Enable the dma request
11 DMA_REQ_EN_SFF	DMA Request Enable for STATFIFO. This bit enables the dma request from STATFIFO to the embedded DMA controller. 0 Disable the dma request 1 Enable the dma request
10–8 STATFF_LEVEL	STATFIFO Full Level. When the number of data in STATFIFO reach this level, STATFIFO full interrupt is generated, or STATFIFO DMA request is sent. 000 4 Double words 001 8 Double words 010 12 Double words 011 16 Double words 100 24 Double words 101 32 Double words 110 48 Double words 111 64 Double words
7 HRESP_ERR_EN	Hresponse Error Enable. This bit enables the hresponse (AHB protocol standard) error interrupt. 0 Disable hresponse error interrupt 1 Enable hresponse error interrupt
6–4 RxFF_LEVEL	**RxFIFO Full Level**. When the number of data in RxFIFO reaches this level, a RxFIFO full interrupt is generated, or an RXFIFO DMA request is sent. If the number of data is smaller, it will send request to bus with small burst size. 000 4 Double words 001 8 Double words 010 16 Double words 011 24 Double words 100 32 Double words 101 48 Double words 110 64 Double words 111 96 Double words
3 SENSOR_16BITS	16-bit Sensor Mode. This bit indicates one 16-bit sensor connected to the 16-bit data ports. This bit should be set if there is one 16-bit sensor connected. This bit should be configured before re-flashing or restarting the embedded DMA controller. 0 Only one 8-bit sensor is connected. 1 One 16-bit sensor is connected.
2 ZERO_PACK_EN	Dummy Zero Packing Enable. This bit causes a dummy zero to be packed with every 3 incoming bytes, forming a 32-bit word. The dummy zero is always packed to the LSB position. This packing function is only available in 8-bit/pixel mode. 0 Zero packing disabled 1 Zero packing enabled

Table continues on the next page...

CSI_CR3 field descriptions (continued)

Field	Description
1 ECC_INT_EN	Error Detection Interrupt Enable. This bit enables and disables the error detection interrupt. This feature only works in BT.656 interlace mode. 0 No interrupt is generated when error is detected. Only the status bit ECC_INT is set. 1 Interrupt is generated when error is detected.
0 ECC_AUTO_EN	Automatic Error Correction Enable. This bit enables and disables the automatic error correction. If an error occurs and error correction is disabled only the ECC_INT status bit is set. This feature only works in BT. 656 interlace mode. 0 Auto Error correction is disabled. 1 Auto Error correction is enabled.

45.6.4 CSI Statistic FIFO Register (CSI_STATFIFO)

The StatFIFO is a read-only register containing statistic data from the sensor. Writing to this register has no effect.

Address: 4080_0000h base + Ch offset = 4080_000Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	STAT																															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

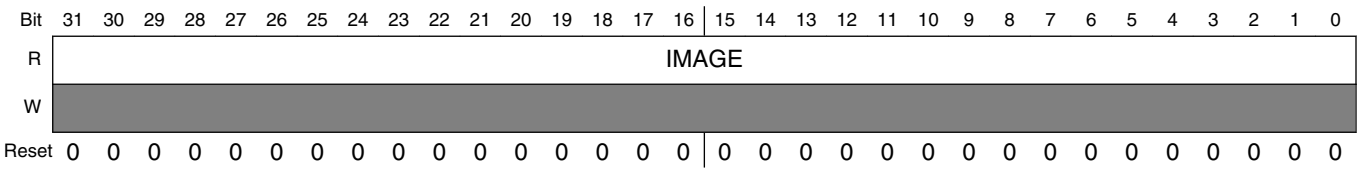
CSI_STATFIFO field descriptions

Field	Description
STAT	Static data from sensor

45.6.5 CSI RX FIFO Register (CSI_RFIFO)

This read-only register contains received image data. Writing to this register has no effect.

Address: 4080_0000h base + 10h offset = 4080_0010h



CSI_RFIFO field descriptions

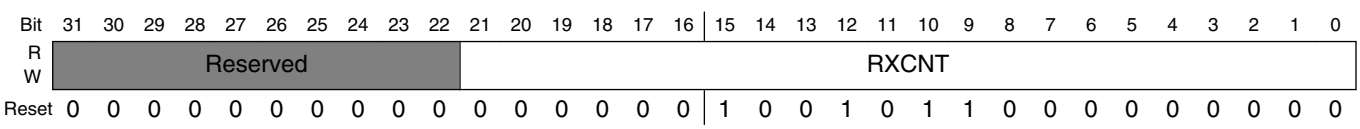
Field	Description
IMAGE	Received image data

45.6.6 CSI RX Count Register (CSI_RXCNT)

This register works for End of Frame (EOF) interrupt generation while width/height is used for DMA done. It should be set to the number of words to receive that would generate an EOF interrupt.

There is an internal counter that counts the number of words read from the RX FIFO. Whenever the RX FIFO is being read, by either the CPU or the embedded DMA controller, the counter value is updated and compared with this register. If the values match, then an EOF interrupt is triggered.

Address: 4080_0000h base + 14h offset = 4080_0014h



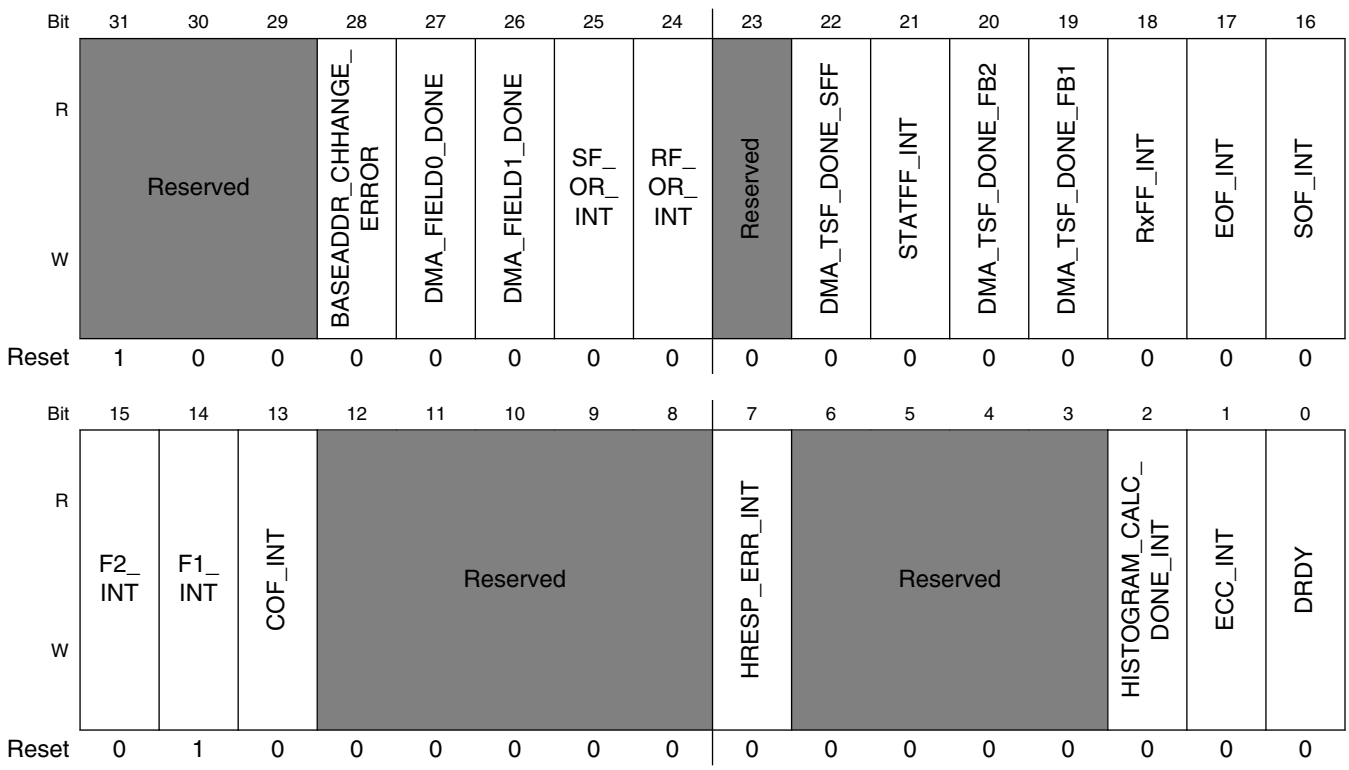
CSI_RXCNT field descriptions

Field	Description
31–22 Reserved	This field is reserved. These bits should read 0.
RXCNT	RxFIFO Count. This 22-bit counter for RXFIFO is updated each time the RXFIFO is read by CPU or DMA.This counter should be set to the expected number of words to receive that would generate an EOF interrupt.

45.6.7 CSI Status Register (CSI_SR)

This read/write register shows sensor interface status, and which kind of interrupt is being generated. The corresponding interrupt bits must be set for the status bit to function. Status bits will function normally even if the corresponding interrupt enable bits are not enabled.

Address: 4080_0000h base + 18h offset = 4080_0018h



CSI_SR field descriptions

Field	Description
31–29 Reserved	This field is reserved.
28 BASEADDR_CHHANGE_ERROR	When using base address switching enable, this bit will be 1 when switching occur before DMA complete. This bit will be clear by writing 1. When this interrupt happens, follow the steps listed below. 1. Unassert the CSI enable, CSIx_CSICR18 bit31, 2. Reflash the DMA, assert the CSIX_CSICR3 bit 14, 3. Assert the CSI enable, CSIx_CSICR18 bit31.
27 DMA_FIELD0_DONE	When DMA field 0 is complete, this bit will be set to 1(clear by writing 1).

Table continues on the next page...

CSI_SR field descriptions (continued)

Field	Description
26 DMA_FIELD1_ DONE	When DMA field 1 is complete, this bit will be set to 1(clear by writing 1).
25 SF_OR_INT	STATFIFO Overrun Interrupt Status. Indicates the overflow status of the STATFIFO register. (Cleared by writing 1) 0 STATFIFO has not overflowed. 1 STATFIFO has overflowed.
24 RF_OR_INT	RxFIFO Overrun Interrupt Status. Indicates the overflow status of the RxFIFO register. (Cleared by writing 1) 0 RXFIFO has not overflowed. 1 RXFIFO has overflowed.
23 Reserved	This field is reserved. This bit should read 0.
22 DMA_TSF_ DONE_SFF	DMA Transfer Done from StatFIFO. Indicates that the dma transfer from StatFIFO is completed. It can trigger an interrupt if the corresponding enable bit is set in CSICR1. This bit can be cleared by writting 1 or reflashing the StatFIFO dma controller in CSICR3.(Cleared by writing 1) 0 DMA transfer is not completed. 1 DMA transfer is completed.
21 STATFF_INT	STATFIFO Full Interrupt Status. Indicates the number of data in the STATFIFO reaches the trigger level. (this bit is cleared automatically by reading the STATFIFO) 0 STATFIFO is not full. 1 STATFIFO is full.
20 DMA_TSF_ DONE_FB2	DMA Transfer Done in Frame Buffer2. Indicates that the DMA transfer from RxFIFO to Frame Buffer2 is completed. It can trigger an interrupt if the corresponding enable bit is set in CSICR1. This bit can be cleared by by writting 1 or reflashing the RxFIFO dma controller in CSICR3. (Cleared by writing 1) 0 DMA transfer is not completed. 1 DMA transfer is completed.
19 DMA_TSF_ DONE_FB1	DMA Transfer Done in Frame Buffer1. Indicates that the DMA transfer from RxFIFO to Frame Buffer1 is completed. It can trigger an interrupt if the corresponding enable bit is set in CSICR1. This bit can be cleared by by writting 1 or reflashing the RxFIFO dma controller in CSICR3. (Cleared by writing 1) 0 DMA transfer is not completed. 1 DMA transfer is completed.
18 RxFF_INT	RXFIFO Full Interrupt Status. Indicates the number of data in the RxFIFO reaches the trigger level. (this bit is cleared automatically by reading the RxFIFO) 0 RxFIFO is not full. 1 RxFIFO is full.
17 EOF_INT	End of Frame (EOF) Interrupt Status. Indicates when EOF is detected. (Cleared by writing 1) 0 EOF is not detected. 1 EOF is detected.
16 SOF_INT	Start of Frame Interrupt Status. Indicates when SOF is detected. (Cleared by writing 1)

Table continues on the next page...

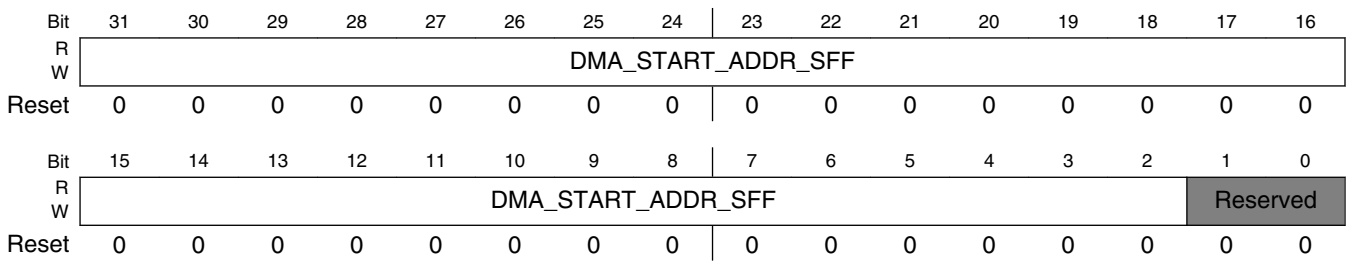
CSI_SR field descriptions (continued)

Field	Description
	0 SOF is not detected. 1 SOF is detected.
15 F2_INT	BT.656 Field 2 Interrupt Status. Indicates the presence of field 2 of video in BT.656 mode. (Cleared automatically when current field does not match) **NOTE:** Only works in BT.656 Interlace mode. 0 Field 2 of video is not detected 1 Field 2 of video is about to start
14 F1_INT	BT.656 Field 1 Interrupt Status. Indicates the presence of field 1 of video in BT.656 mode. (Cleared automatically when current field does not match) **NOTE:** Only works in BT.656 Interlace mode. 0 Field 1 of video is not detected. 1 Field 1 of video is about to start.
13 COF_INT	Change Of Field Interrupt Status. Indicates that a change of the video field has been detected. Only works in BT.656 Interlace mode. Software should read this bit first and then dispatch the new field from F1_INT and F2_INT. (Cleared by writing 1) 0 Video field has no change. 1 Change of video field is detected.
12–8 Reserved	This field is reserved. These bits should read 0.
7 HRESP_ERR_INT	Hresponse Error Interrupt Status. Indicates that a hresponse (AHB protocol standard) error has been detected. (Cleared by writing 1) 0 No hresponse error. 1 Hresponse error is detected.
6–3 Reserved	This field is reserved. These bits should read 0.
2 HISTOGRAM_CALC_DONE_INT	0 Histogram calculation is not finished 1 Histogram calculation is done and driver can access the PIXEL_COUNTERS(CSI_CSICR21~CSI_CSICR276) to get the gray level
1 ECC_INT	BT.656 Error Interrupt. This bit indicates an error has occurred. This only works in BT.656 Interlace mode. (Cleared by writing 1) 0 No error detected 1 Error is detected in BT.656 coding
0 DRDY	RXFIFO Data Ready. Indicates the presence of data that is ready for transfer in the RxFIFO. (Cleared automatically by reading FIFO) 0 No data (word) is ready 1 At least 1 datum (word) is ready in RXFIFO.

45.6.8 CSI DMA Start Address Register - for STATFIFO (CSI_DMASA_STATFIFO)

This register provides the start address for the embedded DMA controller of STATFIFO. The embedded DMA controller will read data from STATFIFO and write it to the external memory from the start address. This register should be configured before activating or restarting the embedded DMA controller.

Address: 4080_0000h base + 20h offset = 4080_0020h



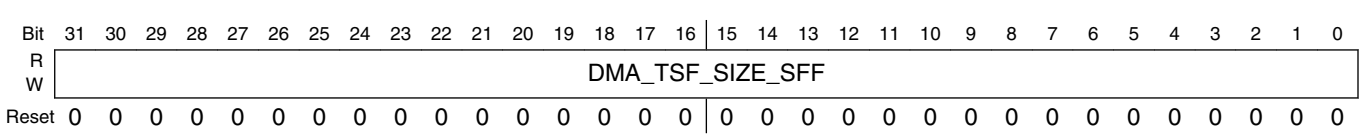
CSI_DMASA_STATFIFO field descriptions

Field	Description
31–2 DMA_START_ADDR_SFF	DMA Start Address for STATFIFO. Indicates the start address to write data. The embedded DMA controller will read data from STATFIFO and write it from this address through AHB bus. **NOTE:** The address should be double words aligned.
Reserved	This field is reserved. These bits should read 0.

45.6.9 CSI DMA Transfer Size Register - for STATFIFO (CSI_DMATS_STATFIFO)

This register provides the total transfer size for the embedded DMA controller of STATFIFO. This register should be configured before activating or restarting the embedded DMA controller.

Address: 4080_0000h base + 24h offset = 4080_0024h



CSI_DMATS_STATFIFO field descriptions

Field	Description
DMA_TSF_SIZE_SFF	DMA Transfer Size for STATFIFO. Indicates how many words to be transfered by the embedded DMA controller. **NOTE:** The size should be double words aligned.

45.6.10 CSI DMA Start Address Register - for Frame Buffer1 (CSI_DMASA_FB1)

This register provides the start address in the frame buffer1 for the embedded DMA controller of RxFIFO. The embedded DMA controller will read data from RxFIFO and write it to the frame buffer1 from the start address. This register should be configured before activating or restarting the embedded DMA controller.

Address: 4080_0000h base + 28h offset = 4080_0028h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

CSI_DMASA_FB1 field descriptions

Field	Description
31–2 DMA_START_ADDR_FB1	DMA Start Address in Frame Buffer1. Indicates the start address to write data. The embedded DMA controller will read data from RxFIFO and write it from this address through AHB bus. **NOTE:** The address should be double words aligned.
Reserved	This field is reserved. These bits should read 0.

45.6.11 CSI DMA Transfer Size Register - for Frame Buffer2 (CSI_DMASA_FB2)

This register provides the start address in the frame buffer2 for the embedded DMA controller of RxFIFO. The embedded DMA controller will read data from RxFIFO and write it to the frame buffer2 from the start address. This register should be configured before activating or restarting the embedded DMA controller.

Address: 4080_0000h base + 2Ch offset = 4080_002Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

CSI_DMASA_FB2 field descriptions

Field	Description
31–2 DMA_START_ADDR_FB2	DMA Start Address in Frame Buffer2. Indicates the start address to write data. The embedded DMA controller will read data from RxFIFO and write it from this address through AHB bus. **NOTE:** The address should be double words aligned.
Reserved	This field is reserved. These bits should read 0.

45.6.12 CSI Frame Buffer Parameter Register (CSI_FBUF_PARA)

This register provides the stride of the frame buffer to show how many words to skip before starting to write the next row of the image. The width of the frame buffer minus the width of the image is the stride. This register should be configured before activating or restarting the embedded DMA controller.

Address: 4080_0000h base + 30h offset = 4080_0030h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CSI_FBUF_PARA field descriptions

Field	Description
31–16 DEINTERLACE_ STRIDE	DEINTERLACE_STRIDE is only used in the deinterlace mode. If line stride feature is supported in deinterlace mode, FBUF_STRIDE and DEINTERLACE_STRIDE need to be configured at the same time. DEINTERLACE_STRIDE is configured the same as line width. FBUF_STRIDE	Frame Buffer Parameter. Indicates the stride of the frame buffer. The width of the frame buffer(in double words) minus the width of the image(in double words) is the stride. The stride should be double words aligned. The embedded DMA controller will skip the stride before starting to write the next row of the image. **NOTE:** Double words is equivalent to 8 bytes.

45.6.13 CSI Image Parameter Register (CSI_IMAG_PARA)

This register provides the width and the height of the image from the sensor. The width and height should be aligned in pixel. The width of the image multiplied by the height is the total pixel size that will be transferred in a frame by the embedded DMA controller. This register should be configured before activating or restarting the embedded DMA controller.

Address: 4080_0000h base + 34h offset = 4080_0034h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	IMAGE_WIDTH																IMAGE_HEIGHT															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

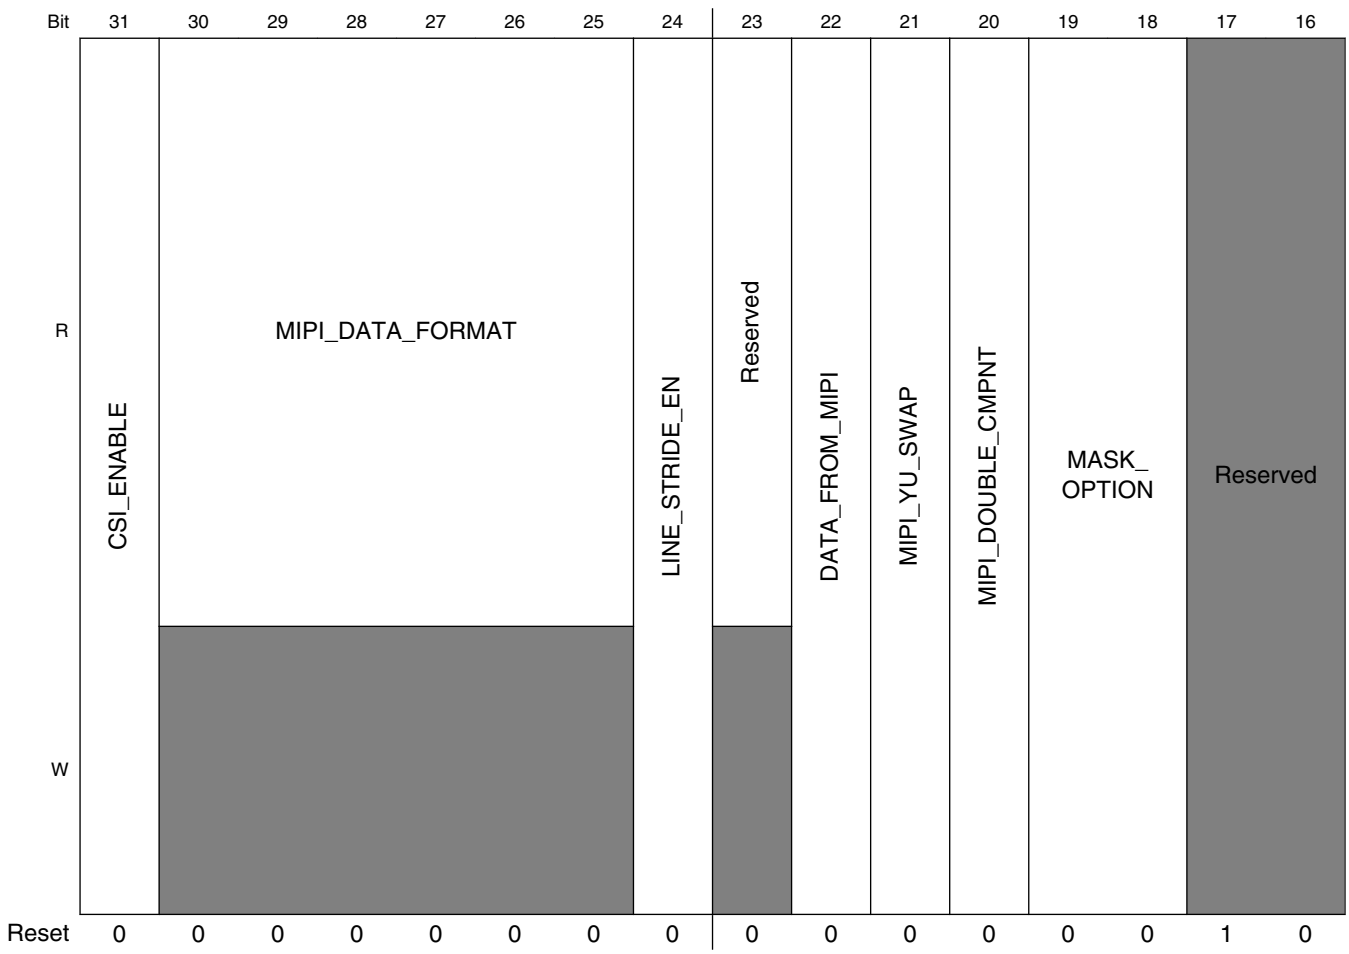
CSI_IMAG_PARA field descriptions

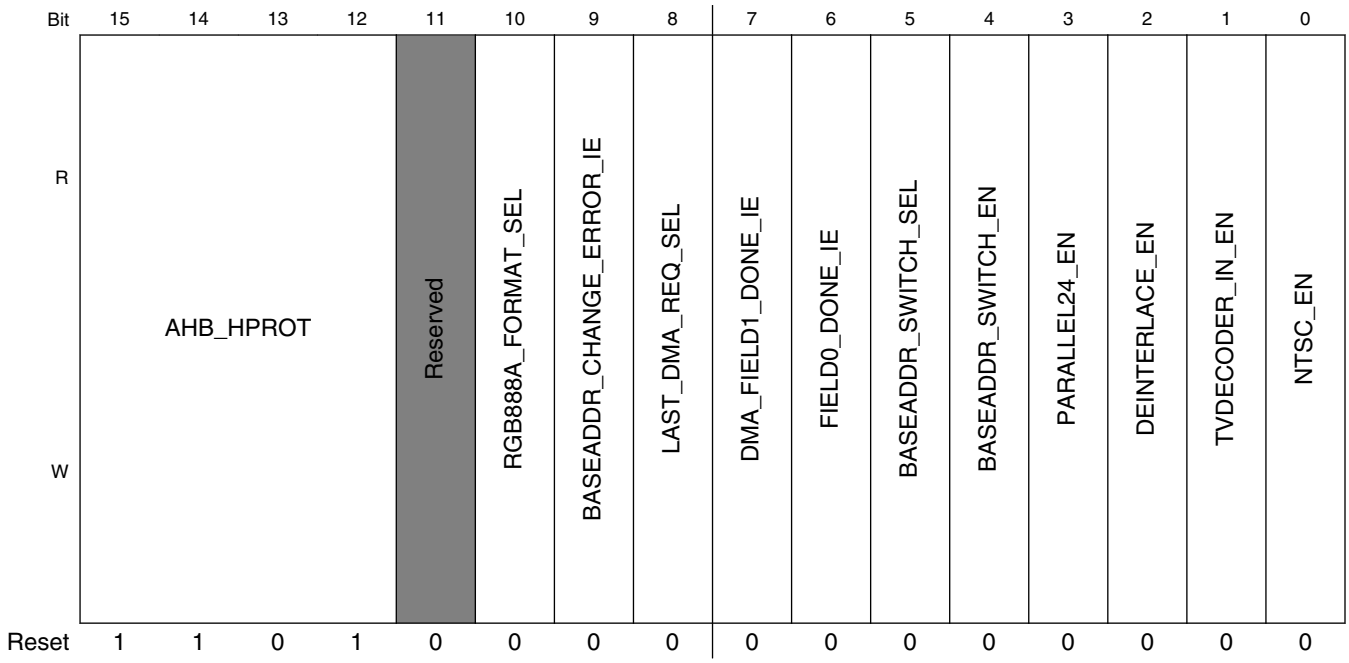
Field	Description
31–16 IMAGE_WIDTH	This field indicates the number of active pixel cycles per line. For 1 cycle/pixel, it equals to IMAGE_WIDTH, and for 2 cycles/pixel it equals to (IMAGE_WIDTH *2). For 24bpp pixel transferred on 8-bit data bus (3 cycle/pixel), it equals to image width. If the input data from the sensor is 8-bit/pixel format, the IMAGE_WIDTH should be a multiple of 8 pixels. If the input data from the sensor is 10-bit/pixel or 16-bit/pixel format, the IMAGE_WIDTH should be a multiple of 4 pixels.
IMAGE_HEIGHT	Image Height. Indicates how many pixels in a column of the image from the sensor. **NOTE:** Image height must be even when deinterlace enabled.

45.6.14 CSI Control Register 18 (CSI_CR18)

This read/write register acts as an extension of the functionality of the CSI Control register 18

Address: 4080_0000h base + 48h offset = 4080_0048h





CSI_CR18 field descriptions

Field	Description
31 CSI_ENABLE	CSI global enable signal. Only when this bit is 1, CSI can start to receive the data and store to memory.
30–25 MIPI_DATA_ FORMAT	Image Data Format Generic Short Packet: 0x08 ~ 0x0F Embedded 8-bit non Image: 0x12 YUV420 (8-bit) 0x18 YUV420 (10-bit) 0x19 YUV420 (8-bit legacy) 0x1A YUV420 (8-bit CSPS) 0x1C YUV420 (10-bit CSPS) 0x1D YUV422 (8-bit) 0x1E YUV422 (10-bit) 0x1F RGB444 0x20 (Not support) RGB555 0x21 (Not support) RGB565 0x22 RGB666 0x23 RGB888 0x24 RAW6 0x28 RAW7 0x29 RAW8 0x2A RAW10 0x2B RAW12 0x2C RAW14 0x2D User defined 1 0x30 User defined 2 0x31

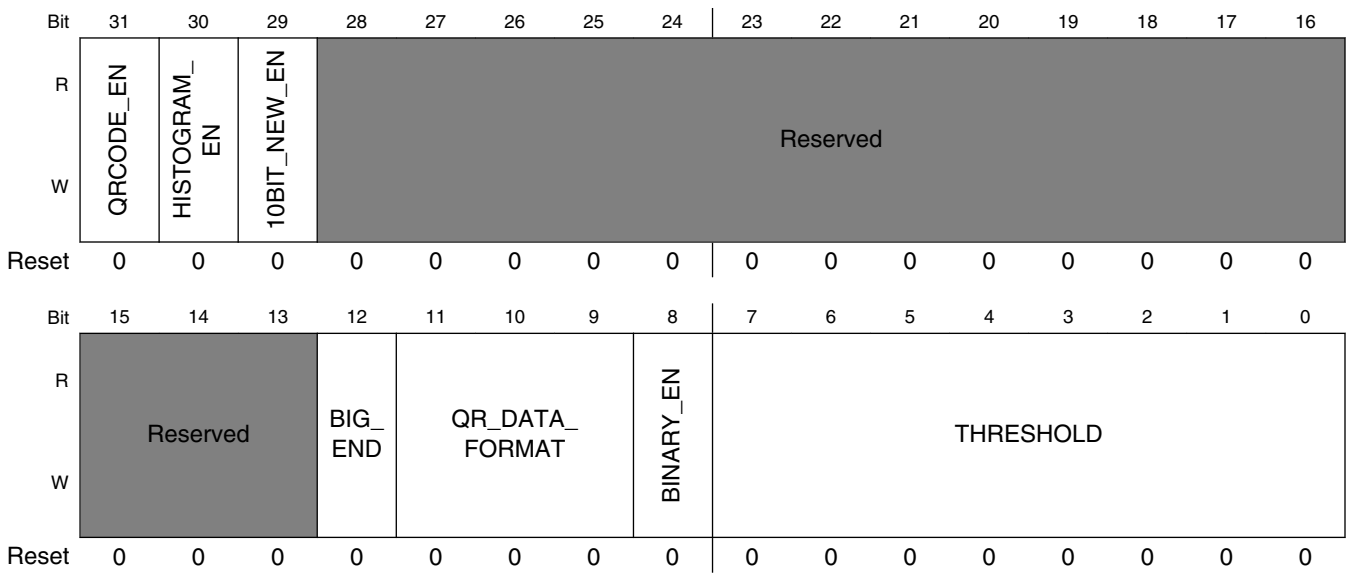
CSI_CR19 field descriptions

Field	Description
31–8 Reserved	This field is reserved.
DMA_RFIFO_ HIGHEST_FIFO_ LEVEL	This byte stores the highest FIFO level achieved by CSI FIFO timely and will be clear by writing 8'ff to it.

45.6.16 CSI Control Register 20 (CSI_CR20)

This read/write register acts as an extension of the functionality of the CSI Control Register 20.

Address: 4080_0000h base + 50h offset = 4080_0050h



CSI_CR20 field descriptions

Field	Description
31 QRCODE_EN	Gray scale mode enable 0 Normal mode 1 Gray scale mode
30 HISTOGRAM_ EN	Histogram enable 0 Histogram disable 1 Histogram enable
29 10BIT_NEW_EN	0 When input 8bits data, it will use the data[9:2] 1 If input is 10bits data, it will use the data[7:0] (optional)

Table continues on the next page...

CSI_CR20 field descriptions (continued)

Field	Description
28–13 Reserved	This field is reserved.
12 BIG_END	0 The newest (most recent) data will be assigned the lowest position when store to memory. 1 The newest (most recent) data will be assigned the highest position when store to memory.
11–9 QR_DATA_FORMAT	000 YU YV one cycle per 1 pixel input 001 UY VY one cycle per1 pixel input 010 Y U Y V two cycles per 1 pixel input 011 U Y V Y two cycles per 1 pixel input 100 YUV one cycle per 1 pixel input 101 Y U V three cycles per 1 pixel input
8 BINARY_EN	0 Output is Y8 format(8 bits each pixel) 1 Output is Y1 format(1 bit each pixel)
THRESHOLD	THRESHOLD used for binary function. When data value > THRESHOLD, output will be 1 Else will be 0.

45.6.17 CSI Control Register (CSI_CR*n*)

These read/write registers acts as an extension of the functionality of the CSI Control Registers. They store pixel counter values from 0 - 255.

Address: 4080_0000h base + 54h offset + (4d × i), where i=0d to 255d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

46.2 Overview

The Mobile Industry Processor Interface (MIPI) Camera Serial Interface 2 (CSI2) Rx block with the PHY and host controller handles the sensor or image input and process for all the input imaging devices.

46.2.1 Block diagram

The block diagram for the MIPI CSI-2 Rx block is given below:

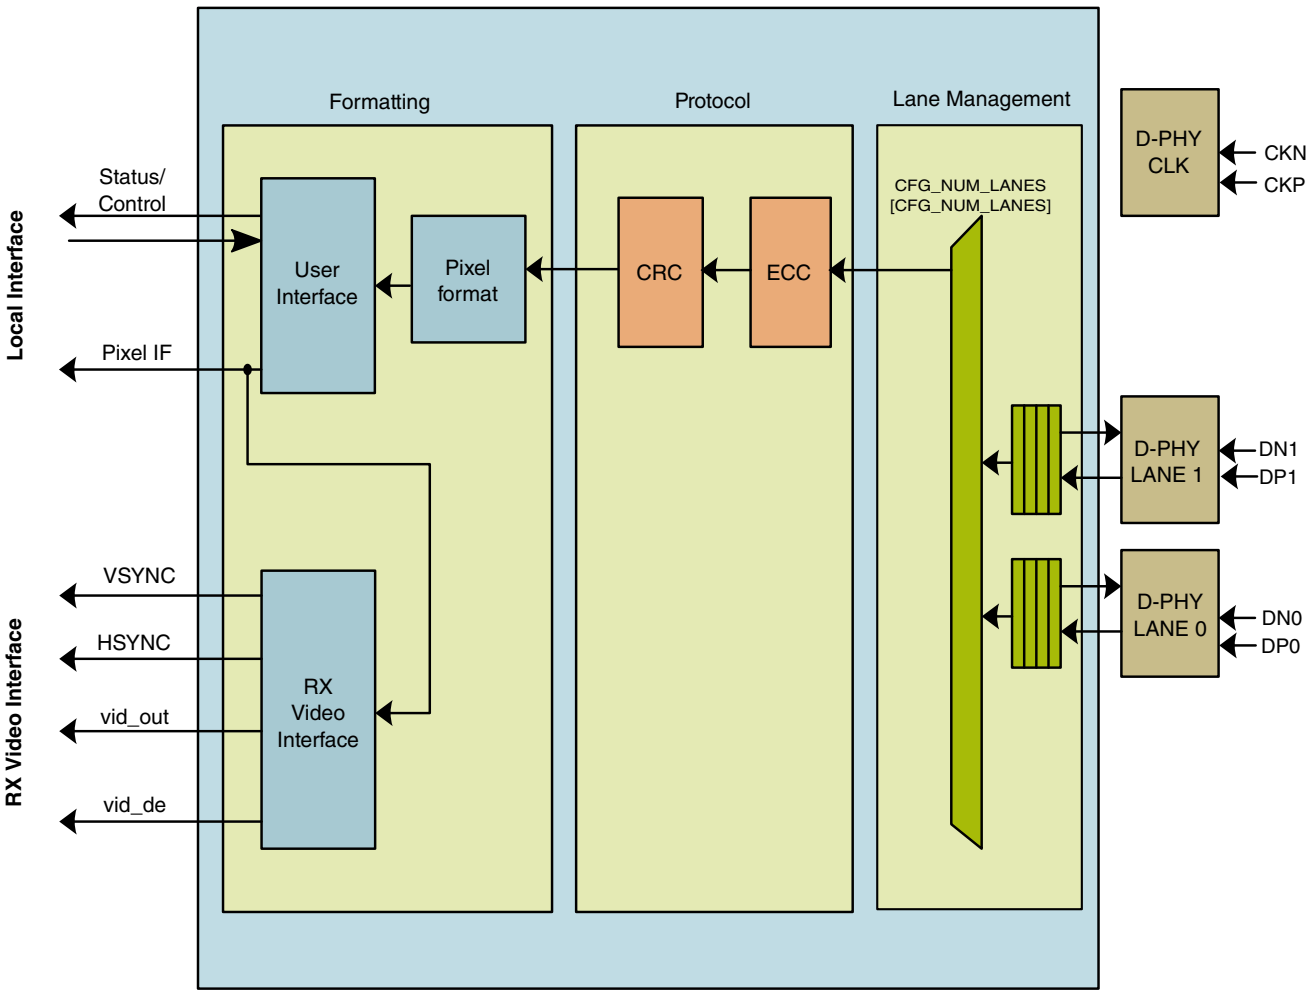

Figure 46-1. MIPI CSI-2 Rx Block Diagram

PHY Layer: It documents the characteristics of the transmission medium, electrical parameters for signaling and for the D-PHY physical layer option, the timing relationship between clock and data lanes. The mechanism for signaling Start Of Transmission (SoT) and End of Transmission (EoT) is specified as well as other out of band information that can be conveyed between transmitting and receiving PHYs. Bit-level and byte-level synchronizations are included as a part of the PHY.

Protocol Layer: It is composed of several layers, each with distinct responsibilities. The CSI2 protocol enables multiple data streams using a single interface on the host processor. The Protocol layer specifies how multiple data streams may be tagged and interleaved so each data stream can be properly reconstructed.

- Byte to Pixel unpacking: The CSI2 specification supports image applications with varying pixel formats from 6bpp to 24bpp. In the receiver, this layer unpacks bytes from the Low level Protocol layer into pixels . Eight bits per pixel data is transferred unchanged by this layer.

- Low Level Protocol (LLP): This includes the means of establishing bit-level and byte-level synchronization for serial data transferred between SoT and EoT events and for passing data to the next layer. The minimum granularity of LLP is one byte. It also includes assignment of bit-value interpretation within the byte, i.e, the Endian assignment.
- Lane Management: The CSI2 controller is lane-scalable for increased performance.On the receiving side, the interface collects bytes from the lanes and merges them together into a recombined data stream that restores the original stream sequence.

Data within the Protocol layer is organized as packets. The header is stripped off at the LLP layer and interpreted by corresponding logic in the receiver.

The CSI-2 Rx Controller Core also includes an Rx Video Interface. This interface watches the local interface of the controller and generates a simplified video output interface. Image packet types which are supported by the Pixel Format block are assembled into a Video output bus which carries the pixel data which is received by the controller. Valid video output data is indicated using the data enable output(s). Horizontal and vertical sync outputs are also provided.

The Local Interface is an easy to use pixel based interface that supports all data types. The Local interface runs at the User Interface clock rate for all implementations. The CSI-2 Rx Controller Core takes care of all packet formatting details and transmission over the MIPI bus.

46.2.2 Features

The MIPI-CSI2 Controller has the following key features:

- Implements the PHY layer, and protocol layer. The protocol layer includes Byte to Pixel unpacking Layer, Low Level protocol, and Lane management
- Supports unidirectional Master operation
- Scalable data lane support, 1 to 2 Data Lanes
- Supports high speed mode (80Mbps - 1.5Gbps) per lane
- Supports 10Mbps data rate in low power mode
- Includes high speed deserializers
- Loopback testability support
- Support for D-PHY Ultra Low Power State (ULPS)
- Error collection support (Rx Only)
- Flexible pixel-based user interface
    - Supports user generated packets
    - Supports single interface

- Supports PHY Protocol Interface (PPI) compatible MIPI D-PHYs
- Support for Rx Video Interface
- Support for APB Control and Status Register (CSR) interface with IRQ

46.3 Functional description

46.3.1 CSI-2 Rx Controller Core Local Interface

The CSI-2 Rx Controller Core Local Interface consists of a Receive Interface.

Packets are received from the MIPI Interface via the Receive Local Interface. The Receive Interface is designed to easily interface to a FIFO on the user side that holds the pixels that are received until the user application can process them.

46.3.1.1 Rx Local Interface Description

The Receive Local Interface is the mechanism with which the user receives packets from the MIPI Interface.

The Receive Local Interface first announces that a packet is being or has been received by asserting the pkt_hdr_valid signal with the other packet information output ports containing details about the packet. Next, the sop_out signal will assert indicating that data is about to arrive at the Receive Local Interface. Dav_out will assert with every cycle of pixel data on the data_out port. The last cycle of receive data is signaled by the assertion of eop_out.

With a single pixel interface, data_out contains a single pixel every clock that dav_out (data valid) is asserted. The single pixel interface must run at a frequency that is equal to number of MIPI lanes times the byte lane frequency.

Table 46-2. Receive Local Interface

Signal	Type	Description
data_out[n-1:0]	Output	Pixel Data output.
dav_out	Output	Data Valid Out. When asserted high, data_out, sop_out, and eop_out outputs are valid.

Table continues on the next page...

Table 46-2. Receive Local Interface (continued)

sop_out	Output	Start of packet signal. This active high signal indicates the first cycle of data on data out. Valid when dav_out asserts high
eop_out[3:0]	Output	Last pixel indicator. Asserts to indicate the last pixel in a transmission. When in single pixel mode, eop_out[0] is used. When in double pixel mode two bits are used, [1:0]. 2'b01 indicates the last pixel is on the lower pixel path. 2'b10 indicates the last pixel is on the upper pixel path. When in quad pixel mode, all four bits are utilized. A value of 4'b0001 indicates the last pixel is on the lowest pixel path portion of data_out. 4'b0010 indicates the last pixel is on the second pixel path of data_out. 4'b0100 indicates the last pixel is on the third pixel path of data_out. 4'b1000 indicates the last pixel is on the fourth and highest pixel path of data_out. Valid when dav_out asserts high.

46.3.1.2 Receive Interface Example Transaction

High Speed receive packets appear immediately on the Receive local interface as they are received.

46.3.1.2.1 Short Packet Receive

The short packets do not contain any data. All the information in a short packet is contained in the 32 bit header. Pkt_hdr_valid asserts indicating that the packet header information contained on pkt_hdr_data_type, pkt_hdr_wc, and pkt_hdr_vc is valid. Short packets are defined as having a pkt_hdr_data_type value that is less than 0x10. With a short packet the CSI-2 Rx Controller Core does not assert sop_out, eop_out, nor dav_out.

The figure below shows the reception of a CSI-2 Short Packet type.

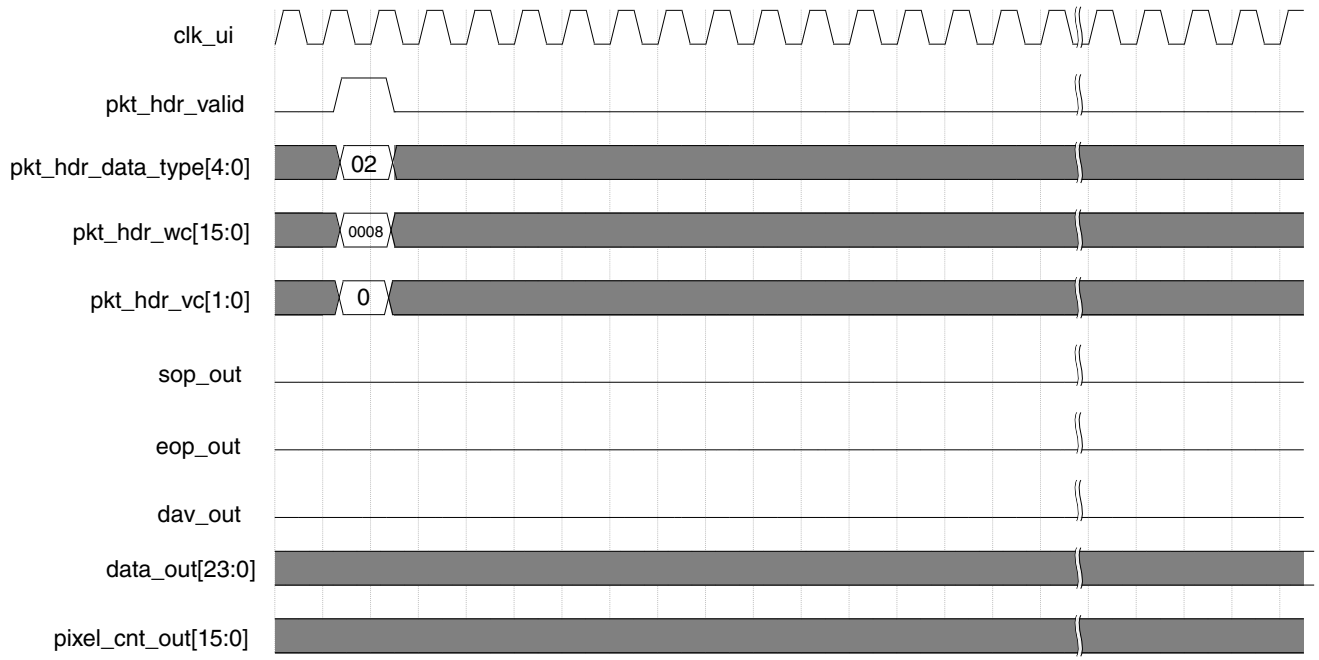

Figure 46-2. Short Packet receive with a data type of Line Start, Line Number of 8 , and Virtual Channel = 0 single pixel configuration

In this example, the data type ix 0x30, a user defined byte data type. Initially, pkt_hdr_valid asserts along with the packet header information. The packet header ports, pkt_hdr_data_type, pkt_hdr_wc, and pkt_hdr_vc indicate that the packet is a user defined data type with a payload of 4 bytes. For unsupported types, the Rx Controller outputs the entire packet minus the two byte CRC value at the end of the packet. The first four bytes are the packet header followed immediately by the 4 bytes of payload data.

The figure below shows a waveform diagram of a received packet on the local interface for an unsupported data type.

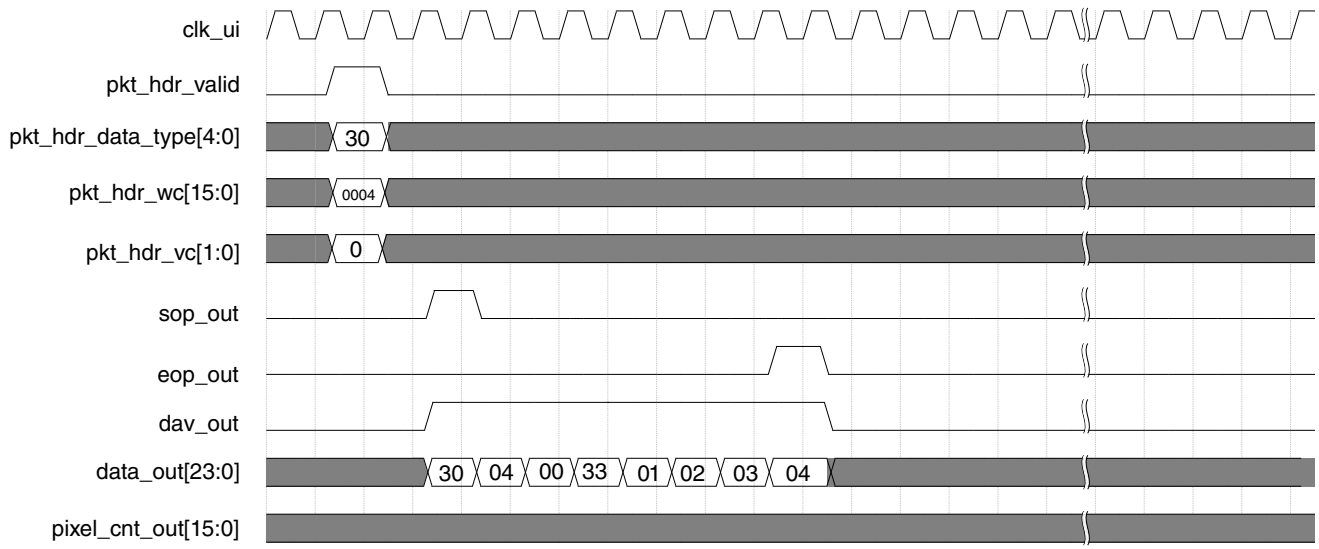

Figure 46-3. Received packet of an unsupported data type, 0x30, user defined data, single pixel configuration

46.3.2 CSI-2 Controller Core Configurations

The CSI-2 Rx Controller Core User Interface supports either a single, double, or quad pixel wide data path. The double and quad wide pixel modes can help reduce the frequency the user interface must run at while the single pixel wide mode can be easier to interface to for some applications.

This chip supports the following:

- Single Pixel Configuration

46.3.2.1 Single Pixel Configuration

The CSI-2 Rx Controller Core User Interface supports a configuration where a single pixel of received data is processed every clock period.

The CSI-2 Rx Controller Core contains minimal pixel buffering (16 pixels or less) so the frequency of that the user interface runs at must be at least high enough to receive the data from the controller at a rate that is equal to or greater than the highest transmission data rate on the MIPI interface for all lanes combined.

46.3.3 CSI-2 Rx Controller Core Data Types Formatting

The CSI-2 Rx Controller Core supports the various CSI-2 Data Types via the data_out port. The following table below describes how the controller presents the various received data types on the data_out output port.

The CSI2 Controller supports the Single Pixel Configuration.

Format	Data Type	Description (single Pixel Configuration)
RGB444	0x20	Blue data is on data_out[3:0], Green on data_out[7:4], and Red on data_out[11:8]
RGB555	0x21	Blue data is on data_out[4:0], Green on data_out[9:5], and Red on data_out[14:10]
RGB565	0x22	Blue data is on data_out[4:0], Green on data_out[10:5], and Red on data_out[15:11
RGB666	0x23	Blue data is on data_out[5:0], Green on data_out[11:6], and Red on data_out[17:12]
RGB888	0x24	Blue data is on data_out[7:0], Green on data_out[15:8], and Red on data_out[23:16]
Legacy YUV420 (8 bit)	0x1A	With Legacy YUV420 8 bit and the Rx Controller configured for single pixel mode the video data is received in UYY…/VYY sequences in odd/even lines. The U component is received with YY in a UYY group on odd lines while the V component is received with the same YY pairs in VYY groups on the even lines. When receiving an odd line data_out[7:0] contains the U component, data_out[15:8] Y1 and data_out[23:16] Y2. On even lines data_out[7:0] contains the V component, data_out[15:8] Y1 and data_out[23:16] Y2.
YUV420 (8bit)	0x18, 0x1C	With YUV420 8 bit and YUV420 8 bit chroma shifted is received as YYYY (odd lines) UYVY (even lines) sequence. With the Rx controller configured for single pixel mode and receiving even numbered lines, data_out[7:0] contains the U1 component, bits [15:8] Y1. On the next data valid cycle bits [7:0] V1, bits [15:8] Y2. When receiving odd lines, data_out[7:0] contains the Y1 component, bits [15:8] Y2. On the next data valid cycle bits [7:0] Y3, bits [15:8] Y4.
YUV420 (10 bit)	0x19, 0x1D	With YUV420 10 bit and YUV420 10 bit chroma shifted is received as YYYY (odd numbered lines) and UYVY (even numbered lines) sequence with each component represented by 10 bits.

Table continues on the next page...

Format	Data Type	Description (single Pixel Configuration)
		With the Rx controller configured for single pixel mode and receiving even numbered lines, data_out[9:0] contains the U1 component, bits [19:10] Y1. On the next data valid cycle bits [9:0] V1, bits [19:10] Y2. When receiving odd lines, data_out[9:0] contains the Y1 component, bits [19:10] Y2. On the next data valid cycle bits [9:0] Y3, bits [19:10] Y4.
YUV422 (8 bit)	0x1E	The data_out[7:0] contains the U1 component, bits [15:8] contains Y1 component. On the next data valid cycle, bits [7:0] contains V1 component, and bits [15:8] contains Y2 component.

46.3.4 Rx Video Interface

The CSI-2 Rx Video Interface is connected internally to the local interface outputs of the CSI-2 Rx Controller Core. This interface provides both the packet header information and the pixel data (after processing by the Pixel Format block). CSI-2 Rx Controller Cores may be built with any number of Pixel Formats supported. The CSI-2 Rx Video Interface only recognizes video formats for which the CSI-2 Rx Controller Core has been configured to support.

The general timing of the video interface is determined by the timing of the packets received by the CSI-2 Rx controller which are used to determine when to generate a Vertical Sync and when to output a line of video data.

The CSI-2 Rx Video Interface may receive several different types of packet data types as shown in the table below.

Packet Type	Data ID	Function
Frame Start Code (FS)	0x00	Indicates start of frame
Frame End Code (FE)	0x01	Indicates end of frame
Line Start Code (LS)	0x02	Indicates start of line
Line End Code (LS)	0x02	Indicates end of line
Image Data Codes (IMG)	various	Image data packets carry the sample data. The CSI-2 Rx Video Interface will respond to those

		Data types which are enabled in the CSI-2 Rx Controller Core. See CSI-2 Rx Controller Core Data Types Formatting

46.3.4.1 Video Interface Output Raster Timing

The output timing of the raster is formed by the packets sent to the CSI-2 Rx Controller Core and is determined by the relative timing of these packets. This timing is controlled by the transmitter and is not determined by the CSI-2 Rx Controller Core. As shown in the figure below, the basic sequence of packets sent by the transmitter (often a sensor or camera) consists of a Frame Start packet (short packet), followed by some number of Image Data packets (long packets) with one Image data packet per video line and the followed by a Frame End packet (short packet). The Frame End packet is followed by pause which determines the Blanking Lines interval. The length of the Image Data packets is determined by the horizontal resolution of the sensor and each line's samples are carried by a single Image Data packet.

NOTE

Note that each Image Data packet may optionally be preceded by a Line Start packet and followed by an optional Line End packet. The Line Start and Line End packets are ignored by the CSI-2 Rx Video Interface.

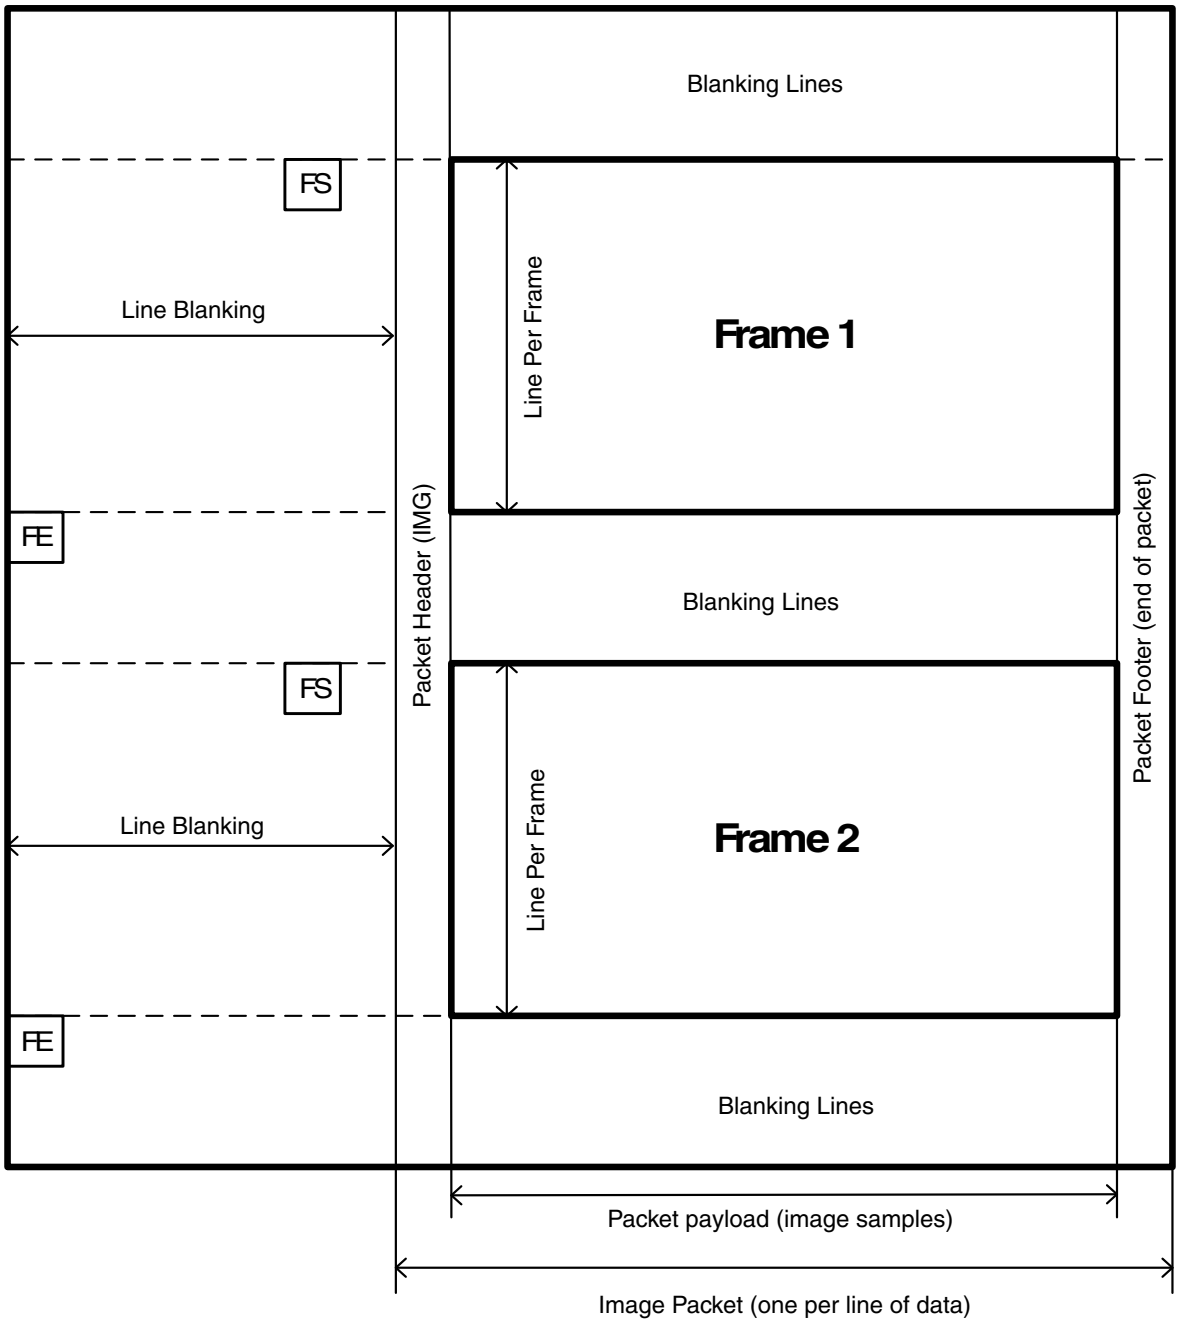

Figure 46-4. Rx Video Interface Raster Timing

NOTE

- FS- Frame Start Packet
- FE- Frame End Packet
- IMG- Image Data Packet

Note that the interface does not generate Horizontal sync pulses during the Blanking Lines.

The CSI-2 Rx Video controller generates a Vertical sync pulse upon the occurrence of every Frame Start packet. Each line of video sample data is preceded by a Horizontal sync pulse.

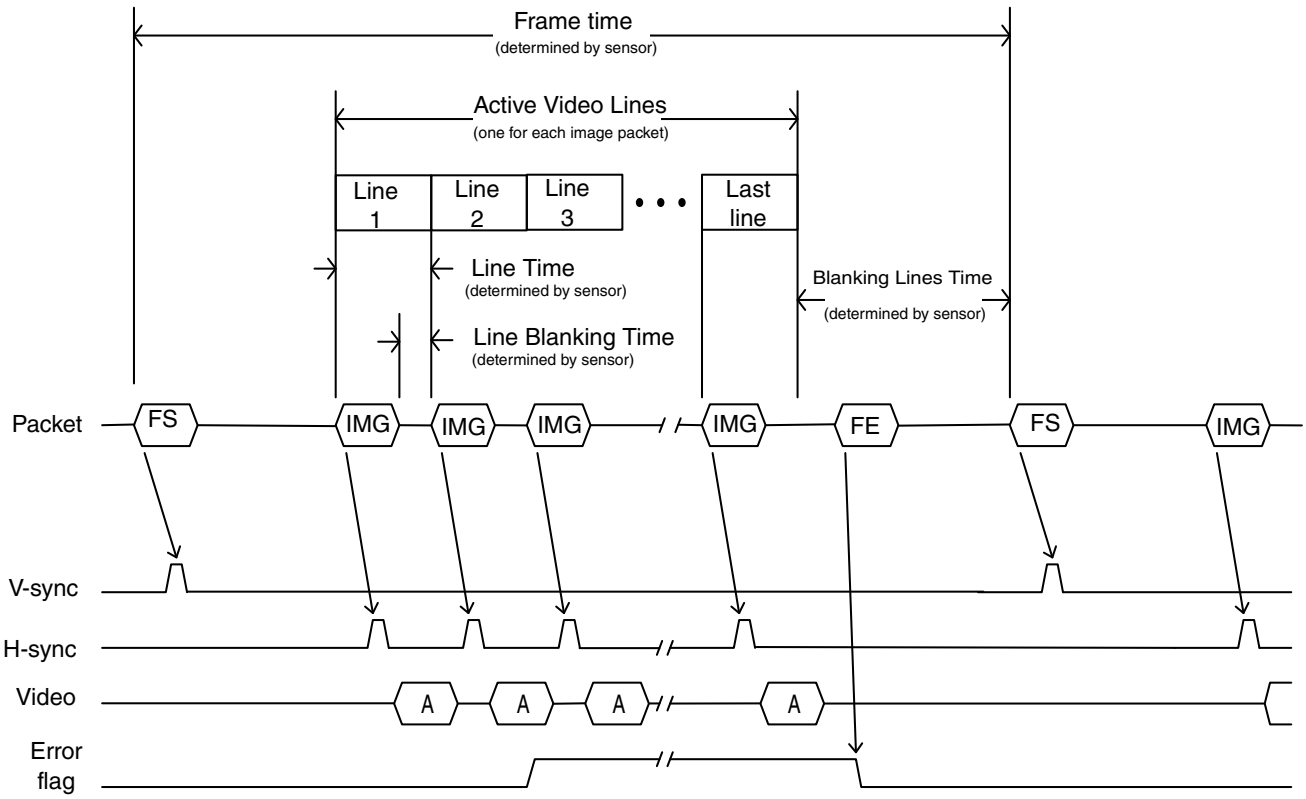

Figure 46-5. Relationship of Packet Stream to Video Interface

NOTE

- FS - Frame start Packet (causes V-sync)
- IMG - Image Data Packet(causes H-sync and Video after FIFO reaches send level)
- FE - Frame End Packet (causes any pending Error Flags which were set in the previous frame)
- A - Time period when video samples are valid (follows H-sync)

The video sample output bus (vid_out) is logically divided up into pixel lanes. The number of pixel lanes is determined by the pixel width of the CSI-2 Controller Core. This width may be one, two or four pixels wide (single, double or quad pixel interface). The bit width of each pixel lane is determined the widest pixel width supported by the core controller's Pixel Format block. When transferring image data whose pixels are narrower than the maximum required width unused more significant bits in each pixel lane will be output as zero.

To determine the validity of the data presented on each pixel lane the CSI-2 Rx Video Interface supplies a data enable output (vid_de) whose width is equal to the number of pixel lanes in the interface. When a data enable bit is high, its pixel lane is valid.

The only time at which all vid_de bits will not be asserted is on the final transfer of video pixels in a scan line. At this time only some of the lower order bits in the vid_de bus will be asserted only if the number of samples per line is not evenly divisible by the number of pixel lanes.

Thus as a design example:

1. Assume a double pixel interface which results in a two video data lanes. Image data packets are 1023 samples long.
2. This would result in 511 transfers of video out with both bits of vid_de set (1022 samples). The last transfer would only have the least significant vid_de bits set to transfer the final sample to achieve the 1023 samples in the scan line.

46.3.4.2 Video Output Port Waveforms

The vid_de port is used to enable capture of valid video pixels from the vid_out bus. The vid_de will have a single bit for each pixel lane in the vid_out bus. Thus for a single pixel interface (one pixel lane) this bus will be a single signal.

The vid_de port will assert all its signals high for all transfers except possibly the last transfer. This last transfer may only assert some number of lower order bits to one and the remaining higher order bits to zero. The number of valid pixel lanes in the last transfer is determined by the number of pixels transferred by the image packet which generated the video line.

The ending value may be predicted by taking number of pixels transferred in an image packet modulo number of pixel lanes. Any non-zero remainder indicates some number of vid_de bits will be zero on the last transfer.

The following table shows the last vid_de value as a function of number of pixel lanes and packet size.

Table 46-3. Last vid_de value depending on Number of Pixel Lanes and Packet Size

MODULO	Last vid_de value (binary) for Single Pixel Interface
0	1
1	NA
2	NA
3	NA

NOTE

MODULO = (Number of pixels in image packet) MOD (number of pixel lanes)

46.3.5 Rx Control and Status Register (CSR) APB Interface

The CSR provides an APB compatible interface that enables control of the controller's configuration inputs via registers accessible via the APB interface.

46.3.6 Clocks

Table 46-4. Clocks

Clock	Description
clk_ui	User interface clock The frequency of clk_ui must be such that the data received on the data_out output is greater than or equal to the total bandwidth of the physical MIPI interface. Clk_ui has no relationship requirement with regards to 'clk' other than the bandwidth requirement mentioned previously.
clk	Input clock to the Rx controller to process data received from D-PHY This clock must be exactly equal to or faster than the receive byte clock, RxByteClkHS_In0, from the Rx D-PHY.
clk_esc	RX Escape Clock This must be the same escape clock that the Rx D-PHY receives.
pclk	Pixel Clock

The Rx controller core requires two clocks for proper operation clk_ui and clk. The clk_ui clock is the clock that the user interface is synchronous to, with all inputs and outputs referenced to the rising edge of clk_ui. The clk input is the clock that the CSI-2 Rx Controller Core uses to process data received from the D-PHY. The clock clk_ui must be of a sufficient frequency to keep up with the incoming data from the CSI-2 MIPI interface.

The clk_esc is Rx Escape Clock. This must be the same escape clock which the RX D-PHY receives.

The data from the D-PHY is clocked into shallow FIFOs (one per D-PHY lane) using a receive clock that the D-PHY generates. There is no direct timing requirements between the D-PHY generated receive clock and the CSI-2 Rx Controller Core's clk or clk_ui input. The frequency of the clock used for the Rx controller's clk input must be of a sufficient frequency that the Rx controller can keep up with the data from D-PHY. The

Rx Controller processes the Rx D-PHY data in a 32 bit wide data sufficient frequency that the Rx Controller can keep up with the receive data from the D-PHY. The Rx Controller processes the Rx D-PHY data in a 32 bit wide data path regardless of whether the CSI-2 MIPI receive data is coming across one, two lanes. The frequency of clk must be exactly equal to or greater than the Rx byte clock coming from the Rx D-PHY.

The CSI-2 Rx Controller Core can supply pixel data to the User application either one, two or four pixels per clock.

When in single Pixel Mode, the minimum frequency for clk_ui must be high enough to keep up with the incoming data rate of the CSI-2 MIPI interface. It is important to realize that the user interface is pixel based and therefore may be wider than the incoming byte data from the MIPI Rx D-PHY. As an example, if RGB888 data is being received, the user interface data width will be 24 bits wide (1 pixel per clk_ui rising edge and each pixel is 24 bits). As an example, let the MIPI interface run at 1000Mbps with a single lane. The data rate into the CSI-2 Rx controller will be 125MBps so clk must run at 125MHz or higher. Since the user interface is 3 bytes wide, clk_ui must run at 125MHz/3 or higher to keep up with the incoming data.

The figure below shows one possible clocking methodology. In this example, the user Clk_Gen module generates the edge aligned clk_ui and clk clocks.

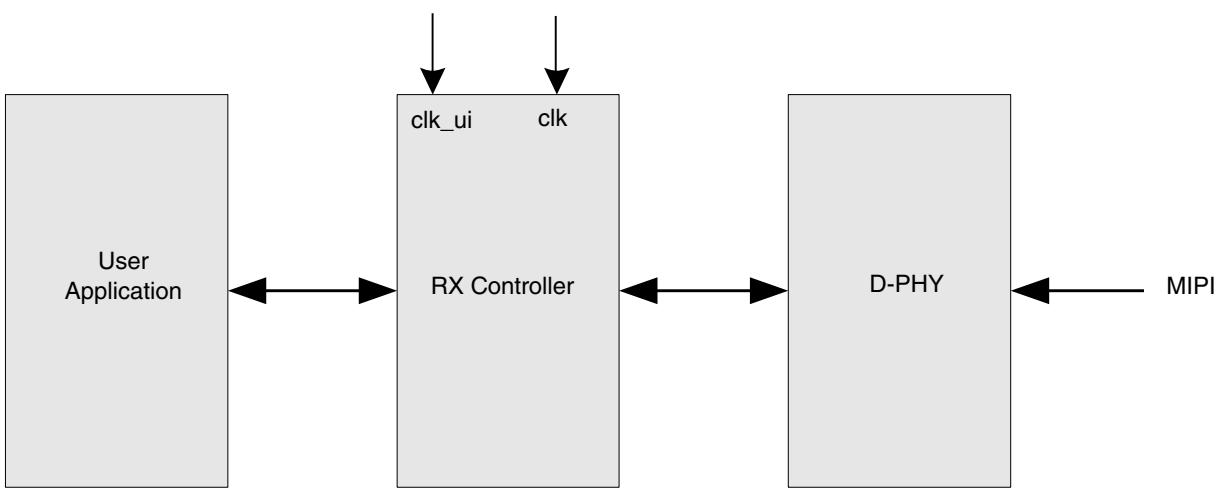

Figure 46-6. CSI-2 Rx Controller Core clocking example

46.3.7 Reset

The MIPI CSI2 contains the following reset signals:

Reset Signal	Description
reset_n	Async reset (active-low) This reset applies to all logic in the Controller Core that is in the ‘clk’ clock domain.
clk_vid_reset_n	Asynchronous active low reset for all logic clocked by clk_vid
clk_ui_reset_n	Async reset (active-low) This reset applies to all logic in the Controller Core that is in the ‘clk_ui’ clock domain.
clk_esc_reset_n	Async reset (active-low) This reset applies to all logic in the Controller Core that is in the ‘clk_esc’ clock domain.
pclk_reset_n	Async reset (active-low) This reset input for all logic in the pclk clock domain.

46.4 External Signals

The table below shows the external signals associated with this block:

Table 46-5. External Signals

Signal	Description	Direction
CKN	Negative MIPI Rx Differential Clock	I
CKP	Positive MIPI Rx Differential Clock	I
DNn	Negative MIPI Rx Differential Data	I
DPn	Positive MIPI Rx Differential Data	I
VSYNC	Video Vsync pulse	O
HSYNC	Video Hsync pulse	O
vid_out	Video Data bus	O
vid_de	Video data pixel lane valid	O

46.5 Initialization

The Initialization procedure for the CSI-2 Rx Controller is as follows:

1. Assert all resets.
2. Wait until clocks to the Rx Controller are stable and ensure D-PHY interface is idle (Stop State on all lanes)
3. De-assert reset to CSR, pclk_reset_n, if CSR is included with the controller. If no CSR go to step 4.

4. Program CSR registers if CSR is present. If CSR is not present, set values to all configuration ports (cfg_* inputs) to appropriate values.
5. De-assert all remaining resets.
6. CSI-2 Rx Controller is ready for use by the next rising edge of clk_ui.

46.6 Memory Map and register definition

This section includes the memory map and detailed descriptions of all registers.

eLCDIF do not support VSYNC mode in this SoC.

47.2 Overview

The enhanced Liquid Crystal Display Interface (eLCDIF) is a general purpose display controller

The eLCDIF block supports the following:

- Displays that support moving pictures and require the RGB interface mode (DOTCLK interface).

47.2.1 Block Diagram

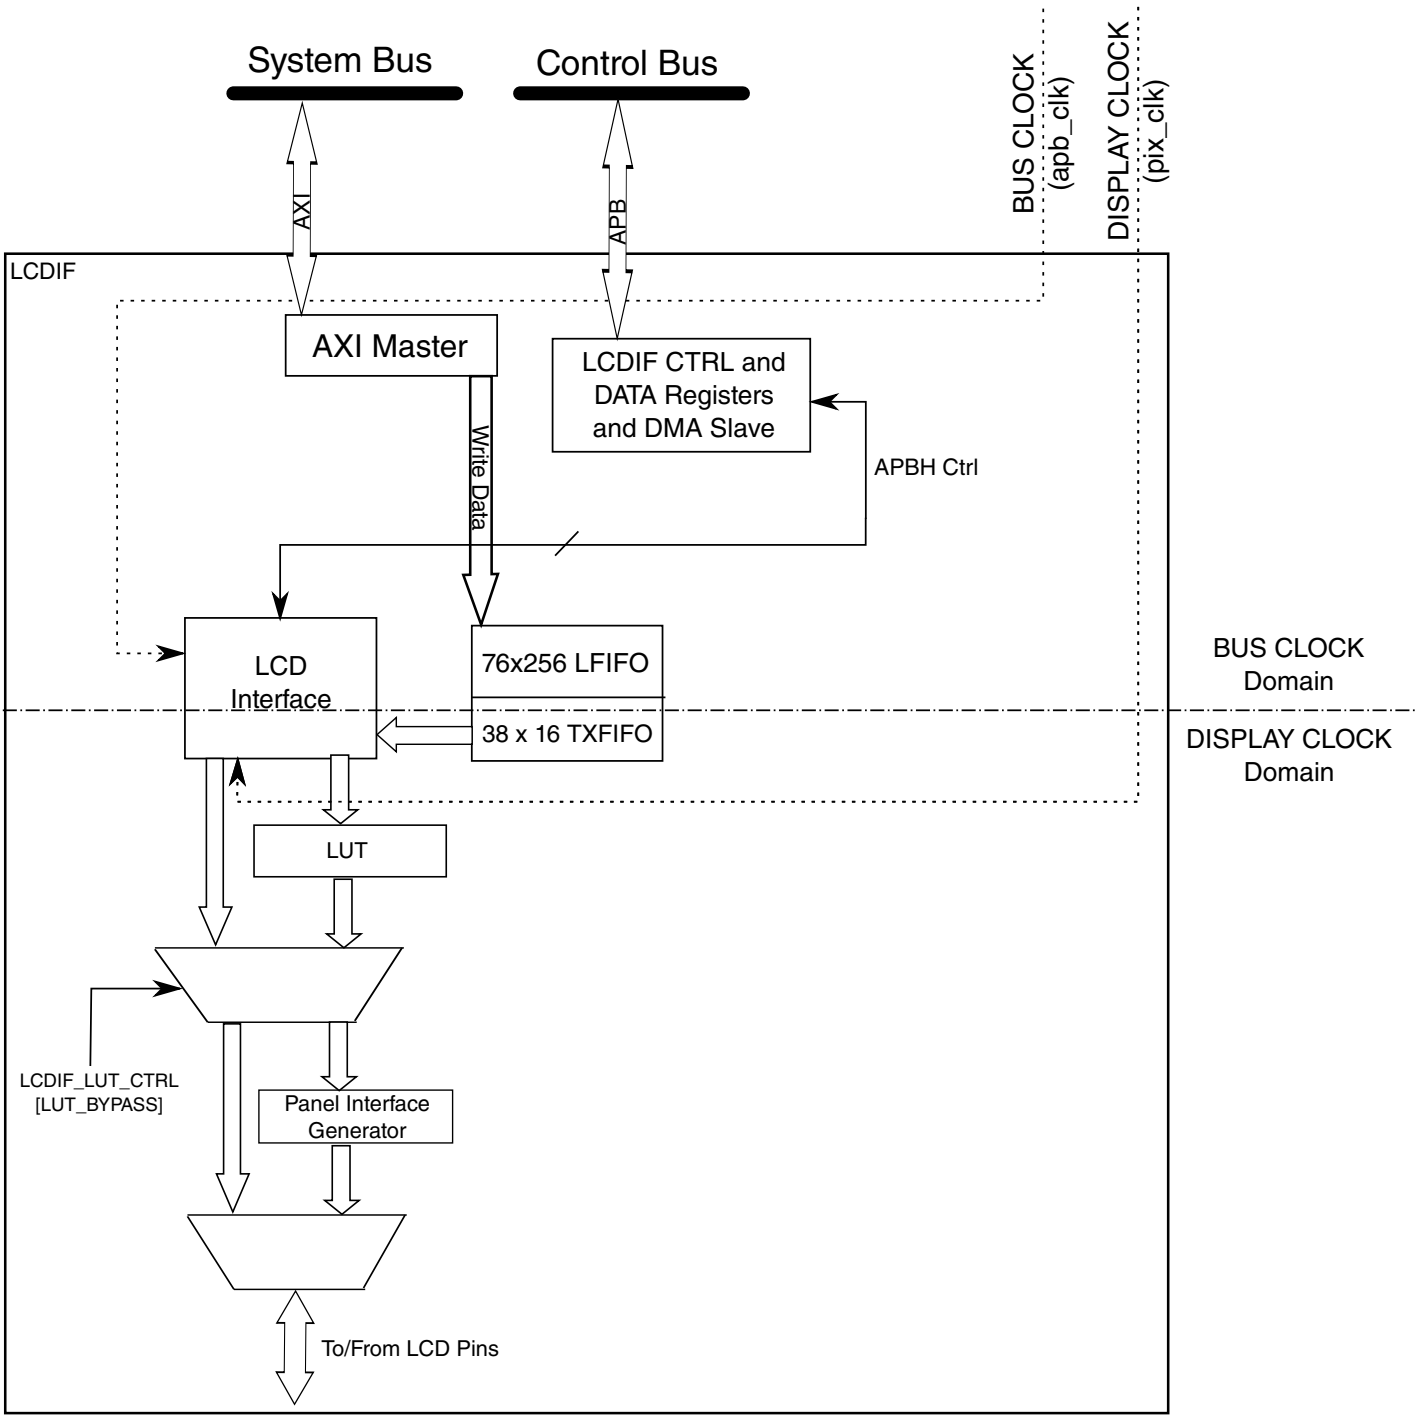

Figure 47-1. Top-Level Block Diagram of eLCDIF subsystem

47.2.2 Features

The eLCDIF provides fully programmable functionality to supported interfaces:

- Bus master interface to source frame buffer data for display refresh. This interface can also be used to drive data for "Smart" displays.
- DMA interface to manage data transfers between "Smart" displays and SoC.
- 8/16/18/24 bit LCD data bus support available depending on I/O mux options.
- Programmable timing and parameters for DOTCLK LCD interfaces.

47.3 Functional Description

The sections listed below describe the pipeline for the eLCDIF interface:

- Bus Interface Mechanisms
- Write Data Path
- Initialization

The differences for each modes are described in the sections listed below:

- DOTCLK Interface

LCDIF pin usage by interface mode is described in eLCDIF Pin Usage by Interface Mode.

47.3.1 Bus Interface Mechanisms

The eLCDIF module has memory-mapped control, data and status registers. It provides several interfaces to transfer data between the display and SoC.

The bus master interface is used to initiate the requests to transfer data from external memory to the display. It is completely autonomous, or no CPU intervention is required, to manage the cyclical nature of refreshing standard display types.

The DMA interface requires the SoC integrated APBDMA engine to manage data transfers on behalf of the eLCDIF. APBDMA descriptor chains are created to manage control and data flow between the eLCDIF and external display. This interface is typically used for "Smart" display types that integrate their own frame buffer and control interface. The APBDMA engine is used to reduce the CPU compute requirements to complete the display solution.

The host CPU executes display drivers to manage the display solution. The following sections describe the system bus interface mechanisms.

47.3.1.1 Bus Master Operation in Write/Display Modes

The eLCDIF block has a bus master interface that initiates requests for data to drive the display. The LCDIF_CTRL[MASTER] bit must be set to 1 to enable the bus master interface. Software should program all control registers required to transfer the frame sequence.

The DOTCLK mode is used to refresh the display at the desired refresh rate and resolution, and drive displays that don't integrate a display buffer memory. When the display is refreshed, the eLCDIF will automatically update the LCDIF_CUR_BUF register with the value in LCDIF_NEXT_BUF at the end of current frame and start fetching the next frame from the new address. If the LCDIF_NEXT_BUF register was not updated within a frame refresh cycle, eLCDIF will keep transmitting the last frame until a new value is programmed into that register.

47.3.1.2 System Bus Master Performance

The performance of the eLCDIF block can be controlled by changing the burst length and the outstanding cycle issuing capability depending on the memory bandwidth requirements. Two fields in the LCDIF_CTRL2 register will throttle system memory requests. The LCDIF_CTRL2[OUTSTANDING_REQS] bitfield will control how many requests the eLCDIF can have in flight on any given clock cycle. This should be programmed based on the expected system bus latency for returned read data. Also, the LCDIF_CTRL2[BURST_LEN_8] bit will set the number of 64 bit words requested for each eLCDIF system bus request to either 8 or 16 QWORDS. Generally, 4 outstanding requests of length 16 will provide enough performance to drive any standard display resolution. These configuration bits are intended to change the access pattern of the eLCDIF to optimize system bus throughput when other system masters will contend for system memory resources.

The LCDIF_THRES register can also be used to optimize bus throughput and power consumption.

The features available with the LCDIF_THRES register require support from system clocking and dynamic priority control.

47.3.1.3 DMA Operation in MPU Read Mode

Data can be transferred between an external display and the SoC using the APBDMA interface. This mode is enabled by setting the LCDIF_CTRL[MASTER] bit to 0 and is typically used with "Smart" displays. The APBDMA module executes DMA descriptor chains to process the desired data flow sequence. The data can be either frame buffer data or display control data.

47.3.2 Write Data Path

eLCDIF supports raster based frame buffers and there is no support for tiled buffers.

There are several options to accommodate endianness of display buffers in memory before the data is processed for the external display. The LCDIF_CTRL[INPUT_DATA_SWIZZLE] field provides the following options for data word multiplexing:

```
00 (0): No swizzle (little-endian)
01 (1): Swap bytes 0 and 3, swap bytes 1 and 2 (big-endian)
10 (2): Swap half-words
11 (3): Swap bytes within each half-word
```

The LCDIF_CTRL[WORD_LENGTH] field indicates the input data/pixel format. LCDIF_TRANSFER_COUNT register denotes how much data is contained in each frame. The LCDIF_TRANSFER_COUNT[H_COUNT] field indicates the number of pixels per line and LCDIF_TRANSFER_COUNT[V_COUNT] indicates the total number of lines per frame. The LCDIF_CTRL1[BYTE_PACKING_FORMAT] field can be used to specify which bytes within the 32-bit word are going to be valid. For example, if the entire 32-bit word is valid, LCDIF_CTRL1[BYTE_PACKING_FORMAT] should be set to 0xF, if only lower 3 bytes of each word in the frame buffer are valid, then LCDIF_CTRL1[BYTE_PACKING_FORMAT] should be set to 0x7.

The LCDIF_CTRL[LCD_DATABUS_WIDTH] field suggests the width of the bus going to the display controller. There is an option to source all 32 bits of the input word and transfer it to the output I/O display interface. If the LCDIF_CTRL[LCD_DATABUS_WIDTH] is not the same as LCDIF_CTRL[WORD_LENGTH], eLCDIF will perform RGB to RGB color space conversion. For example, if the input frame has fewer bits per pixel than the display, as in a 16 bpp input frame going to 24 bpp LCD, eLCDIF will pad the MSBs of each color to the LSBs of the same color for each pixel. If the input frame has more bits per pixel than the display, for example, 24 bpp input frame going to 16 bpp LCD, eLCDIF will drop the LSBs of each color channel to convert to the lower color depth. eLCDIF also has the capability to support delta pixel displays by swizzling the R, G and B colors of each pixel in the odd and even lines of the frame separately by programming the

LCDIF_CTRL2[ODD_LINE_PATTERN] and the LCDIF_CTRL2[EVEN_LINE_PATTERN] bit fields. This operation occurs after the RGB-to-RGB color space conversion operation.

The following list shows how the different input/output combinations can be obtained:

- LCDIF_CTRL[WORD_LENGTH]=1 indicates that the input is 8-bit data. Any combination of LCDIF_CTRL1[BYTE_PACKING_FORMAT] is permissible.

  Limitation: LCDIF_TRANSFER_COUNT[H_COUNT] must be a multiple of the sum of BYTE_PACKING_FORMAT [3], BYTE_PACKING_FORMAT [2], BYTE_PACKING_FORMAT [1] and BYTE_PACKING_FORMAT [0]. LCDIF_CTRL[LCD_DATABUS_WIDTH] must be 1, indicating an 8-bit data bus.

- LCDIF_CTRL[WORD_LENGTH]=0 implies the input frame buffer is RGB 16 bits per pixel. LCDIF_CTRL[DATA_FORMAT_16_BIT] field determines the pixels are RGB 555 or RGB 565.

  Limitation: LCDIF_CTRL1[BYTE_PACKING_FORMAT] should be 0x3 or 0xC if there is only one pixel per word. If there are two pixels per word, it should be 0xF and LCDIF_TRANSFER_COUNT[H_COUNT] will be restricted to be a multiple of 2 pixels.

- LCDIF_CTRL[WORD_LENGTH]=2 indicates that input frame buffer is RGB 18 bits per pixel, that is, RGB 666. The valid RGB values can be left-aligned or right-aligned within a 32-bit word. The alignment of the valid 18 bits within a word is indicated by the LCDIF_CTRL[DATA_FORMAT_18_BIT] bit.

  Limitation: LCDIF_CTRL1[BYTE_PACKING_FORMAT] can be 0x7, 0xE or 0xF. Packed pixels are not supported in this case. LCDIF_TRANSFER_COUNT[H_COUNT] can be any number.

- LCDIF_CTRL[WORD_LENGTH]=3 indicates that the input frame-buffer is RGB 24 bits per pixel (RGB 888). If LCDIF_CTRL1[BYTE_PACKING_FORMAT] is 0x7, it indicates that there is only one pixel per 32-bit word and there is no restriction on LCDIF_TRANSFER_COUNT[H_COUNT]. This is also the option that provides 32 bit output depending on the I/O muxing options available. The fourth byte, or bits [31:24], and connected to the I/Os if this muxing is available in the chip package.

  Limitation: If LCDIF_CTRL1[BYTE_PACKING_FORMAT] is 0xF, it indicates that the pixels are packed, that is, there are 4 pixels in 3 words or 12 bytes and LCDIF_TRANSFER_COUNT[H_COUNT] must be a multiple of 4 pixels.

After the RGB to RGB color space conversions, there is one more opportunity to swizzle the data before sending it out to the display or the encoder. This can be done with the LCDIF_CTRL[CSC_DATA_SWIZZLE] field, and it provides the same options as the LCDIF_CTRL[INPUT_DATA_SWIZZLE] register.

Finally, there is an option to shift the output data before sending it out to the display. This is done based on the LCDIF_CTRL[SHIFT_DIR] and LCDIF_CTRL[SHIFT_NUM_BITS] fields.

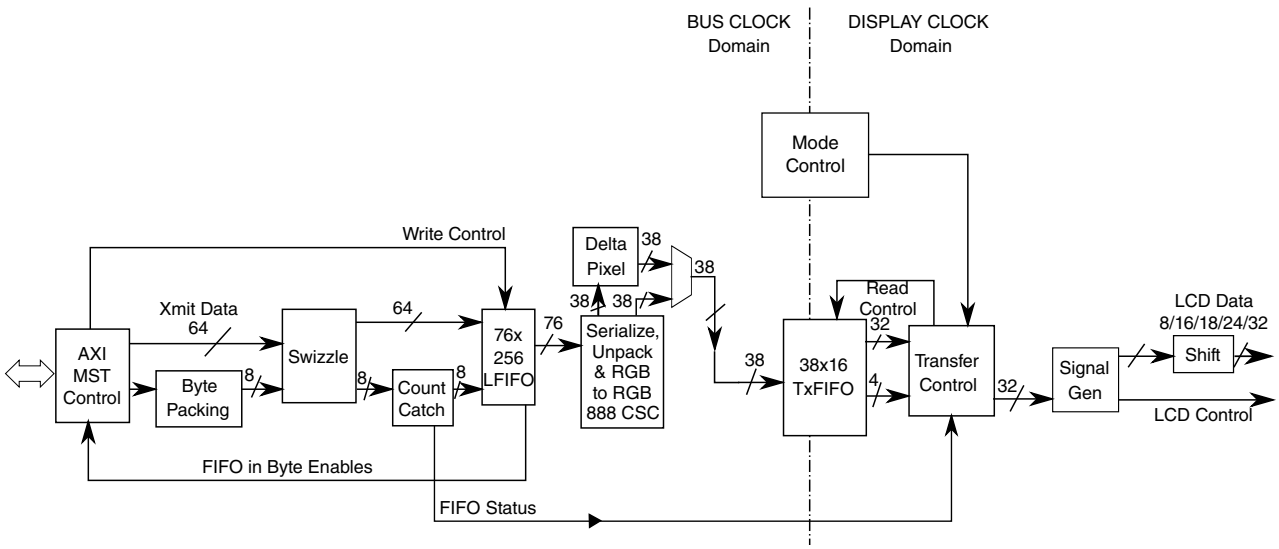

Figure 47-2. General Operations in Write Data Path

The examples in the following figures illustrate some different combinations of register programming for write mode. Assume that the data transferred over the system bus within a 32 bit word is organized as {A7-A0, B7-B0, C7-C0, D7-D0} in 8-bit mode and {A15-A0, B15-B0} in 16-bit mode.

In this example, all 32 bits of the input word are transferred out over an 8 bit display bus. Each byte within the 32 bit word is shifted to the right with zeros appended to bits D[7:6]. The input data bits [7:2] are shifted to the right by 2 bits and presented on the D[5:0].

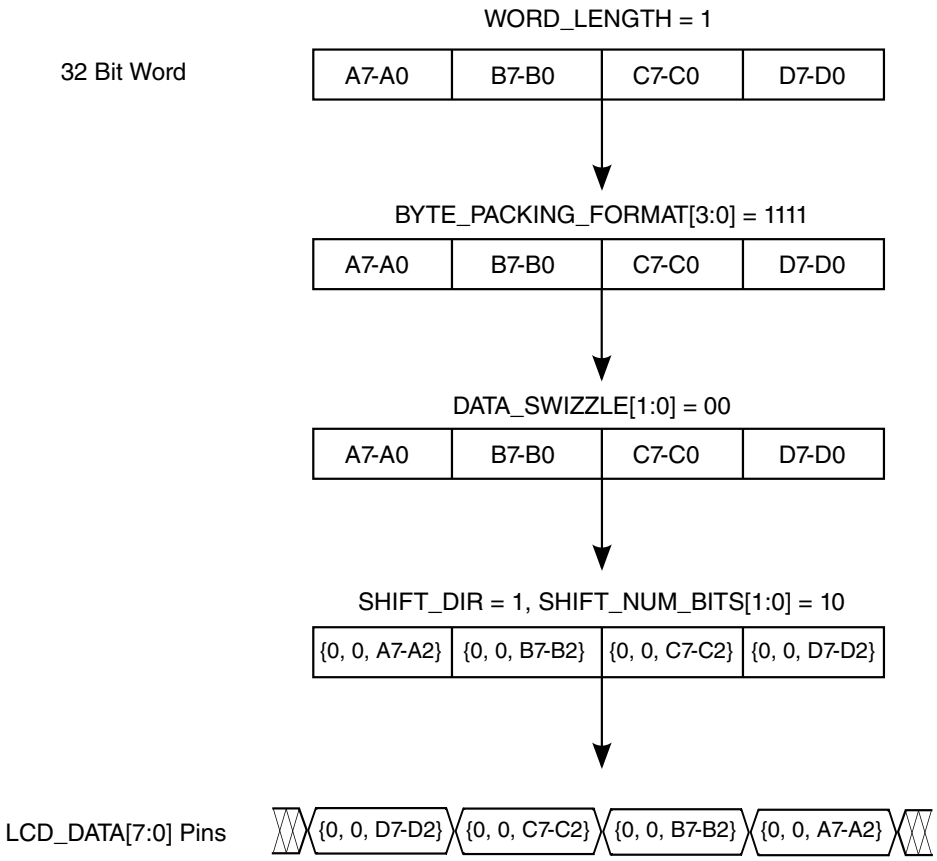

Figure 47-3. Register programming for write mode

In this 8 bit display interface example, one byte of the input word is deleted and not transferred over the external 8 bit display interface. This mode could be used to transfer 24bpp pixels over the 8 bit interface. In this case, the 4th unused byte is not transferred.

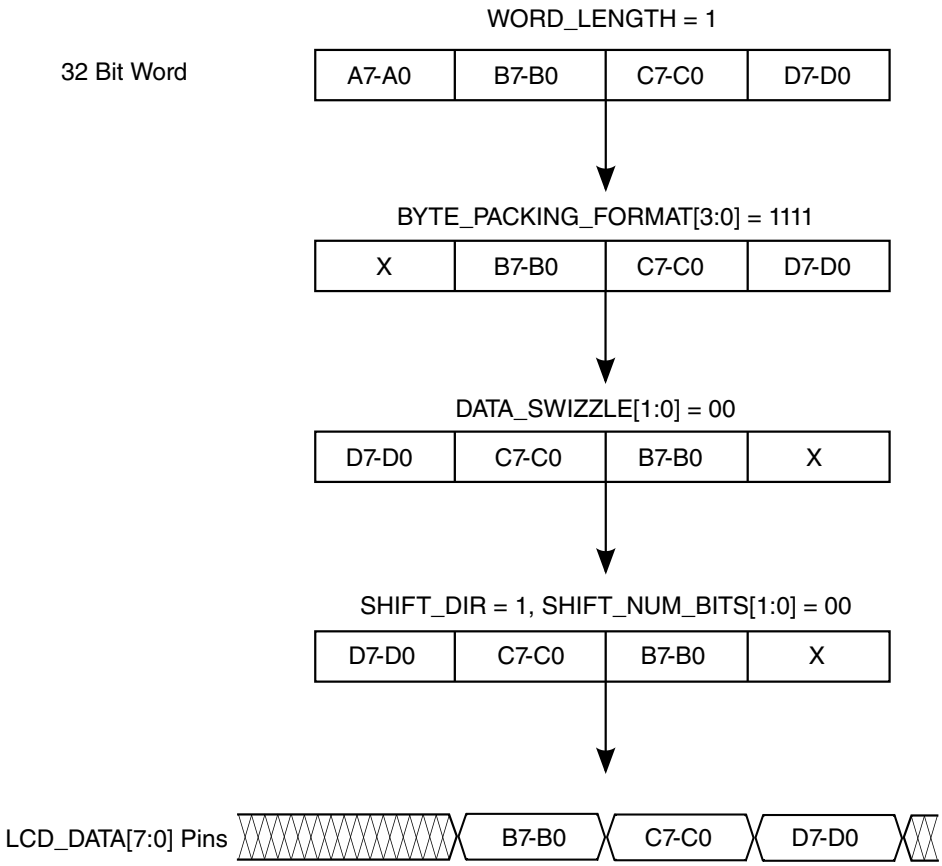

Figure 47-4. Register programming for write mode

The following example uses a 16 bit display interface. Each 16 bit half word is shifted to the right by two bits with zeros appended to the most significant two bits.

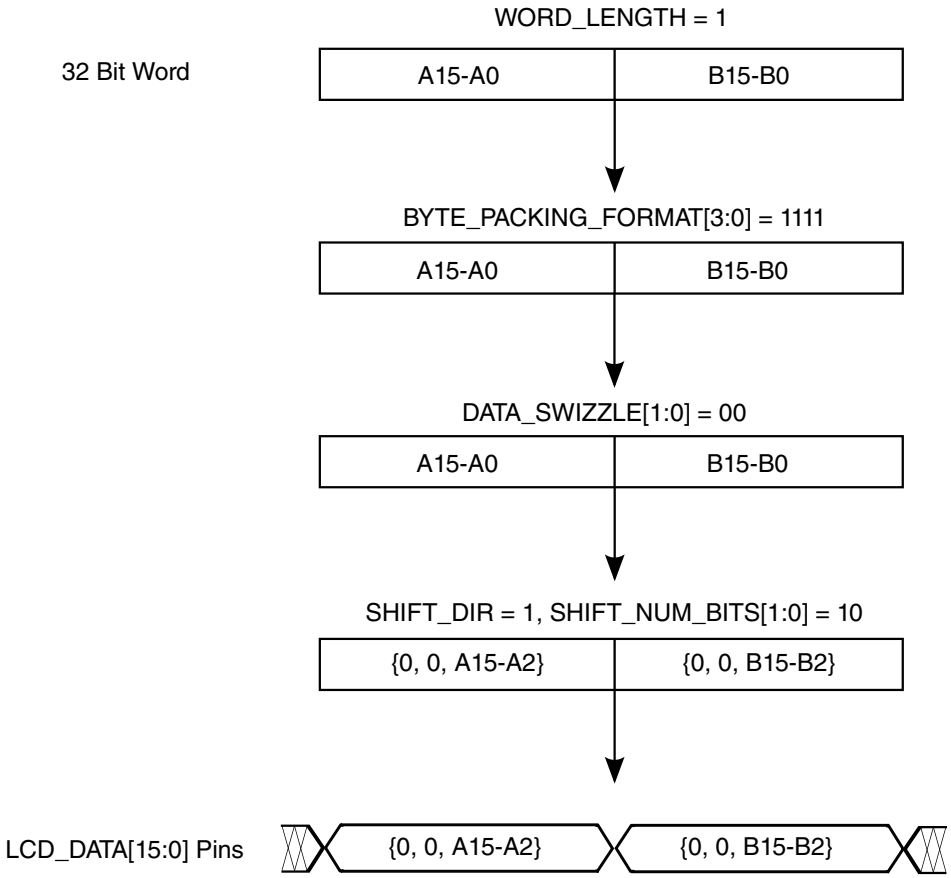

Figure 47-5. Register programming for write mode

This example indicates how an unpacked frame buffer can sourced for display. Only a single 16 bit half word within the 32 bit word is tranferred out via the 16 display bus.

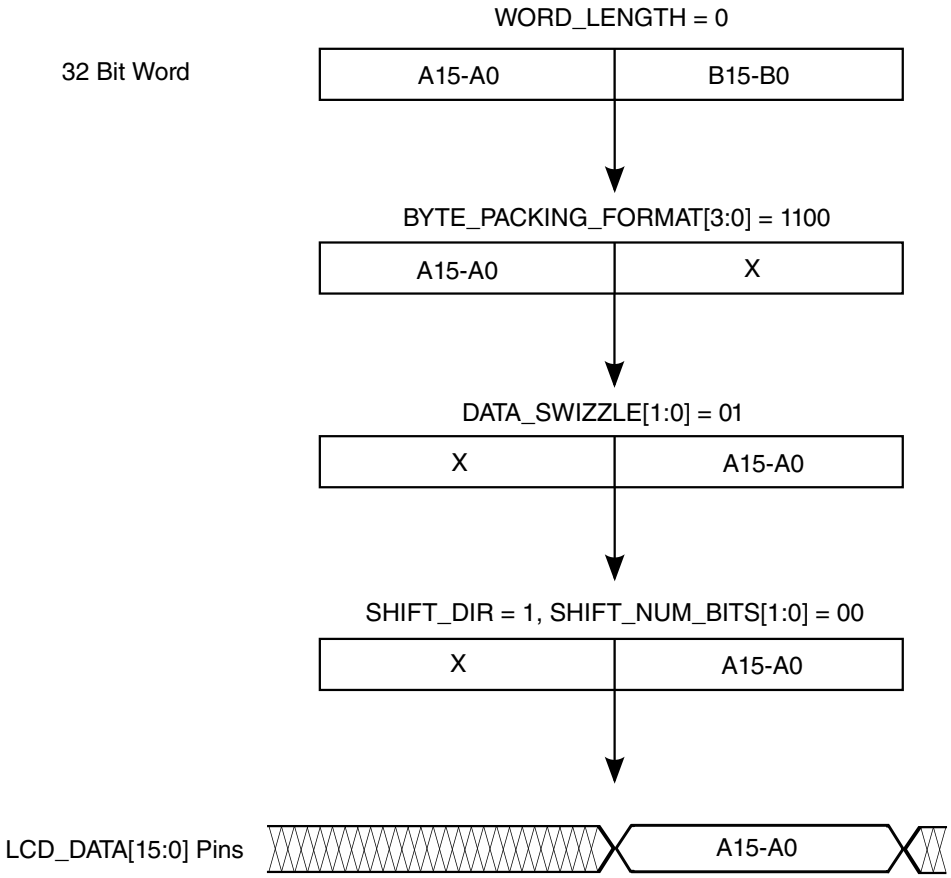

Figure 47-6. Register programming for write mode

47.3.3 DOTCLK Interface

The DOTCLK interface is another mode used in moving picture displays.

It includes the VSYNC, HSYNC, DOTCLK and (optional) ENABLE signals. The interface is popularly called the RGB interface if the ENABLE signal is present.

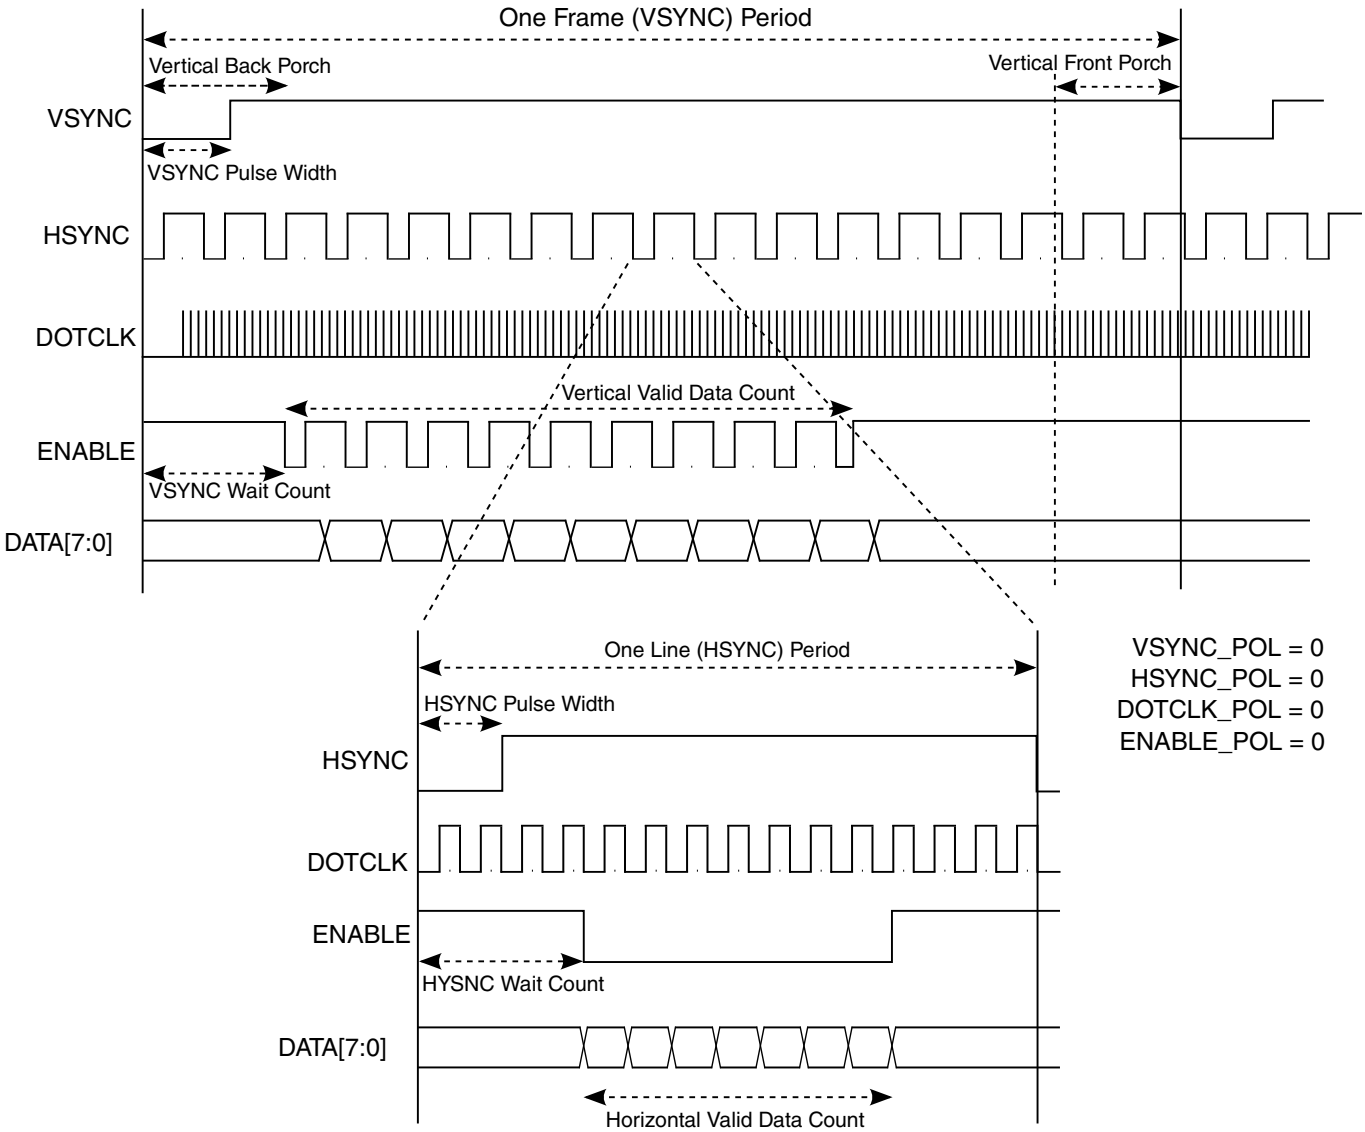

Figure 47-7. DOTCLK protocol with programmable parameters

The DOTCLK mode writes data at high speed to the LCD, and the display operation is synchronized with the VSYNC, HSYNC, ENABLE and DOTCLK signals. The polarities, periods and pulse-widths of the sync signals are programmable using the LCDIF_VDCTRL0-4 registers. The units for the VSYNC signal must be number of horizontal lines and can be selected using the VSYNC_PULSE_WIDTH_UNIT and VSYNC_PERIOD_UNIT bit fields. The VERTICAL_WAIT_CNT is by default given the same unit as the VSYNC_PERIOD. The DISPLAY CLOCK (pix_clk) frequency is managed by the CCM.

In DOTCLK mode, LCDIF_CTRL_BYPASS_COUNT bit must be set to 1. To end the current transfer, the software should make the DOTCLK_MODE bit 0, so that all data that is currently in the LCDIF LFIFO and TXFIFO is transmitted. Once that transfer is complete, the block will automatically clear the RUN bit and issue the cur_frame_done interrupt.

Refer to Write Data Path for more details.

47.3.3.1 Code Example

The following code shows an example for programming a 320x240 display.

NOTE

Setting up the display must be done via SPI.

```
// Note: Common initialization steps in Initialization must also be
// executed along with the following code
BF_CS1 (LCDIF_CTRL, DOTCLK_MODE, 1);
BF_CS1 (LCDIF_CTRL, BYPASS_COUNT, 1); //Always for DOTCLK mode
BF_CS1 (LCDIF_VDCTRL0, VSYNC_OEB, 0); //Vsync is always an output in the DOTCLK mode
BF_CS4 (LCDIF_VDCTRL0, VSYNC_POL, 0, HSYNC_POL, 0, DOTCLK_POL, 0, ENABLE_POL, 0);
BF_CS1 (LCDIF_VDCTRL0, ENABLE_PRESENT, 1);
BF_CS2 (LCDIF_VDCTRL0, VSYNC_PERIOD_UNIT, 1, VSYNC_PULSE_WIDTH_UNIT, 1);
BF_CS1 (LCDIF_VDCTRL0, VSYNC_PULSE_WIDTH, 2);
BF_CS1 (LCDIF_VDCTRL1, VSYNC_PERIOD, 280);
BF_CS2 (LCDIF_VDCTRL2, HSYNC_PULSE_WIDTH, 10, HSYNC_PERIOD, 360); //Assuming
                                                    //  LCD_DATABUS_WIDTH is 24bit
BF_CS2 (LCDIF_VDCTRL3, VSYNC_ONLY, 0);
BF_CS2 (LCDIF_VDCTRL3, HORIZONTAL_WAIT_CNT, 20, VERTICAL_WAIT_CNT, 20);
BF_CS1 (LCDIF_VDCTRL4, DOTCLK_H_VALID_DATA_CNT, 320);//Note that DOTCLK_V_VALID_DATA_CNT is
                                //implicitly assumed to be HW_LCDIF_TRANSFER_COUNT_V_COUNT
BF_CS1 (LCDIF_VDCTRL4, SYNC_SIGNALS_ON, 1);
BF_CS1 (LCDIF_CTRL, RUN, 1);
```

To stop the transfer completely, the ideal way is to make DOTCLK_MODE = 0. In that case, the block will transmit the contents in the FIFO and reset the RUN bit.

47.3.4 LUT

The Lookup Table (LUT) is used to expand the 8 bits pixel to 24 bits pixel before output to external displayer. This module is used when input data from memory is 8-bits in width under limited bandwidth system and external displayer has a 24 bits requirement.

There are two 256x24 bits LUT memory in eLCDIF module in case of changing LUT during active display. When using LUT function, it should be initialized through single PIO register writing first. Writing data to register LCDIF_LUT0_DATA will trigger storing data to lut0 memory and increase the lut0 memory address LCDIF_LUT0_ADDR

automatically. Writing data again to register LCDIF_LUT0_DATA will store the data to memory and increase the memory address accordingly. The same operation is performed while writing to LCDIF_LUT1_DATA and LCDIF_LUT1_ADDR.

After initialization, LCDIF_CUR_BUF_ADDR bit 0 determines which LUT is used during active display.

Lastly, when there is active display, it will use the lowest 8 bits eLCDIF data as LUT address and output the 24 bits from the lookup table.

47.3.5 Panel Interface Generator (Pigeon Mode)

There are several panel interface signal outputs (CLK signal not included), each of them with dedicated timing purpose as default. This is called "Legacy Mode". Pigeon Mode is a timing mode which can be independently enabled on any of the timing signals, with a unified flexible configuration. Signals within pigeon mode can be programmed into any supported signals, and are interchangeable. The following are the legacy timing signals which support pigeon mode:

- PIGEON[00] – LCD_DATA16
- PIGEON[01] – LCD_DATA17
- PIGEON[02] – LCD_DATA18
- PIGEON[03] – LCD_DATA19
- PIGEON[04] – LCD_DATA20
- PIGEON[05] – LCD_DATA21
- PIGEON[06] – LCD_DATA22
- PIGEON[07] – LCD_DATA23
- PIGEON[08] – LCD_ENABLE
- PIGEON[09] – LCD_HSYNC
- PIGEON[10] – LCD_VSYNC
- PIGEON[11] – LCD_CLK

Each pigeon signal has one local counter with a configurable start point and incremental condition. It will be compared to configuration register value for signal assertion/de-assertion control, plus delta offset for data alignment and other options like polarity/logic operation. A detailed running scenario is as follows:

1. Start local counter on the MASK rising edge (reference point/start point)
2. Increment on event selected through INC_SEL
3. Count and match SET_CNT: assert signal, reset counter (SET_CNT==0 means assert immediately on MASK's rising edge)
4. Count and match CLR_CNT: de-assert signal, stop counter (CLR_CNT==0 means de-assert on MASK's falling edge)

NOTE

When local counter is running, further changes to MASK are not cared unless CLR_CNT==0

MASK is the start point for local counter created using a combination any of the options (ANDed) from below:

1. STATE_MASK= (FS|FB|FD|FE) AND (LS|LB|LD|LE)

   In this case you have 8 bits to select in which vertical/horizontal state your counter starts ticking. This is the most common use-case because timing signals generally relate to scan states.

   For example, for a line timing signal start on Line Begin phase during Frame Begin/ Frame Data lines, use the configuration below:

Table 47-2. State Mask Combinations

STATE_MASK	LS	LB=1	LD	LE
FS				
FB=1		X		
FD=1		X		
FE				

2. MASK_CNT/MASK_CNT_SEL (global counter)

   Sometimes a more accurate reference point is required, such as "line 20 in a frame", or "line 12 in Frame Begin state" or "pixel 23 in LD phase". For such use-cases, several Global Counters shared by all pigeons are provided. Global counter type (line counter/frame counter/state counter, etc.) is selected using MASK_CNT_SEL, when global counter matches the MASK_CNT value. The pigeon local counter will start ticking.

3. Use another pigeon signal as mask (SIG_LOGIC=MASK)

   For some tightly coupled signals it is possible to use one as a reference to generate another.

   INC_SEL- select local counter tick event
   a. pclk - pixel clk
   b. line - line start pulse
   c. frame - frame start pulse
   d. another - another pigeon signal

OFFSET- offset on pclk basis: Some signals need to come out slightly earlier or later than programmed. For example, the CE type signal usually aligns with the Line Data phase, but some panels need it as one cycle pulse before Line Data. The user can set OFFSET to a negative value to achieve this.

Global counters (selectable through MASK_CNT_SEL):

- HCNT / VCNT : normal pclk counter / line counter
- HSTATE_CNT / VSTATE_CNT: similar to above, but reset when state changes
- HSTATE_CYCLE / VSTATE_CYCLE: (see figure below for definition of CYCLE/ PERIOD/CNT)

  Some panels have multiple Gate Drivers/Source Drivers, so Frame Data / Line Data state may be further split to match each driver, and signals such as CE[n] are only valid during part n of Line Data. For such signals, use LCDIF_PIGEON_CTRL[*_PERIOD] to specify PERIOD where CNT is reset and CYCLE is included. Then the user can select CYCLE as MASK_CNT to generate mask for CE[n].

- FRAME_CNT / FRAME_CYCLE (only for frame-crossing signals): frame cycle counter doesn't have a reset condition; use LCDIF_PIGEON_CTRL1[FRAME_CNT_CYCLES] to reset it.

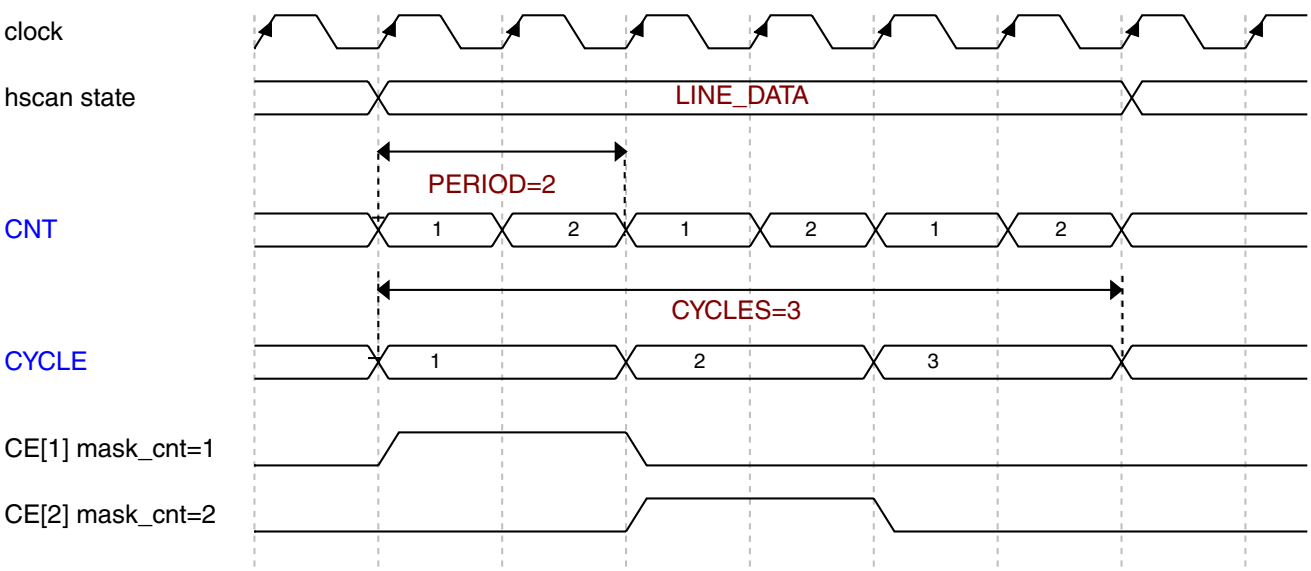

Figure 47-8. Definition of CNT, CYCLE, PERIOD

The following are register settings for the figure above:

- LCDIF_PIGEON_CTRL0[LD_PERIOD]=2
- MASK_CNT_SEL = 1 // HSTATE_CYCLE

- MASK_CNT = 1 // CE[1]
- MASK_CNT = 2 // CE[2]

47.3.6 eLCDIF Pin Usage by Interface Mode

The following tables detail how the eLCDIF level interface pins are used based on the desired mode of operation. The chip level I/Os should also be configured to be consistent with the desired eLCDIF operating mode.

NOTE

There is an option to internally mux the HSYNC, DOTCLK and ENABLE signals in the DOTCLK mode by setting the LCDIF_VDCTRL3[MUX_SYNC_SIGNALS] bit.

Table 47-3. Pin use in DOTCLK Mode

PIN NAME	8-bit DOTCLK LCD IF	16-bit DOTCLK LCD IF	18-bit DOTCLK LCD IF	24-bit DOTCLK LCD IF

47.3.7 CRC Polynomial

The eLCDIF uses the CRC32 polynomial to calculate the data signature. The initial value for the CRC calculation is 0xFFFFFFFF.

$$x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$$

Figure 47-9. Polynomial function for CRC32

The CRC generator uses the XOR-ed combination of the input data bits and the previous result bits.

47.3.8 Clocks

The following table describes the clock sources for eLCDIF. Please see Clock Controller Module (CCM) for clock setting, configuration and gating information.

Table 47-4. Clocks

Clock Name	Description
apb_clk	AXI Clock
pix_clk	Pixel Clock

47.3.9 Reset

The Bus Clock (apb_clk) and Display Clock (pix_clk) must be running before making any changes to LCDIF_CTRL[SFTRST] or LCDIF_CTRL[CLKGATE] bits. A soft reset (SFTRST) can take multiple clock periods to complete, so do not set CLKGATE when setting SFTRST. The reset process gates the clocks automatically.

To reset the eLCDIF module, follow the steps shown below:

1. Ungate the clock by setting LCDIF_CTRL[CLKGATE] =0
2. Set LCDIF_CTRL[SFTRST] =1 to trigger reset
3. Wait until LCDIF_CTRL[CLKGATE] asserts
4. Repeat step 1
5. Set LCDIF_CTRL[SFTRST]= 0 to release reset

47.3.10 Interrupts

The eLCDIF module supports a number of interrupts to aid controlling and status reporting of the block.

All the interrupts have individual mask bits for enabling or disabling each of them. They all get funneled through a single interrupt line connected to the interrupt collector (ICOLL).

The following list describes the different interrupts supported by eLCDIF:

- Underflow interrupt is asserted when the clock domain crossing FIFO (TXFIFO) becomes empty but the block is in active display portion during that time. Software should take corrective action to make sure that this does not happen.

- In the bus master mode, the overflow interrupt will be asserted if the block has requested more data than it's FIFOs could hold.
- Cur_frame_done interrupt occurs at the end of every frame .

47.4 External Signals

The following table describes the external signals of eLCDIF:

Table 47-5. External Signals

Signal	Description	Direction
BUSY	Busy signal	I
DOTCLK	Clock Signal	I
CS	Chip Select signal	O
DATAn	Data signal	I/O
ENABLE	Enable signal	I/O
HSYNC	Horizontal Sync	I
VSYNC	Vertical Sync	I

47.5 Initialization

This section describes write modes.

47.5.1 Write Modes

The following initialization steps are common to all eLCDIF write modes of operation before entering any particular mode.

Initialization steps:

1. Configure the external I/Os to correctly interface the external display, when required.
2. Start the Display Clock (pix_clk) clock and set the appropriate frequency by programming the registers in CCM.
3. Start the Bus Clock (apb_clk) and set the appropriate frequency by programming the registers in CCM.
4. Start the Display Clock (pix_clk) clock and set the appropriate frequency by programming the registers in CCM.
5. Start the Bus Clock (apb_clk) and set the appropriate frequency by programming the registers in CCM.

6. Bring the eLCDIF out of soft reset and disable the clock gate bit.
7. Set the transfer mode of operation to bus master. The LCDIF_CTRL[MASTER] bit determines the transfer mode selected. To select bus master mode, set LCDIF_CTRL[MASTER] =1 (to select APBDMA, set LCDIF_CTRL[MASTER] =0).
8. Set the LCDIF_CTRL[INPUT_DATA_SWIZZLE] according to the endianness of the eLCDIF controller. Also, set the LCDIF_CTRL[DATA_SHIFT_DIR] and LCDIF_CTRL[SHIFT_NUM_BITS] if it is required to shift the data left or right before it is output.
9. Set the LCDIF_CTRL[WORD_LENGTH] field appropriately: 0 = 16-bit input, 1 = 8-bit input, 2 = 18-bit input, 3 = 24/32-bit input. Also, select the correct 16/18/24 bit data format with the corresponding fields in LCDIF_CTRL register.
10. Set the LCDIF_CTRL1[BYTE_PACKING_FORMAT] field according to the input frame.
11. Set the LCDIF_CTRL[LCD_DATABUS_WIDTH] appropriately: 0 = 16-bit output, 1 = 8-bit output, 2 = 18-bit output, 3 = 24/32-bit output.
12. Enable the necessary IRQs.

47.6 eLCDIF Memory Map/Register Definition

Some of the eLCDIF registers (XXX_SET, XXX_CLR, and XXX_TOG) allow direct bit field masking and access.

- When writing 1 to XXX_SET bit fields, these registers allow setting the masked 1 bit fields, while keeping unchanged all bit fields which remain on 0 logic state.
- When writing 1 to XXX_CLR bit fields, these registers allow clearing the masked 1 bit fields, while keeping unchanged all other bit fields which remained on 0 logic state.
- When writing 1 to XXX_TOG bit fields, these registers allow inverting the logic state of all masked 1 bit fields, while they keep unchanged the remaining bit fields which were kept on 0 logic state.

LCDIF Hardware Register Format Summary

47.6.1 LCDIF General Control Register (LCDIF_CTRL*n*)

The LCD Interface Control Register provides overall control of the LCDIF block. The LCDIF Control Register provides a variety of control functions to the programmer. These functions allow the interface to be very flexible to work with a variety of LCD controllers, and to minimize overhead and increase performance of LCD programming. The register has been organized such that switching between the different LCD modes can be done with minimum PIO writes.

Address: 4080_4000h base + 0h offset + (4d × i), where i=0d to 3d

LCDIF_CTRL*n* field descriptions

Field	Description
31 SFTRST	This bit must be set to zero to enable normal operation of the LCDIF. When set to one, it forces a block level reset.
30 CLKGATE	This bit must be set to zero for normal operation. When set to one it gates off the clocks to the block.
29 -	Reserved
28 -	This field is reserved. Reserved

Table continues on the next page...

LCDIF_CTRL*n* field descriptions (continued)

Field	Description
27 - Reserved	This field is reserved.
26 DATA_SHIFT_DIR	Use this bit to determine the direction of shift of transmit data. 0x0 **TXDATA_SHIFT_LEFT** — Data to be transmitted is shifted LEFT by SHIFT_NUM_BITS bits. 0x1 **TXDATA_SHIFT_RIGHT** — Data to be transmitted is shifted RIGHT by SHIFT_NUM_BITS bits.
25–21 SHIFT_NUM_BITS	The data to be transmitted is shifted left or right by this number of bits.
20 - Reserved	This field is reserved.
19 BYPASS_COUNT	When this bit is 0, it means that LCDIF will stop the block operation and turn off the RUN bit after the amount of data indicated by the LCDIF_TRANSFER_COUNT register has been transferred out. When this bit is set to 1, the block will continue normal operation indefinitely until it is told to stop. This bit must be 0 in MPU and VSYNC modes, and must be 1 in DOTCLK and DVI modes of operation.
18 - Reserved	This field is reserved.
17 DOTCLK_MODE	Set this bit to 1 to make the hardware go into the DOTCLK mode, i.e. VSYNC/HSYNC/DOTCLK/ENABLE interface mode. ENABLE is optional, selected by the ENABLE_PRESENT bit. Toggle this bit from 1 to 0 to make the hardware go out of DOTCLK mode after completing all data transfer and deasserting the RUN bit.
16 - Reserved	This field is reserved.
15–14 INPUT_DATA_SWIZZLE	This field specifies how to swap the bytes fetched by the bus master interface. The swizzle function is independent of the WORD_LENGTH bit. The supported swizzle configurations are: 0x0 **NO_SWAP** — No byte swapping.(Little endian) 0x0 **LITTLE_ENDIAN** — Little Endian byte ordering (same as NO_SWAP). 0x1 **BIG_ENDIAN_SWAP** — Big Endian swap (swap bytes 0,3 and 1,2). 0x1 **SWAP_ALL_BYTES** — Swizzle all bytes, swap bytes 0,3 and 1,2 (aka Big Endian). 0x2 **HWD_SWAP** — Swap half-words. 0x3 **HWD_BYTE_SWAP** — Swap bytes within each half-word.
13–12 CSC_DATA_SWIZZLE	This field specifies how to swap the bytes after the data has been converted into an internal representation of 24 bits per pixel and before it is transmitted over the LCD interface bus. The data is always transmitted with the least significant byte/hword (half word) first after the swizzle takes place. So, INPUT_DATA_SWIZZLE takes place first on the incoming data, and then CSC_DATA_SWIZZLE is applied. The swizzle function is independent of the WORD_LENGTH or the LCD_DATABUS_WIDTH fields. If RGB_TO_YCRCB422_CSC bit is set, the swizzle occurs on the Y, Cb, Cr values. The supported swizzle configurations are: 0x0 **NO_SWAP** — No byte swapping.(Little endian) 0x0 **LITTLE_ENDIAN** — Little Endian byte ordering (same as NO_SWAP). 0x1 **BIG_ENDIAN_SWAP** — Big Endian swap (swap bytes 0,3 and 1,2). 0x1 **SWAP_ALL_BYTES** — Swizzle all bytes, swap bytes 0,3 and 1,2 (aka Big Endian). 0x2 **HWD_SWAP** — Swap half-words. 0x3 **HWD_BYTE_SWAP** — Swap bytes within each half-word.
11–10 LCD_DATABUS_WIDTH	LCD Data bus transfer width. **NOTE:** When LUT enabled, this field should be set to 0x01.

Table continues on the next page...

LCDIF_CTRL*n* field descriptions (continued)

Field	Description
	0x0 **16_BIT** — 16-bit data bus mode. 0x1 **8_BIT** — 8-bit data bus mode. 0x2 **18_BIT** — 18-bit data bus mode. 0x3 **24_BIT** — 24-bit data bus mode.
9–8 WORD_LENGTH	Input data format. 0x0 **16_BIT** — Input data is 16 bits per pixel. 0x1 **8_BIT** — Input data is 8 bits wide. 0x2 **18_BIT** — Input data is 18 bits per pixel. 0x3 **24_BIT** — Input data is 24 bits per pixel.
7 -	This field is reserved. Reserved
6 ENABLE_PXP_ HANDSHAKE	If this bit is set and LCDIF_MASTER bit is set, the LCDIF will act as bus master and the handshake mechanism between LCDIF and PXP will be turned on. If LCDIF_MASTER bit is not set, this bit becomes a don't care.
5 MASTER	Set this bit to make the LCDIF act as a bus master. If this bit is reset, the LCDIF will support APBDMA or PIO mode.
4 RSRVD0	This field is reserved. Reserved bits. Write as 0.
3 DATA_ FORMAT_16_ BIT	When this bit is 1 and WORD_LENGTH = 0, it implies that the 16-bit data is in ARGB555 format. When this bit is 0 and WORD_LENGTH = 0, it implies that the 16-bit data is in RGB565 format. When WORD_LENGTH is not 0, this bit does not care.
2 DATA_ FORMAT_18_ BIT	Used only when WORD_LENGTH = 2, i.e. 18-bit. 0x0 **LOWER_18_BITS_VALID** — Data input to the block is in 18 bpp format, such that lower 18 bits contain RGB 666 and upper 14 bits do not contain any useful data. 0x1 **UPPER_18_BITS_VALID** — Data input to the block is in 18 bpp format, such that upper 18 bits contain RGB 666 and lower 14 bits do not contain any useful data.
1 DATA_ FORMAT_24_ BIT	Used only when WORD_LENGTH = 3, i.e. 24-bit. Note that this applies to both packed and unpacked 24-bit data. 0x0 **ALL_24_BITS_VALID** — Data input to the block is in 24 bpp format, such that all RGB 888 data is contained in 24 bits. 0x1 **DROP_UPPER_2_BITS_PER_BYTE** — Data input to the block is actually RGB 18 bpp, but there is 1 color per byte, hence the upper 2 bits in each byte do not contain any useful data, and should be dropped.
0 RUN	When this bit is set by software, the LCDIF will begin transferring data between the SoC and the display. This bit must remain set until the operation is complete.

47.6.2 LCDIF General Control1 Register (LCDIF_CTRL1*n*)

The LCDIF Control Register provides overall control of the LCDIF block.

The LCDIF Control1 Register provides additional programming to the LCDIF. It implements some bits which are unlikely to change often in a particular application. It also carries interrupt-related bits which are common across more than one mode of operation.

Address: 4080_4000h base + 10h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

LCDIF_CTRL1*n* field descriptions

Field	Description
31 IMAGE_DATA_SELECT	Command Mode MIPI image data select bit. This bit will control MIPI DSI SYS_ADDR[1]. This bit should only be changed when RUN is 0.
30 CS_OUT_SELECT	This bit is CS0/CS1 valid select signals. When set 0x0, LCDIF_CSn0 output valid, and LCSIF_CSn1 will alway output 1. WHne set to 0x1, LCDIF_CSn1 output valid, and LCSIF_CSn0 will alway output 1.
29–28 -	This field is reserved. Reserved bits. Write as 0.
27 -	This field is reserved. Reserved.
26 BM_ERROR_IRQ_EN	This bit is set to enable bus master error interrupt in the LCDIF master mode.
25 BM_ERROR_IRQ	This bit is set to indicate that an interrupt is requested by the LCDIF block. This bit is cleared by software by writing a one to its SCT clear address. This bit will be set when the LCDIF is in master mode and an error response was returned by the slave.

Table continues on the next page...

LCDIF_CTRL1*n* field descriptions (continued)

Field	Description
	0x0 **NO_REQUEST** — No Interrupt Request Pending. 0x1 **REQUEST** — Interrupt Request Pending.
24 RECOVER_ON_ UNDERFLOW	Set this bit to enable the LCDIF block to recover in the next field/frame if there was an underflow in the current field/frame.
23 INTERLACE_ FIELDS	Set this bit if it is required that the LCDIF block fetches odd lines in one field and even lines in the other field. It will work only in LCDIF_MASTER is set to 1.
22 START_ INTERLACE_ FROM_ SECOND_FIELD	The default is to grab the odd lines first and then the even lines. Set this bit if it is required to grab the even lines first and then the odd lines. (Line numbers start from 1, so odd lines are 1,3,5,etc. and even lines are 2,4,6, etc.)
21 FIFO_CLEAR	Set this bit to clear all the data in the latency FIFO (LFIFO), TXFIFO and the RXFIFO.
20 IRQ_ON_ ALTERNATE_ FIELDS	If this bit is set, the LCDIF block will assert the cur_frame_done interrupt only on alternate fields, otherwise it will issue the interrupt on both odd and even field. This bit is mostly relevant if INTERLACE_FIELDS is set.
19–16 BYTE_ PACKING_ FORMAT	This bitfield is used to show which data bytes in a 32-bit word are valid. Default value 0xf indicates that all bytes are valid. For 8-bit transfers, any combination in this bitfield will mean valid data is present in the corresponding bytes. In the 16-bit mode, a 16-bit half-word is valid only if adjacent bits [1:0] or [3:2] or both are 1. A value of 0x0 will mean that none of the bytes are valid and should not be used. For example, set the bit field value to 0x7 if the display data is arranged in the 24-bit unpacked format (A-R-G-B where A value does not have be transmitted).
15 OVERFLOW_ IRQ_EN	This bit is set to enable an overflow interrupt in the TXFIFO in the write mode.
14 UNDERFLOW_ IRQ_EN	This bit is set to enable an underflow interrupt in the TXFIFO in the write mode.
13 CUR_FRAME_ DONE_IRQ_EN	This bit is set to 1 enable an interrupt every time the hardware enters in the vertical blanking state.
12 VSYNC_EDGE_ IRQ_EN	This bit is set to enable an interrupt every time the hardware encounters the leading VSYNC edge in the VSYNC and DOTCLK modes, or the beginning of every field in DVI mode.
11 OVERFLOW_ IRQ	This bit is set to indicate that an interrupt is requested by the LCDIF block. This bit is cleared by software by writing a one to its SCT clear address. A latency FIFO (LFIFO) overflow in the write mode (MPU/VSYNC/DOTCLK/DVI mode) was detected, data samples have been lost. 0x0 **NO_REQUEST** — No Interrupt Request Pending. 0x1 **REQUEST** — Interrupt Request Pending.
10 UNDERFLOW_ IRQ	This bit is set to indicate that an interrupt is requested by the LCDIF block. This bit is cleared by software by writing a one to its SCT clear address. A TXFIFO underflow in the write mode (MPU/VSYNC/DOTCLK/DVI mode) was detected. Could produce an error in the DOTCLK / DVI modes. 0x0 **NO_REQUEST** — No Interrupt Request Pending. 0x1 **REQUEST** — Interrupt Request Pending.

Table continues on the next page...

LCDIF_CTRL1*n* field descriptions (continued)

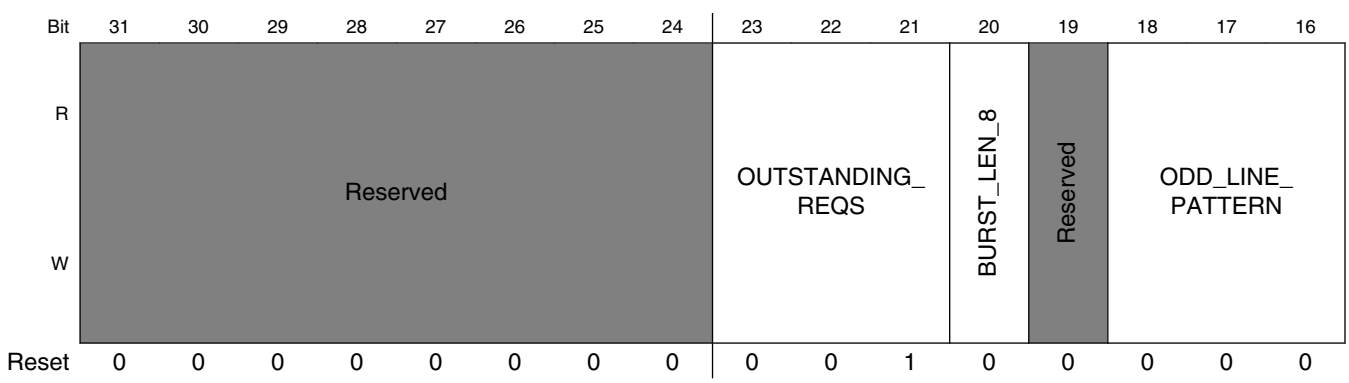
Field	Description
9 CUR_FRAME_DONE_IRQ	This bit is set to indicate that an interrupt is requested by the LCDIF block. This bit is cleared by software by writing a one to its SCT clear address. It indicates that the hardware has completed transmitting the current frame and is in the vertical blanking period in the DOTCLK/DVI modes. In the MPU and VSYNC modes, this IRQ is asserted at the end of the data transfer indicated by LCDIF_TRANSFER_COUNT register. 0x0 **NO_REQUEST** — No Interrupt Request Pending. 0x1 **REQUEST** — Interrupt Request Pending.
8 VSYNC_EDGE_IRQ	This bit is set to indicate that an interrupt is requested by the LCDIF block. This bit is cleared by software by writing a one to its SCT clear address. It is set whenever the leading VSYNC edge is detected in the VSYNC and DOTCLK modes. In the DVI mode, it is asserted every time the block enters a new field. 0x0 **NO_REQUEST** — No Interrupt Request Pending. 0x1 **REQUEST** — Interrupt Request Pending.
7–3 RSRVD0	This field is reserved. Reserved bits. Write as 0.
2 -	This field is reserved. Reserved
1 -	This field is reserved. Reserved.
0 -	This field is reserved. Reserved.

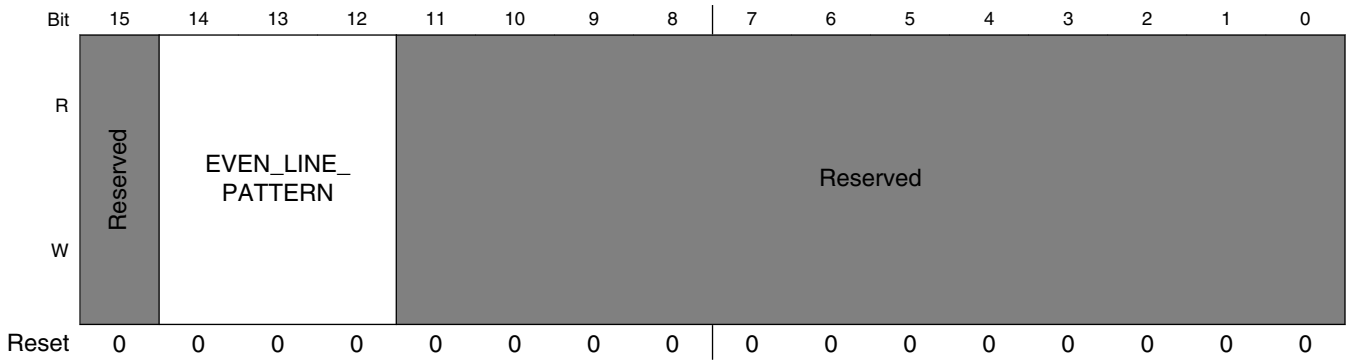
47.6.3 LCDIF General Control2 Register (LCDIF_CTRL2*n*)

The LCDIF Control Register provides overall control of the LCDIF block.

The LCDIF Control2 Register provides additional programming to the LCDIF. It implements some bits which are unlikely to change often in a particular application.

Address: 4080_4000h base + 20h offset + (4d × i), where i=0d to 3d





LCDIF_CTRL2*n* field descriptions

Field	Description
31–24 RSRVD5	This field is reserved. Reserved bits. Write as 0.
23–21 OUTSTANDING_ REQS	This bitfield indicates the maximum number of outstanding transactions that LCDIF should request when it is acting as a bus master. Default is 2 outstanding transactions. 0x0 **REQ_1** — 0x1 **REQ_2** — 0x2 **REQ_4** — 0x3 **REQ_8** — 0x4 **REQ_16** —
20 BURST_LEN_8	By default, when the LCDIF is in the bus master mode, it will issue AXI bursts of length 16 (except when in packed 24 bpp mode, it will issue bursts of length 15). When this bit is set to 1, the block will issue bursts of length 8 (except when in packed 24 bpp mode, it will issue bursts of length 9). Note that this bitfield is only applicable when LCDIF_MASTER is set to 1.
19 RSRVD4	This field is reserved. Reserved bits. Write as 0.
18–16 ODD_LINE_ PATTERN	This field determines the order of the RGB components of each pixel in ODD lines (line numbers 1,3,5,..). 0x0 **RGB** — 0x1 **RBG** — 0x2 **GBR** — 0x3 **GRB** — 0x4 **BRG** — 0x5 **BGR** —
15 RSRVD3	This field is reserved. Reserved bits. Write as 0.
14–12 EVEN_LINE_ PATTERN	This field determines the order of the RGB components of each pixel in EVEN lines (line numbers 2,4,6,..). 0x0 **RGB** — 0x1 **RBG** — 0x2 **GBR** — 0x3 **GRB** — 0x4 **BRG** — 0x5 **BGR** —

Table continues on the next page...

LCDIF_CTRL2*n* field descriptions (continued)

Field	Description
RSRVD0	This field is reserved. Reserved bits. Write as 0.

47.6.4 LCDIF Horizontal and Vertical Valid Data Count Register (LCDIF_TRANSFER_COUNT)

This register tells the LCDIF how much data will be sent for this frame, or transaction. The total number of words is a product of the V_COUNT and H_COUNT fields. The word size is specified by the WORD_LENGTH field.

This register gives the dimensions of the input frame. For normal operation, but V_COUNT and H_COUNT should be non-zero.

Address: 4080_4000h base + 30h offset = 4080_4030h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	V_COUNT																H_COUNT															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LCDIF_TRANSFER_COUNT field descriptions

Field	Description
31–16 V_COUNT	Number of horizontal lines per frame which contain valid data. In DOTCLK mode, V_COUNT should be the same as the number of active horizontal lines in a progressive frame.
H_COUNT	Total valid data (pixels) in each horizontal line. The data size is given by the WORD_LENGTH. In 24-bit packed format (WORD_LENGTH=0x3, BYTE_PACKING_FORMAT=0xF), the H_COUNT must be a multiple of 4 pixels. In 16-bit packed format (WORD_LENGTH=0x0, BYTE_PACKING_FORMAT=0xF), the H_COUNT must be a multiple of 2 pixels.

47.6.5 LCD Interface Current Buffer Address Register (LCDIF_CUR_BUF)

This register indicates the address of the current frame being transmitted by LCDIF.

When the LCDIF is behaving as a master, this address points to the address of the current frame of data being sent out via the LCDIF. When the current frame is done, the LCDIF block will assert the cur_frame_done interrupt for software to take action. The block will also copy the LCDIF_NEXT_BUF_ADDR into this bitfield so that the software can program the next frame address into the LCDIF_NEXT_BUF_ADDR bitfield. This address must always be double-word aligned.

Address: 4080_4000h base + 40h offset = 4080_4040h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	ADDR																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LCDIF_CUR_BUF field descriptions

Field	Description
ADDR	Address of the current frame being transmitted by LCDIF.

47.6.6 LCD Interface Next Buffer Address Register (LCDIF_NEXT_BUF)

This register indicates the address of next frame that will be transmitted by LCDIF.

When the LCDIF is behaving as a master, this address points to the address of the next frame of data that will be sent out via the LCDIF. It is up to the software to make sure that this register is programmed before the end of the current frame, otherwise it might result in old data going out the LCDIF. This address must always be double-word aligned.

Address: 4080_4000h base + 50h offset = 4080_4050h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	ADDR																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LCDIF_NEXT_BUF field descriptions

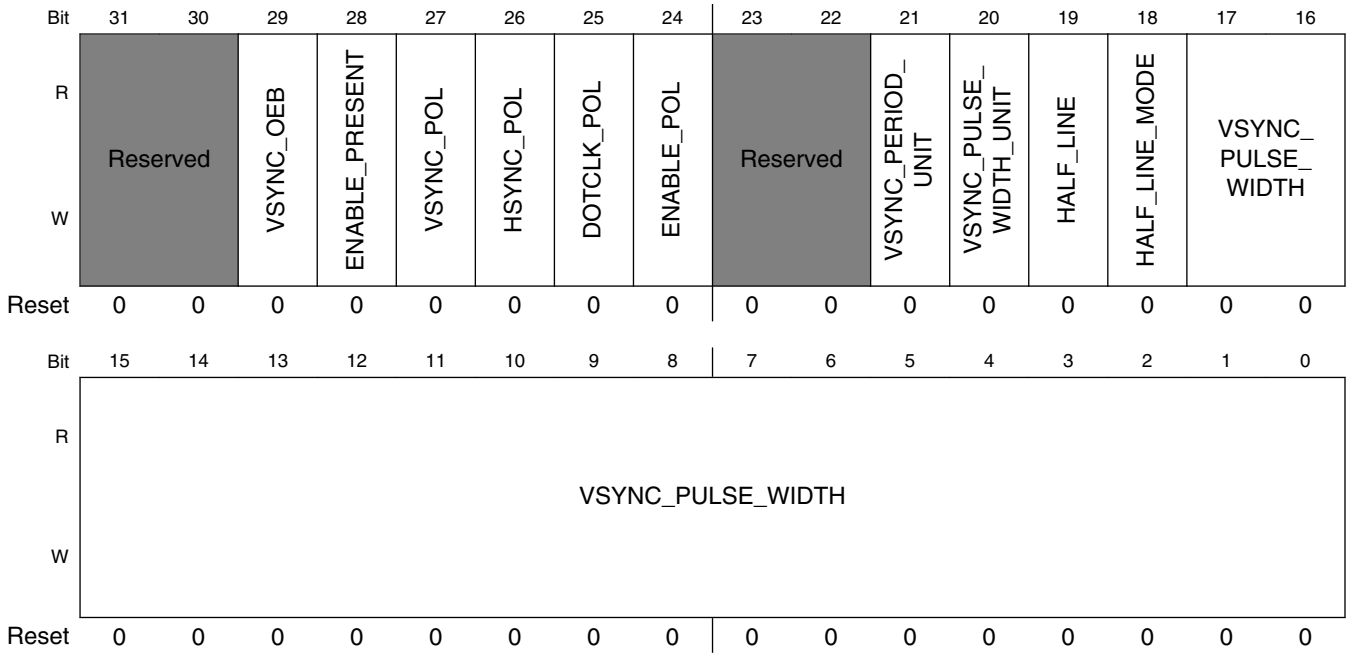
Field	Description
ADDR	Address of the next frame that will be transmitted by LCDIF.

47.6.7 LCDIF VSYNC Mode and Dotclk Mode Control Register0 (LCDIF_VDCTRL0*n*)

This register is used to control the VSYNC and DOTCLK modes of the LCDIF so as to work with different types of LCDs like moving picture displays and delta pixel displays.

This register gives general programmability to the VSYNC signal including polarity, direction, pulse width, etc.

Address: 4080_4000h base + 70h offset + (4d × i), where i=0d to 3d



LCDIF_VDCTRL0*n* field descriptions

Field	Description
31–30 RSRVD2	This field is reserved. Reserved bits. Write as 0.
29 VSYNC_OEB	0 means the VSYNC signal is an output, 1 means it is an input. Should be set to 0 in the DOTCLK mode. 0x0 **VSYNC_OUTPUT** — The VSYNC pin is in the output mode and the VSYNC signal has to be generated by the LCDIF block. 0x1 **VSYNC_INPUT** — The VSYNC pin is in the input mode and the LCD controller sends the VSYNC signal to the block.
28 ENABLE_ PRESENT	Setting this bit to 1 will make the hardware generate the ENABLE signal in the DOTCLK mode, thereby making it the true RGB interface along with the remaining three signals VSYNC, HSYNC and DOTCLK.
27 VSYNC_POL	Default 0 active low during VSYNC_PULSE_WIDTH time and will be high during the rest of the VSYNC period. Set it to 1 to invert the polarity.
26 HSYNC_POL	Default 0 active low during HSYNC_PULSE_WIDTH time and will be high during the rest of the HSYNC period. Set it to 1 to invert the polarity.
25 DOTCLK_POL	Default is data launched at negative edge of DOTCLK and captured at positive edge. Set it to 1 to invert the polarity. Set it to 0 in DVI mode.
24 ENABLE_POL	Default 0 active low during valid data transfer on each horizontal line.
23–22 RSRVD1	This field is reserved. Reserved bits. Write as 0.
21 VSYNC_ PERIOD_UNIT	Default 0 for counting VSYNC_PERIOD in terms of DISPLAY CLOCK (pix_clk) cycles. Set it to 1 to count in terms of complete horizontal lines. DISPLAY CLOCK (pix_clk) cycles should be used in the VSYNC mode, while horizontal line should be used in the DOTCLK mode.
20 VSYNC_PULSE_ WIDTH_UNIT	Default 0 for counting VSYNC_PULSE_WIDTH in terms of DISPLAY CLOCK (pix_clk) cycles. Set it to 1 to count in terms of complete horizontal lines.

Table continues on the next page...

LCDIF_VDCTRL0*n* field descriptions (continued)

Field	Description
19 HALF_LINE	Setting this bit to 1 will make the total VSYNC period equal to the VSYNC_PERIOD field plus half the HORIZONTAL_PERIOD field (i.e. VSYNC_PERIOD field plus half horizontal line), otherwise it is just VSYNC_PERIOD. Should be only used in the DOTCLK mode, not in the VSYNC interface mode.
18 HALF_LINE_ MODE	When this bit is 0, the first field (VSYNC period) will end in half a horizontal line and the second field will begin with half a horizontal line. When this bit is 1, all fields will end with half a horizontal line, and none will begin with half a horizontal line.
VSYNC_PULSE_ WIDTH	Number of units for which VSYNC signal is active. For the DOTCLK mode, the unit is determined by the VSYNC_PULSE_WIDTH_UNIT. If the VSYNC_PULSE_WIDTH_UNIT is 0 for DOTCLK mode, VSYNC_PULSE_WIDTH must be less than HSYNC_PERIOD. For the VSYNC interface mode, it should be in terms of number of DISPLAY CLOCK (pix_clk) cycles only.

47.6.8 LCDIF VSYNC Mode and Dotclk Mode Control Register1 (LCDIF_VDCTRL1)

This register is used to control the VSYNC signal in the VSYNC and DOTCLK modes of the block.

This register determines the period and duty cycle of the VSYNC signal when it is generated in the block.

Address: 4080_4000h base + 80h offset = 4080_4080h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	VSYNC_PERIOD																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LCDIF_VDCTRL1 field descriptions

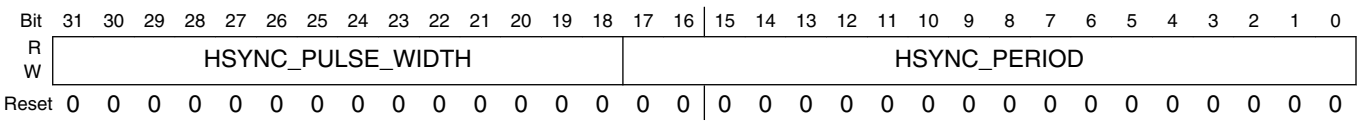
Field	Description
VSYNC_PERIOD	Total number of units between two positive or two negative edges of the VSYNC signal. If HALF_LINE is set, it is implicitly calculated to be VSYNC_PERIOD plus half HSYNC_PERIOD.

47.6.9 LCDIF VSYNC Mode and Dotclk Mode Control Register2 (LCDIF_VDCTRL2)

This register is used to control the HSYNC signal in the DOTCLK mode of the block.

This register determines the period and duty cycle of the HSYNC signal when it is generated in the block.

Address: 4080_4000h base + 90h offset = 4080_4090h



LCDIF_VDCTRL2 field descriptions

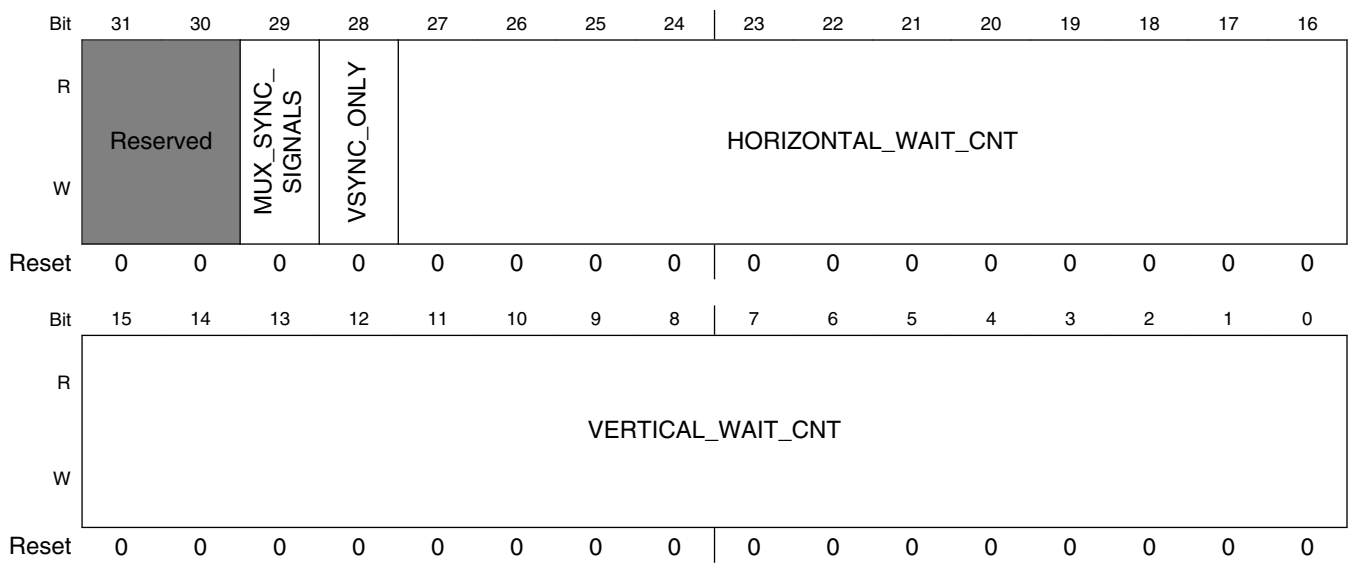
Field	Description
31–18 HSYNC_PULSE_WIDTH	Number of DISPLAY CLOCK (pix_clk) cycles for which HSYNC signal is active.
HSYNC_PERIOD	Total number of DISPLAY CLOCK (pix_clk) cycles between two positive or two negative edges of the HSYNC signal.

47.6.10 LCDIF VSYNC Mode and Dotclk Mode Control Register3 (LCDIF_VDCTRL3)

This register is used to determine the vertical and horizontal wait counts.

This register determines the back porches of HSYNC and VSYNC signals when they are generated by the block.

Address: 4080_4000h base + A0h offset = 4080_40A0h



LCDIF_VDCTRL3 field descriptions

Field	Description
31–30 RSRVD0	This field is reserved. Reserved bits, write as 0.

Table continues on the next page...

LCDIF_VDCTRL3 field descriptions (continued)

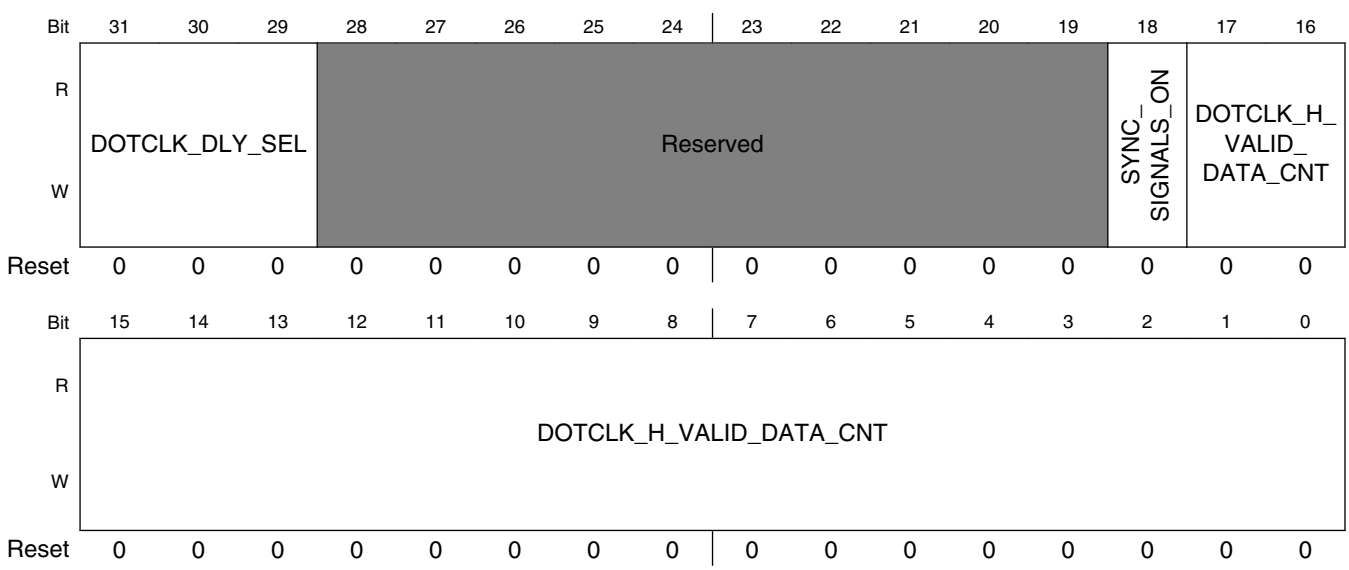
Field	Description
29 MUX_SYNC_ SIGNALS	When this bit is set, the LCDIF block will internally mux HSYNC with LCD_D14, DOTCLK with LCD_D13 and ENABLE with LCD_D12, otherwise these signals will go out on separate pins. This feature can be used to maintain backward compatible with 37xx.
28 VSYNC_ONLY	This bit must be set to 1 in the VSYNC mode of operation, and 0 in the DOTCLK mode of operation.
27–16 HORIZONTAL_ WAIT_CNT	In the DOTCLK mode, wait for this number of clocks from falling edge (or rising if HSYNC_POL is 1) of HSYNC signal to account for horizontal back porch plus the number of DOTCLKs before the moving picture information begins.
VERTICAL_ WAIT_CNT	In the VSYNC interface mode, wait for this number of DISPLAY CLOCK (pix_clk) cycles from the falling VSYNC edge (or rising if VSYNC_POL is 1) before starting LCD transactions and is applicable only if WAIT_FOR_VSYNC_EDGE is set. Minimum is CMD_SETUP+5. In the DOTCLK mode, it accounts for the vertical back porch lines plus the number of horizontal lines before the moving picture begins. The unit for this parameter is inherently the same as the VSYNC_PERIOD_UNIT.

47.6.11 LCDIF VSYNC Mode and Dotclk Mode Control Register4 (LCDIF_VDCTRL4)

This register is used to control the DOTCLK mode of the block.

This register determines the active data in each horizontal line in the DOTCLK mode. Note that the total number of active horizontal lines in the DOTCLK mode is the same as the V_COUNT bitfield in the LCDIF_TRANSFER_COUNT register.

Address: 4080_4000h base + B0h offset = 4080_40B0h



LCDIF_VDCTRL4 field descriptions

Field	Description
31–29 DOTCLK_DLY_SEL	This bitfield selects the amount of time by which the DOTCLK signal should be delayed before coming out of the LCD_DOTCK pin. 0 = 2ns; 1=4ns;2=6ns;3=8ns. Remaining values are reserved.
28–19 RSRVD0	This field is reserved. Reserved bits, write as 0.
18 SYNC_SIGNALS_ON	Set this field to 1 if the LCD controller requires that the VSYNC or VSYNC/HSYNC/DOTCLK control signals should be active at least one frame before the data transfers actually start and remain active at least one frame after the data transfers end. The hardware does not count the number of frames automatically. Rather, the VSYNC edge interrupt can be monitored by software to count the number of frames that have occurred after this bit is set and then the RUN bit can be set to start the data transactions. This bit must always be set in the DOTCLK mode of operation, and it must be set in the VSYNC mode of operation when VSYNC signal is an output.
DOTCLK_H_VALID_DATA_CNT	Total number of DISPLAY CLOCK (pix_clk) cycles on each horizontal line that carry valid data in DOTCLK mode.

47.6.12 Bus Master Error Status Register (LCDIF_BM_ERROR_STAT)

This register reflects the virtual address at which the AXI master received an error response from the slave.

When the BM_ERROR_IRQ is asserted, the address of the bus error is updated in the register.

Address: 4080_4000h base + 190h offset = 4080_4190h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	ADDR																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LCDIF_BM_ERROR_STAT field descriptions

Field	Description
ADDR	Virtual address at which bus master error occurred.

47.6.13 CRC Status Register (LCDIF_CRC_STAT)

This register reflects the CRC value of each frame sent out by LCDIF. The CRC is done on the final output bus, so the value will be dependent on the LCD_DATABUS_WIDTH bitfield even if the input data is the same.

This register will be updated when the CUR_FRAME_DONE_IRQ is asserted.

Address: 4080_4000h base + 1A0h offset = 4080_41A0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	CRC_VALUE																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LCDIF_CRC_STAT field descriptions

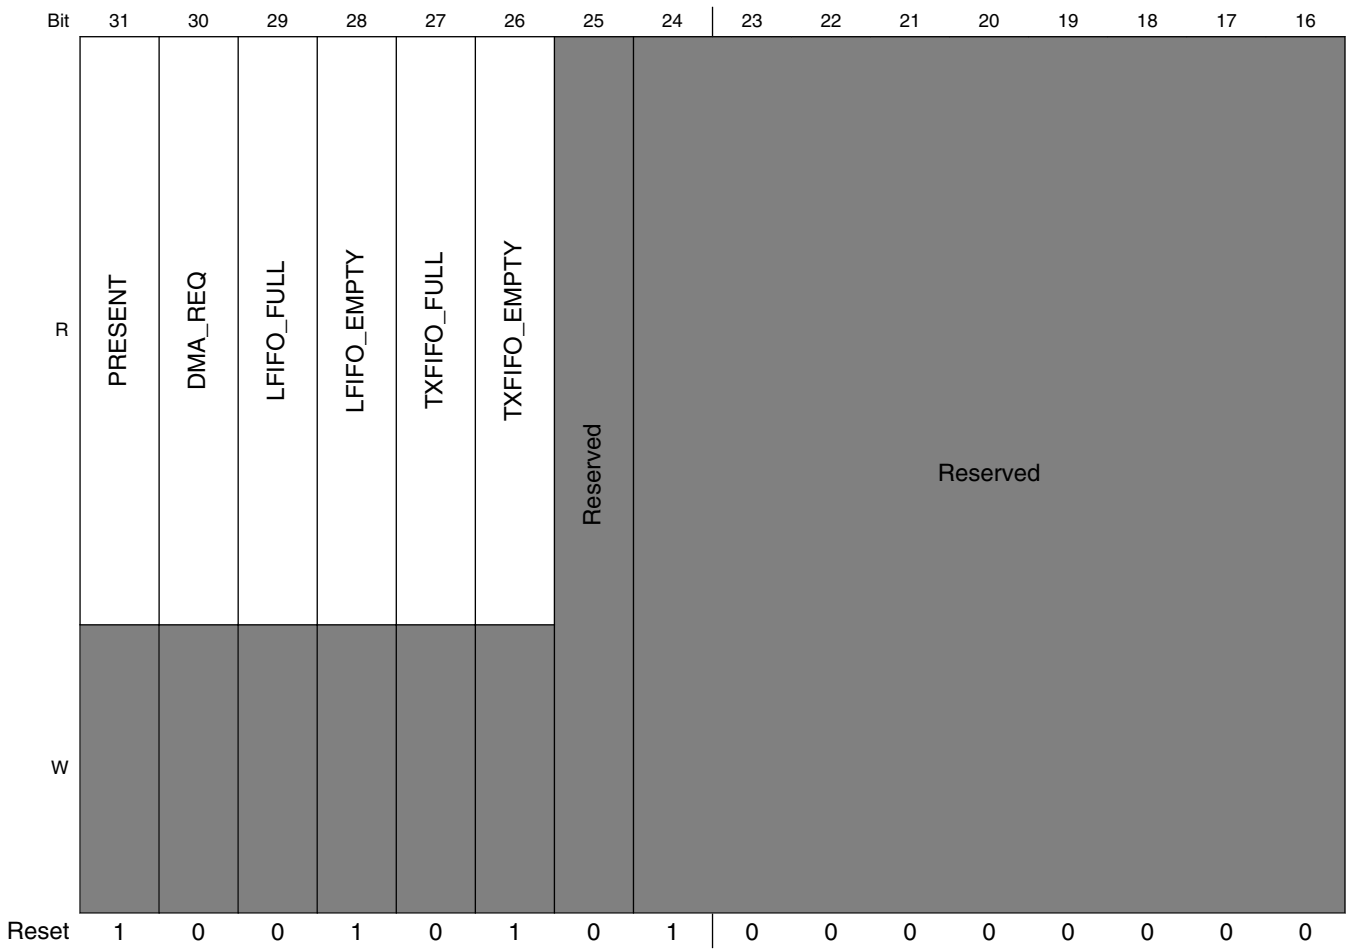
Field	Description
CRC_VALUE	Calculated CRC value. Display output valid data will be calculated by CRC32 and updated during each frame. Refer to CRC Polynomial for details.

47.6.14 LCD Interface Status Register (LCDIF_STAT)

The LCD interface status register can be used to check the current status of the LCDIF block.

The LCD interface status register that contains read only views of some parameters or current state of the block.

Address: 4080_4000h base + 1B0h offset = 4080_41B0h



LCDIF_STAT field descriptions

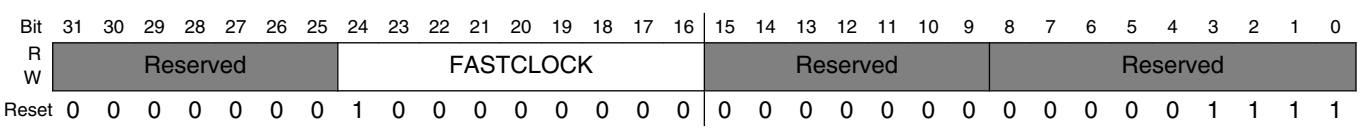
Field	Description
31 PRESENT	0: LCDIF not present on this product 1: LCDIF is present.
30 DMA_REQ	Reflects the current state of the DMA Request line for the LCDIF. The DMA Request line toggles for each new request.
29 LFIFO_FULL	Read only view of the signals that indicates LCD LFIFO is full.
28 LFIFO_EMPTY	Read only view of the signals that indicates LCD LFIFO is empty.
27 TXFIFO_FULL	Read only view of the signals that indicates LCD TXFIFO is full.
26 TXFIFO_EMPTY	Read only view of the signals that indicates LCD TXFIFO is empty.
25 -	This field is reserved. Reserved
24–9 RSRVD0	This field is reserved. Reserved bits. Write as 0.
LFIFO_COUNT	Read only view of the current count in Latency buffer (LFIFO).

47.6.15 LCDIF Threshold Register (LCDIF_THRES)

This register is used to activate control signals when the number of pixels reaches the programmed threshold. These control signals, in turn, can be used to manipulate access priority or dynamically change the input clock frequency to meet the required pixel throughput.

Memory request priority threshold register.

Address: 4080_4000h base + 200h offset = 4080_4200h



LCDIF_THRES field descriptions

Field	Description
31–25 RSRVD2	This field is reserved. Reserved bits. Write as 0.
24–16 FASTCLOCK	This value should be set to a value of pixels, from 0 to 511. When the number of pixels in the input pixel FIFO is LESS than this value, the fast clock control output will be raised. This signal can be used to reduce the system bus clock frequency to save power during horizontal or vertical blanking intervals.
15–9 RSRVD1	This field is reserved. Reserved bits. Write as 0.

Table continues on the next page...

LCDIF_THRES field descriptions (continued)

Field	Description
RSRVD	This field is reserved. Reserved bits. Write as 0.

47.6.16 LCDIF Pigeon Mode Control0 Register (LCDIF_PIGEONCTRL0*n*)

This register contains global counter settings for Pigeon Mode also houses general purpose timing adjustment registers

Address: 4080_4000h base + 380h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

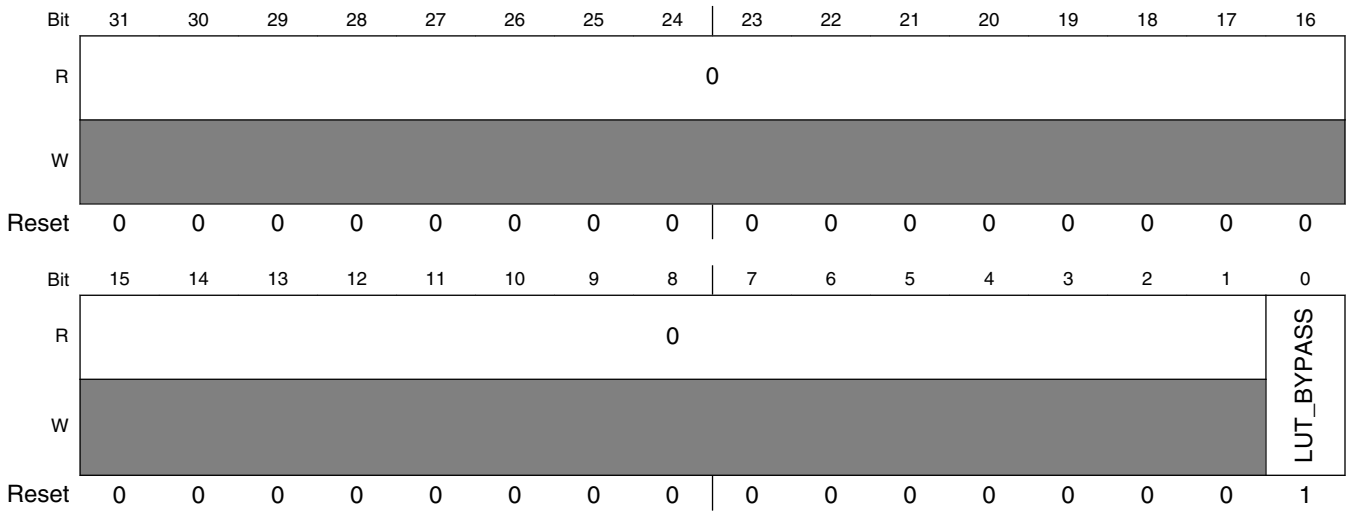
8–4 SIG_ANOTHER	Select another signal for logic operation or as mask or counter tick event 0 **CLEAR_USING_MASK** — Keep active until mask off
SIG_LOGIC	Logic operation with another signal: DIS/AND/OR/COND 0 **DIS** — No logic operation 1 **AND** — sigout = sig_another AND this_sig 2 **OR** — sigout = sig_another OR this_sig 3 **MASK** — mask = sig_another AND other_masks

47.6.22 Look Up Table Control Register (LCDIF_LUT_CTRL)

Address: 4080_4000h base + B00h offset = 4080_4B00h

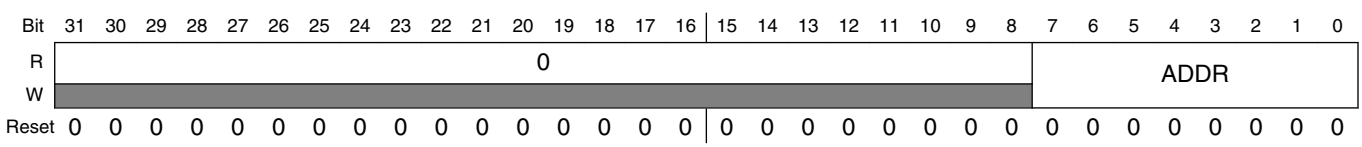


LCDIF_LUT_CTRL field descriptions

Field	Description
31–1 Reserved	This read-only field is reserved and always has the value 0.
0 LUT_BYPASS	Setting this bit will bypass the LUT memory resource completely. No pixel transformations will occur at last stage before output to external displayer.

47.6.23 Lookup Table 0 Index Register (LCDIF_LUT0_ADDR)

Address: 4080_4000h base + B10h offset = 4080_4B10h



LCDIF_LUT0_ADDR field descriptions

Field	Description
31–8 Reserved	This read-only field is reserved and always has the value 0.

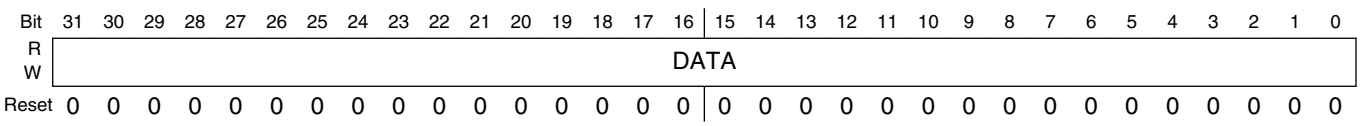
Table continues on the next page...

LCDIF_LUT0_ADDR field descriptions (continued)

Field	Description
ADDR	LUT indexed address pointer. This address into the LUT memory is always four byte aligned for PIO access. The least two significant bits are not used to drive the LUT memory array. For PIO LUT access, when the LUT data register is written, the contents of the LUT at the address specified by this address field will be loaded with a 32-bit DWORD. This address pointer will be incremented after the LUT data is written. This will provide recursive writes to the LUT data register to initialize the entire LUT array with recursive writes to the LUT data register.

47.6.24 Lookup Table 0 Data Register (LCDIF_LUT0_DATA)

Address: 4080_4000h base + B20h offset = 4080_4B20h

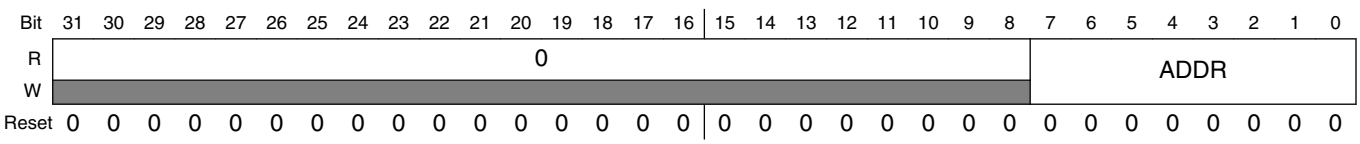


LCDIF_LUT0_DATA field descriptions

Field	Description
DATA	Writing this field will load 4 bytes, aligned to four byte boundaries, of data indexed by the ADDR field of the REG_LUT_CTRL register.

47.6.25 Lookup Table 1 Index Register (LCDIF_LUT1_ADDR)

Address: 4080_4000h base + B30h offset = 4080_4B30h



LCDIF_LUT1_ADDR field descriptions

Field	Description
31–8 Reserved	This read-only field is reserved and always has the value 0.
ADDR	LUT indexed address pointer. This address into the LUT memory is always four byte aligned for PIO access. The least two significant bits are not used to drive the LUT memory array. For PIO LUT access, when the LUT data register is written, the contents of the LUT at the address specified by this address field will be loaded with a 32-bit DWORD. This address pointer will be incremented after the LUT data is

NOTE

Global Alpha Blending is limited to 2-layer Porter-Duff Alpha Blending, but works well with other blending modes.

48.2 Overview

The LCD Interface v2 (LCDIFv2) is a system master that fetches graphics stored in memory and displays them on a TFT LCD panel or connects to a display interface depending on the chip configuration. A wide range of panel sizes are supported and the timing of the interface signals is highly configurable. Graphics are read directly from memory and blended in real-time, which allows for dynamic content creation with minimal CPU intervention. Graphics can be encoded in a variety of formats for optimum memory usage.

48.2.1 Block diagram

The block diagram for LCDIFv2 is shown below:

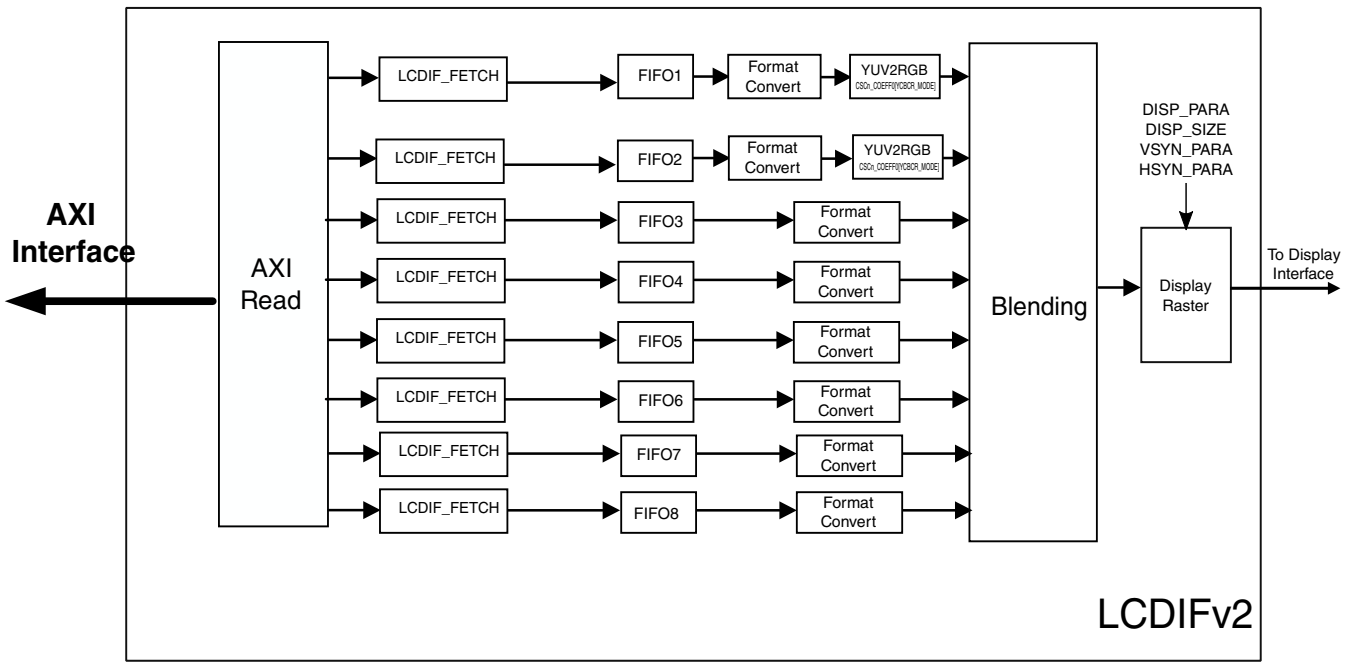

Figure 48-1. LCDIFv2 block diagram

The LCDIFv2 manages the graphical content of the panel through separate registers for each layers. There are 8 layers available in the LCDIFv2 and each can be configured with:

- Horizontal and vertical size of graphic (CTRLDESCLn_1)
- Position of graphic on the panel (CTRLDESCLn_2)
- Address of graphic in memory (CTRLDESCLn_4)
- Color formats or Color palettes, and type of Alpha Blending mode (CTRLDESCLn_5)
- Background colors for each layer if not active (CTRLDESCLn_6)

The values in these registers may be changed at any time, the panel content will be updated automatically in the panel refresh cycle when CTRLDESCLx_5[SHADOW_LOAD_EN] is set. The Alpha Blending Mode can be set as either global/embedded Alpha or Porter Duff mode (For the Porter Duff mode, all the active layers for blending should in the same mode).

NOTE

The Color Space Conversion (CSC) is only supported in Layer1 and Layer2.

48.2.2 Features

The LCDIFv2 includes the following features:

- Support for DOTCLK mode only in display mode
- Display layers can support up to maximum 8 layers of alpha blending:
  - 1 Background (BG) layer for static background image
  - 1 Foreground (FG) layer for video
  - 6 User Interface (UI) layers for the icons, test, moving pointers etc.
  - The UI layers are for small objects which can be stored in OCRAM
  - The index color (1/2/4/8 bpp) support for each layer and lookup with separate Color Look-Up Table (CLUT) memory to 32 bits ARGB pixel
- Each layer supports:
  - Programmable plane size (Width/Height/Pitch) and X/Y offset on the panel
  - Background color for plane graphics
  - Embedded alpha and global alpha
  - Index color (1/2/4/8 bpp)
  - Other layer encoding formats:
    - 16bpp(RGB565)
    - 16bpp(ARGB1555)
    - 16bpp(ARGB4444)
    - YCbCr422(Can support up to two YCbCr layer in blending operation)
    - 24bpp(RGB888)
    - 32bpp(ARGB8888)
    - 32bpp(ABGR8888)
- Support for one parallel camera interface input and the following data formats of CSI-2:
  - 16bpp(YUV422 8-bit)
  - 24bpp(RGB888)
  - 18bpp(RGB666)
  - 16bpp(RGB565)
  - 15bpp(RGB555)
  - 12bpp(RGB444)

48.3 Functional description

The LCDIFv2 is a master on the bus fabric; it fetches graphic source information directly from memory and dynamically performs blending operation before send data to a TFT LCD panel.

As the LCDIFv2 is a master on the NIC, it can access directly any memory or device connected to the NIC as a slave. Therefore, any compatible graphic stored anywhere on-chip can be displayed on the connected TFT LCD panel with no further intervention from CPU.

48.3.1 Graphics and data format

The memory location of the graphic that is displayed on the layer is defined by register in the control descriptor for the layer. This 32-bit value can contain the address of any memory location in the memory map of the system.

The format of the data that describes the graphic is defined by the BPP bit field in the control descriptor for the layer. By choosing an appropriate format, it is possible to optimize the memory required by the graphics in use.

The LCDIFv2 can support the conversion of YUV422 data to RGB888 data on layer 0 and 1. If YCbCr422 input is present, software must change the coefficient registers appropriately, and set the CSC_COEFF0[YCBCR_MODE] bitfield to ensure proper conversion of YUV versus YCBCR data.

The table below indicates the expected coefficients for YUV and YCbCr modes of operation:

Table 48-2. Coefficient Table

Coefficient	YUV	YCbCr
Yoffset	0x000	0x1F0 (-16)
UVoffset	0x000	0x180 (-128)
C0	0x100 (1.00)	0x12A (1.164)
C1	0x123 (1.140)	0x198 (1.596)
C2	0x76B (-0.581)	0x730 (-0.813)
C3	0x79B (-0.394)	0x79C (-0.392)
C4	0x208 (2.032)	0x204 (2.017)

There are six modes where the RGB values of the pixels are stored directly in the graphic. In these modes, the LCDIFv2 treats the data as describing a direct RGB color. The modes are:

- ABGR8888, where the data defines 8-bit values for the blue, green, red, and alpha components of the image.
- ARGB8888, where the data defines 8-bit values for the red, green, blue, and alpha components of the image.
- RGB888, where the data defines 8-bit values for the red, green, and blue components of the image.
- RGB565 where the data defines 5-bit values for the red and blue components, and 6-bit values for the green component of the image.
- ARGB1555 where the data defines 5-bit values for the red, green, and blue components, and a 1-bit value for the alpha component of the image.
- ARGB4444, where the data defines 4-bit values for the red, green, blue, and alpha components of the image.

The three 16-bit formats (RGB565, ARGB1555, and ARGB4444) are promoted to full 8 bit per component format by shifting the bits left so that the MSB of the component in the 16-bit format becomes the MSB of the 24/32 bpp (bit per pixel) format, and the LSB is filled with the value of the MSBs. Please check the table below for different modes:

Table 48-3. Modes

Format	Original	After promoting
RGB565	10000:010000:11011	10000**100**:01000**001**:11011**110**
ARGB4444	1010:0011:1100:0101	1010**1010**:00110011:1100**1100**:0101**0101**
ARGB1555	1:10100:01000:11011	1**1111111**:10100**101**:01000**010**:1101**110**

There are four indexed color formats (1/2/4/8 bpp) where the data in the graphic does not define the RGB color to display. Instead, the data defines the entry in a color look-up table (CLUT) that contains a palette of ARGB colors. The maximum number of colors in the CLUT is defined by the size of the data stored in the graphic. For 1 bpp graphics, there is a maximum of two colors in the CLUT. For 2 bpp, there is a maximum of four colors. For 4 bpp and 8 bpp data, the maximums are 16 and 256 colors.

There is a set storage format for each data format provided by the LCDIFv2. These formats can be seen in the following tables.

Table 48-4. Data Layout for ARGB8888

Address offset	[31:24]	[23:16]	[15:8]	[7:0]	[31:24]	[23:16]	[15:8]	[7:0]
0x00	A1	R1	G1	B1	A0	R0	G0	B0
0x08	A3	R3	G3	B3	A2	R2	G2	B2

In the following table, the YCbCr422 format encodes chroma information across two pixels. Therefore, the chroma values apply to the even pixel denoted in the table and its adjacent odd pixel.

Table 48-5. Data layout for YCbCr422 format

Address offset	[31:24]	[23:16]	[15:8]	[7:0]	[31:24]	[23:16]	[15:8]	[7:0]
0x00	Y3	Cr2	Y2	Cb2	Y1	Cr0	Y0	Cb0
0x08	Y7	Cr6	Y6	Cb6	Y5	Cr4	Y4	Cb4

Table 48-6. Data Layout for 24 bpp

Address offset	[31:24]	[23:16]	[15:8]	[7:0]	[31:24]	[23:16]	[15:8]	[7:0]
0x00	G2	B2	R1	G1	B1	R0	G0	B0
0x08	B5	R4	G4	B4	R3	G3	B3	R2

For 16 bpp, data expected is in the form of RGB565, ARGB1555 or ARGB4444.

The LCDIFv2 includes interrupt status bit that indicates when it has completed fetching graphics from memory for the current frame refresh. If required, this flag (INT_STATUS_Dx[DMA_DONE]) can used to determine when changes can be made to the source graphic content.

48.3.2 Alpha blending modes

This section describes the Alpha blending modes of the LCDIFv2 module.

The below figure shows how the pixel blending takes place inside the LCDIFv2. When there are 8 layers overlap in the FIFOs for a given pixel output, the alpha blending takes place from the FIFO1(layer 0) and FIFO2 (layer 1) first, and then the output result takes alpha blending with FIFO3(layer2), and so on until FIFO8(layer(7)).

Users control the graphical content of the TFT panel by manipulating the configuration of elements in the LCDIFv2 called layers. The LCDIFv2 provides 8 independent layers that all display graphics with fixed blending pipeline, the blending setting on each layer allows the pixels on that layer to be opaque, partially transparent, or fully transparent, which allows them to combine with pixels on other layers that they overlap.

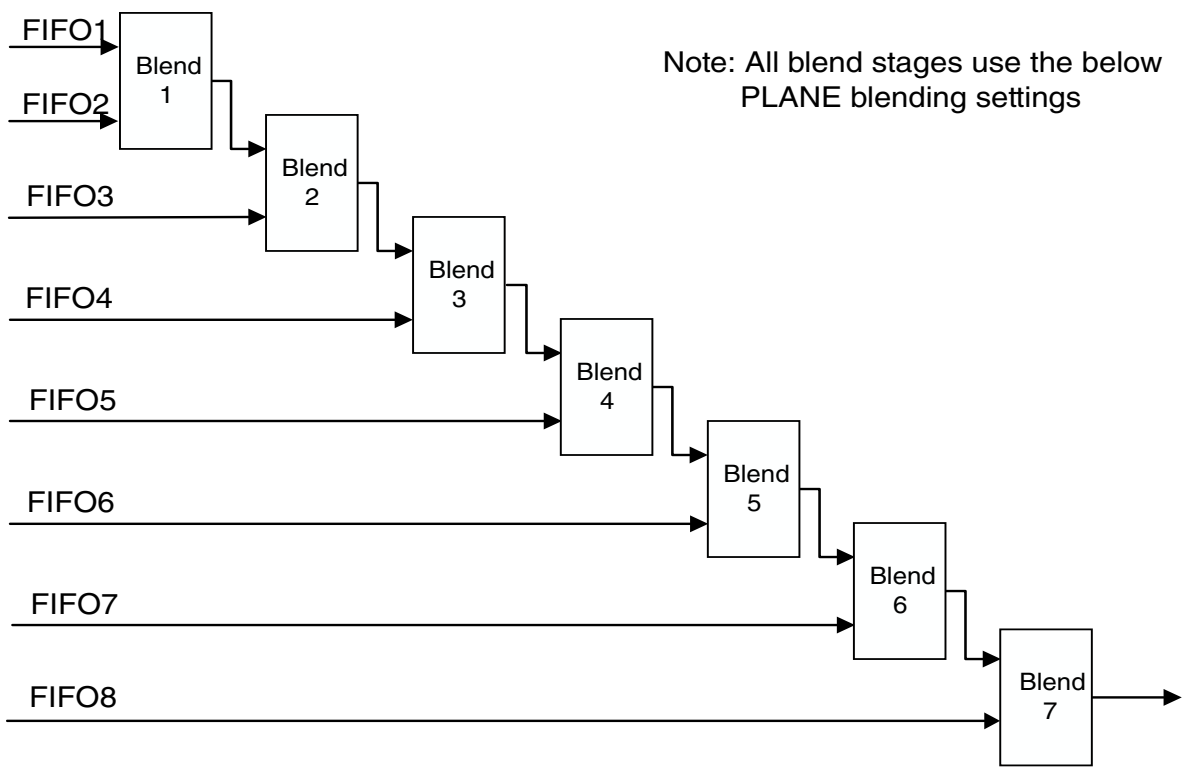

Figure 48-2. Alpha blending diagram

There are two alpha blending modes in LCDIFv2, one is the normal blending mode using single alpha parameter (Embedded Alpha or Global Alpha), another one is the Porter Duff blending mode used in the 2D engine. The Porter Duff blending includes 12 blending modes to describe the digital image composite. These processes include Clear, Source Only, Destination Only, Source Over, Source In, Source Out, Source Atop, Destination Over, Destination In, Destination Out, Destination Atop and XOR. Through these processes, it can achieve any 2D image composite.

The figure below shows the Porter Duff alpha blending flow. All the control bits are included in the CTRLDESCLn_5 register for the layer.

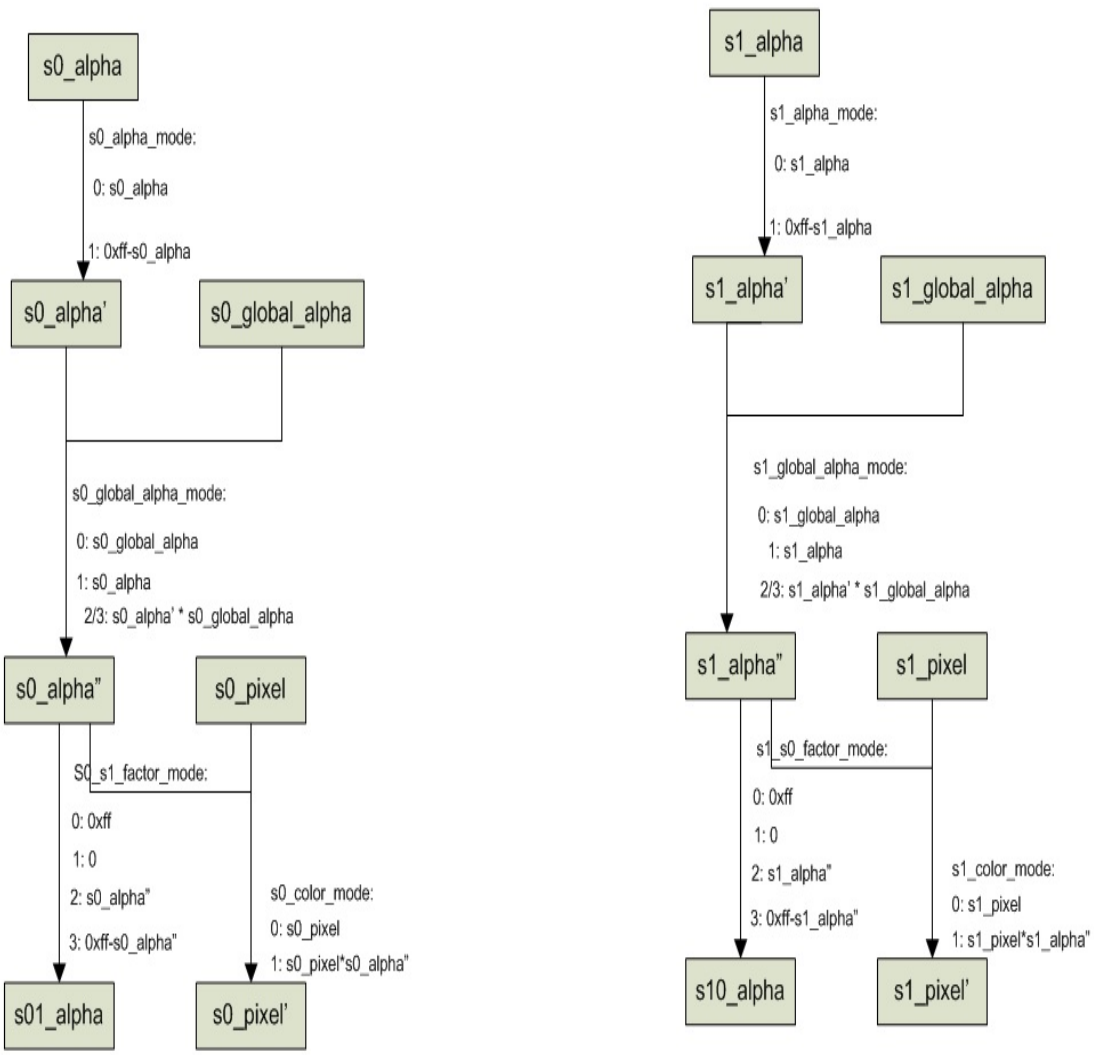

Figure 48-3. Porter Duff Alpha Blending Flow

48.3.3 Clocks

The table below shows the clocks described in this module:

Table 48-15. Clocks

Clocks	Description
pix_clk	Pixel Clock This clock should be configured according to TFT panel specification for supported display resolution
apb_clk	System Bus access clock
b_clk	LCDIFv2 peripheral access bus clock connected to apb_clk

NOTE

There is no frequency restriction between pix_clk and b_clk in the LCDIFv2, but for better performance for multiple layers data fetch, higher b_clk can provide more available bandwidth from system memory to avoid FIFO under-run.

48.3.4 Reset

There is one hardware reset input to LCDIFv2 (reset_b). The reset is asynchronous and forces all internal registers into their reset state when it is active-low.

There is one software reset bit (CTRL[SW_RESET]), which can reset all the internal registers, except the user configured registers.

48.3.5 Interrupts

There are two output interrupt signals (lcdif_d0_irq, and lcdif_d1_irq) in this module. They have similar functions and can be used for different CPU domains in the SOC.

- The INT_ENABLE_Dx[VSYNC] interrupt flag indicates that the LCDIFv2 has begun the next panel refresh period.
- The INT_ENABLE_Dx[UNDERRUN] interrupt flag indicates the TXFIFO for display is in an underrun condition.
- The INT_ENABLE_Dx[VS_BLANK] interrupt flag indicates the start of the vertical blanking period.
- The INT_ENABLE_Dx[FIFO_EMPTY]/INT_ENABLE_Dx[DMA_DONE]/ INT_ENABLE_Dx[DMA_ERR] interrupt flags for each layer indicate the status of pixel FIFO, frame buffer fetch, and AXI interface.

48.4 External Signals

Table 48-16. Signal Descriptions

Signal	Direction	Description
DOTCLK	OUTPUT	Pixel clock used to drive the display panel
VSYNC	OUTPUT	Vertical sync signal, indicating the beginning of a new frame
HSYNC	OUTPUT	Horizontal sync signal, indicating the beginning of a new line
ENABLE	OUTPUT	Data Enable. Indicates when there is valid pixel data
DATA[23:0]	OUTPUT	Red, green and blue data output

48.5 Application information

The figure below shows the details of software flow for the LCDIFv2.

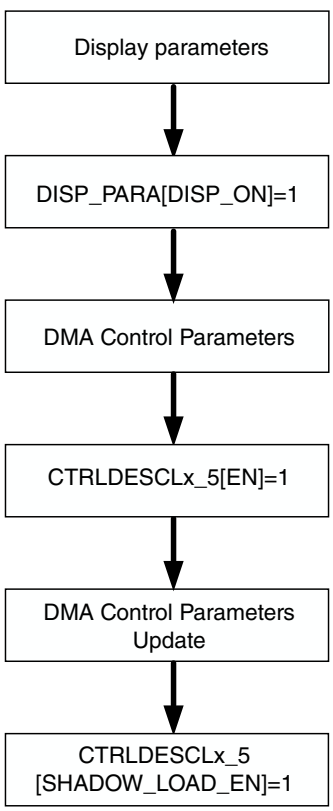

Figure 48-4. Recommended Software flow diagram

48.6 Memory Map and register definition

This section includes the LCDIFv2 module memory map and detailed descriptions of all registers.

48.6.1.2 LCDIFv2 display control Register (CTRL)

48.6.1.2.1 Offset

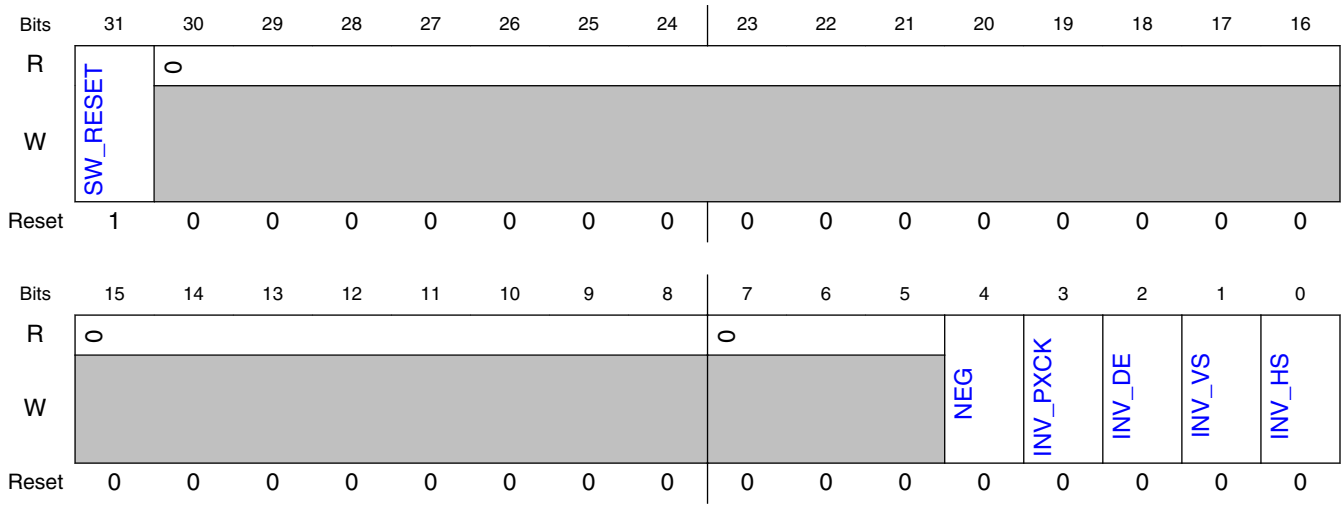
This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
CTRL	0h	LCDIFv2 display control Register
CTRL_SET	4h	Writing 1 to a bit in this register ensures that the corresponding bit in CTRL is 1
CTRL_CLR	8h	Writing 1 to a bit in this register ensures that the corresponding bit in CTRL is 0
CTRL_TOG	Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in CTRL

48.6.1.2.2 Function

This register control the polarity for HSYNC/VSYNC/DE of display

48.6.1.2.3 Diagram



48.6.1.2.4 Fields

Field	Function
31 SW_RESET	Software Reset This bit is high active. If it is set to 1, all logical will be reset. 0b - No action 1b - All LCDIFv2 internal registers are forced into their reset state. User registers are not affected
30-16 —	Reserved
15-8 —	Reserved
7-5 —	Reserved
4 NEG	Indicates if value at the output (pixel data output) needs to be negated 0b - Output is to remain same 1b - Output to be negated
3 INV_PXCK	Polarity change of Pixel Clock 0b - Display samples data on the falling edge 1b - Display samples data on the rising edge
2 INV_DE	Invert Data Enable polarity 0b - Data enable is active high 1b - Data enable is active low
1 INV_VS	Invert Vertical synchronization signal 0b - VSYNC signal not inverted (active HIGH) 1b - Invert VSYNC signal (active LOW)
0 INV_HS	Invert Horizontal synchronization signal 0b - HSYNC signal not inverted (active HIGH) 1b - Invert HSYNC signal (active LOW)

48.6.1.3 Display Parameter Register (DISP_PARA)

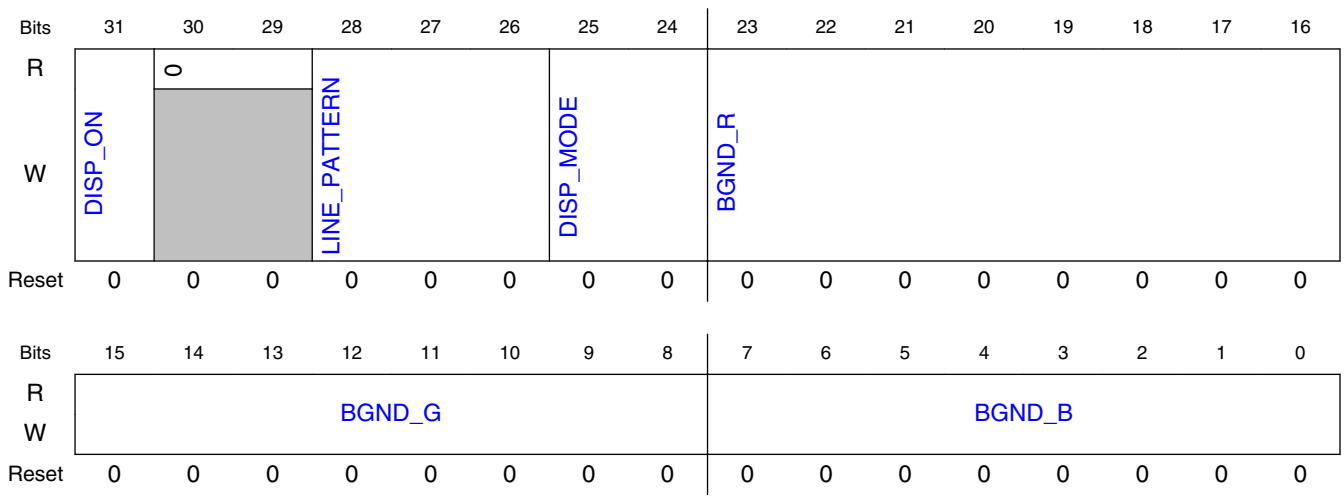
48.6.1.3.1 Offset

Register	Offset
DISP_PARA	10h

48.6.1.3.2 Function

Display Parameter Register

48.6.1.3.3 Diagram



48.6.1.3.4 Fields

Field	Function
31 DISP_ON	Display panel On/Off mode 0b - Display Off 1b - Display On
30-29 —	Reserved
28-26 LINE_PATTERN	LCDIFv2 line output order 000b - RGB 001b - RBG 010b - GBR 011b - GRB

Table continues on the next page...

Field	Function
	100b - BRG 101b - BGR
25-24 DISP_MODE	LCDIFv2 operating mode 00b - Normal mode. Panel content controlled by layer configuration 01b - Test Mode1(BGND Color Display) 10b - Test Mode2(Column Color Bar) 11b - Test Mode3(Row Color Bar)
23-16 BGND_R	Red component of the default color displayed in Test Mode 1.
15-8 BGND_G	Green component of the default color displayed in Test Mode 1.
7-0 BGND_B	Blue component of the default color displayed in Test Mode 1.

48.6.1.4 Display Size Register (DISP_SIZE)

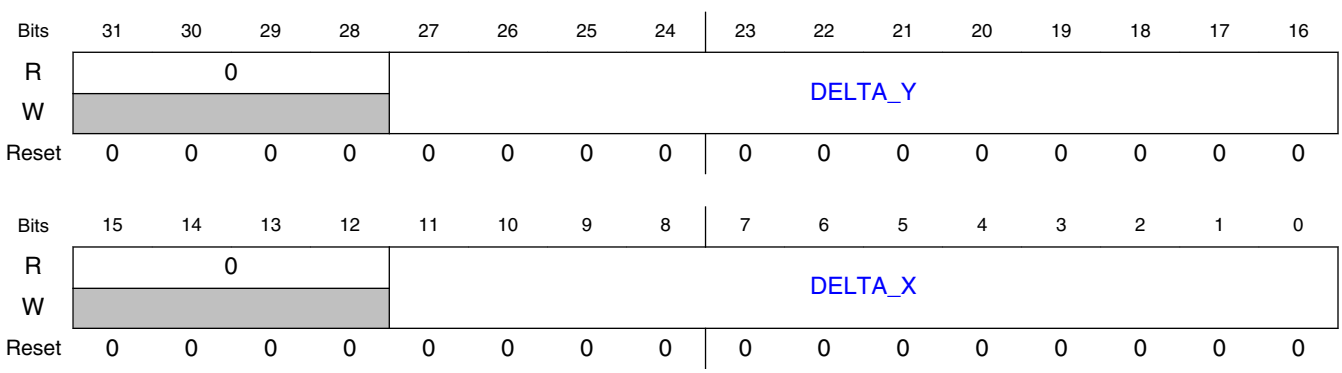
48.6.1.4.1 Offset

Register	Offset
DISP_SIZE	14h

48.6.1.4.2 Function

Display Size Register

48.6.1.4.3 Diagram



48.6.1.4.4 Fields

Field	Function
31-28 —	Reserved
27-16 DELTA_Y	Sets the display size vertical resolution in pixels
15-12 —	Reserved
11-0 DELTA_X	Sets the display size horizontal resolution in pixels

48.6.1.5 Horizontal Sync Parameter Register (HSYN_PARA)

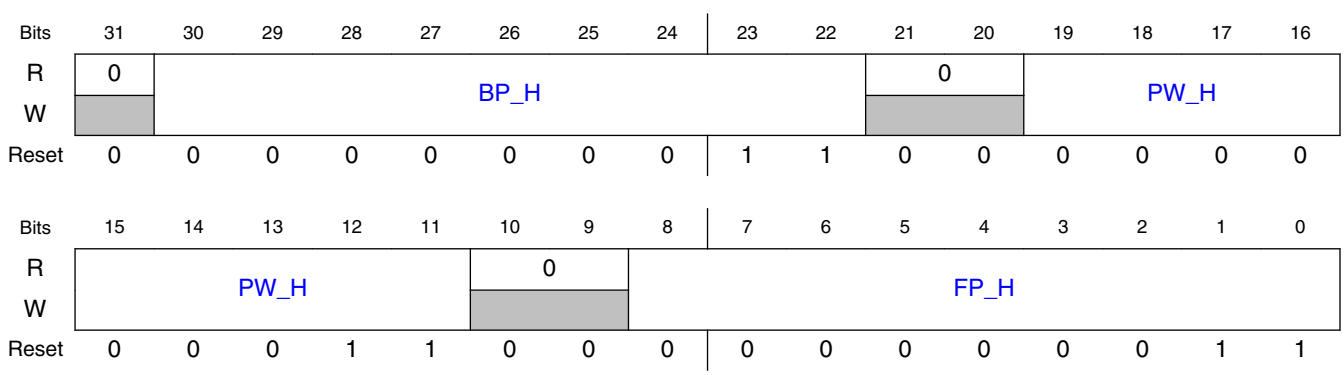
48.6.1.5.1 Offset

Register	Offset
HSYN_PARA	18h

48.6.1.5.2 Function

HSYN_PARA register sets timing parameters related to the horizontal synchronization signal generation for the TFT. The fields FP_H, BP_H, and PW_H stand for HSYNC signal front-porch, back-porch, and active pulse width, respectively

48.6.1.5.3 Diagram



48.6.1.5.4 Fields

Field	Function
31 —	Reserved
30-22 BP_H	HSYNC back-porch pulse width (in pixel clock cycles). Pulse width has a minimum value of 1
21-20 —	Reserved
19-11 PW_H	HSYNC active pulse width (in pixel clock cycles). Pulse width has a minimum value of 1
10-9 —	Reserved
8-0 FP_H	HSYNC front-porch pulse width (in pixel clock cycles). Pulse width has a minimum value of 1

48.6.1.6 Vertical Sync Parameter Register (VSYN_PARA)

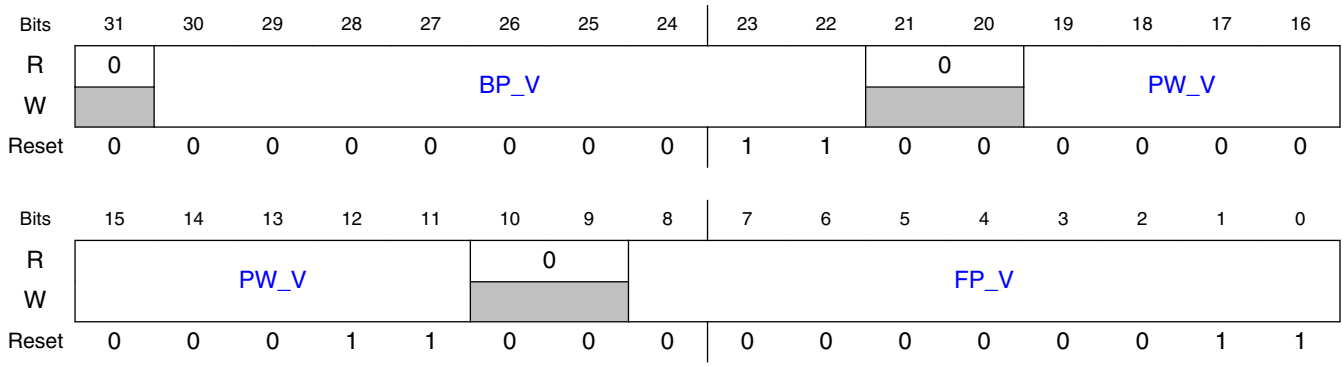
48.6.1.6.1 Offset

Register	Offset
VSYN_PARA	1Ch

48.6.1.6.2 Function

VSYN_PARA register sets timing parameters of the TFT related to the vertical synchronization signal generation. The fields FP_V, BP_V, and PW_V stand for VSYNC signal front-porch, back-porch, and active pulse width, respectively

48.6.1.6.3 Diagram



48.6.1.6.4 Fields

Field	Function
31 —	Reserved
30-22 BP_V	VSYNC back-porch pulse width (in horizontal line cycles). Pulse width has a minimum value of 1
21-20 —	Reserved
19-11 PW_V	VSYNC active pulse width (in horizontal line cycles). Pulse width has a minimum value of 1
10-9 —	Reserved
8-0 FP_V	VSYNC front-porch pulse width (in horizontal line cycles). Pulse width has a minimum value of 1

48.6.1.7 Interrupt Status Register for domain 0 (INT_STATUS_D0)

48.6.1.7.1 Offset

Register	Offset
INT_STATUS_D0	20h

48.6.1.7.2 Function

Interrupt Status Register for domain 0

48.6.1.12 Control Descriptor Layer 1 Register (CTRLDESCL0_1 - CTRLDESCL7_1)

48.6.1.12.1 Offset

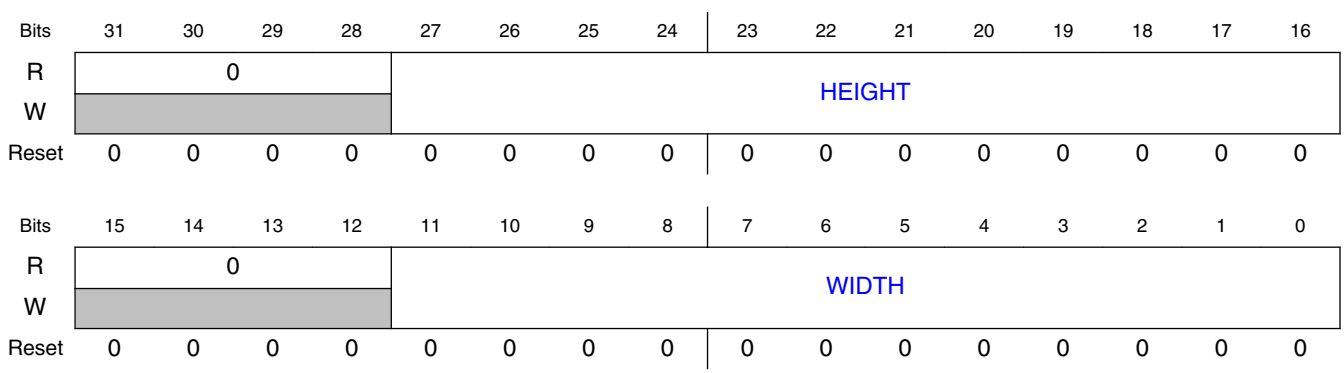
For a = 0 to 7:

Register	Offset
CTRLDESCLa_1	200h + (a × 40h)

48.6.1.12.2 Function

This register sets the height and width of the layer associated with the register

48.6.1.12.3 Diagram



48.6.1.12.4 Fields

Field	Function
31-28 —	Reserved
27-16 HEIGHT	Height of the layer in pixels
15-12 —	Reserved
11-0 WIDTH	Width of the layer in pixels The layer width must be in multiples of the number of pixels that can be stored in 32 bits, and therefore differs depending on color encoding. For example, if 2 bits per pixel format is used, then the layer width must be configured in multiples of 16

48.6.1.13 Control Descriptor Layer 2 Register (CTRLDESCL0_2 - CTRLDESCL7_2)

48.6.1.13.1 Offset

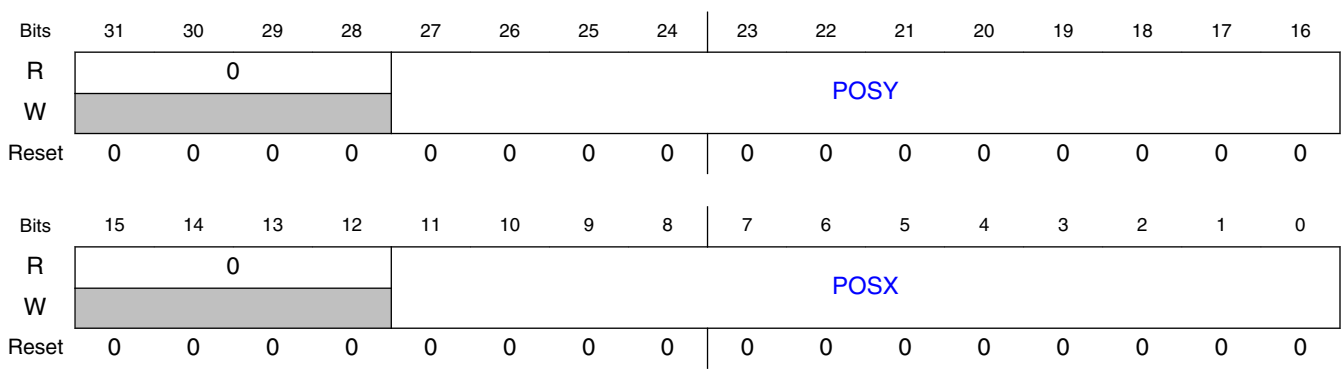
For a = 0 to 7:

Register	Offset
CTRLDESCLa_2	204h + (a × 40h)

48.6.1.13.2 Function

This register sets the origin (top/left) of the layer associated with the register

48.6.1.13.3 Diagram



48.6.1.13.4 Fields

Field	Function
31-28 —	Reserved
27-16 POSY	The vertical position of top row of the layer, where 0 is the top row of the panel, only positive values are below the top row of the panel
15-12 —	Reserved
11-0 POSX	POS X The horizontal position of left-hand column of the layer, where 0 is the left-hand column of the panel, only positive values are to the right the left-hand column of the panel

48.6.1.14 Control Descriptor Layer 3 Register (CTRLDESCL0_3 - CTRLDESCL7_3)

48.6.1.14.1 Offset

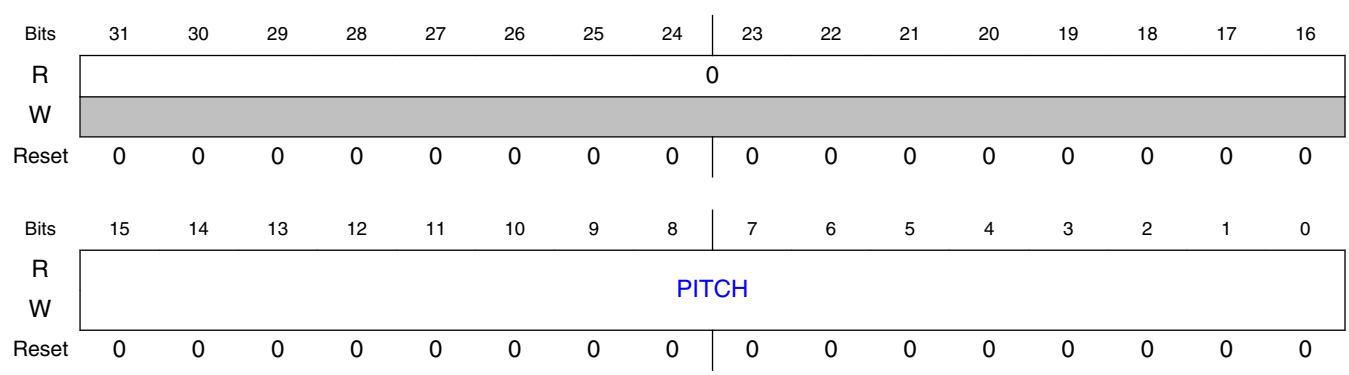
For a = 0 to 7:

Register	Offset
CTRLDESCLa_3	208h + (a × 40h)

48.6.1.14.2 Function

This register sets the buffer line pitch of layer data

48.6.1.14.3 Diagram



48.6.1.14.4 Fields

Field	Function
31-16 —	Reserved
15-0 PITCH	Number of bytes between 2 vertically adjacent pixels in system memory. Byte granularity is supported, but SW should align to 64B boundry

48.6.1.15 Control Descriptor Layer 4 Register (CTRLDESCL0_4 - CTRLDESCL7_4)

48.6.1.15.1 Offset

For a = 0 to 7:

Register	Offset
CTRLDESCLa_4	20Ch + (a × 40h)

48.6.1.15.2 Function

This register sets the beginning address of layer data

48.6.1.15.3 Diagram

48.6.1.15.4 Fields

Field	Function
31-0 ADDR	Address of layer data in the memory. The address programmed should be 64-bit aligned

48.6.1.16 Control Descriptor Layer 5 Register (CTRLDESCL0_5 - CTRLDESCL7_5)

48.6.1.16.1 Offset

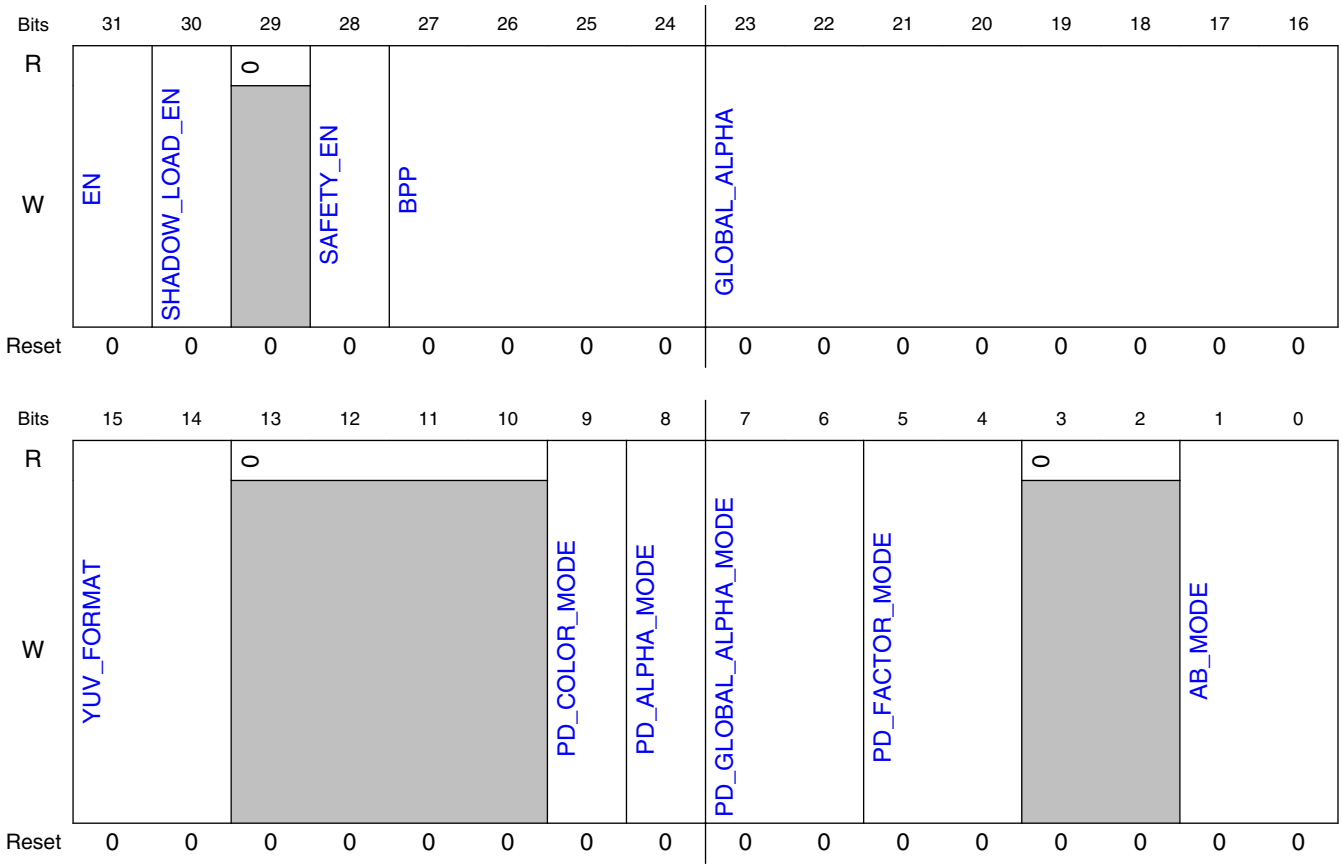
For a = 0 to 7:

Register	Offset
CTRLDESCLa_5	210h + (a × 40h)

48.6.1.16.2 Function

This register controls various graphics options and whether the layer is enabled

48.6.1.16.3 Diagram



48.6.1.16.4 Fields

Field	Function
31 EN	Enable the layer for DMA 0b - OFF 1b - ON
30 SHADOW_LOAD_EN	Shadow Load Enable The SHADOW_LOAD_EN bit is written to 1 by software after all DMA control registers are written. If set to 1, shadowed control registers are updated to the active control registers on VSYNC of next frame. If set to 0, shadowed control registers are not loaded into the active control registers. The previous active control register settings will be used to process the next frame. Hardware will automatically clear this bit, when the shadow registers are loaded to the active control regsisters
29 —	Reserved
28 SAFETY_EN	Safety Mode Enable Bit 0b - Safety Mode is disabled 1b - Safety Mode is enabled for this layer
27-24 BPP	Layer encoding format (bit per pixel) 0000b - 1 bpp 0001b - 2 bpp

Table continues on the next page...

Field	Function
	0010b - 4 bpp 0011b - 8 bpp 0100b - 16 bpp (RGB565) 0101b - 16 bpp (ARGB1555) 0110b - 16 bpp (ARGB4444) 0111b - YCbCr422 (Only layer 0/1 can support this format) 1000b - 24 bpp (RGB888) 1001b - 32 bpp (ARGB8888) 1010b - 32 bpp (ABGR8888)
23-16 GLOBAL_ALPHA	Global Alpha When AB_MODE=01b, this is the legacy global alpha When AB_MODE=11b, this is the global alpha used in Porter Duff function
15-14 YUV_FORMAT	The YUV422 input format selection 00b - The YVYU422 8bit sequence is U1,Y1,V1,Y2 01b - The YVYU422 8bit sequence is V1,Y1,U1,Y2 10b - The YVYU422 8bit sequence is Y1,U1,Y2,V1 11b - The YVYU422 8bit sequence is Y1,V1,Y2,U1
13-10 —	Reserved
9 PD_COLOR_MODE	Porter Duff alpha mode 0b - Straight mode for Porter Duff color 1b - Inversed mode for Porter Duff color
8 PD_ALPHA_MODE	Porter Duff alpha mode 0b - Straight mode for Porter Duff alpha 1b - Inversed mode for Porter Duff alpha
7-6 PD_GLOBAL_ALPHA_MODE	Porter Duff global alpha mode 00b - Using global alpha 01b - Using local alpha 10b - Using scaled alpha 11b - Using scaled alpha
5-4 PD_FACTOR_MODE	Porter Duff factor mode 00b - Using 1 01b - Using 0 10b - Using straight alpha 11b - Using inverse alpha
3-2 —	Reserved
1-0 AB_MODE	Alpha Blending Mode 00b - No alpha Blending (The SAFETY_EN bit need set to 1) 01b - Blend with global ALPHA 10b - Blend with embedded ALPHA 11b - Blend with Porter Duff enable

48.6.1.17 Control Descriptor Layer 6 Register (CTRLDESCL0_6 - CTRLDESCL7_6)

48.6.1.17.1 Offset

For a = 0 to 7:

48.6.1.18 Color Space Conversion Coefficient Register 0 (CSC0_COEF0 - CSC1_COEF0)

48.6.1.18.1 Offset

Register	Offset
CSC0_COEF0	218h
CSC1_COEF0	258h

48.6.1.18.2 Function

The Coefficient 0 register contains coefficients used in the color space conversion algorithm. The Y and UV offsets are added to the source buffer to normalize them before the conversion. C0 is the coefficient that is used to multiply the luma component of the data for all three RGB components

// The equations used for Colorspace conversion are:

// R = C0*(Y+YOFFSET) + C1(V+UV_OFFSET)

// G = C0*(Y+YOFFSET) + C3(U+UV_OFFSET) + C2(V+UV_OFFSET)

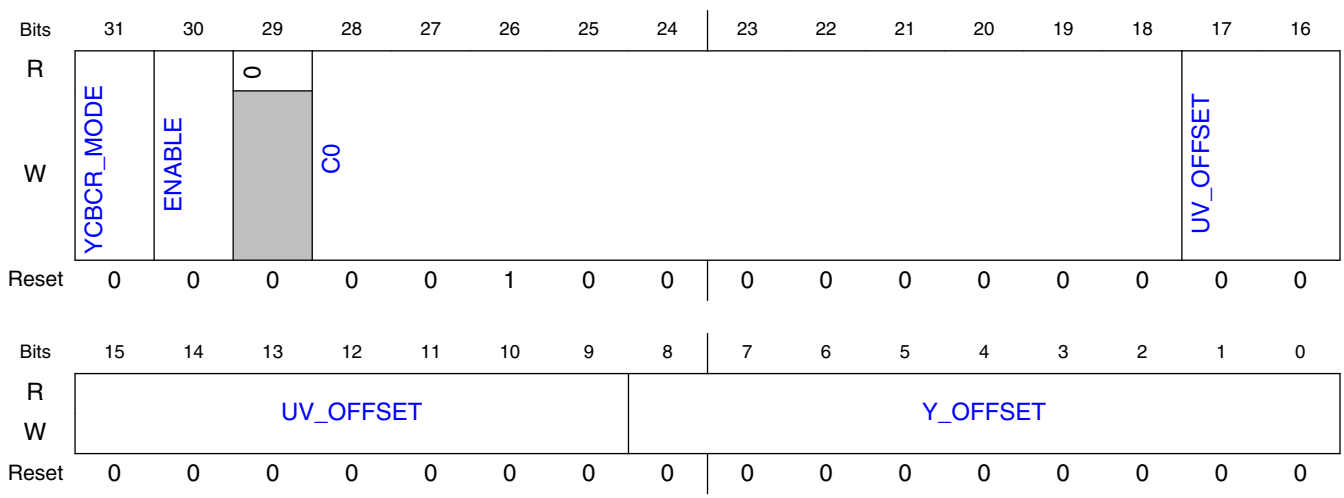
// B = C0*(Y+YOFFSET) + C4(U+UV_OFFSET)

REG_CSCCOEF0_WR(0x04030000); // YUV coefficients: C0, Yoffset, UVoffset

REG_CSCCOEF1_WR(0x01230208); // YUV coefficients: C1, C4

REG_CSCCOEF2_WR(0x076B079C); // YUV coefficients: C2, C3

48.6.1.18.3 Diagram



48.6.1.18.4 Fields

Field	Function
31 YCBCR_MODE	This bit changes the behavior when performing U/V converting 0b - Converting YUV to RGB data 1b - Converting YCbCr to RGB data
30 ENABLE	Enable the CSC unit in the LCDIFv2 plane data path 0b - The CSC is bypassed and the input pixels are RGB data already 1b - The CSC is enabled and the pixels will be converted to RGB data
29 —	Reserved
28-18 C0	Two's compliment Y multiplier coefficient. YUV=0x100 (1.000) YCbCr=0x12A (1.164)
17-9 UV_OFFSET	UV OFFSET Two's compliment phase offset implicit for CbCr data. Generally used for YCbCr to RGB conversion. YCbCr=0x180, YUV=0x000 (typically -128 or 0x180 to indicate normalized -0.5 to 0.5 range)
8-0 Y_OFFSET	Y OFFSET Two's compliment amplitude offset implicit in the Y data. For YUV, this is typically 0 and for YCbCr, this is typically -16 (0x1F0)

48.6.1.19 Color Space Conversion Coefficient Register 1 (CSC0_COEF1 - CSC1_COEF1)

48.6.1.19.1 Offset

Register	Offset
CSC0_COEF1	21Ch
CSC1_COEF1	25Ch

48.6.1.19.2 Function

The Coefficient 1 register contains coefficients used in the color space conversion algorithm. C1 is the coefficient that is used to multiply the chroma (Cr/V) component of the data for the red component. C4 is the coefficient that is used to multiply the chroma (Cb/U) component of the data for the blue component. Both values should be coded as a two's compliment fixed point number with 8 bits right of the decimal

The dpi_pclk can be sourced from either eLCDIF or LCDIFv2 depending on the configuration in the Video Multiplexer (VIDEO_MUX) block. For detailed information, refer to VID_MUX_CTRL[MIPI_DSI_SEL] field in Video Multiplexer Memory Map and register definition.

49.2 Overview

The Mobile Industry Processor Interface (MIPI) Display Serial Interface (DSI) controller implements all protocol functions defined in the MIPI DSI Specification. The MIPI DSI controller provides an interface that allows communication with MIPI DSI-compliant peripherals.

The MIPI DSI D-PHY is a source-synchronous physical layer supporting the MIPI Alliance standard for D-PHY.

49.2.1 Block Diagram

The figure below illustrates the DSI Host Controller Core structure. The DSI Host Controller Core operates on the host (transmit) side of a DSI link.

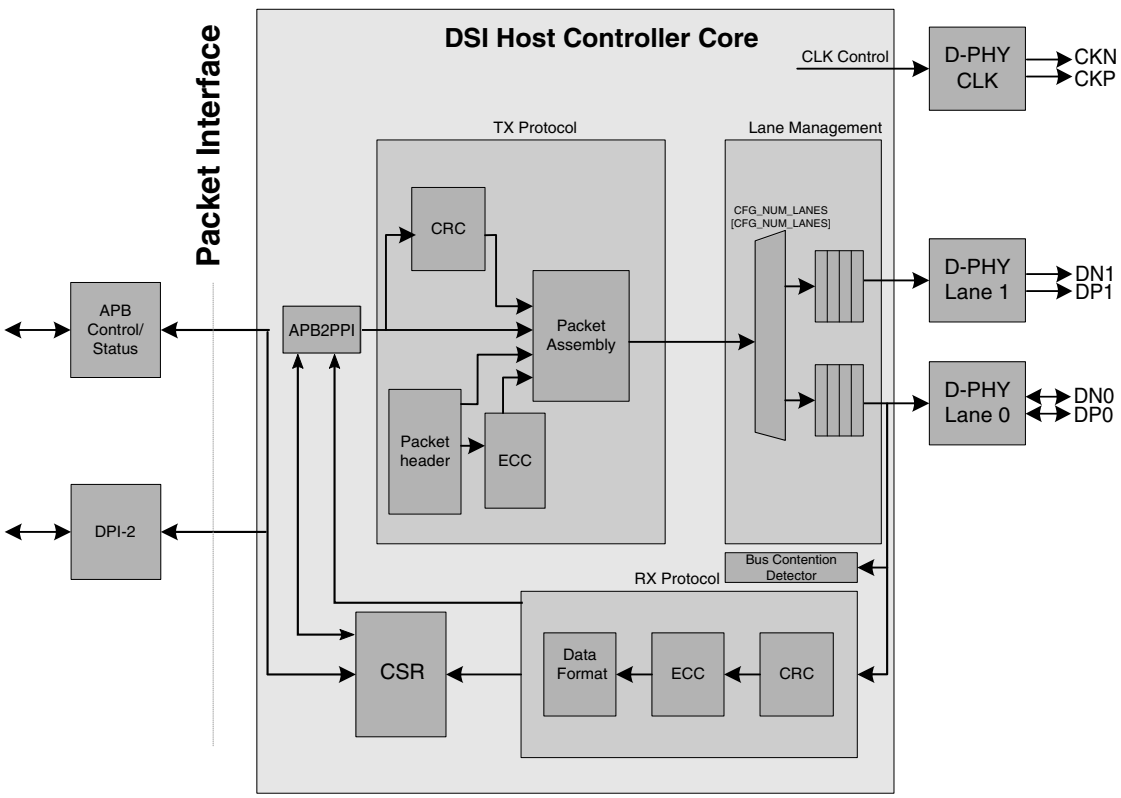

Figure 49-1. DSI Host Controller Core Block Diagram

The DSI Host Controller Core implements all three layers defined by the DSI Specification: Pixel to Byte Packing (handled by DPI Interface), Low Level Protocol, and Lane Management. The DSI Host Controller Core sends and receives DSI commands via the Packet Interface.

The Packet Interface is an easy-to-use data interface that accepts commands and data, and sends it over the DSI link. It supports the use of 2 D-PHY lanes. The DSI Host Controller Core takes care of all packet formatting details and transmission over the MIPI bus.

The DPI Translator connects to the DSI Host Controller Core via the Packet Interface. DPI masters may connect directly to the DPI Translator to send commands across the DSI link.

Sending commands and receiving information through the DSI link is also possible through the APB to PPI gasket. See MIPI DSI Host APB PKT IF Memory Map/Register section for details about the DSI registers which allow the APB to PPI setup and communication.

49.2.2 Features

Key features of the MIPI DSI Controller Core include:

- Implements all three DSI Layers (Pixel to Byte packing, Low Level Protocol, Lane Management)
- Support for Command and Video Modes
- Host Version
- Scalable data lane support, 1 to 2 Data Lanes
  - Bidirectional support on lane 0
- Supports High Speed and Low Power operation
- Support for all DSI data types and formats
- Supports ULPS mode
- Full Low-Level Protocol Error and Contention detection and reporting
- Supports continuous and non-continuous Clock Lane operation
- Supports multiple packets per transmission
- Support for all three Video Mode packet sequences
  - Non-Burst Mode with Sync Pulses
  - Non-Burst Mode with Sync Events
  - Burst mode
- Support for bus turnaround signaling
- Flexible packet based user interface
  - APB interface (status and control)
  - Display Pixel Interface Core (DPI-2)
- Supports PHY Protocol Interface (PPI) compatible MIPI D-PHYs
- MIPI Alliance Specification for Display Serial Interface Version 1.1 compliant

The DSI Host Controller DPI-2 Interface Core provides the following features:

- Support for Type 2,3, and 4 displays
- Support for 16, 18 and 24 bit Pixel data and all alignment configurations
- Support for 16, 18, 24, and 18 bit loosely packed DSI data types
- Supports DSI video modes
  - Non-Burst Mode with Sync Pulses
  - Non-Burst Mode with Sync Events
  - Burst Mode
- Supports normal or inverted HSYNC and VSYNC signals

- Handles clock domain crossing from DPI Pixel clock to the Host controller TX Byte clock
- Interfaces directly to the Host Controller's DSI Packet Interface
- Comes already integrated with the DSI Host Controller

The MIPI DSI D-PHY supports the MIPI Standard for D-PHY. It features one clock lane, two data lanes, and high speed Serializers and Deserializers. The D-PHY also supports high speed and low power modes.

49.3 Functional description

49.3.1 Packet Interface

The DSI Host Controller Core Packet Interface consists of Transmit, Receive, and Control and Status sections. Through these interfaces, the user application can take complete control of the DSI interface, sending all video timing, sending DSI commands, receiving DSI reads, monitoring the status of the interface and responding to error reporting.

User application may have access to DSI Host Controller Core Packet Interface through APB_PKT_IF registers. For information on how to send a packet or receive a read request for a packet, refer to Application Information

49.3.1.1 Transmit Ports

The Transmit Packet Interface is the mechanism with which the user creates packets to send over the MIPI Interface.

For Long Packets, the user provides the Data Type (DT) and Word Count (WC) to the controller. The Controller then creates a packet header and pulls the packet data from the Packet Interface and out to the D-PHY to transmit.

For Short Packets, the user provides the Data Type (DT) and required parameters (if any) to the controller. The Controller then creates the short packet and sends it to the D-PHY to transmit. This interface enables the user application to transmit and receive any type of DSI packet.

49.3.1.2 Receive Ports

The Receive Packet Interface returns data from the Peripheral to the user. The user is provided the Data Type (DT), Word Count (WC), and Rx Payload Data.

This interface enables the user application to receive any type of DSI packet.

49.3.2 Status Interface Ports

The Status Interface Core provides for reading the Status of the DSI Host Controller Core via a simple interface. All signals in the Status Interface are synchronous to the clk_byte clock.

NOTE

The Packet Interface signals are accessible by user application through the following DSI_HOST device registers:

- CFG_STATUS_OUT
- CFG_HTX_TO_COUNT
- CFG_LRX_H_TO_COUNT

Refer to DSI_HOST device sections for details.

49.3.3 Interface Cores

There are several interface cores for the DSI Host Controller Core. These interface cores provide industry standard interfaces to the DSI Host Controller Core to simplify interfacing and integration the DSI Host Controller Core to your application. When selected, these interface cores provide additional ports to the DSI Host Controller core.

49.3.3.1 DPI-2 Interface Host Bridge Core

The DPI-2 Interface Host Bridge Core provides a DPI-2 compliant interface to the DSI Host controller. The DPI-2 Interface Host Bridge Core handles converting the DPI-2 interface into a packet format that is compatible with the DSI Host Controller Core's Packet Interface, and that adheres to the DSI specification. The DPI-2 Interface Core handles all pixel-to-byte packing for all DPI data types.

A block diagram of the DPI-2 Interface Host Bridge Core is shown below. The DPI-2 Host Bridge Core accepts a MIPI compliant DPI-2 set of signals (vsync, hsync, pixel data), creates DSI packets for the video timing events and video data and transmits those packets via the DSI Host Controller's Packet Interface.

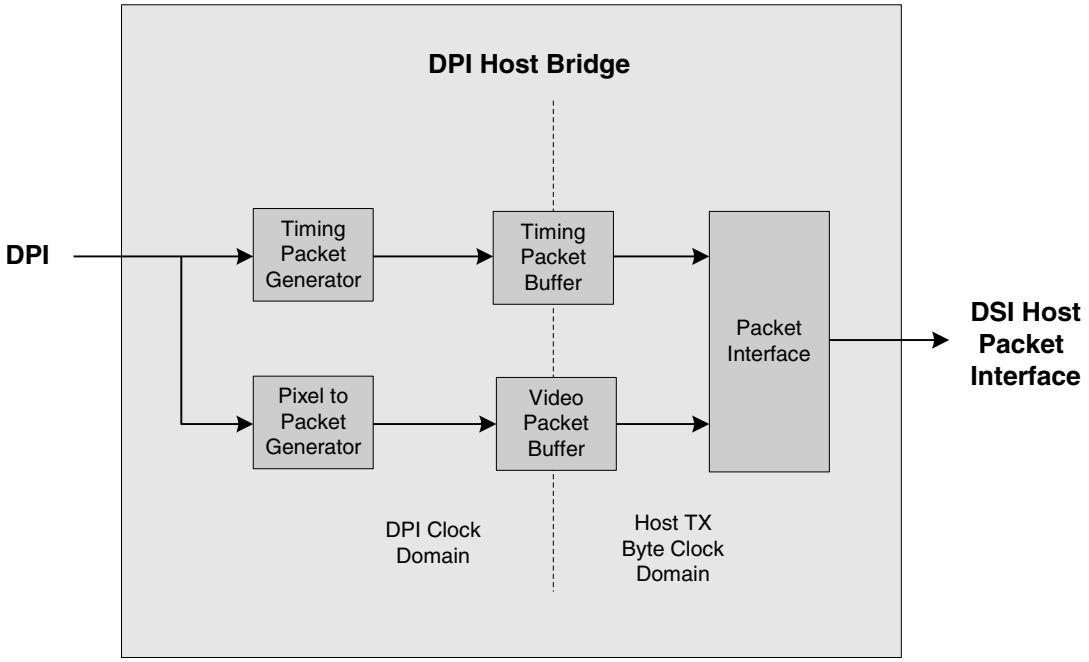

Figure 49-2. DPI-2 Host Bridge Core Block Diagram

49.3.3.1.1 DPI-2 Interface Ports

The DPI-2 Interface module provides a MIPI compliant DPI-2 interface to the DSI Host Controller Core. In addition to the standard DPI-2 interface signals there are several configuration and status ports that allow the user to adjust the behavior of the DPI-2 Interface module to better suit a particular application.

NOTE

The DPI configuration signals herein described are accessible through DSI_HOST_DPI_INTFC device registers (please refer to MIPI DSI Host Memory Map/Register section for details).

49.3.3.1.2 DPI-2 Video Timing Recreation over DSI

The DSI Host DPI-2 module is designed to preserve the receive video timing by properly spacing the DSI packets that carry the DPI video information and by inserting blanking packets into the packet stream. In order to achieve this goal, the DSI Host controller needs to have the cfg_host_dpi_hfp, cfg_host_dpi_hbp, and cfg_host_dpi_hsa ports properly set. The values of these ports reflect the size of the hfp, hbp, and has in terms of DSI packet bytes, values such that the number of DSI bytes when transmitted takes approximately the same amount of absolute time as the video event took on the DPI interface.

To relate pixel sizes on the DPI interface to DSI packet bytes, use the following relationship:

```
Time of DPI event - time to transmit x number of bytes on the DSI interface

      dpi_event_size * dpi_pclk_period = number_of_dsi_bytes * 8 * dsi_hs_bit_period /
cfg_num_lanes
```

Solving for number_of_dsi_bytes:

```
number_of_dsi_bytes = dpi_event_size * dpi_pclk_period * cfg_num_lanes / (8 *
dsi_hs_bit_period)

      number_of_dsi_bytes - value to set the cfg_host_dpi_hfp (hbp, or hsa) port to
      dpi_event_size - size of the video event in pixels (hfp, hbp, hsa)
      dpi_pclk_period - period of dpi_pclk
      dsi_hs_bit_period - bit period of the mipi data lanes in High Speed mode
      cfg_num_lanes - host controller setting for number of active lanes,1 = 2 lanes)
```

49.3.4 RAM Usage

The DSI Host Controller Core requires on-chip RAM arrays. These RAM arrays and their corresponding sizes are listed in the table below.

All RAM arrays used in this core are configured as two-port, having the following attributes:

- Two address buses, one for the write port and one for read port
- Two data buses, one for write data on the write port and one for read data on the read port
- Two clock inputs, one for the write port and one for the read port. (Note: In some cases, the core logic will connect the same clock to both the read and write clock inputs of the RAM.)

Ram Purpose	Size (Depth x Width)
DPI Core Pixel Data FIFO	2048 x 32
APB to Packet Interface TX FIFO	64 x 32
APB to Packet Interface RX FIFO	64 x 32

49.3.5 DSI DPHY

49.3.5.1 DPHY Overview

The DSI Host Controller Core D-PHY Interface connects directly to MIPI PPI compliant D-PHYs. The DSI Host Controller Core uses this interface to transmit data, send Escape sequences, receive and transmit triggers, and detect and report D-PHY error conditions.

The figure below shows the block diagram of the MIPI DSI D-PHY. It consists of a clock lane module and two data lane modules. Each of these PHY Lane Modules communicates through a differential line to a complementary PHY at the other side of the lane interconnect.

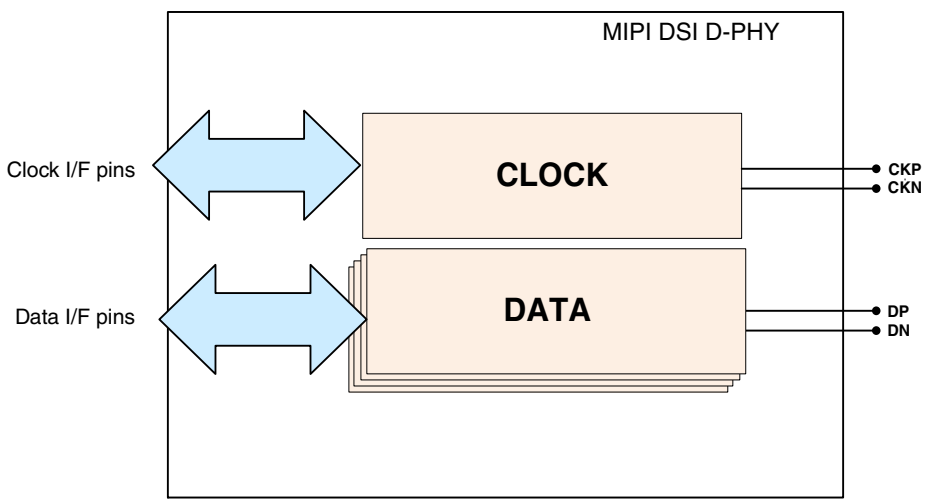

Figure 49-3. MIPI D-PHY Block Diagram

The figure below shows the D-PHY Lane components:

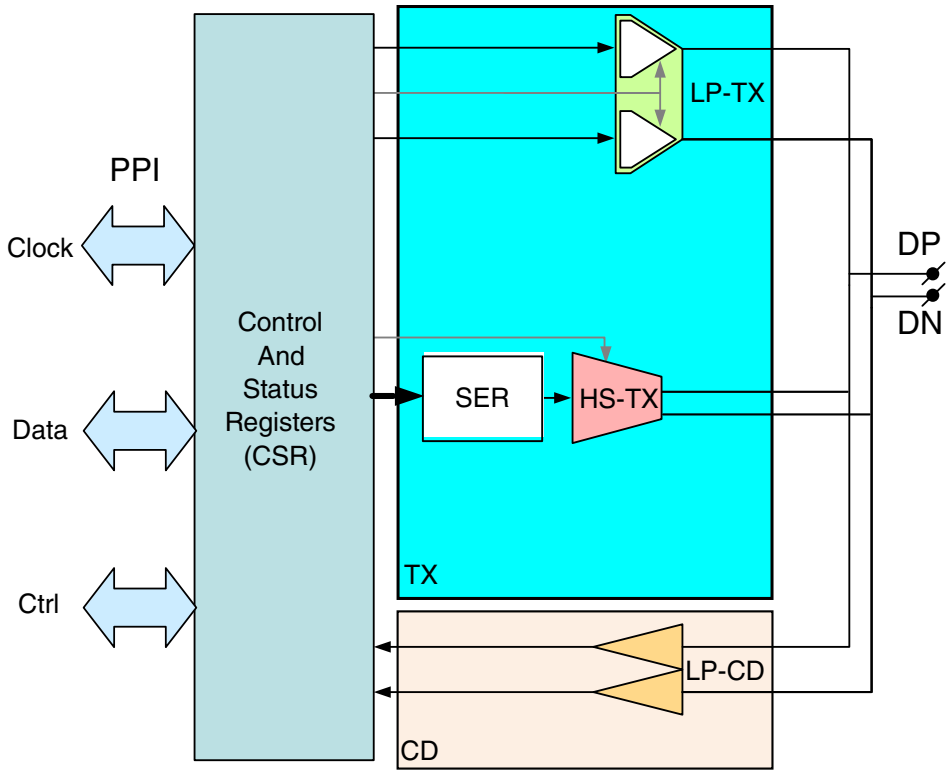

Figure 49-4. D-PHY Lane Diagram

The DATAy are bidirectional lanes and consist of High-Speed Transmitter (HS-TX), Low-Power Transmitter (LP-TX), Serializer (SER), and Low- Power Contention Detector (LP-CD).

The Clock lane is a bidirectional lane and consists of High-Speed Transmitter (HS-TX), and Low-Power Transmitter (LP-TX).

The Control and Interface Logic (CIL) module interfaces with the Protocol and determines the global operation of the Lane Module. The interface between the D-PHY and the protocol is called the PHY-Protocol Interface (PPI).

During normal operation, a Lane switches between Low-Power and High-Speed mode. Bidirectional Lanes can also switch communication direction. The change of operating mode or direction requires enabling and disabling of certain electrical functions. These enable and disable events do not cause glitches on the Lines that would result in a detection of an incorrect signal level. Therefore, all mode and direction changes are smooth to always ensure a proper detection of the Line signals.

49.3.5.1.1 High-Speed Transmitter (HS-TX)

The High-Speed Transmit interface is used to transmit High-Speed data across the MIPI interface. All signals are synchronous to the PPI TX byte clock, TxByteClkHS, and are PPI compliant.

The differential output voltage VOD is defined as the difference of the voltages V_{DP} and V_{DN} at the DP and DN pins, respectively.

VOD =VDP −VDN

The output voltages V_{DP} and V_{DN} at the DP and DN pins will not exceed the high-speed output high voltage V_{OHHS}. The common-mode voltage V_{CMTX} is defined as the arithmetic mean value of the voltages at the DP and DN pins:

VCMTX = (VDP + V DN)/2

V_{OD} and V_{CMTX} are graphically shown in Figure 4 for ideal HS signals. Figure 5 shows single ended HS signals with the possible kinds of distortion of the differential output and common mode voltages. V_{OD} and V_{CMTX} may be slightly different for driving a Differential-1 or a Differential-0 on the pins.

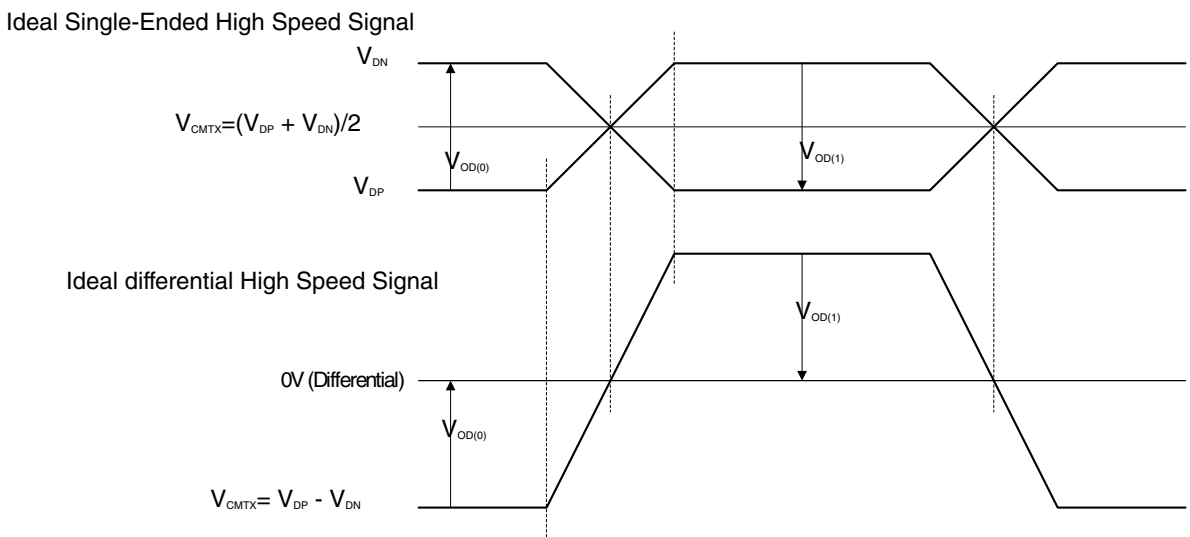

Figure 49-5. Ideal Single-ended and Resulting Differential HS Signals

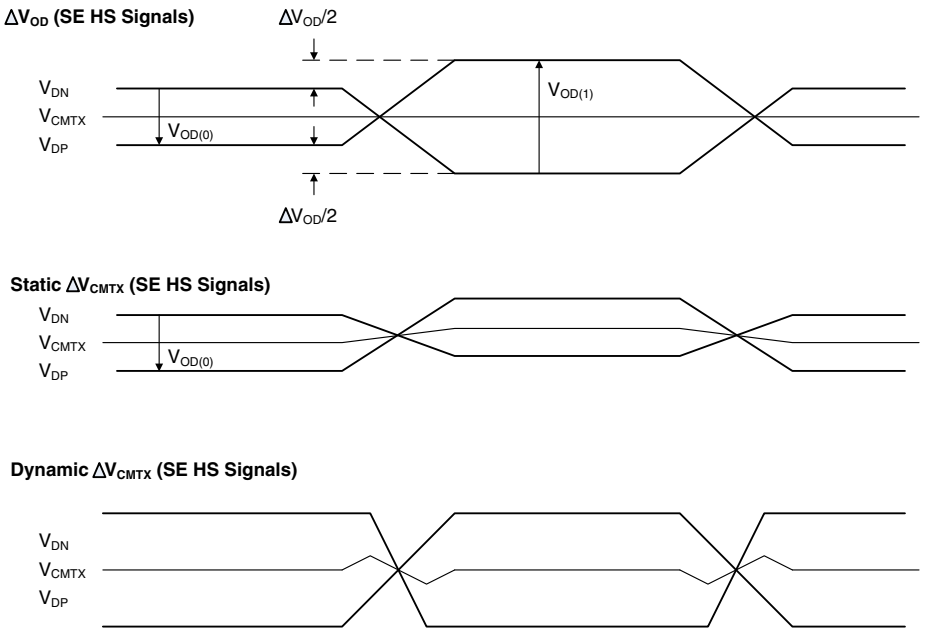

Figure 49-6. Possible ΔVcmtx and ΔVod Distortions of the Single-Ended HS Signals

The output differential voltage mismatch ΔVOD is defined as the difference of the absolute values of the differential output voltage in the Differential-1 state VOD(1) and the differential output voltage in the Differential-0 state VOD(0). This is expressed by:

$\Delta V = |V_{OD(1)}| - |V_{OD(0)}|$

If VCMTX(1) and VCMTX(0) are the common-mode voltages for static Differential-1 and Differential- 0 states respectively, then the common-mode reference voltage is defined by:

$V_{CMTX,\,REF} = (V_{CMTX(1)} + V_{CMTX(0)})/2$

The transient common-mode voltage variation is defined by:

$\Delta V_{CMTX\,(t)} = V_{CMTX\,(t)} - V_{CMTX,REF(t)}$

The static common-mode voltage mismatch between the Differential-1 and Differential-0 state is given by:

$\Delta V_{CMTX\,(1,0)} = (V_{CMTX\,(1)} - V_{CMTX\,(0)})/2$

A test circuit for the measurement of VOD and VCMTX is shown:

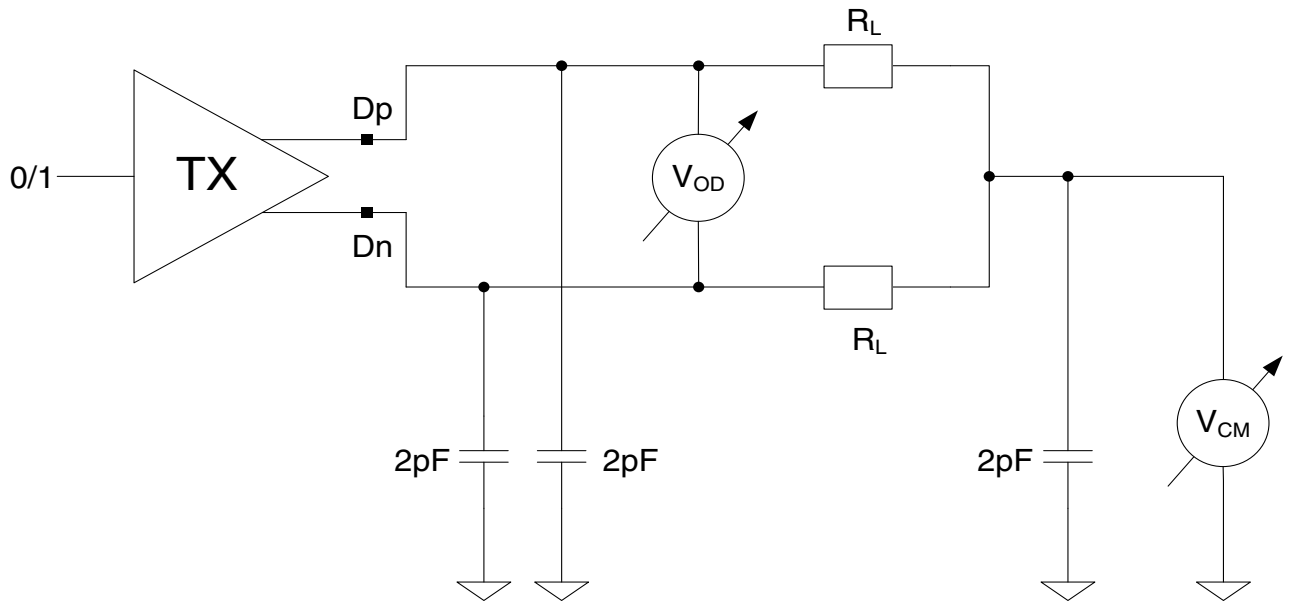

Figure 49-7. Test Circuit for Vcmtx and Vod measurement

The single-ended output impedance of the transmitter at both the DP and DN pins is denoted by Z_{OS}. ΔZ_{OS} is the mismatch of the single ended output impedances at the DP and DN pins, denoted by ZOSDP and ZOSDN respectively. This mismatch is defined as the ratio of the absolute value of the difference of Z_{OSDP} and Z_{OSDN} and the average of those impedances:

$$\Delta Z_{OS} = (2*|Z_{OSDP} - Z_{OSDN}|)/(Z_{OSDP} + Z_{OSDN})$$

The output impedance ZOS and the output impedance mismatch ΔZOS is compliant with High Speed Transmitter DC Specifications for both the Differential-0 and Differential-1 states for all allowed loading conditions. It is recommended the design keep the output impedance during state transitions as close as possible to the steady state value. The output impedance ZOS can be determined by injecting an AC current into the DP and DN pins and measuring the peak-to-peak voltage amplitude. The test circuit for such a measurement is shown in Figure 7, where RL are load resistors and VTEST,PP is a test signal applied at the common-mode node via an AC coupling capacitor CAC. The frequency of the test signal is fTEST.

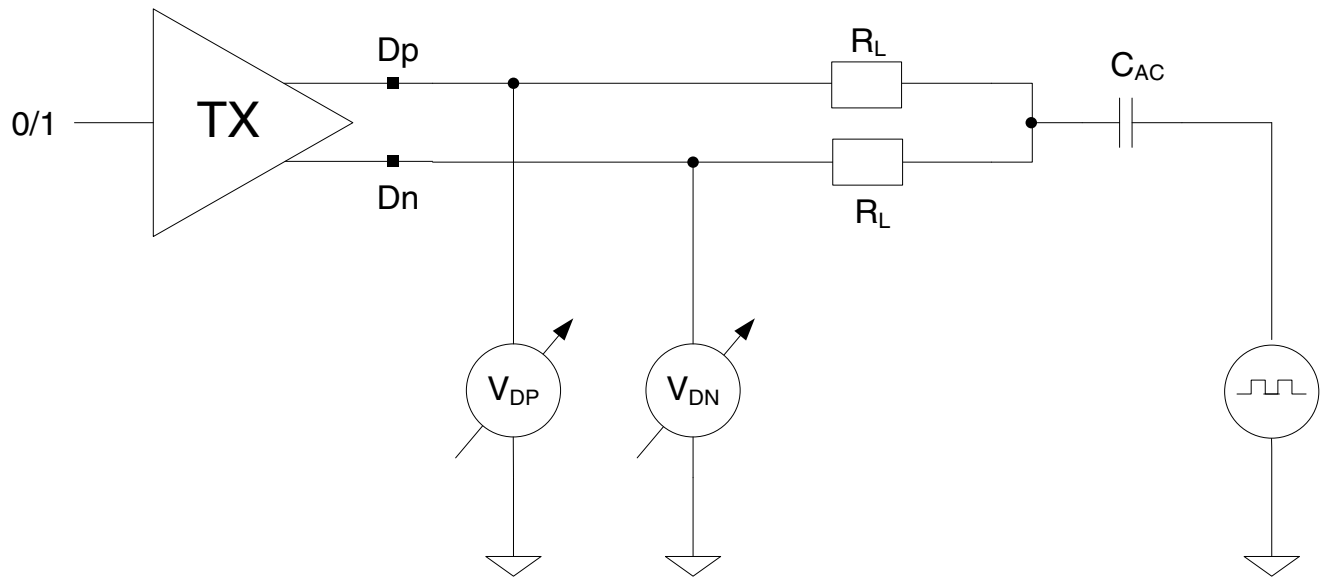

Figure 49-8. Test Circuit for Output Impedance measurements

Assuming negligible effect of the coupling capacitor, the example circuit gives the following relation between peak-to-peak pin voltage VPIN,PP and ZOS. This equation can be used for both DN and DP pins individually.

$Z_{OS} = (V_{PIN,PP} * RL)/(V_{TEST,PP} - Z_{PIN,PP})$

Where VPIN,PP is the peak-to-peak voltage at the pin DP or DN.

49.3.5.1.2 Low-Power Transmitter (LP-TX)

The Low-Power transmitter is a slew-rate controlled push-pull driver. It is used for driving the Lines in all Low-Power operating modes. The LP transmitter has been optimized to minimize static power consumption. The slew-rate of signal transitions is bounded in order to keep EMI low. The LP transmitter will not drive the pad pin potential statically beyond the maximum value of V_{OH}. V_{OH} is the thevenin output, high-level voltage in the high-level state, when the pad pin is not loaded. V_{OL} is the thevenin output, low-level voltage in the LP transmit mode. This is the voltage at an unloaded pad pin in the low-level state.

49.3.5.1.3 Low-Power Contention Detector (LP-CD)

Contention can be inferred from any of the following conditions:

- LP high fault is detected when the LP transmitter is driving high and the pin voltage is less than VIL.
- LP low fault is detected when the LP transmitter is driving low and the pad pin voltage is greater than VIHCD. An LP low fault will not be detected when the pin voltage is less than VILCD.

The general operation of a contention detector is similar to that of an LP receiver with lower threshold voltages. Although the DC specifications differ, the AC specifications of the LP-CD are defined to match those of the LP receiver. The LP-CD sufficiently filters the input signal to avoid false triggering on short events

The LP-CD threshold voltages (VILCD, VIHCD) are shown along with the normal signaling voltages:

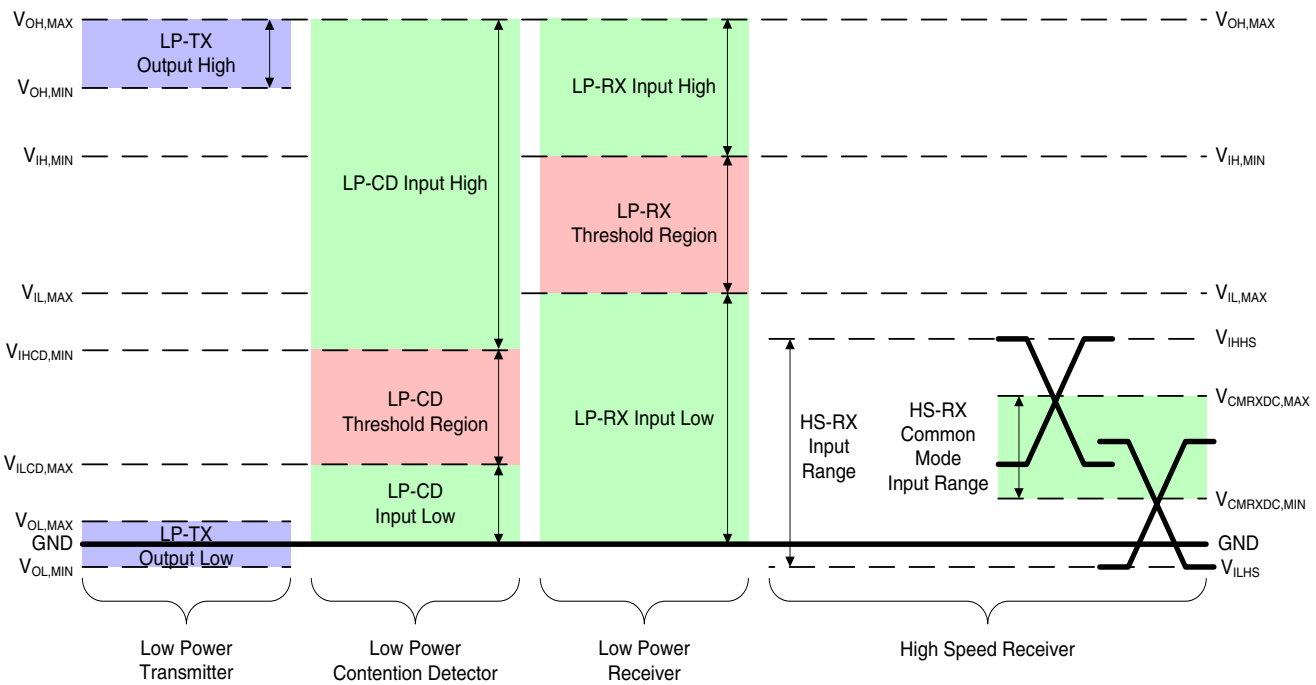

Figure 49-9. Signaling and MIPI Contention Voltage Levels

49.3.5.1.4 Input Characteristics

No structure within the PHY may be damaged when a DC signal that is within the signal voltage range VPIN is applied to a pad pin for an indefinite period of time. $V_{PIN(absmax)}$ is the maximum transient output voltage at the transmitter pin. The voltage on the transmitter's output pin will not excel $V_{PIN,MAX}$ for a period greater than $T_{VPIN(absmax)}$. When the PHY is in the low-power receive mode the pad pin leakage current will be I_{LEAK} when the pad signal voltage is within the signal voltage range of V_{PIN}. The

specification of ILEAK assures interoperability of any PHY in the LP mode by restricting the maximum load current of an LP transmitter. The test circuit for leakage current measurement is shown:

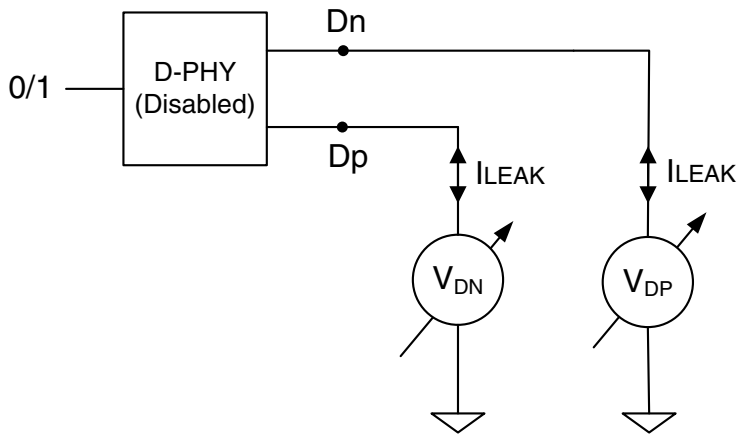

Figure 49-10. Pin-Leakage Measurement DC specification

49.3.5.1.5 High-Speed Serializer

The HS-Serializer converts 8-bits parallel data into 1 bit data stream to be transmitted by HSTX module. The CSR should clock out 8-bits parallel data, HSTX_DATA[7:0], on D0_HS_BYTE_CLKS rising edges. Then the Serializer will capture HSTX_DATA[7:0] on D0_HS_BYTE_CLKS rising edges and the signal connected to HSTX_DATA[0] is transmitted first. There is setup timing constraint and hold timing constraint designated to the rising edge of D0_HS_BYTE_CLKS.

The figure shows the relationship between HS_TXCLKP, HS_TXCLKN, HS_SER_LD, HS_BYTE_CLKS and HSTX_DATA[7:0]. It also shows how the 8-bits of parallel bits are mapped into the serial link:

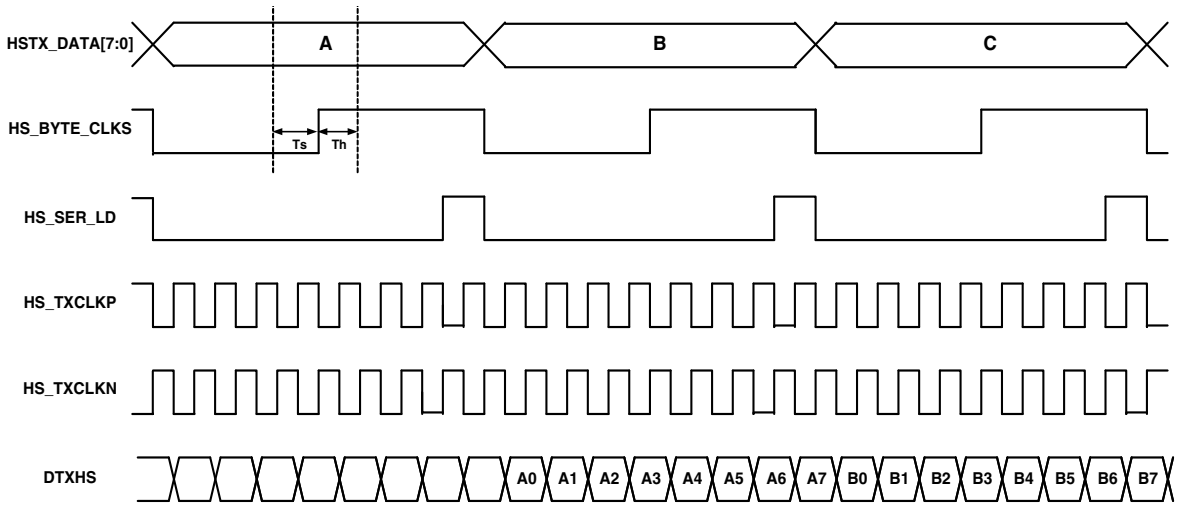

Figure 49-11. Serializer Timing Diagram

49.3.5.1.6 Operating Modes

49.3.5.1.6.1 High-Speed Transmit from the Master Side

The figure shows an example of a High-Speed transmission on the Master side. While TxRequestHS is low, the Lane Module ignores the value of TxDataHS. To begin transmission, the protocol drives TxDataHS with the first byte of data and asserts TxRequestHS. This data byte is accepted by the PHY on the first rising edge of TxByteClkHS with TxReadyHS also asserted. At this point, the protocol logic drives the next data byte onto TxDataHS. After every rising clock cycle with TxReadyHS active, the protocol supplies a new valid data byte or ends the transmission. After the last data byte has been transferred to the Lane Module, TxRequestHS is driven low to cause the Lane Module to stop the transmission and enter Stop state. The minimum number of bytes transmitted could be as small as one.

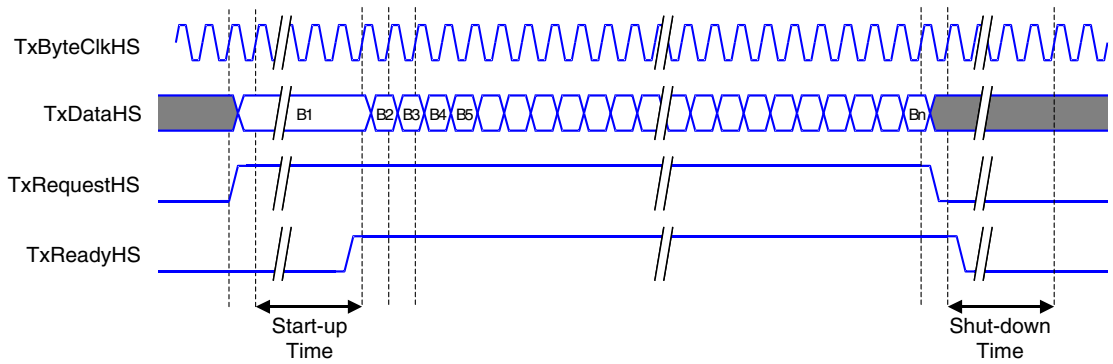

Figure 49-12. High-Speed Transmission from the Master Side

49.3.5.1.6.2 Low-Power Data Transmission

For Low-Power data transmission the TxClkEsc is used. The Protocol directs the Data Lane to enter Low-Power data transmission Escape mode by asserting TxRequestEsc with TxLpdtEsc high. The Low-Power transmit data is transferred on the TxDataEsc lines when TxValidEsc and TxReadyEsc are both active at a rising edge of TxClkEsc. The byte is transmitted in the time after the TxDataEsc is accepted by the Lane Module (TxValidEsc = TxReadyEsc = high). The Protocol knows the byte transmission is finished when TxReadyEsc is asserted. After the last byte has been transmitted, the protocol de-asserts TxRequestEsc to end the Low-Power data transmission. This causes TxReadyEsc to return low. Whenever TxRequestEsc transitions from high-to-low, it always remains in the low state for a minimum of two TxClkEsc clock cycles. The figure shows an example Low-Power data transmission operation.

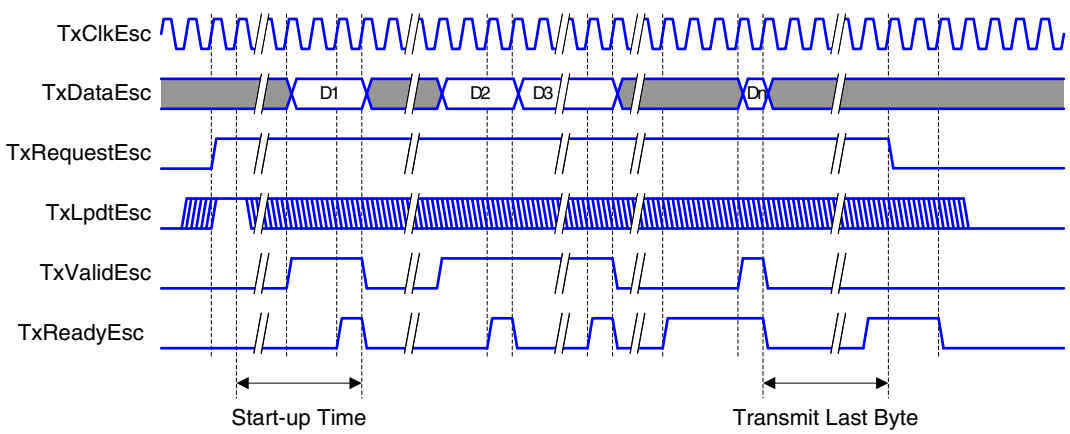

Figure 49-13. Low-Power Data Transmission

49.3.5.1.6.3 Turn-around

If the Master side and Slave side Lane Modules are both bi-directional, it is possible to turn around the Link for Escape mode signaling. Which side is allowed to transmit is determined by passing a “token” back and forth. That is, the side currently transmitting passes the token to the receiving side. If the receiving side acknowledges the turn-around request, as indicated by driving the appropriate line state, the direction is switched. The figure shows an example of two turn-around events. At the beginning, the local side is the transmitter, as shown by Direction=0. When the protocol on this side wishes to turn the Lane around (i.e. give the token to the other side), it asserts TurnRequest for at least one cycle of TxClkEsc. This initiates the turn around procedure. The remote side acknowledges the turn-around request by driving the appropriate states on the Lines. When this happens, the local Direction signal changes from transmit (0) to receive (1). The remote side initiates a turn-around request, passing the token back to the local side. When this happens, the local Direction signal changes back to transmit (0). The transmitter is in control of the Link direction and decides when to turn the Link around, passing control to the receiver. If the remote side does not acknowledge the turnaround request, the Direction signal does not change.

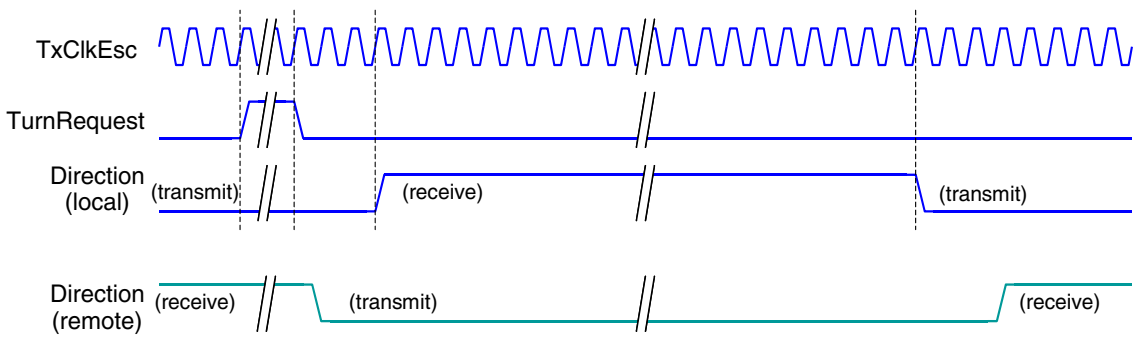

Figure 49-14. Turn-around Actions Transmit-to-Receive and Back to Transmit

49.3.5.2 DPHY PLL

The MIPI DSI DPHY PLL is a high performance PLL based frequency synthesizer that incorporates a lock detector, independent output divider, and supports power down modes. The PLL block diagram is shown below.

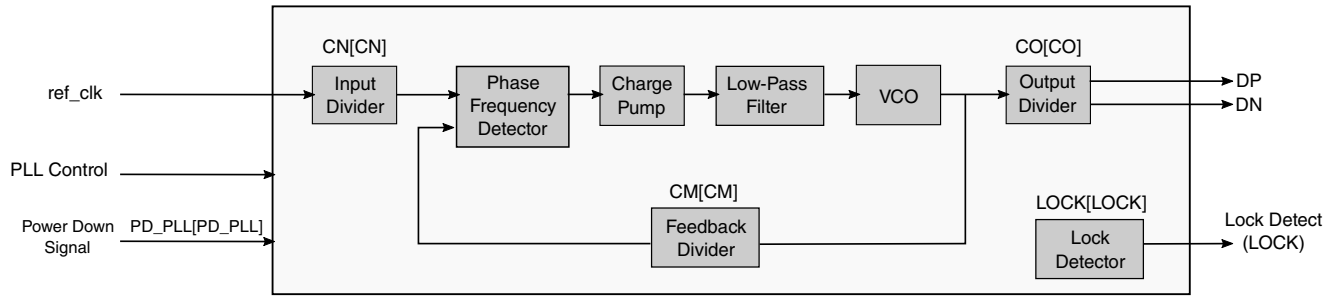

Figure 49-15. MIPI DSI DPHY PLL Block Diagram

The DPHY PLL input clock is ref_clk. The PLL output multiplies the input frequency by `(CM / (CN * CO))`.

NOTE

The input frequency ranges from 24 MHz till 200 MHz. The input divider has to be programmed such that the frequency after the input divider ranges from 24 MHz till 30 MHz.

NOTE

The VCO output frequency range is 640 MHz to 1500 MHz.

The power down signal (PD) is active-high and used to power down the PLL. Asserting PD will reset the PLL to it's initial state. To ensure proper PLL functionality, ref_clk needs to be stable before PLL power up. The expected power-on sequence for the DSI DPHY PLL is illustrated below.

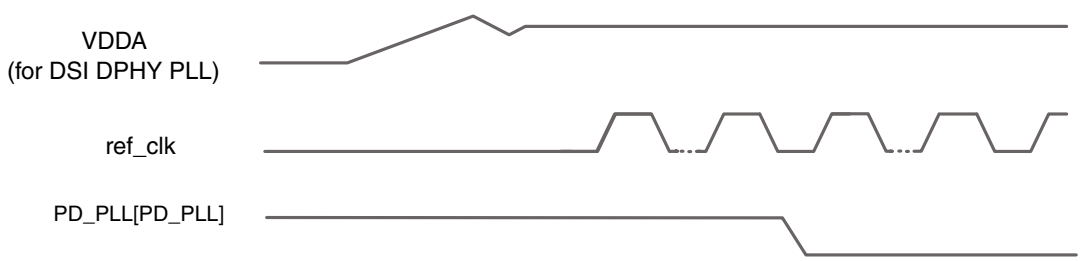

Figure 49-16. MIPI DSI DPHY PLL Power-on Sequence

49.3.5.3 DPHY Programming

The following sections detail the programming of the MIPI DSI DPHY high-speed timers.

49.3.5.3.1 High-Speed Prepare Timer ($T_{HS-PREPARE}$)

Calculate the value for clock lane high-speed prepare timer (mc_PRG_HS_PREPARE) using Table 49-2 and Table 49-3 :

Table 49-2. Clock Lane High-Speed prepare timer range

	Min (ns)	Max (ns)	PRG HS PREPARE	$T_{CLK-PREPARE}$ (ns)
$T_{CLK-PREPARE}$	38	95	1	75

1. Assuming TxClkEsc = 20 MHz (T_{per} = 50 ns)
2. When MC_PRG_HS_PREPARE[MC_PRG_HS_PREPARE] = 0, $T_{CLK-PREPARE}$ = 1 x TxClkEsc Period

   When MC_PRG_HS_PREPARE[MC_PRG_HS_PREPARE] = 1, $T_{CLK-PREPARE}$ = 1.5 x TxClkEsc Period
3. There is a calculation inaccuracy (of 0.5 x Tperiod of TxClkEsc) due to an expected mismatch coming from delays on the low power signals inside Hard-Macro before low power data begins transmission on the high-speed serial interface.

Calculate the value for data lane high-speed prepare timer (m_PRG_HS_PREPARE[1:0]) using Table 49-3 and Table 49-4 :

Table 49-3. Data Lane High-Speed prepare timer range

	Min	Max
$T_{HS-PREPARE}$	40 ns + 4 x UI	85 ns + 6 x UI

Table 49-4. Data Lane High-Speed prepare timer for different data rates

Data Rate	Min (ns)	Max (ns)	PRG HS PREPARE[1:0]	$T_{HS-PREPARE}$
1.5 Gbps	42.67	89	01	75
1.0 Gbps	44	91	01	75
500 Mbps	48	97	01	75
250 Mbps	56	109	10	100
80 Mbps	90	160	10	100

1. Assuming TxClkEsc = 20 MHz (T_{per} = 50 ns)
2. When M_PRG_HS_PREPARE[M_PRG_HS_PREPARE] = 00, $T_{HS-PREPARE}$ = 1 x TxClkEsc Period

   When M_PRG_HS_PREPARE[M_PRG_HS_PREPARE] = 01, $T_{HS-PREPARE}$ = 1.5 x TxClkEsc Period

When M_PRG_HS_PREPARE[M_PRG_HS_PREPARE] = 10, $T_{HS-PREPARE}$ = 2 x TxClkEsc Period

When M_PRG_HS_PREPARE[M_PRG_HS_PREPARE] = 11, $T_{HS-PREPARE}$ = 2.5 x TxClkEsc Period

3. There is a calculation inaccuracy (of 0.5 x Tperiod of TxClkEsc) due to an expected mismatch coming from delays on the low power signals inside Hard-Macro before low power data begins transmission on the high-speed serial interface.

49.3.5.3.2 High-Speed Zero Timer($T_{HS-ZERO}$)

Calculate the value for clock lane high-speed zero timer (mc_PRG_HS_ZERO) using the formula below:

- $T_{CLK-ZERO}$= (mc_PRG_HS_ZERO + 3)*(TxByteClkHS Period)
- TxByteClkHS = 1/8 Data Rate
- When MC_PRG_HS_ZERO[MC_PRG_HS_ZERO] = 000110 @ 250 Mb/s, $T_{CLK-ZERO}$ = (6+3) * 32 ns = 288 ns
- When MC_PRG_HS_ZERO[MC_PRG_HS_ZERO] = 100000 @ 1 Gb/s, $T_{CLK-ZERO}$ = (32+3) * 8 ns = 280 ns

Calculate the value for data lane high-speed zero timer (m_PRG_HS_ZERO) using the formula below:

- $T_{HS-ZERO}$ = (m_PRG_HS_ZERO + 6)*(TxByteClkHS Period)
- TxByteClkHS = 1/8 Data Rate
- When M_PRG_HS_ZERO[M_PRG_HS_ZERO] = 00001 @ 250 Mb/s, $T_{HS-ZERO}$ = (1+6) * 32 ns = 224 ns
- When M_PRG_HS_ZERO[M_PRG_HS_ZERO] = 01001 @ 1 Gb/s, $T_{HS-ZERO}$ = (9+6) * 8 ns = 120 ns

49.3.5.3.3 High-Speed Trail Timer ($T_{HS-TRAIL}$)

Calculate the value for the high-speed trail timer (PRG_HS_TRAIL) using the formula below:

- $T_{HS-TRAIL}$= (PRG_HS_TRAIL)*(TxByteClkHS Period)
- TxByteClkHS = 1/8 Data Rate
- When M_PRG_HS_TRAIL[M_PRG_HS_TRAIL] = 0100 @ 250 Mb/s, >$T_{HS-TRAIL}$ = 4 * 32 ns = 128 ns
- When M_PRG_HS_TRAIL[M_PRG_HS_TRAIL] = 1100 @ 1 Gb/s, >$T_{HS-TRAIL}$ = 12 * 8 ns = 96 ns

49.3.5.4 Packet Data and Pixel Formats

The DSI Host Controller Core and the external DSI Peripheral explicitly handle and exchanges 32-bit words encapsulated as packet data. The mapping between pixel formats and pixel data must be done on both sides by user application on both sides of the DSI link. The DSI spec gives many examples of common pixel formats. The DSI Host Controller Core and external DSI Peripheral have no preference or limitation on which pixel formats it will handle. The IP which provides video source packet data through DPI-2 interface (e.g. eLCDIF) onto DSI should also be configured by the user application to match the pixel formats expected by the DSI Host Controller.

The DPI-2 interface core handles pixel to byte packing and byte to pixel unpacking according to the MIPI DSI specification.

49.3.6 DSI Host Clocks

The DSI Host Controller contains the following clocks:

Table 49-5. Clocks

Clock	Description
ref_clk	Reference clock (Used by DPHY)
clk_byte	Byte clock (Generated by DPHY and used for packet generation)
clk_tx_esc	TX escape mode clock (Used for internal LPDT state machines and low-power transmissions)
dpi_pclk	DPI Pixel Clock
TxClkEsc	Escape mode Transmit Clock. This clock is directly used to generate escape sequences. The period of this clock determines the symbol time for low power signals. It is therefore constrained by the normative part of the DPHY specification. **NOTE:** The max frequency of TxClkEsc is 20 MHz and the Min frequency of TxClkEsc is 12 MHz.
TxByteClkHS	High-Speed Transmit Byte Clock. This is used to synchronize PPI signals in the High-Speed transmit clock domain. It is recommended that all transmitting Data Lane Modules share on TxByteClkHS signal. The frequency of TxByteClkHS is exactly 1/8 the High-Speed bit rate.

The figure below depicts the various clocks used in the DSI Host:

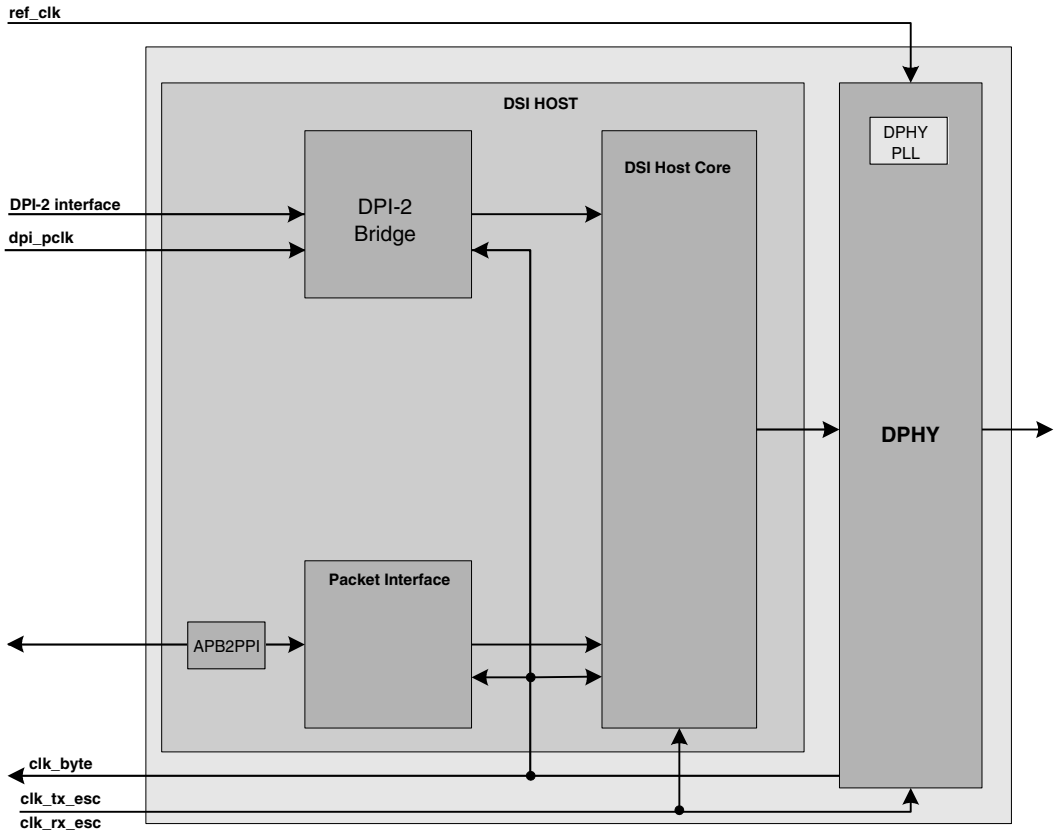

Figure 49-17. DSI Host Controller Clocking Diagram

49.3.6.1 ref_clk

The reference clock is used by the DPHY (DPHY PLL) to generate the High Speed MIPI clock and High Speed Data Lane signaling. The frequency of the resulting clock generated from DPHY PLL is typically equal to the high speed bit rate of the data lanes. The DPHY will also use this clock to generate the clk_byte clock output used by the Host DSI Controller and user application logic.

The MIPI DPHY PLL must be setup through the MIPI_DSI_HOST_FSL_IP1_DPHY INTFCx registers, prior to starting DSI Host Controller and DPHY operation. For details, please refer to MIPI DSI Host IP1 DPHY INTFC Memory section.

49.3.6.2 clk_byte

The clk_byte clock is generated by the DPHY (DPHY PLL) and the frequency is 1/8th the data rate of the DPHY Data Lane High Speed data rate. A DPHY configured to generate High Speed data at 1Gbps/lane would generate a 125MHz clk_byte clock.

The clk_byte clock is used by the DSI Host Controller to interface to the MIPI Tx DPHY High Speed PPI interface. The DSI Host Controller's Packet Interface is synchronous to the clk_byte clock.

49.3.6.3 dpi_pclk

The dpi_pclk clock is used on the Host DPI-2 interface. All of the Host DPI-2 signals are synchronous to this clock. The DSI Host Controller's DPI Bridge module handles transferring video data received in the dpi_pclk clock domain over to the clk_byte clock domain.

The dpi_pclk and clk_byte frequencies are related by the following formula:
clk_byte_freq >= dpi_pclk_freq * DPI_pixel_size / (8 * (cfg_num_lanes + 1))

cfg_num_lanes = the configuration port setting that selects the number of active MIPI DPHY data lanes clk_byte_freq = frequency of clk_byte which is 1/8th the High Speed data lane rate. dpi_pclk_freq = frequency of the dpi_pclk clock on the DPI-2 interface. DPI_pixel_size = size of pixels, in bits, on the DPI-2 interface

If the clk_byte frequency does not meet this requirement, the MIPI interface will not be able to keep up with the video stream on the DPI-2 interface resulting in dropped video lines.

NOTE

For more information on this clock, please see the Chip-specific bridge topic.

49.3.6.4 clk_tx_esc

The clk_tx_esc clock is used by the MIPI Tx DPHY for state control and low power data transmission. The DSI Host Controller also uses clk_tx_esc for the portion of controller logic that interfaces to the MIPI Tx DPHY that are synchronous to clk_tx_esc. The frequency of clk_tx_esc is defined by the requirements of the MIPI interface and the MIPI Tx DPHY. For details about the clk_tx_esc source, please refer to the chip-specific MIPI-DSI clocking section.

49.3.7 Reset

The MIPI DSI Host contains the following reset signals:

Reset Signal	Description
reset_dpi_n	Asynchronous reset in the dpi_pclk clock domain (Active-low signal)
reset_byte_n	Asynchronous reset to all logic in the clk_byte clock domain (Active-low signal)
reset_esc_n	Asynchronous reset to all logic in the clk_esc clock domain (Active-low signal)

49.4 External Signals

The table below shows the external signals in this module.

Table 49-6. External Signals

External Signal	Description	Direction
DNn	Differential Data Signal (Negative)	O
DPn	Differential Data Signal (Positive)	O
CKN	Differential Clock Signal (Negative)	O
CKP	Differential Clock Signal (Positive)	O

49.5 Application Information

49.5.1 Steps to Transmit a Packet

1. If the transmit packet is a long data type, write payload data to TX_PAYLOAD[PAYLOAD]
2. Write transmit packet information to PKT_CONTROL[CTRL]
3. Write any value to SEND_PACKET[TX_SEND] to start a packet transmission
4. Wait for packet transmit to complete. Either wait for an interrupt from the apb interface or monitor PKT_STATUS register.

49.5.2 Steps to perform a Packet Read Request

1. Follow the steps for transmitting a packet as shown above, but with a data type that is a read command. You won't have payload data for a read request so the first step can be skipped

2. Write 1 to PKT_CONTROL[25] to turn the bus around (BTA) after the transmission is complete so that the peripheral can send the read data back
3. Monitor PKT_STATUS[2] for the direction to check if the peripheral bus has control
4. Set PKT_CONTROL[25] bit to 0
5. Wait for receive packet by either waiting for the interrupt or monitoring PKT_STATUS[7] to indicate an Rx packet has been received
6. Read the receive packet header information and Rx payload data if read is a long data type

49.6 Initialization

The Initialization procedure for the DSI Host Controller is as follows:

1. Assert all resets through the chip-specific registers provided for this purpose:
   - reset_dpi_n
   - reset_byte_n
   - reset_esc_n
2. Setup DSI related clocks through chip-specific registers provided for this purpose (refer to CCM for details).
3. Setup MIPI DSI application by programming all DSI Host Controller and DSI DPHY required parameters (refer to Memory Map and register definition for details).
4. De-assert all remaining resets through the Chip-specific registers provided for this purpose:
   - reset_dpi_n
   - reset_byte_n
   - reset_esc_n

The DSI Host Controller should be ready for use now.

49.7 Memory Map and register definition

This section includes the DSI Host module memory map and detailed descriptions of all registers.

49.7.1 DSI HOST register descriptions

49.7.1.1 DSI_HOST memory map

MIPI_DSI.DSI_HOST base address: 4080_C000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Configure Number of Lanes (CFG_NUM_LANES)	32	RW	0000_0000h
4h	Configure Noncontinuous Clock (CFG_NONCONTINUOUS_CLK)	32	RW	0000_0000h
8h	Configure TCLK-PRE DPHY (CFG_T_PRE)	32	RW	0000_0000h
Ch	Configure TCLK Wait (CFG_T_POST)	32	RW	0000_0000h
10h	Configure Transmit Gap (CFG_TX_GAP)	32	RW	0000_0000h
14h	Configure Auto Insert EoTp (CFG_AUTOINSERT_EOTP)	32	RW	0000_0000h
18h	Configure Extra Packets after EOTP (CFG_EXTRA_CMDS_AFTER_EOTP)	32	RW	0000_0000h
1Ch	Configure HTX Timeout Count (CFG_HTX_TO_COUNT)	32	RW	0000_0000h
20h	Configure Low-Power Receive Timeout Count (CFG_LRX_H_TO_COUNT)	32	RW	0000_0000h
24h	Configure BTA_H Timeout Count (CFG_BTA_H_TO_COUNT)	32	RW	0000_0000h
28h	Configure Twakeup (CFG_TWAKEUP)	32	RW	0000_0000h
2Ch	Configure Status Out (CFG_STATUS_OUT)	32	R	0000_0000h
30h	Receive Error Status (RX_ERROR_STATUS)	32	R	0000_0000h

49.7.1.2 Configure Number of Lanes (CFG_NUM_LANES)

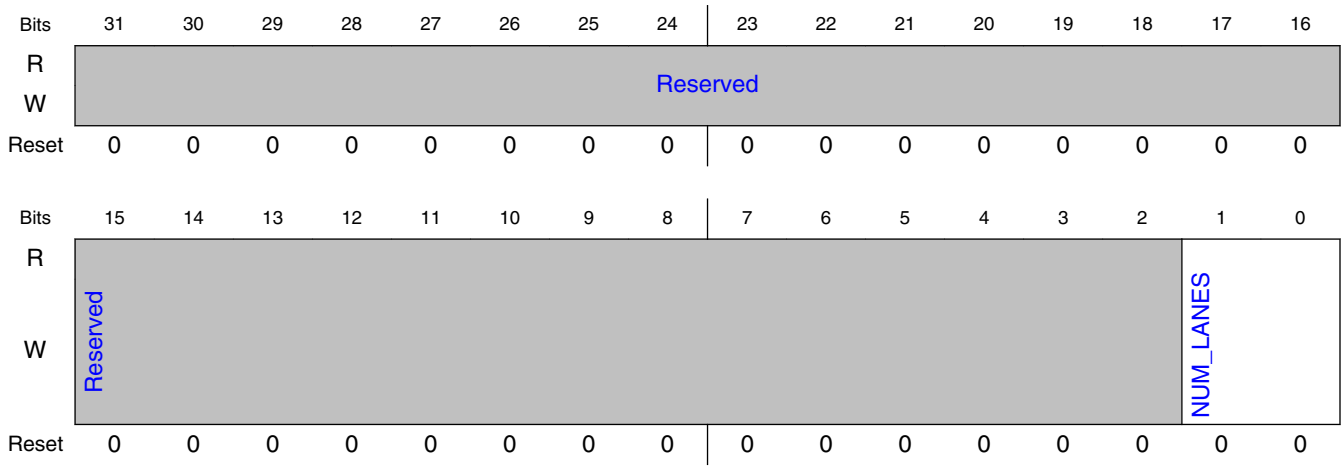
49.7.1.2.1 Offset

Register	Offset
CFG_NUM_LANES	0h

49.7.1.2.2 Function

Sets the number of active lanes that are to be used for transmitting data.

49.7.1.2.3 Diagram



49.7.1.2.4 Fields

Field	Function
31-2 —	Reserved
1-0 NUM_LANES	Number of active lanes. 00b - 1 lane 01b - 2 lanes

49.7.1.3 Configure Noncontinuous Clock (CFG_NONCONTINUOUS_CLK)

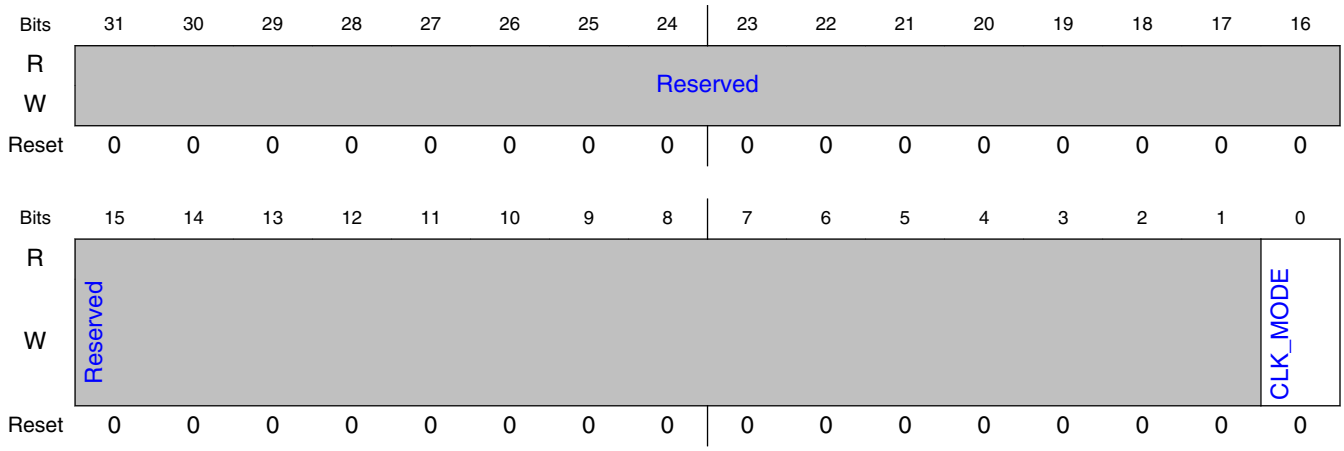
49.7.1.3.1 Offset

Register	Offset
CFG_NONCONTINUOUS_CLK	4h

49.7.1.3.2 Function

Sets the Host Controller into non-continuous MIPI clock mode. When in non-continuous clock mode, the high speed clock will transition into low power mode between transmissions.

49.7.1.3.3 Diagram



49.7.1.3.4 Fields

Field	Function
31-1 —	Reserved
0 CLK_MODE	Clock Mode 0b - Continuous high speed clock 1b - Non-Continuous high speed clock

49.7.1.4 Configure TCLK-PRE DPHY (CFG_T_PRE)

49.7.1.4.1 Offset

Register	Offset
CFG_T_PRE	8h

49.7.1.4.2 Function

Sets the number of byte clock periods ('clk_byte' input) that the controller will wait after enabling the clock lane for HS operation before enabling the data lanes for HS operation. This setting represents the TCLK-PRE DPHY timing parameter. The minimum value for this port is 1.

49.7.1.4.3 Diagram

Field	Function
31-8 —	Reserved
7-0 NUM_PERIODS	Number of Periods 0 - Zero clock periods (Not supported) 1 - One clock period 2 - Two clock periods ... ..

49.7.1.5 Configure TCLK Wait (CFG_T_POST)

49.7.1.5.1 Offset

Register	Offset
CFG_T_POST	Ch

49.7.1.5.2 Function

Sets the number of byte clock periods ('clk_byte' input) to wait before putting the clock lane into LP mode after the data lanes have been detected to be in Stop State. This setting represents the DPHY timing parameters TLPX + TCLK-PREPARE + TCLK-ZERO + TCLK-PRE requirement for the clock lane before the data lane is allowed to change from LP11 to start a high speed transmission. The minimum value for this port is 1.

49.7.1.5.3 Diagram

49.7.1.7 Configure Auto Insert EoTp (CFG_AUTOINSERT_EOTP)

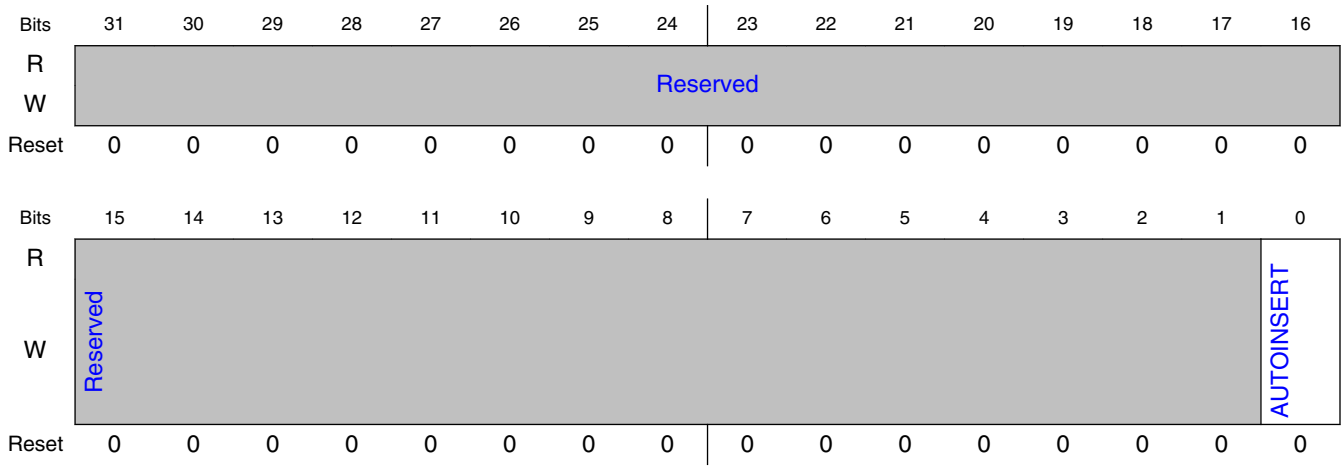
49.7.1.7.1 Offset

Register	Offset
CFG_AUTOINSERT_EOTP	14h

49.7.1.7.2 Function

Enables the Host Controller to automatically insert an EoTp short packet when switching from HS to LP mode.

49.7.1.7.3 Diagram



49.7.1.7.4 Fields

Field	Function
31-1 —	Reserved
0 AUTOINSERT	Auto Insert **NOTE:** AUTOINSERT must always equal 1 when using Video mode. 0b - EoTp is not automatically inserted 1b - EoTp is automatically inserted

49.7.1.8 Configure Extra Packets after EOTP (CFG_EXTRA_CMDS_AFTER_EOTP)

49.7.1.8.1 Offset

Register	Offset
CFG_EXTRA_CMDS_AFTER_EOTP	18h

49.7.1.8.2 Function

Configures the DSI Host Controller to send extra End Of Transmission Packets after the end of a packet. The value is the number of extra EOTP packets sent.

49.7.1.8.3 Diagram

Field	Function
31-16 —	Reserved
15-0 FIFO_SEND_LEVEL	FIFO Send Level 0 - Zero pixels 1 - 1 pixel 2 - 2 pixels ... ...

49.7.2.4 Interface Color Coding (INTERFACE_COLOR_CODING)

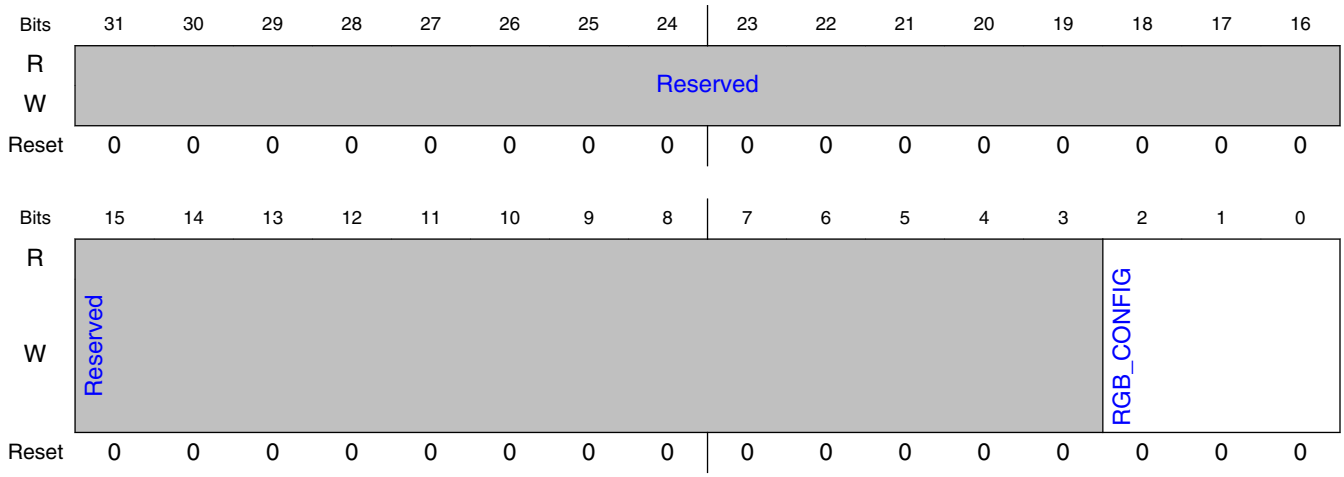
49.7.2.4.1 Offset

Register	Offset
INTERFACE_COLOR_CODING	8h

49.7.2.4.2 Function

Sets the distribution of RGB bits within the 24-bit d bus, as specified by the DPI specification.

49.7.2.4.3 Diagram



49.7.2.4.4 Fields

Field	Function
31-3 —	Reserved
2-0 RGB_CONFIG	RGB Bit Configuration. 000b - 16-bit Configuration 1 001b - 16-bit Configuration 2 010b - 16-bit Configuration 3 011b - 18-bit Configuration 1 100b - 18-bit Configuration 2 101b - 24-bit 110b,111b - Reserved

49.7.2.5 Pixel Format (PIXEL_FORMAT)

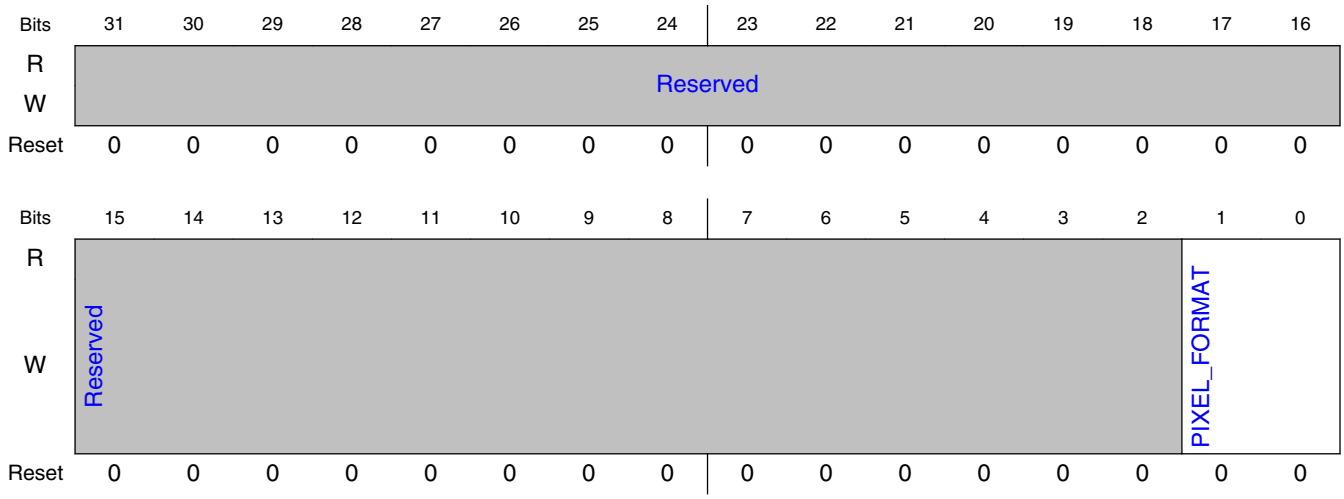
49.7.2.5.1 Offset

Register	Offset
PIXEL_FORMAT	Ch

49.7.2.5.2 Function

Sets the DSI packet type of the pixels.

49.7.2.5.3 Diagram



49.7.2.5.4 Fields

Field	Function
31-2 —	Reserved
1-0 PIXEL_FORMAT	Pixel Format 00b - 16 bit 01b - 18 bit 10b - 18 bit loosely packed 11b - 24 bit

49.7.2.6 Vertical Sync Polarity (VSYNC_POLARITY)

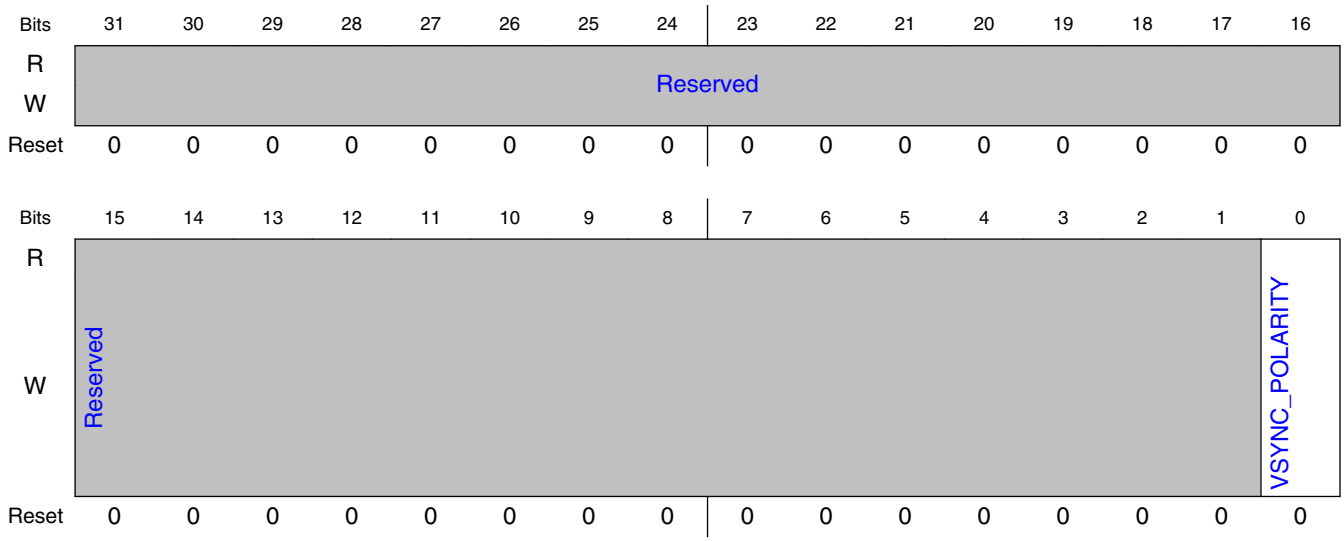
49.7.2.6.1 Offset

Register	Offset
VSYNC_POLARITY	10h

49.7.2.6.2 Function

Sets polarity of dpi_vsync_input.

49.7.2.6.3 Diagram



49.7.2.6.4 Fields

Field	Function
31-1 —	Reserved
0 VSYNC_POLARITY	VSYNC Polarity 0b - Active low 1b - Active high

49.7.2.7 Horizontal Polarity (HSYNC_POLARITY)

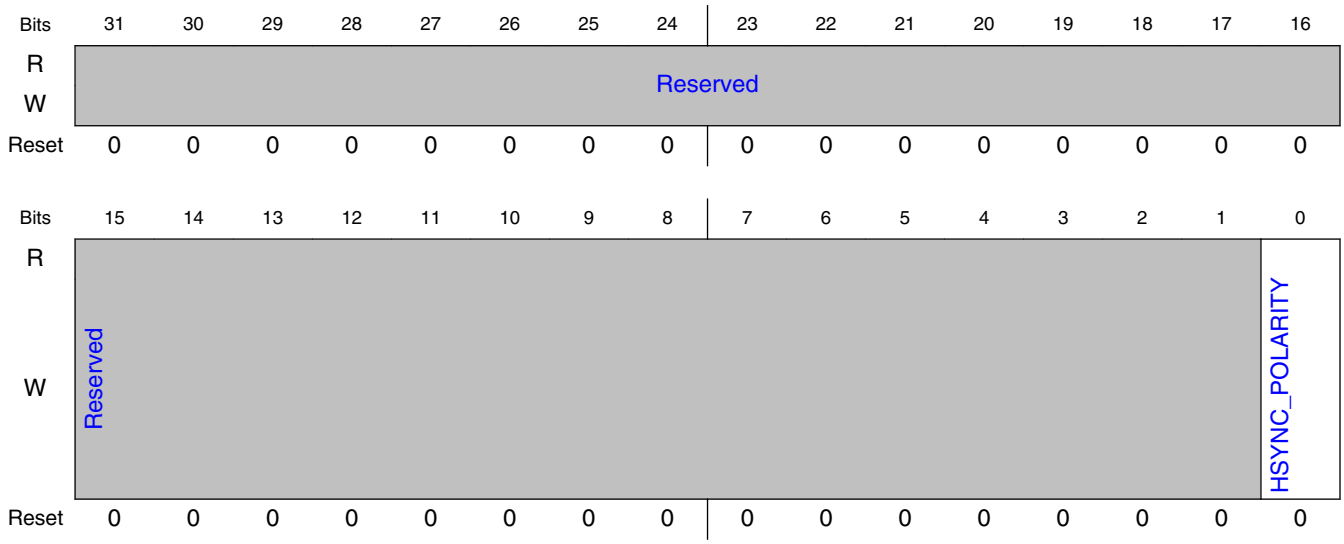
49.7.2.7.1 Offset

Register	Offset
HSYNC_POLARITY	14h

49.7.2.7.2 Function

Sets polarity of dpi_hsync_input.

49.7.2.7.3 Diagram



49.7.2.7.4 Fields

Field	Function
31-1 —	Reserved
0 HSYNC_POLARITY	HSYNC Polarity 0b - Active low 1b - Active high

49.7.2.8 Video Mode (VIDEO_MODE)

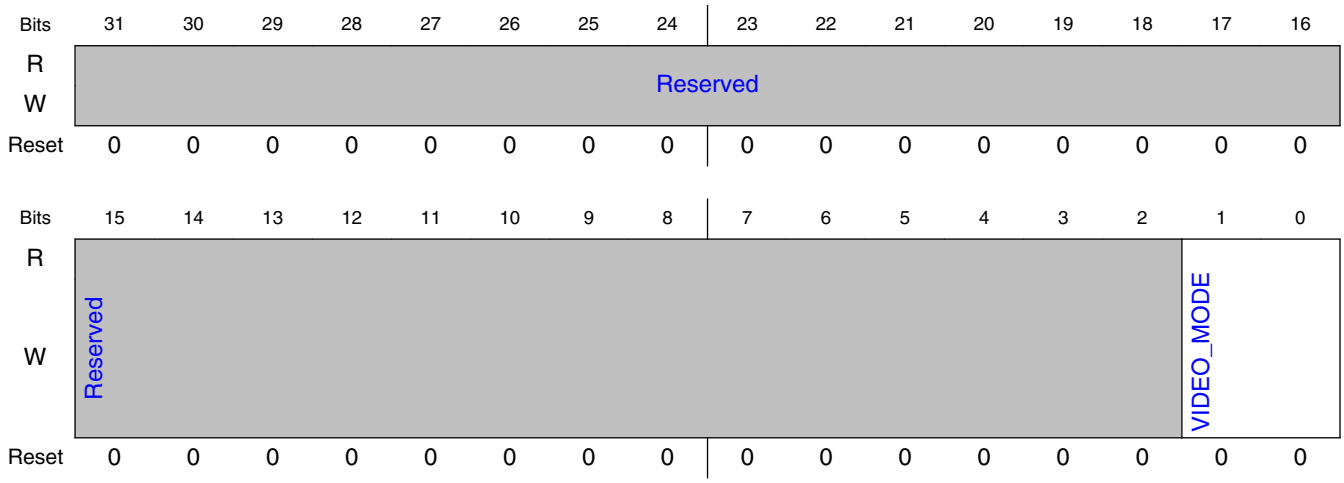
49.7.2.8.1 Offset

Register	Offset
VIDEO_MODE	18h

49.7.2.8.2 Function

Selects the DSI video mode for which the host DPI module generates packets.

49.7.2.8.3 Diagram



49.7.2.8.4 Fields

Field	Function
31-2 —	Reserved
1-0 VIDEO_MODE	Video Mode 00b - Non-Burst mode with Sync Pulses 01b - Non-Burst mode with Sync Events 10b - Burst mode 11b - Reserved

49.7.2.9 Horizontal Front Porch (HFP)

49.7.2.9.1 Offset

Register	Offset
HFP	1Ch

49.7.2.9.2 Function

Sets the DSI packet payload size, in bytes, of the horizontal front porch blanking packet.

49.7.2.9.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

7-0 NUM_LINES	Number of lines 0 - Zero line 1 - 1 line 2 - 2 lines ... ...

49.7.2.15 BLLP Mode (BLLP_MODE)

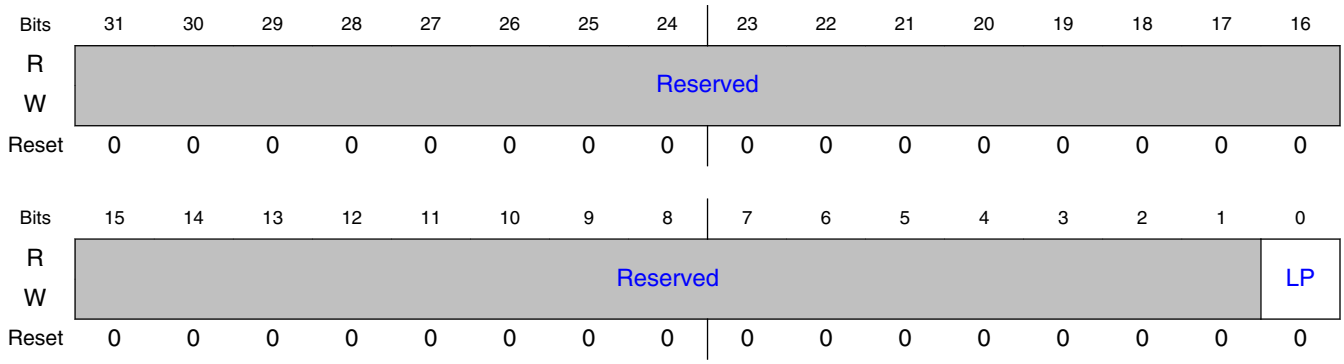
49.7.2.15.1 Offset

Register	Offset
BLLP_MODE	34h

49.7.2.15.2 Function

Optimize bllp periods to Low Power mode when possible.

49.7.2.15.3 Diagram



49.7.2.15.4 Fields

Field	Function
31-1 —	Reserved
0 LP	Low Power mode when possible. 0b - Blanking packets are sent during BLLP periods 1b - LP mode is used for BLLP periods

49.7.2.16 Use Null Packet BLLP (USE_NULL_PKT_BLLP)

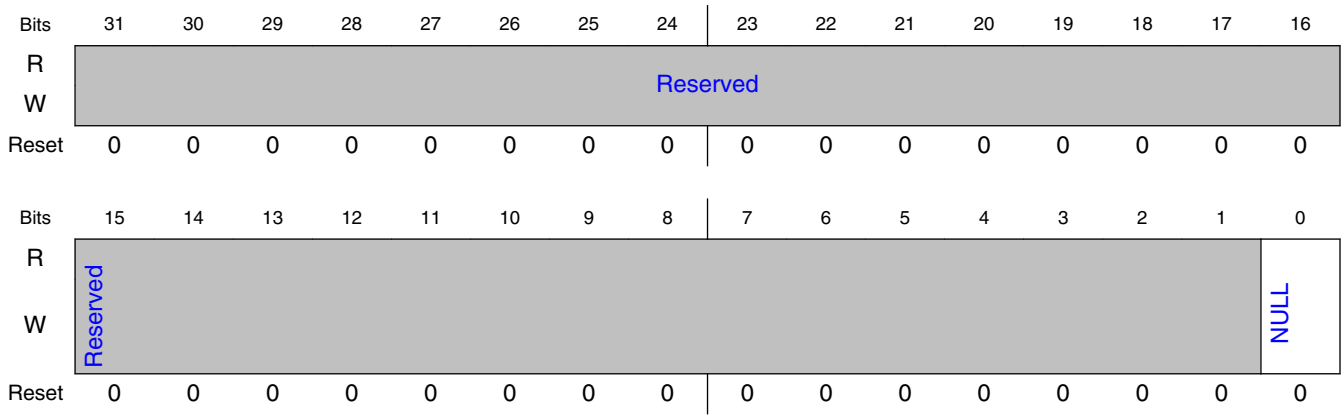
49.7.2.16.1 Offset

Register	Offset
USE_NULL_PKT_BLLP	38h

49.7.2.16.2 Function

Selects type of blanking packet to be sent during bllp.

49.7.2.16.3 Diagram



49.7.2.16.4 Fields

Field	Function
31-1 —	Reserved
0 NULL	Null 0b - Blanking packet used in bllp region 1 1b - Null packet used in bllp region

49.7.2.17 Vertical Active (VACTIVE)

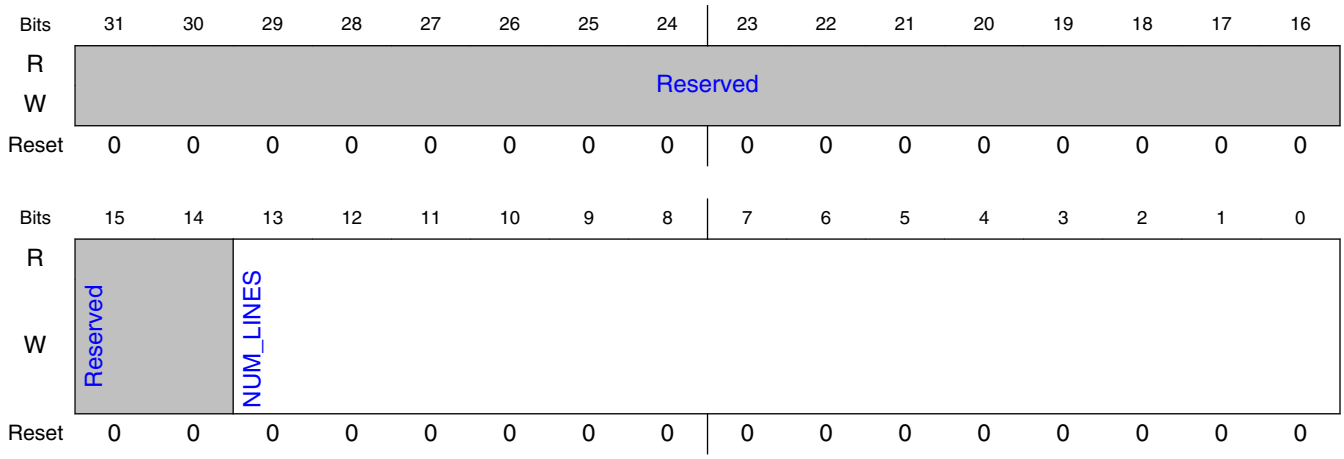
49.7.2.17.1 Offset

Register	Offset
VACTIVE	3Ch

49.7.2.17.2 Function

Sets the number of lines in the vertical active aread.

49.7.2.17.3 Diagram



49.7.2.17.4 Fields

Field	Function
31-14 —	Reserved
13-0 NUM_LINES	Number of lines 0 - Zero line 1 - 1 line 2 - 2 lines ... ...

49.7.3 DSI HOST APB PKT Interface register descriptions

49.7.3.1 APB_PKT_IF memory map

MIPI_DSI.DSI_HOST_APB_PKT_IF base address: 4080_C280h

Offset	Register	Width (In bits)	Access	Reset value
0h	Transmit Payload Data Write (TX_PAYLOAD)	32	RW	0000_0000h
4h	Packet Control (PKT_CONTROL)	32	RW	0000_0000h

Table continues on the next page...

Offset	Register	Width (In bits)	Access	Reset value
8h	Send Packet (SEND_PACKET)	32	RW	0000_0000h
Ch	Packet Status (PKT_STATUS)	32	R	0000_0000h
10h	Packet FIFO Write Level (PKT_FIFO_WR_LEVEL)	32	R	0000_0000h

31-0 PAYLOAD	Payload

49.7.3.3 Packet Control (PKT_CONTROL)

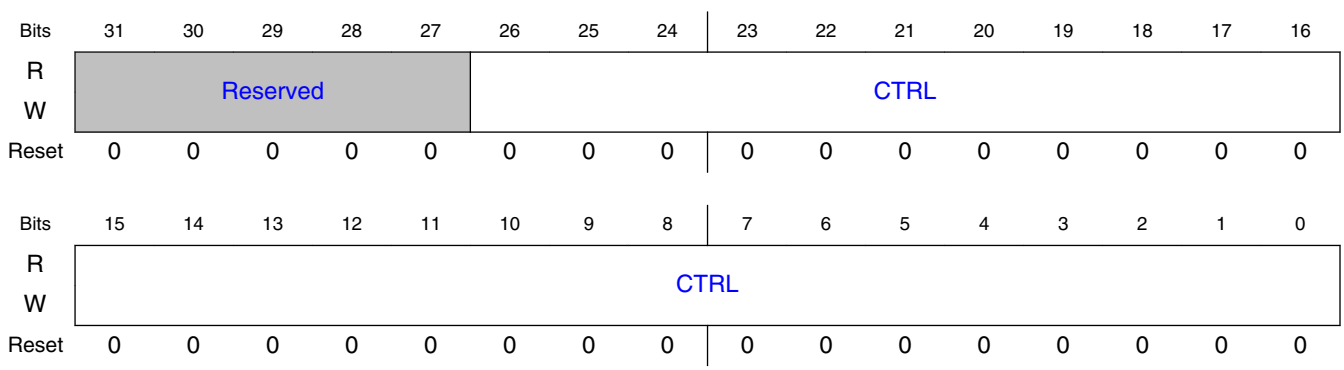
49.7.3.3.1 Offset

Register	Offset
PKT_CONTROL	4h

49.7.3.3.2 Function

Transmit packet control.

49.7.3.3.3 Diagram



49.7.3.3.4 Fields

Field	Function
31-27 —	Reserved
26-0 CTRL	Control [15:0] - Packet word count [17:16] - Reserved

Field	Function
	[23:18] - Packet Header DSI Data Type [24] - Lp or HS select: 0 - LP mode, 1 - HS mode [25] - perform BTA after packet is sent [26] - perform BTA only, no packet Tx

49.7.3.4 Send Packet (SEND_PACKET)

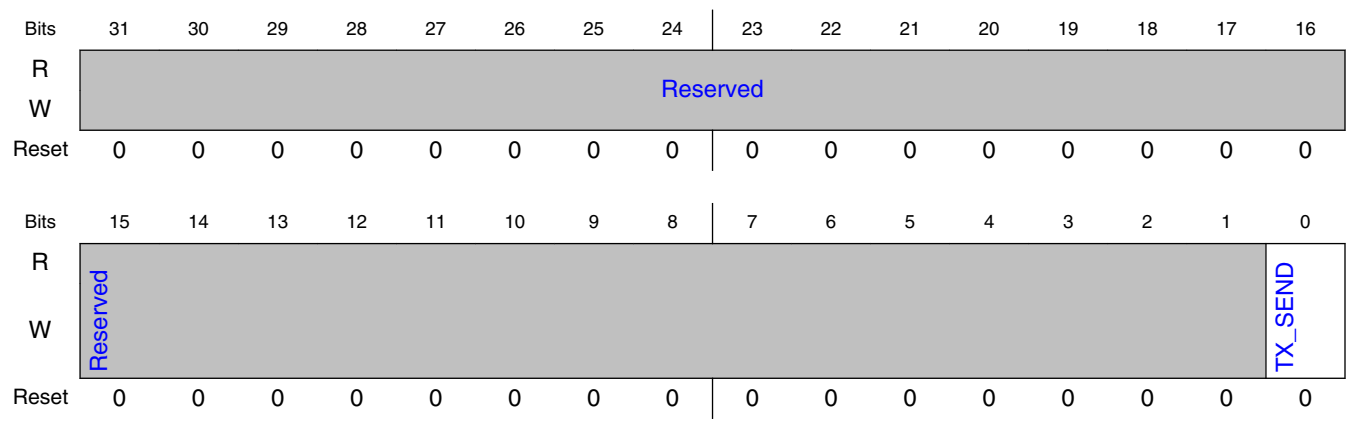
49.7.3.4.1 Offset

Register	Offset
SEND_PACKET	8h

49.7.3.4.2 Function

Writes to this register causes the packet described in dsi_host_pkt_control to be sent.

49.7.3.4.3 Diagram



49.7.3.4.4 Fields

Field	Function
31-1 —	Reserved
0 TX_SEND	Transmit send packet 0b - Packet not sent 1b - Packet is sent

49.7.3.5 Packet Status (PKT_STATUS)

49.7.3.5.1 Offset

Register	Offset
PKT_STATUS	Ch

49.7.3.5.2 Function

Status of APB to packet interface.

49.7.3.5.3 Diagram

Clocking	CCM	Clock Management Clock Control Module (CCM)
Power management	PMU	Power Management Power Management Unit
Signal multiplexing	IOMUX	External Signals and Pin Multiplexing IOMUX
Interrupts, DMA Events and XBAR Assignments	-	Interrupts, DMA Events and XBAR Assignments

50.2 Overview

The Video Multiplexer (VIDEO_MUX) contains mux controls between the following camera and display blocks:

- Parallel CSI
- MIPI CSI-2
- CSI
- MIPI DSI
- Parallel LCDIF
- LCDIFv2
- eLCDIF
- DCIC

50.2.1 Block diagram

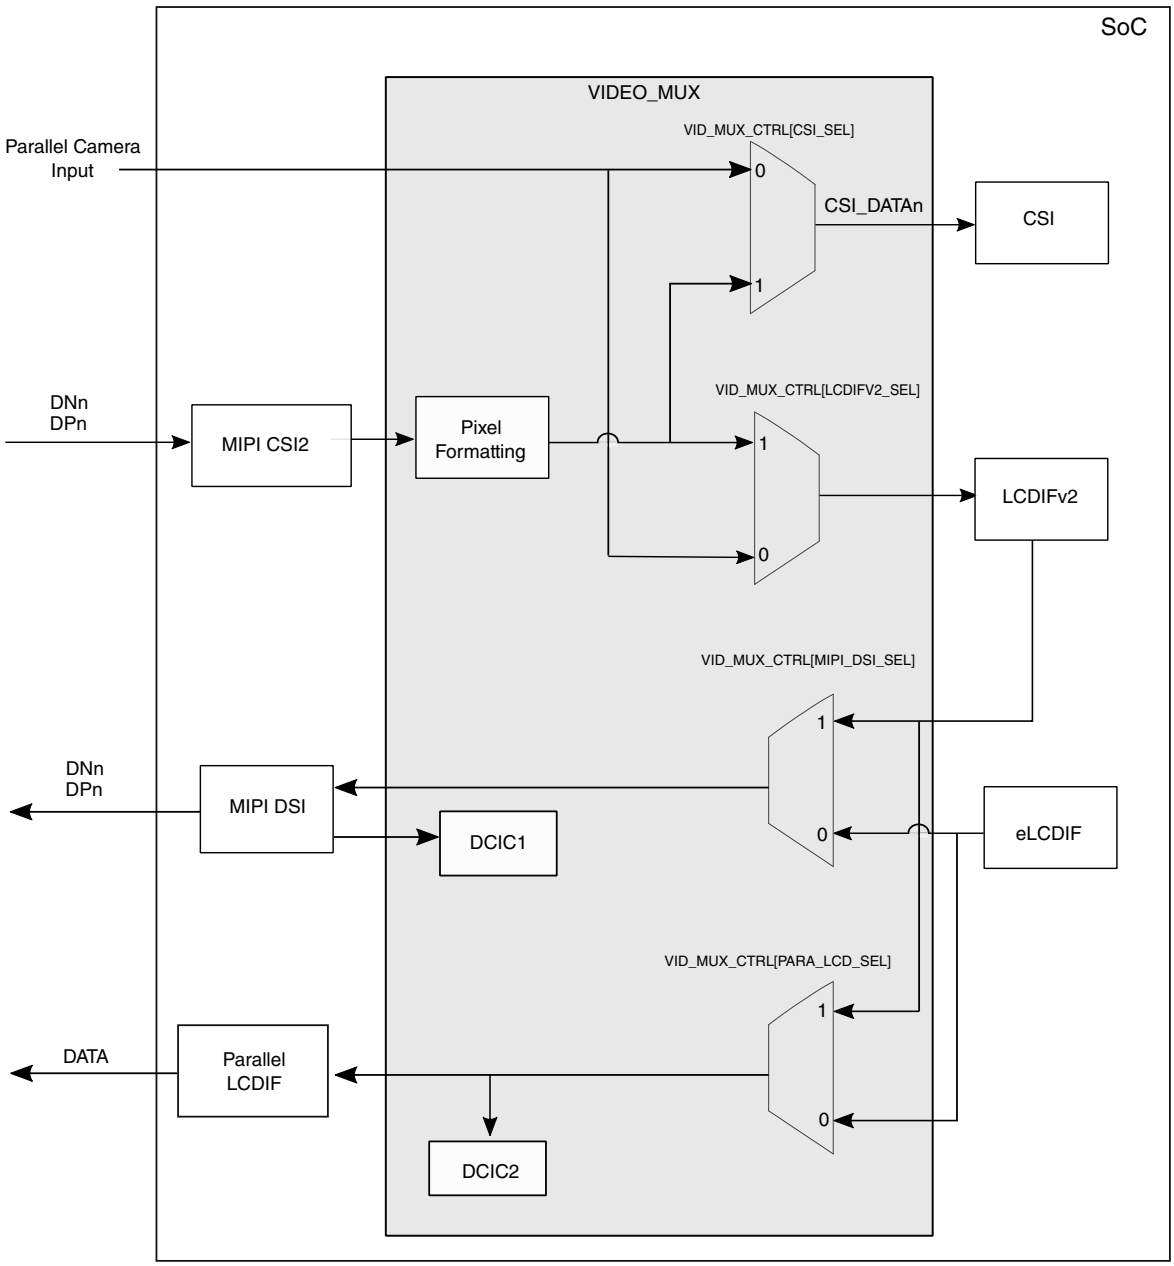

Figure 50-1. VIDEO_MUX block diagram

The pixel reformatting block converts the data format of MIPI CSI2 to meet the requirements of Pixel Link.

50.2.2 Features

This block includes the following features:

- Display Content Integrity Checker (DCIC) for Parallel LCDIF and MIPI DSI
- Support for two displays at one time

50.3 Functional description

The following sections describe functional details of this module.

50.3.1 Operation

The VIDEO_MUX block is a multiplexer which selects between various camera and display inputs and provide a desired output. The following selects are provided in this block:

- Input is selected between Parallel CSI and MIPI CSI2. The output can be either to CSI or LCDIFv2.
- Input is selected between eLCDIF and LCDIFv2. The output can be either to MIPI DSI or Parallel LCD display.

The DCIC function is provided to ensure the video data to the displays is not corrupted.

50.3.2 Clocks

The table below describes clocks of this module.

Table 50-2. Clocks

Clock	Description
ipg_clk_s	Peripheral access clock for register accesses

50.3.3 Reset

There are no special considerations.

50.4 External Signals

Table 50-3. External Signals Table

Module	External Signal	Description	I/O
CSI	CSI_DATAn	Data Sensor Signals, part of 16-bit Sensor Data Bus (Bayer, YUV,YCrCb, RGB)	I
	CSI_FIELD	CSI Field Signal	I
	CSI_HSYNC	Horizontal Sync (Blank Signal)	I

50.5 Initialization

There are no special considerations.

50.6 Memory Map and register definition

This section includes the VIDEO_MUX module memory map and detailed descriptions of all registers.

50.6.1 VIDEO_MUX register descriptions

50.6.1.1 VIDEO_MUX memory map

VIDEO_MUX base address: 4081_8000h

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)
0	Video mux Control Register (VID_MUX_CTRL)	32	RW	0000_0000
4	Video mux Control Register (VID_MUX_CTRL_SET)	32	RW	0000_0000
8	Video mux Control Register (VID_MUX_CTRL_CLR)	32	RW	0000_0000
C	Video mux Control Register (VID_MUX_CTRL_TOG)	32	RW	0000_0000
20	Pixel Link Master(PLM) Control Register (PLM_CTRL)	32	RW	0000_0000
24	Pixel Link Master(PLM) Control Register (PLM_CTRL_SET)	32	RW	0000_0000
28	Pixel Link Master(PLM) Control Register (PLM_CTRL_CLR)	32	RW	0000_0000
2C	Pixel Link Master(PLM) Control Register (PLM_CTRL_TOG)	32	RW	0000_0000
30	YUV420 Control Register (YUV420_CTRL)	32	RW	0000_0000
34	YUV420 Control Register (YUV420_CTRL_SET)	32	RW	0000_0000
38	YUV420 Control Register (YUV420_CTRL_CLR)	32	RW	0000_0000
3C	YUV420 Control Register (YUV420_CTRL_TOG)	32	RW	0000_0000
50	Data Disable Register (CFG_DT_DISABLE)	32	RW	0000_0000
54	Data Disable Register (CFG_DT_DISABLE_SET)	32	RW	0000_0000
58	Data Disable Register (CFG_DT_DISABLE_CLR)	32	RW	0000_0000
5C	Data Disable Register (CFG_DT_DISABLE_TOG)	32	RW	0000_0000
70	MIPI DSI Control Register (MIPI_DSI_CTRL)	32	RW	0000_0000

Table continues on the next page...

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)
74	MIPI DSI Control Register (MIPI_DSI_CTRL_SET)	32	RW	0000_0000
78	MIPI DSI Control Register (MIPI_DSI_CTRL_CLR)	32	RW	0000_0000
7C	MIPI DSI Control Register (MIPI_DSI_CTRL_TOG)	32	RW	0000_0000

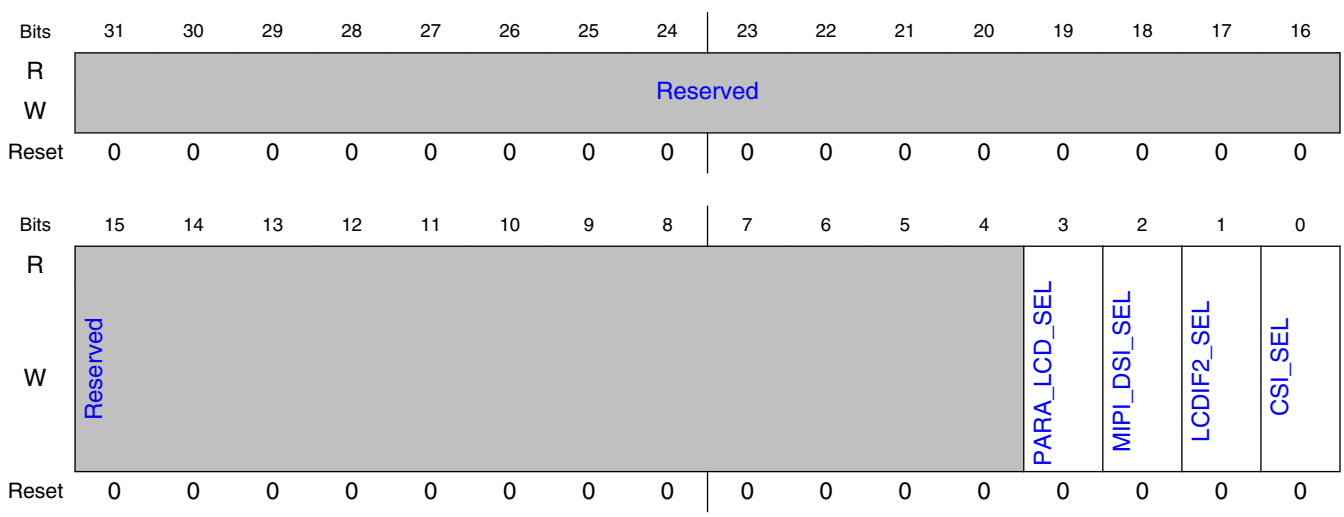
50.6.1.2 Video mux Control Register (VID_MUX_CTRL)

This register contains mux controls

50.6.1.2.1 Offset

Register	Offset	Description
VID_MUX_CTRL	0h	Video mux Control Register
VID_MUX_CTRL_SET	4h	Writing a 1 to a bit in this register sets the corresponding bit in VID_MUX_CTRL
VID_MUX_CTRL_CLR	8h	Writing a 1 to a bit in this register clears the corresponding bit in VID_MUX_CTRL
VID_MUX_CTRL_TOG	Ch	Writing a 1 to a bit in this register toggles the corresponding bit in VID_MUX_CTRL

50.6.1.2.2 Diagram



50.6.1.2.3 Fields

Field	Description
31-4 —	Reserved
3 PARA_LCD_SEL	Parallel LCDIF video data input mux selector 0 - Parallel LCDIF video data is from eLCDIF 1 - Parallel LCDIF video data is from LCDIFv2
2 MIPI_DSI_SEL	MIPI DSI video data input mux selector 0 - MIPI DSI video data is from eLCDIF 1 - MIPI DSI video data is from LCDIFv2
1 LCDIF2_SEL	LCDIF2 sensor data input mux selector 0 - LCDIFv2 sensor data is from Parallel CSI 1 - LCDIFv2 sensor data is from MIPI CSI
0 CSI_SEL	CSI sensor data input mux selector 0 - CSI sensor data is from Parallel CSI 1 - CSI sensor data is from MIPI CSI

50.6.1.3 Pixel Link Master(PLM) Control Register (PLM_CTRL)

These inputs will override the transmitted data on Pixel Link

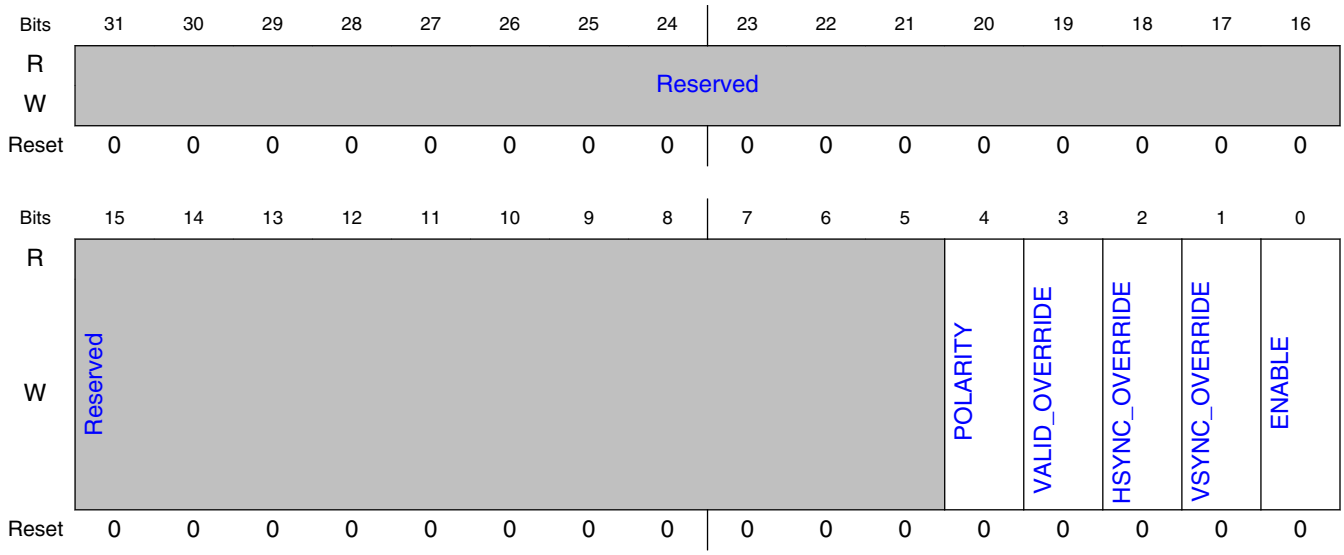
NOTE

If PLM_CTRL[VSYNC_OVERRIDE]= 0 and PLM_CTRL[HSYNC_OVERRIDE] = 0, PLM_CTRL[VALID_OVERRIDE] must be 1.

50.6.1.3.1 Offset

Register	Offset	Description
PLM_CTRL	20h	Pixel Link Master(PLM) Control Register
PLM_CTRL_SET	24h	Writing a 1 to a bit in this register sets the corresponding bit in PLM_CTRL
PLM_CTRL_CLR	28h	Writing a 1 to a bit in this register clears the corresponding bit in PLM_CTRL
PLM_CTRL_TOG	2Ch	Writing a 1 to a bit in this register toggles the corresponding bit in PLM_CTRL

50.6.1.3.2 Diagram



50.6.1.3.3 Fields

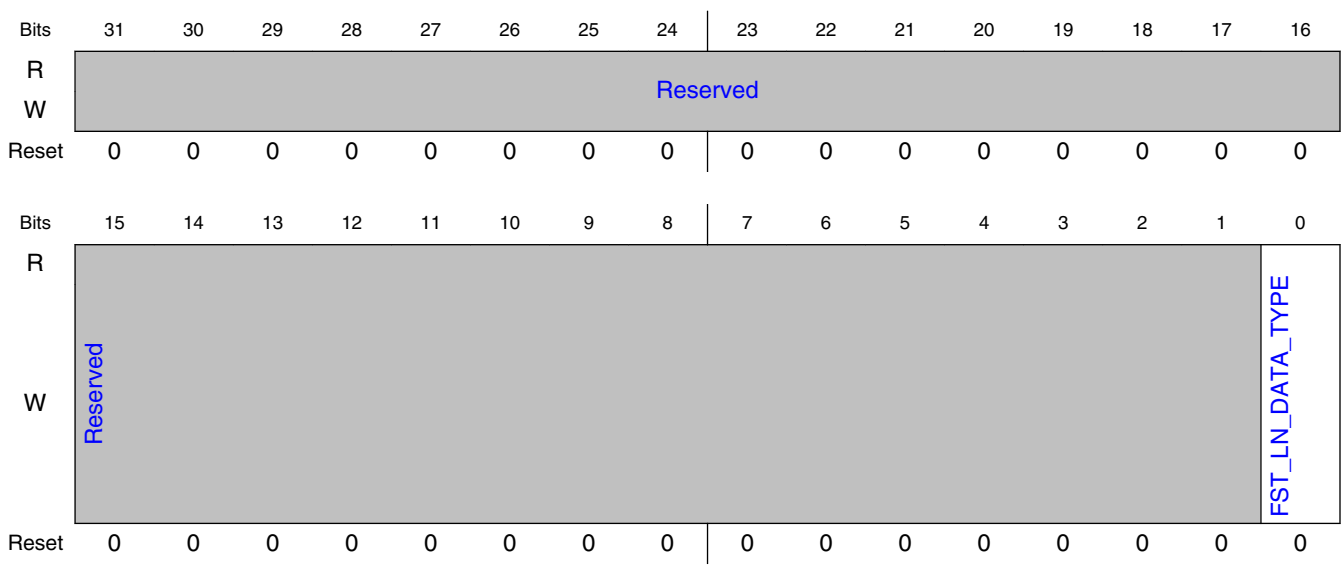
Field	Description
31-5 —	Reserved
4 POLARITY	Polarity of HYSNC/VSYNC 0 - Keep the current polarity of HSYNC and VSYNC 1 - Invert the polarity of HSYNC and VSYNC
3 VALID_OVERRIDE	Valid override This override is used to drive valid on the Pixel Link 0 - HSYNC and VSYNC is asserted 1 - HSYNC and VSYNC is not asserted
2 HSYNC_OVERRIDE	HSYNC override This override is used to force the PLM HSYNC input to be 1 0 - HSYNC is not asserted 1 - HSYNC is asserted
1 VSYNC_OVERRIDE	VSYNC override This override is used to force the PLM VSYNC input to be 1 0 - VSYNC is not asserted 1 - VSYNC is asserted
0 ENABLE	Enable the output of HYSNC and VSYNC 0 - No active HSYNC and VSYNC output 1 - Active HSYNC and VSYNC output

50.6.1.4 YUV420 Control Register (YUV420_CTRL)

50.6.1.4.1 Offset

Register	Offset	Description
YUV420_CTRL	30h	YUV420 Control Register
YUV420_CTRL_SET	34h	Writing a 1 to a bit in this register sets the corresponding bit in YUV420_CTRL
YUV420_CTRL_CLR	38h	Writing a 1 to a bit in this register clears the corresponding bit in YUV420_CTRL
YUV420_CTRL_TOG	3Ch	Writing a 1 to a bit in this register toggles the corresponding bit in YUV420_CTRL

50.6.1.4.2 Diagram



50.6.1.4.3 Fields

Field	Description
31-1 —	Reserved
0	Data type of First Line

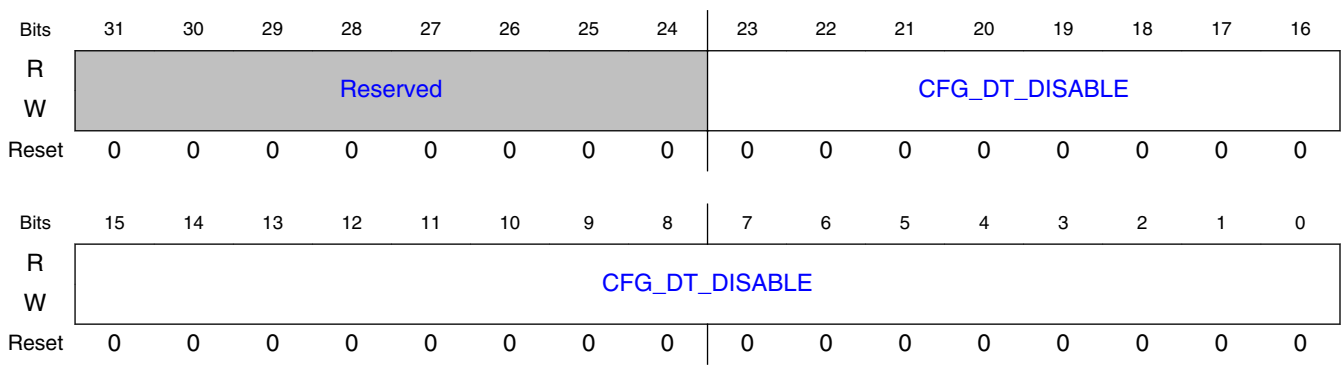
Field	Description
FST_LN_DATA_TYPE	0 - Odd (default) 1 - Even

50.6.1.5 Data Disable Register (CFG_DT_DISABLE)

50.6.1.5.1 Offset

Register	Offset	Description
CFG_DT_DISABLE	50h	Data Disable Register
CFG_DT_DISABLE_SET	54h	Writing a 1 to a bit in this register sets the corresponding bit in CFG_DT_DISABLE
CFG_DT_DISABLE_CLR	58h	Writing a 1 to a bit in this register clears the corresponding bit in CFG_DT_DISABLE
CFG_DT_DISABLE_TOG	5Ch	Writing a 1 to a bit in this register toggles the corresponding bit in CFG_DT_DISABLE

50.6.1.5.2 Diagram



50.6.1.5.3 Fields

Field	Description
31-24 —	Reserved
23-0	Data Type Disable Disable the data type. Each bit represents one data type.

Field	Description
CFG_DT_DISABLE	1'b0 - Enable data type 1'b1 - Disable data type **YUV Image Data Types:** [0]: YUV420_8BIT [1]: YUV420_10BIT [2]: LEGACY_YUV420_8BIT [3]: Reserved [4]: YUV420_8BIT_CS [5]: YUV420_10BIT_CS [6]: YUV422_8BIT [7] YUV422_10BIT **RGB Image Data Types:** [8]: RGB444 [9]: RGB555 [10] RGB565 [11]: RGB666 [12]: RGB888 [13-15]: Reserved **Raw Image Data Types** [16]: RAW6 [17]: RAW7 [18]: RAW8 [19]: RAW10 [20]: RAW12 [21]: RAW14 [22-23]: Reserved

50.6.1.6 MIPI DSI Control Register (MIPI_DSI_CTRL)

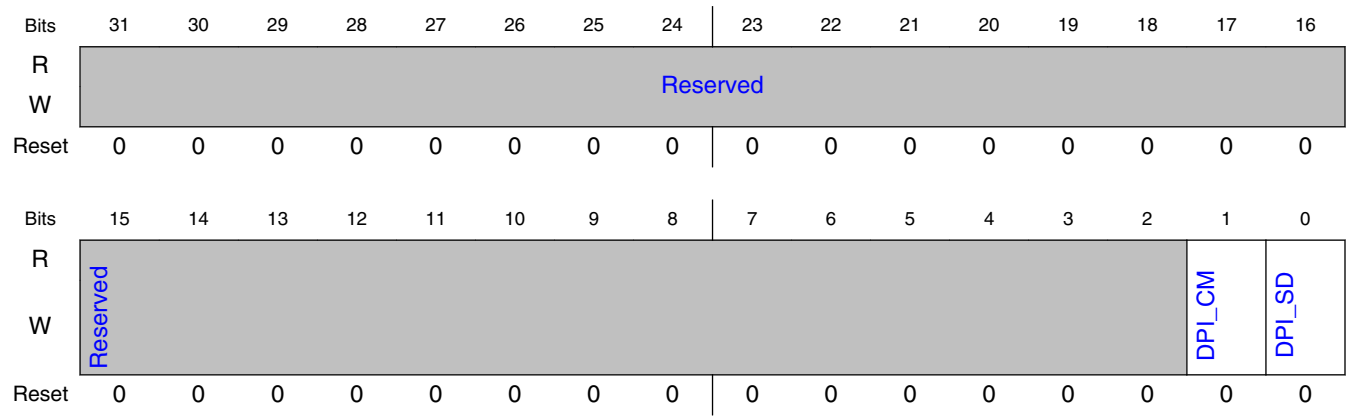
50.6.1.6.1 Offset

Register	Offset	Description
MIPI_DSI_CTRL	70h	MIPI DSI Control Register
MIPI_DSI_CTRL_SET	74h	Writing a 1 to a bit in this register sets the corresponding bit in MIPI_DSI_CTRL

Table continues on the next page...

Register	Offset	Description
MIPI_DSI_CTRL_CLR	78h	Writing a 1 to a bit in this register clears the corresponding bit in MIPI_DSI_CTRL
MIPI_DSI_CTRL_TOG	7Ch	Writing a 1 to a bit in this register toggles the corresponding bit in MIPI_DSI_CTRL

50.6.1.6.2 Diagram



50.6.1.6.3 Fields

Field	Description
31-2 —	Reserved
1 DPI_CM	Color Mode control This field is used to change the number of displayed colors 0 - Normal Mode 1 - 8-color mode (compared to Full-color mode)
0 DPI_SD	Shut Down – Control to shutdown display (type 4 only) 0 - No effect 1 - Send shutdown command

Chapter 51
Display Content Integrity Checker (DCIC)

51.1 Chip-specific DCIC information

Table 51-1. Reference links to related information

Topic	Related module(s)	Reference
System memory map	-	System Memory Map
Clocking	CCM	Clock Management Clock Control Module (CCM)
Power management	PMU	Power Management Power Management Unit
Signal multiplexing	IOMUX	External Signals and Pin Multiplexing IOMUX
Interrupts, DMA Events and XBAR Assignments	-	Interrupts, DMA Events and XBAR Assignments

51.2 Overview

The Display Content Integrity Checker (DCIC) verifies whether safety-critical information sent to a display has been corrupted. This type of verification is required in some safety-sensitive systems, like the warning icons in an vehicle cluster, and includes compliance with the ASIL B (Automotive Safety Integrity Level B) specification.

51.2.1 Block Diagram

The top level block diagram of the DCIC module is provided below.

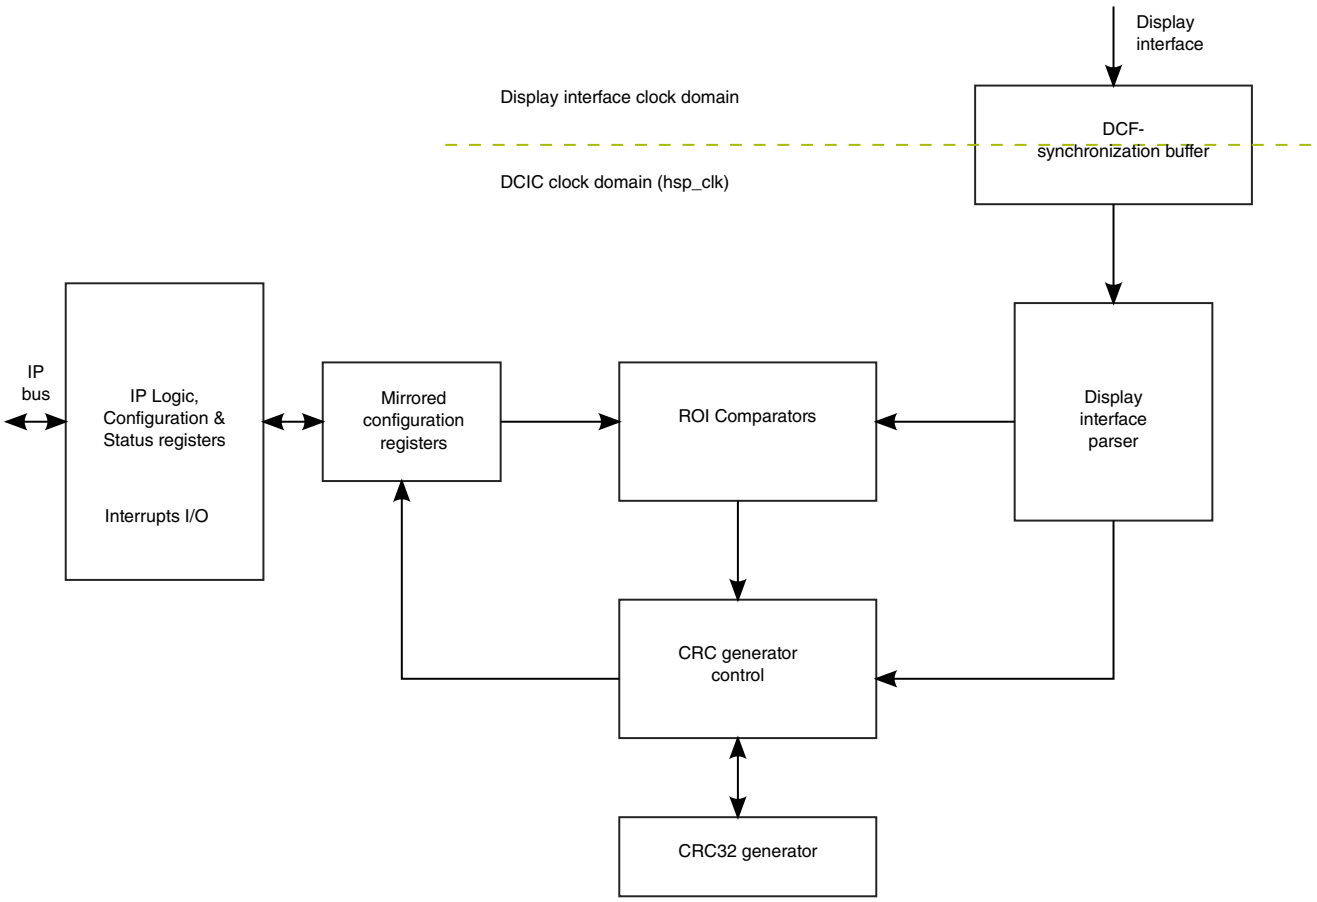


Figure 51-1. DCIC block diagram

51.2.2 Features

The DCIC module includes the following features:

- Pixel clock up to 75 MHz.
- Configurable polarity of the Display Interface control signals.
- 24-bit pixel data bus.
- Support for up to 16 rectangular ROIs (Regions of Interest) with configurable location and size.
- Independent CRC32 signature calculation for each ROI.
- External controller mismatch indication signal.

51.3 Functional Description

The following sections describe the functional details of this module.

51.3.1 Generic synchronous parallel display interface

The following figure depicts the LCD interface timing for a generic active matrix color TFT panel. In the figure, the signals are shown with negative polarity, but both polarity modes are supported by the DCIC module through the configuration of the appropriate bits in the DCIC Control Register.

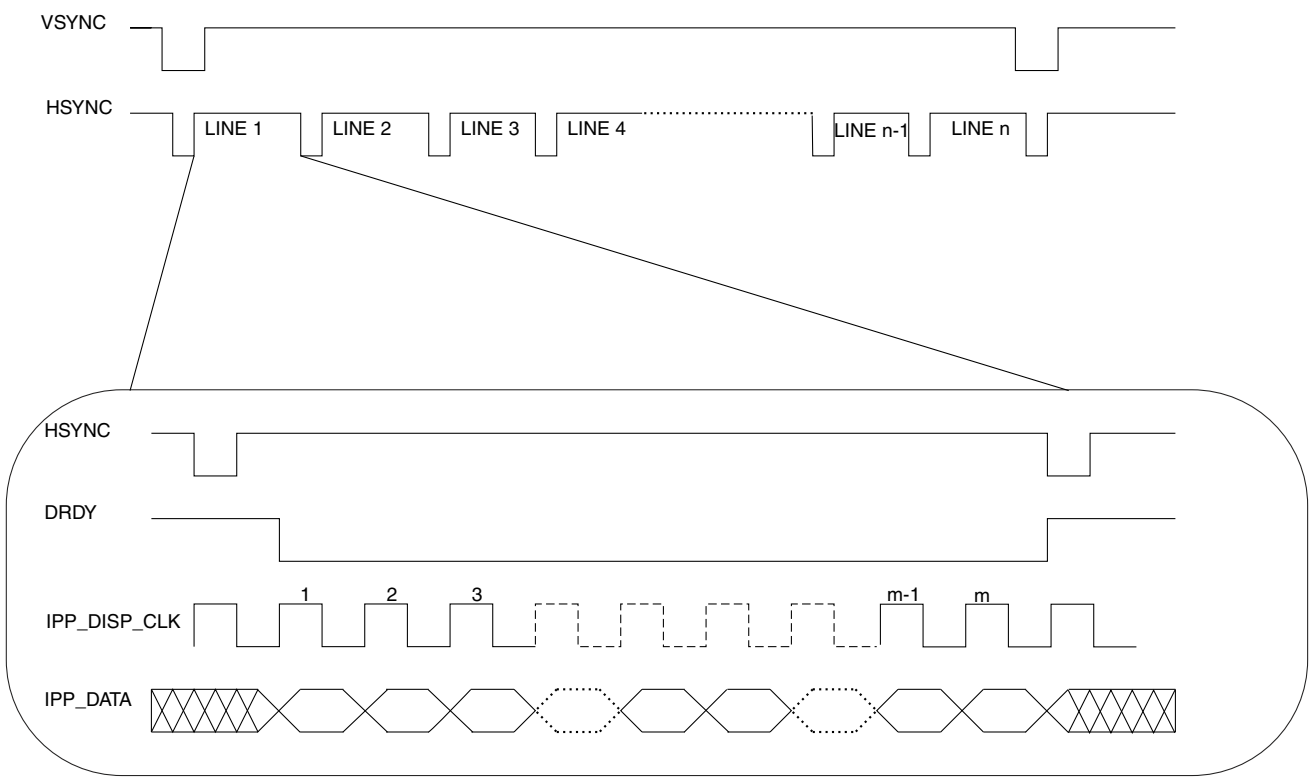

Figure 51-2. Interface Timing Diagram for TFT (Active Matrix) Panels

The sequence of events for the active matrix interface timing is as follows:

- IPP_DISP_CLK latches data into the panel on it's negative edge, when positive polarity is selected. In active mode, IPP_DISP_CLK runs continuously.
- HSYNC causes the panel to start a new line.
- VSYNC causes the panel to start a new frame. It always encompasses at least one HSYNC pulse.
- DRDY acts like an output enable signal. This output enables the data to be shifted onto the display. When disabled, the data is invalid and the trace is off.

51.3.2 CRC Polynomial

The DCIC uses the CRC32 polynomial to calculate the data signature. The initial value for the CRC calculation is 0x00000000.

$$x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$$

Figure 51-3. Polynomial function for CRC32

The CRC generator uses the XOR-ed combination of the input data bits and the previous result bits.

51.3.3 External controller mismatch indication signal

Apart from the interrupts to the SoC core, the DCIC provides an additional mismatch indication for the external controller. The EXT_DCIC signal, if enabled (DCIC_DCICIC[EXT_SIG_EN]), continuously oscillates at a rate which is an integer division of the main clock (hsp_clk).

- When the status bit of the mismatch interrupt is set, i.e., from the mismatch detection until the CPU clears the bit: division x16
- Otherwise: division x4

The indication signal is idle while the integrity check is disabled.

51.3.4 Mode of operation

After the DCIC is configured and enabled, provided that the eLCDIF/LCDIFv2 is already enabled, the first VSYNC is being watched. The VSYNC assertion zeroizes the main position counters and initializes the CRC storage registers.

Each HSYNC assertion after the first line in the frame that holds valid pixel data (non blanking) will signal a new line, i.e., increment Y-counter and zeroize X-counter. Each valid data cycle (DATA_EN asserted) will increment the X-counter. Thus, the X & Y values used to configure the module should be the coordinates on the actual visual part of the screen without blanking intervals. The X & Y position counters are constantly compared to the ROIs configuration. When the current position matches one of the enabled ROIs, it triggers the enablement of the CRC generator, which will use the current pixel data and the previous pixel CRC result for this ROI. The result of the new calculation is stored separately for each ROI. The next VSYNC signal, apart from

signalling the start of a new frame, will load the calculated CRC value into the DCIC_DCICRCSn register. These values will then be compared to the expected signatures and the appropriate status bits/interrupts will be asserted.

51.3.5 Interrupts

There are two maskable interrupts:

- Functional - Asserted when the signature match results are ready.
- Error - Asserted when there is a signature mismatch.

Both interrupts are generated immediately after completing the signature match check. Software should clear the interrupts by writing "1" to the DCIC_DCICS[FI_STAT] and DCIC_DCICS[ROI_MATCH_STAT] bits. Since the DCIC_DCICS[EI_STAT] bit is a result of the OR between all the DCIC_DCICS[ROI_MATCH_STAT] bits, it will be cleared automatically when these bits are cleared.

Interrupt masks can be set/reset only while the DCIC_DCICIC[FREEZE_MASK] bit is not set. This bit cannot be set back to zero.

Please see the IRQ chapter for the interrupt assignments.

51.3.6 Resets

Disabling and enabling the module operation (DCIC_DCICC[IC_EN]) will reset all the logic except for the configuration registers domain. The reset will be active immediately. The status bits of the DCIC Status Register will also be cleared.

51.3.7 Clocks

Table 51-2. Clocks

Clock	Description
hsp_clk	Main module clock driving the DCIC logic and IP registers.

An Asynchronous FIFO is used to sample raw display interface signals and transfer them into the DCIC fast clock domain (hsp_clk).

The IP registers are driven by the same fast clock (hsp_clk) and are synchronized to the system IP Bus clock by the external IP_SYNC module.

The display interface clock is always slower than the DCIC fast clock.

51.3.8 Power saving

Disabling the module by clearing the DCIC_DCICC[IC_EN] bit, will stop all module activities, including the sampling of the input signals into the FIFO.

51.4 External Signals

Table 51-3. External Signals

Signal	Description	Direction
EXT_DCIC	Variable frequency, oscillating signal indicating the comparison status for the external controller.	O

51.5 System Considerations

- The DCIC always assumes a 24-bit pixel. For proper functionality with lower color depth, one must ensure that:
  - When the CPU calculates the reference signature, it applies the same mapping of a pixel to a 24-bit field as that performed by the eLCDIF/LCDIFv2.
  - The display is connected to the appropriate pins.
  - The simplest mapping would be:
    - Map the pixel to the data bus in the same way as for 24 bpp.
    - Set the values at the extra LSBs to zero.
- Parameter updates
  - The reference signature can be updated from frame to frame, in coordination with the changing content since it is used only once per frame, just before the interrupt.
  - Each ROI can be independently enabled/disabled between frames since the enable bit is double buffered.
  - The size and location of a ROI can be modified while it is disabled.
  - Display interface signals polarity can be changed only when the module is disabled.
- ROIs do not overlap, i.e., each pixel belongs to a single ROI at most.

- The DCIC operation is intended for monitoring relatively static portions of the graphic interface, otherwise it will be a complicated software task to keep up with frame synchronization and update of expected signature for each frame.
- There should be no processing done at the eLCDIF/LCDIFv2 on monitored ROIs, which cannot be taken in consideration by software when calculating the expected signature.

51.6 DCIC Memory Map/Register Definition

NOTE

All write accesses have to be full word (32-bit) accesses. No error/abort will be responded in case of different access size, but no data will be written. Similarly, there will be no error response in case of access to undefined memory space.

Read access will return 32-bit data, which may be truncated on the system level in case it was not a full word access.

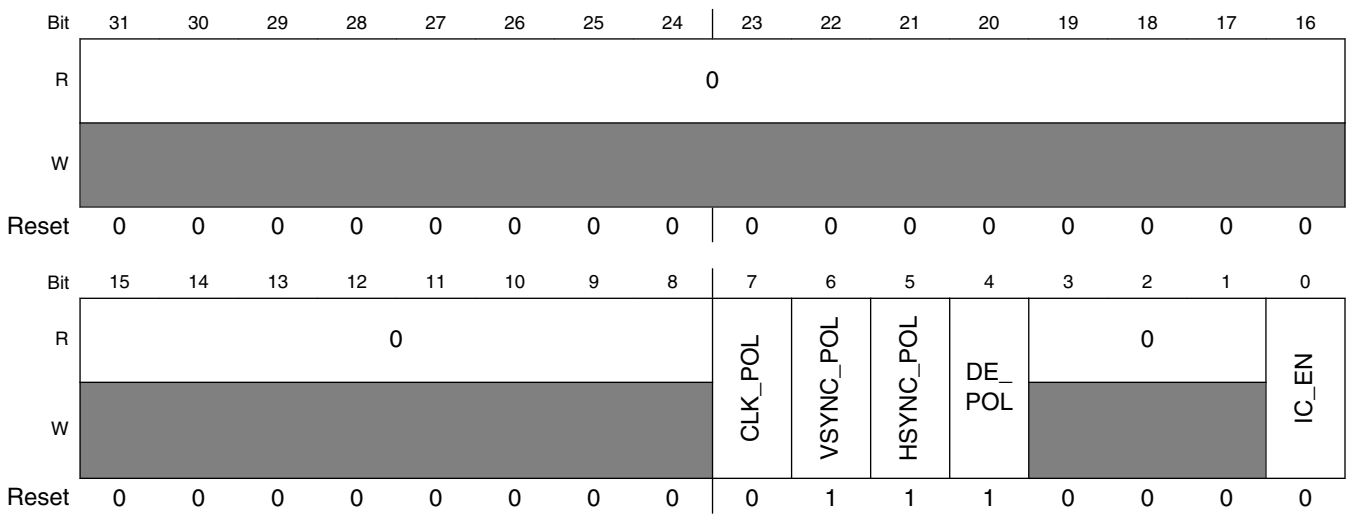
51.6.1 DCIC Control Register (DCICx_DCICC)

This register is used to configure the polarity of the signals and to enable/disable the DCIC module operation.

Address: Base address + 0h offset



DCICx_DCICC field descriptions

Field	Description
31–8 Reserved	This read-only field is reserved and always has the value 0.
7 CLK_POL	DISP_CLK signal polarity. 0 Not inverted (default). 1 Inverted.

Table continues on the next page...

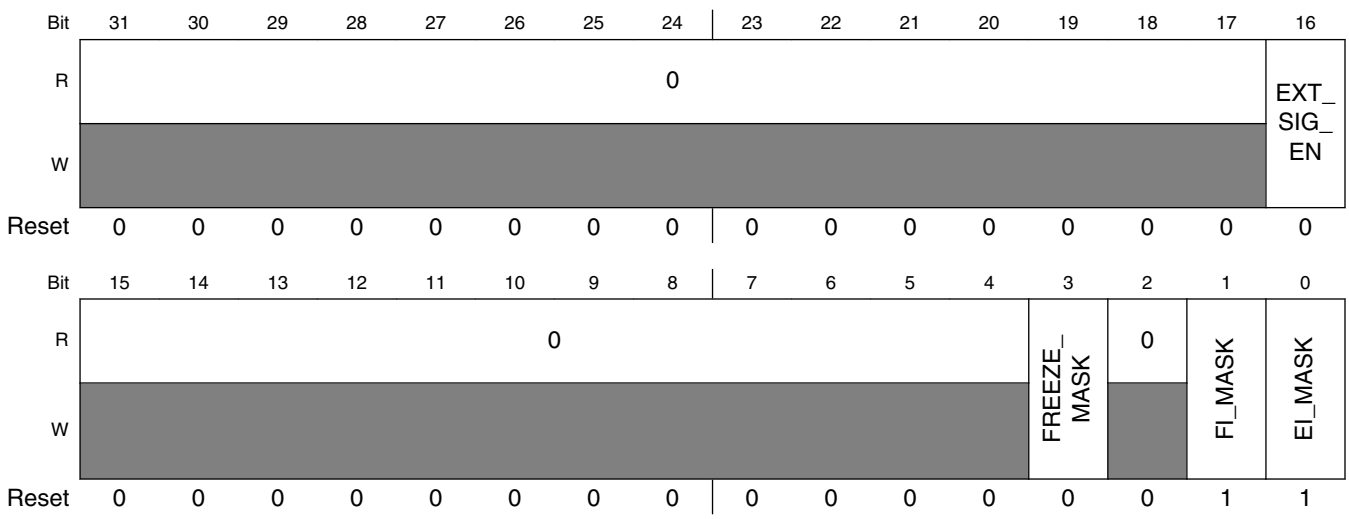
DCICx_DCICC field descriptions (continued)

Field	Description
6 VSYNC_POL	VSYNC_IN signal polarity. 0 Active High. 1 Active Low.
5 HSYNC_POL	HSYNC_IN signal polarity. 0 Active High. 1 Active Low.
4 DE_POL	DATA_EN_IN signal polarity. 0 Active High. 1 Active Low.
3–1 Reserved	This read-only field is reserved and always has the value 0.
0 IC_EN	Integrity Check enable. Main enable switch. 0 Disabled 1 Enabled

51.6.2 DCIC Interrupt Control Register (DCICx_DCICIC)

DCIC Interrupt Control Register

Address: Base address + 4h offset



DCICx_DCICIC field descriptions

Field	Description
31–17 Reserved	This read-only field is reserved and always has the value 0.

Table continues on the next page...

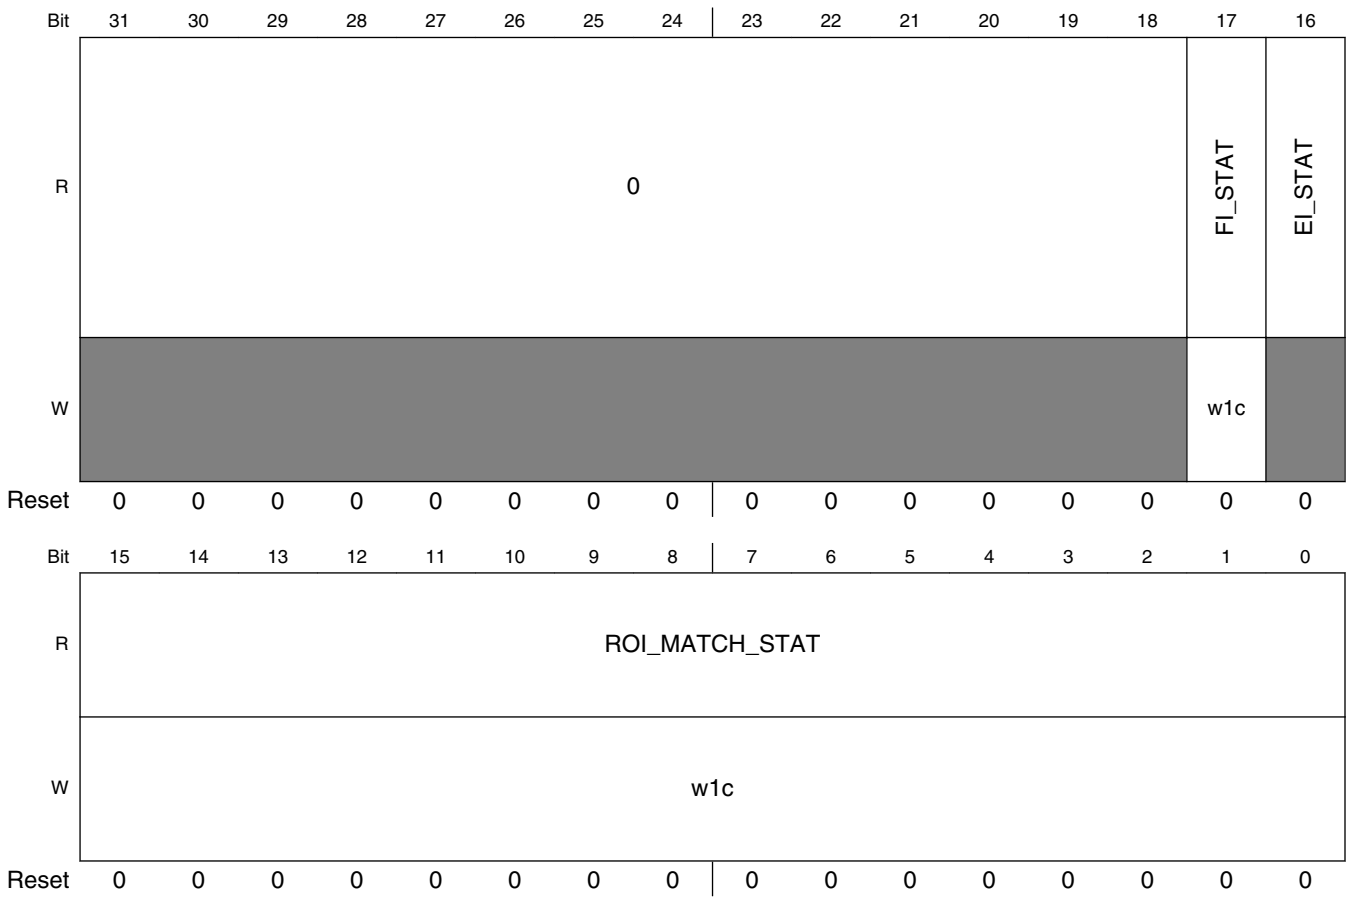
DCICx_DCICIC field descriptions (continued)

Field	Description
16 EXT_SIG_EN	External controller mismatch indication signal. 0 Disabled 1 Enabled
15–4 Reserved	This read-only field is reserved and always has the value 0.
3 FREEZE_MASK	Disable change of interrupt masks. "Sticky" bit which can be set once and cleared by reset only. 0 Masks change allowed 1 Masks are frozen
2 Reserved	This read-only field is reserved and always has the value 0.
1 FI_MASK	Functional Interrupt mask. Can be changed only while FREEZE_MASK = 0. 0 Mask disabled - Interrupt assertion enabled 1 Mask enabled - Interrupt assertion disabled
0 EI_MASK	Error Interrupt mask. Can be changed only while FREEZE_MASK = 0. 0 Mask disabled - Interrupt assertion enabled 1 Mask enabled - Interrupt assertion disabled

51.6.3 DCIC Status Register (DCICx_DCICS)

DCIC Status Register

Address: Base address + 8h offset



DCICx_DCICS field descriptions

Field	Description
31–18 Reserved	This read-only field is reserved and always has the value 0.
17 FI_STAT	Functional Interrupt status. Write "1" to clear. 0 No pending Interrupt 1 Pending Interrupt
16 EI_STAT	Error Interrupt status. Result of "OR" operation on the ROI_MATCH_STAT[15:0] bits. Cleared when these bits are clear. 0 No pending Interrupt 1 Pending Interrupt
ROI_MATCH_ STAT	Each set bit of this field indicates there was a mismatch at the appropriate ROIs signature during the last frame.

Table continues on the next page...

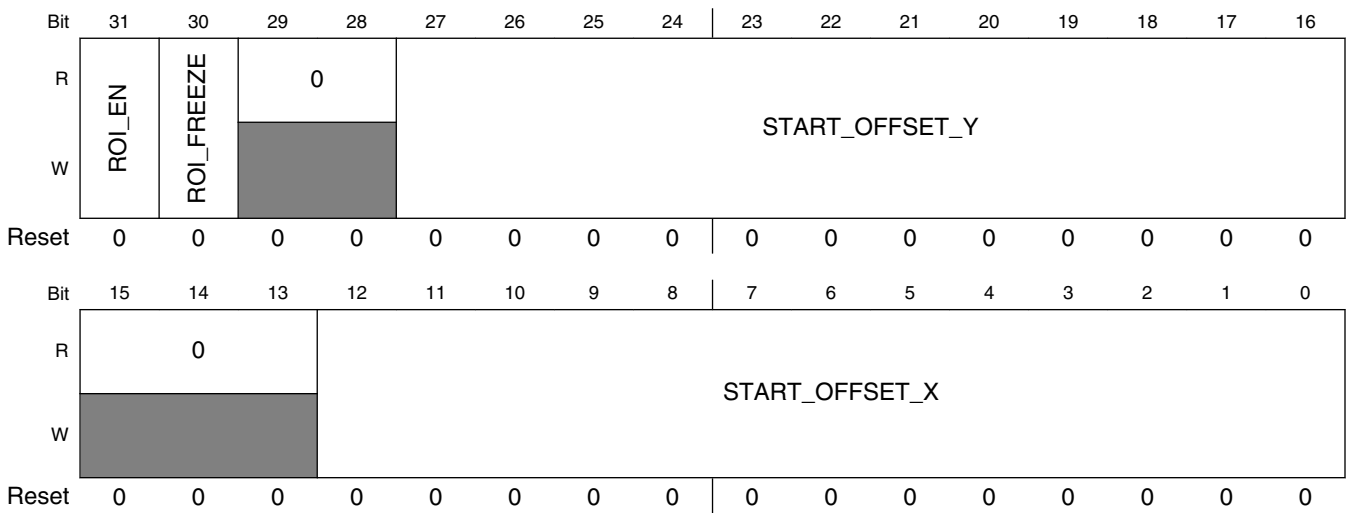
DCIC*x*_DCICS field descriptions (continued)

Field	Description
	Valid only for active ROIs. Write "1" to clear. 0 ROI calculated CRC matches expected signature 1 Mismatch at ROI calculated CRC

51.6.4 DCIC ROI Config Register (DCIC*x*_DCICRC*n*)

DCIC ROIn Configuration Register

Address: Base address + 10h offset + (16d × i), where i=0d to 15d



DCIC*x*_DCICRC*n* field descriptions

Field	Description
31 ROI_EN	ROI tracking enable 0 Disabled 1 Enabled
30 ROI_FREEZE	When set, the only parameter of the ROI that can be changed is the reference signature. "Sticky" bit - can be set once and cleared by reset only. 0 ROI configuration can be changed 1 ROI configuration is frozen
29–28 Reserved	This read-only field is reserved and always has the value 0.
27–16 START_ OFFSET_Y	Row number of ROIs upper-left corner (Y coordinate) Range: 0 to 2^12-1

Table continues on the next page...

DCIC*x*_DCICRC*n* field descriptions (continued)

Field	Description
15–13 Reserved	This read-only field is reserved and always has the value 0.
START_ OFFSET_X	Column number of ROIs upper-left corner (X coordinate) Range: 0 to 2^13-1

51.6.5 DCIC ROI Size Register (DCIC*x*_DCICRS*n*)

DCIC ROIn Size Register

Address: Base address + 14h offset + (16d × i), where i=0d to 15d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

DCIC*x*_DCICRCS*n* field descriptions

Field	Description
CALCULATED_ SIGNATURE	32-bit actual signature (CRC calculation result) for the ROI during the last frame. Updated automatically at the beginning of a next frame.

Chapter 52
Pixel Pipeline (PXP)

52.1 Chip-specific PXP information

Table 52-1. Reference links to related information

Topic	Related module(s)	Reference
System memory map	-	System Memory Map
Clocking	CCM	Clock Management Clock Control Module (CCM)
Power management	PMU	Power Management Power Management Unit
Signal multiplexing	IOMUX	External Signals and Pin Multiplexing IOMUX
Interrupts, DMA Events and XBAR Assignments	-	Interrupts, DMA Events and XBAR Assignments

52.2 Overview

The Pixel Processing Pipeline (PXP) is used to process graphics buffers or composite video and graphics data before sending to an LCD display or TV encoder. It is used to minimize the memory footprint required for the display pipeline and provide an area and performance optimized to both SDRAM-less and SRAM-based systems.

The PXP integrates of several independent processing stages into a cohesive strategy to create flexible pixel pipeline.

52.2.1 Block Diagram

The PXP block diagram is shown below:

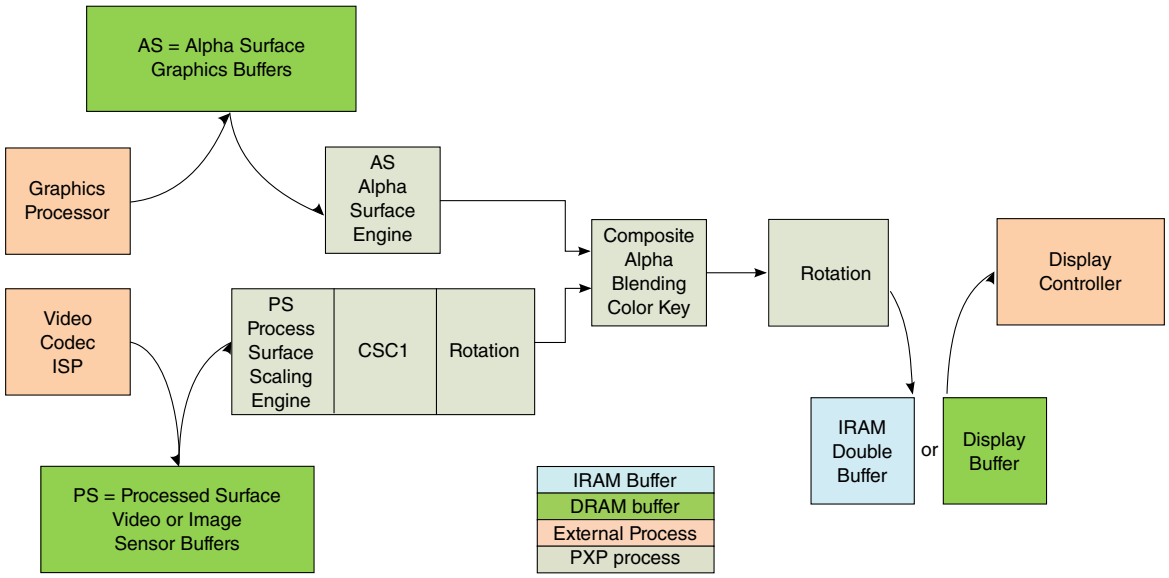

Figure 52-1. PXP Architecture

By integrating multiple blocks, intermediate buffer operations to external memory are removed, reducing external memory bandwidth, power, and software control complexity.

The PXP combines the following into a single processing engine:

- Scaling
- Color Space Conversion (CSC)
- Rotation

52.2.2 Features

The following features are supported in PXP:

- BitBlit
- Flexible image compositions
- Porter-Duff operation
- Image rotation (90°, 180°, 270°)
- Image resize
- Color space conversion
- Multiple pixel format support (RGB, YUV444, YUV422, YUV420, YUV400)
- Standard 2D-DMA operation

52.3 Functional Description

52.3.1 Top-level architecture

The PXP consist of several pipelined blocks that perform the video source frame scaling, color space conversion, alpha-blending/color key algorithm, secondary CSC, pixel correction.

The entire pipeline operate within the requirements of the PXP architecture, and perform operations on either 8x8 or 16x16 pixel blocks in the representative source buffers. The entire pipeline operate within the context of two iteration counters that iterate through the appropriate grid of input blocks to produce the rotated output grid blocks in scan-line order.

Figure 52-1 shows the high-level architecture of the scaling, color space conversion, blending, pixel correction,rotation engines.The Alpha Surface Engine fetches one RGB graphics plane alpha surface (AS). The scaling engine fetches a single processed surface (PS), which can be blended with the AS surface.Although the PXP processes NxN pixel macro blocks, each of the AS or PS surfaces can have any pixel alignment within the output buffer. There are no restrictions and any pixel coordinates within the output buffer are valid. The upper left origin of the output buffer is defined as pixel (0,0). The upper left and lower right coordinates for each of the AS and PS are inclusive within the output buffer.

Figure 52-2 represents a sample output buffer configuration with both an AS and PS included. The alignment of each AS and PS within the output buffer can be at any arbitrary pixel locations. For example, the PS has an upper left coordinate (ULC) of (2,2) and a lower right coordinate (LRC) at pixel (13,13). The maximum value for the ULC and LRC for each of the AS and PS is bounded by the LRC of the output buffer, (15,15) for this example.

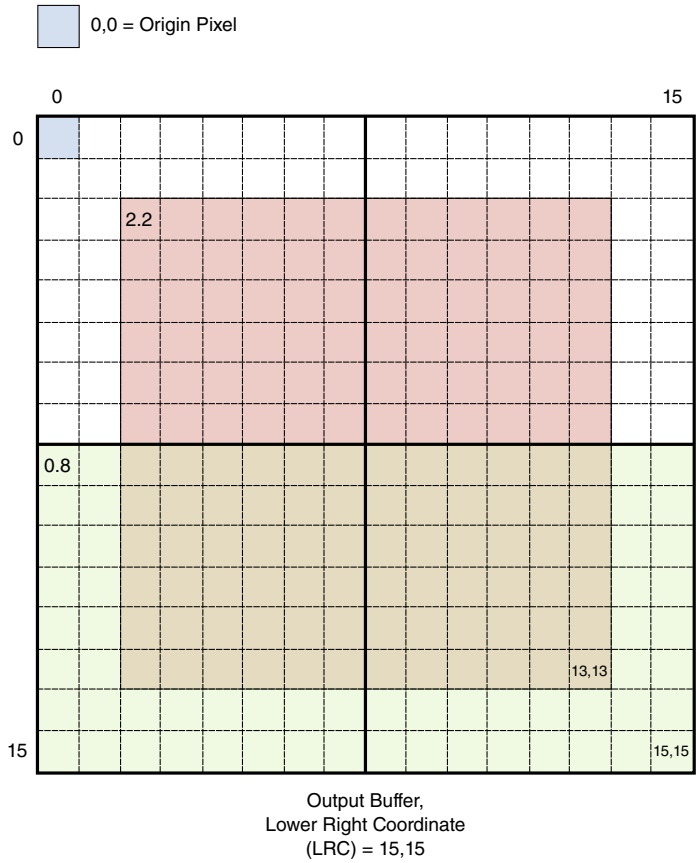

Figure 52-2. Sample output buffer configuration

The AS engine supports RGB pixel formats, and the PS engine supports RGB, YUV, and YCbCr pixel formats. The CSC1 can be used to convert to RGB pixel formats so that the PS surface can be blended with the AS surfaces in the compositing engine in the RGB color space. There is a single rotation engine in the PXP with a programmable location with two possible rotations, one after PS processing, other just before the transfer to display buffer. Rotation can occur after image composition or at the output of the PS engine. In the first scenario, all the data produced by the AS and PS engines is rotated. When the rotation module is programmed to rotate only PS images, the AS is not rotated, and AS pixels are combined with rotated PS surfaces.

52.3.1.1 Processing Details

The PXP architecture has been driven primarily by the requirement that the output buffer must be processed and rotated without intermediate frame buffer stored in external memory.

This reduces the use of external memory bandwidth requirements thus reducing overall system power consumed.

Since the output of the rotation block must be NxN pixel blocks in scan order, the entire pipeline will operate on NxN pixel blocks. In essence, the pipeline will be able to operate on blocks in a random access fashion, but the entire pipeline will operate within the context of two iteration counters that will iterate through the horizontal and vertical input blocks to generate the required output block.

Processing Pipeline

The control block will coordinate the processing of the pixel blocks within the source and destination image buffers. It begins by issuing a command to each stage of the pipeline requesting that operations be done for the block at offset x, y. When the block accepts the command, it asserts its acknowledge signal for a single cycle to indicate the acceptance and allow the control unit to move to the next block.

When the PS and AS fetch engines have received a command, they will fetch the required data and place it into their fetch buffers. If compositing the RGB AS surface with the PS surface, then the output of the PS engine needs to be converted to the RGB color space using CSC1, since all compositing occurs in the RGB color space. For YUV output pixel formats, the CSC1 unit can be enabled to convert pixels into the RGB space for subsequent compositing with AS pixels. If the final output color space is YUV and there is no compositing required (AS not present, for example), then the CSC unit can be bypassed and the pixel data path will pass the YUV pixels to the rotation engine. For YUV output formats, scaling operations, and rotation operations are still valid, but blending RGB AS surfaces with YUV PS surfaces is NOT supported.

NOTE

If input format and output format are both YUV, the CSC1_COFF0[YCBCR_MODE] need be set according to the input format even when CSC1 is bypassed.

The alpha blender/color key module will process a pixel any time that both inputs present valid data.

A handshake will be created between each stage and a pipeline controller to handle the advance of the pipeline and generation of the iteration counters. The pipeline controller will also maintain the interlocks with the LCD interface for the case where the LCD display and pixel processing pipeline use the SRAM to maintain the double buffer block intermediate buffer.

52.3.1.2 Scaling Operation

The scaling engine operates on YUV (or YCbCr) 422 or 420 and any RGB formatted pixels. Each color plane is sourced from color planes indicated by different base address registers.

The scaling source data can be stored as 3 individual planes for each Y, U, and V data, stored as two planes as a single Y and interleaved UV plane, or stored as a single plane with YUV/RGB interleaved on a per byte basis.

The scaled output image is presented to the CSC1 module as YUV444 or RGB888 pixels with a single byte for each color channel. The scaler can reduce an input image by a maximum factor of 16. In this case, the output image will be 1/16 the dimension of the input image in each of the X and Y axis. There are no limits, essentially, on increasing the source image size. The theoretical maximum increase is 4096 since a 12 bit fractional step function is used when scaling an input image. Scaling in either axis, X or Y is independent, so a source image can appear stretched in either direction.

All source images pass through the scale engine. The PXP alpha blend module and AS pixel streams are in the RGB888 format, so PS pixel buffers must be converted to the RGB888 format for alpha blending. The scaling engine works with the CSC1 module to translate YUV/YCbCr pixel formats to RGB888 for output frame buffer compositing using the alpha blender. The CSC1 unit can be bypassed so compositing can occur in the alpha engine.

The scaling operation is divided into two scaling steps. The first step is a decimation scaler, and the second step is a bilinear filter. The decimation filter provide a maximum down scaling factor of 8, and the subsequent bilinear filter provides a maximum scaling factor of 2. Combined, the maximum scaling factor can be up to 16. The decimation and bilinear scaling engines are independently programmable. There is also an initial offset that is programmable to allow more source data to be considered in the bilinear scaling engine.

52.3.1.3 Decimation Image Scaling

The first of two scaling engines is the decimation filter.

The intent of the decimation filter is to use as much source data as is possible to create the output image frame buffer. The decimation filter simply discards certain pixels from the source PS image depending on the reduction selected.

For RGB pixel formats, each color channel is treated equally since there is the same amount of pixel data within each color plane. For YUV422/420 formats, the chroma samples are already subsampled by 2. In these decimation scenarios, the chroma

decimation factor is adjusted to account for the pre-decimation of the chroma samples. For example, since YUV422 is already sub-sampled by 2 horizontally, an X decimation factor of 2 does not apply to the YUV422 pixels in the X direction. All the chroma samples are passed on to the bilinear filter in this case. As another example, an X decimation factor of 4 will decimate the chroma samples by 2, since this factor combined with the pre-decimation factor of 2 in the pixel source buffers totals an overall decimation factor of 4.

The following example will show which pixels (in green) in a source RGB buffer that are passed to the bilinear filter for an X decimation factor of 2 and a Y decimation factor of 4. All pixels coincident with dashed lines are discarded.

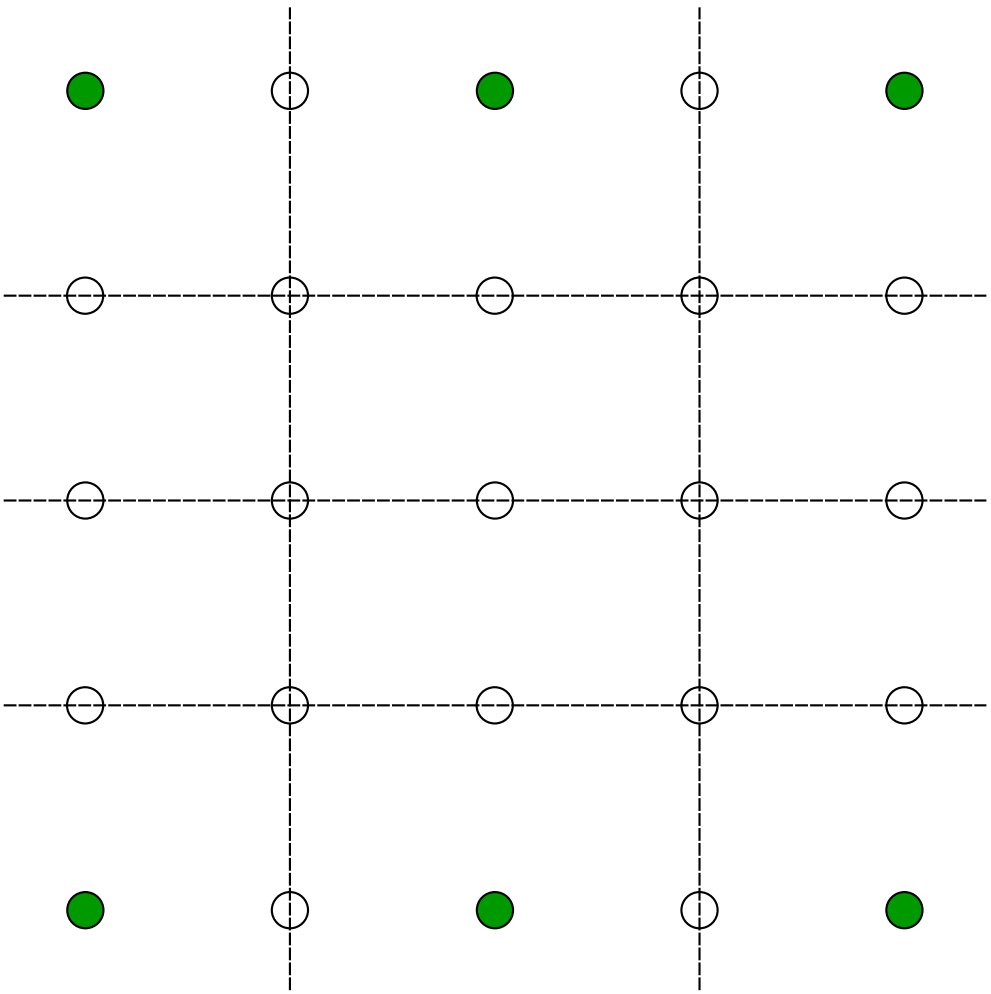

Figure 52-3. RGB decimation X /2, Y /4

Using the same decimation factor as the above scenario for RGB pixels, but using YUV420 source buffers, it can be shown that the decimation factor for the Y and UV components of data are decimated differently. This is due to the pre-decimation of the chroma samples in the source frame buffers. Figure 4: YUV420 decimation X /2, Y /4 indicates that the U/V samples in the X direction are not decimated, but the Y samples in the X direction are decimated by the factor of 2.

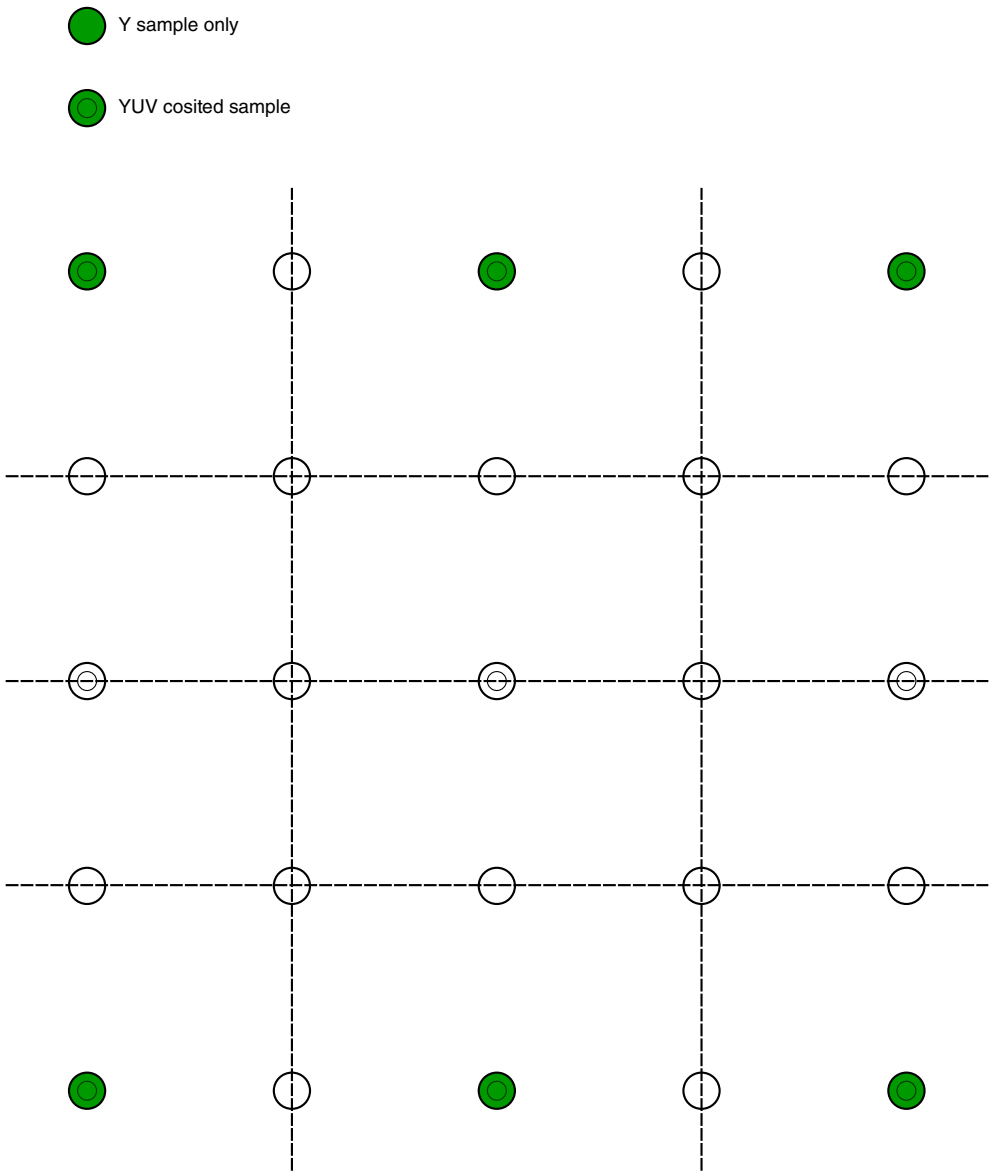

Figure 52-4. YUV420 decimation X /2, Y /4

52.3.1.4 Bilinear Image Scaling Filter

The PXP implements a bilinear scaling filter to resize an input image to a different resolution for display output.

The bilinear filter is a weighted average of the four nearest pixels that can be sourced to approximate the pixel in the output frame buffer.

When scaling YUV data, the UV values are offset by 0x80 (top bit inverted) to shift the signed UV bits into an unsigned equivalent with a range of 0 to 255. YCbCr data does not have to be shifted since it is defined as an unsigned byte. The REG_CSC1_COEF0[YCBCR_MODE] bit controls whether this operation is applied to the input UV bytes.

After scaling, the offset is removed so that the range for UV data is signed from -128 to 127.

The reason for this adjustment is based on the implementation of an unsigned scaling engine, and therefore, is to ensure that the scaled values are handled properly. Consider the following table:

Format	pixel0	pixel1	average	Result
decimal	-2	+2	0	Correct
CbCr	0x7E	0x82	0x80	Correct (0x80 is 0 in CbCr)
UV	0xFE	0x02	0x80	Incorrect (0x80 is -128 in UV)
decimal	-32	+16	-8	Correct
CbCr	0x60	0x90	0x78	Correct (0x78 is -8 in CbCr)
UV	0xE0	0x10	0x78	Incorrect (0x78 is +120 in UV)

To compute the output pixel value at position as indicated by P, consider the diagram below.

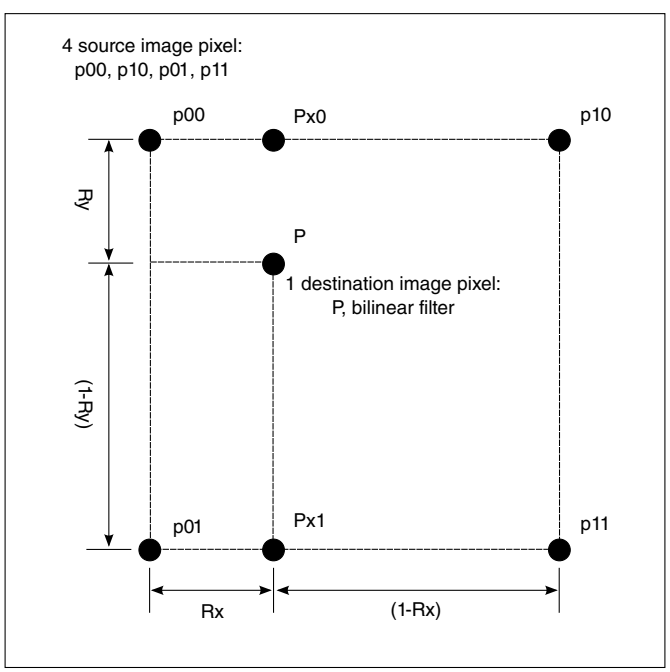

Figure 52-5. Output Pixel Value

A step function is used to indicate the position of the pixel "P" in the output frame. This position may not coincide with a single pixel position in the input frame buffer. In this case, the four closest pixels in the input frame are used to approximate the value of the pixel in the output frame.

The PXP scaler first computes a linear filter in the X axis to create the two intermediate pixel values Px0 and Px1. The step function's X fractional component is used to provide the weighting factor for blending p00 with p10 to provide Px0. Likewise, Px1 is also derived from a linear filter using p01 and p11.

The equations for Px0 and Px1 are as follows:

Px0 = p00*(1-Rx) + p10*Rx

Px1 = p01*(1-Rx) + p11*Rx

The PXP scaler uses the intermediate X pixels Px0 and Px1 and implements a bilinear filter on these two pixel values to produce the final pixel value at position P. The remainder of the step function for the Y axis is used to compute the weighted average pixel result. The equation for final filtered pixel is:

P = Px0*(1-Ry) + Px1*Ry

52.3.1.5 YUV 4:2:2 Image Scaling

The following figure illustrates the positioning of YUV samples for the 4:2:2 formats. There are twice as many Y luma samples then U and V chroma samples horizontally.

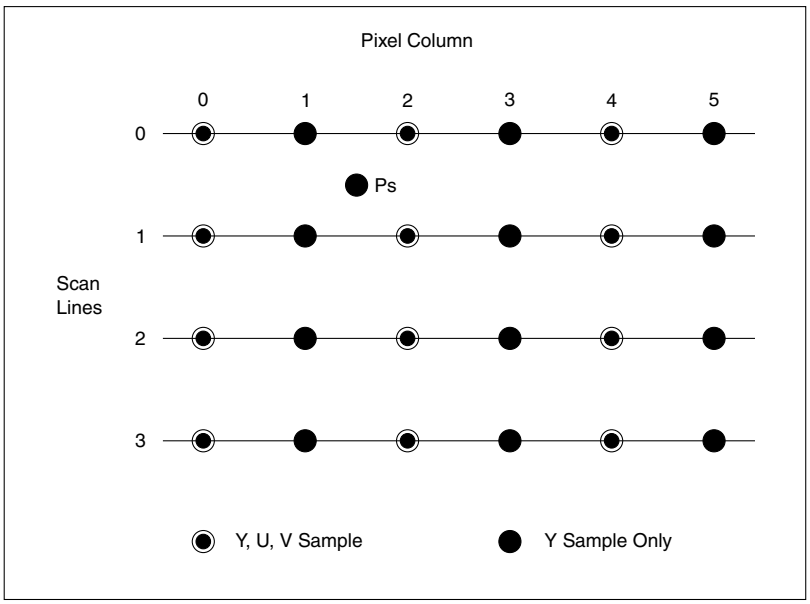

Figure 52-6. YUV Sample Positioning, 4:2:2

Consider the scaled output pixel Ps (pixel scaled) which has an accumulated step function of X=1.5 and Y=0.5. The remainder for the step function is Rx = 0.5 and Ry = 0.5. Or, the sub pixel position of output pixel Ps is half way between line 0 and 1 and half way between column 1 and 2.

The Y output component of Ps is simply the bilinear function of the four nearest Y samples from the input image. Specifically, the Y values at [1,0], [2,0], [1,1], and [2,1] are used to compute the Y for Ps.
